## ABSTRACT

The present paper reports the occurrence of the Chinese mitten crab, *Eriocheir sinensis* H. Milne Edwards, 1854, in Portugal and thus extends its known southerly distribution for Europe. Available Portuguese data are presented and discussed including a possible new size record for the northeastern Atlantic region.

## RÉSUMÉ

La présence du Crabe Chinois, *Eriocheir sinensis* H. Milne Edwards, 1854, est signalée au Portugal, ce qui étend sa distribution en Europe vers le sud. Les données portugaises sont fournies et discutées, y compris un possible record de taille pour la région atlantique nord-orientale.

The Chinese mitten crab, *Eriocheir sinensis* H. Milne Edwards, 1854, is a species of the temperate zone of eastern Asia, inhabiting China from the province of Fukien in the south to the west of Korea in the north (Panning, 1938).

Since its introduction into Germany in 1912 (Peters & Panning, 1933), several authors have reported on the dispersal of the mitten crab throughout Europe from the Netherlands (Otto & Kamps, 1935; Adema, 1991), Denmark (Jensen, 1936), Czechoslovakia (Panning, 1938), Belgium (Leloup, 1943; Adema, 1991), France (Hoestland, 1959), Finland and Sweden (Haahtela, 1963), and the British Isles, (Ingle, 1986). In the 1980's the European range of this crab stretched from the Bay of Biscay to the Baltic Sea (Christiansen, 1982).

Since 1994, 30 individuals of the Chinese mitten crab were caught during beam trawl sampling surveys for fish and crustaceans, in the Tagus estuary, Portugal (fig. 1). According to local fishermen, the mitten crab appeared in the Tagus basin during the late 1980's and from 1988 to 1990 the species was abundant, but the population has decreased over the past seven years. The farthest upstream record was an individual caught 80 km from the estuary. Mitten crabs are caught

TABLE I

Data concerning the 30 individuals of *Eriocheir sinensis* H. Milne Edwards, 1854, caught in the Tagus estuary, Portugal

Date	Salinity (ppt)	Temperature (°C)	Depth (m)	Water transparency (cm)	Carapace width (mm)	Carapace length (mm)	Sex

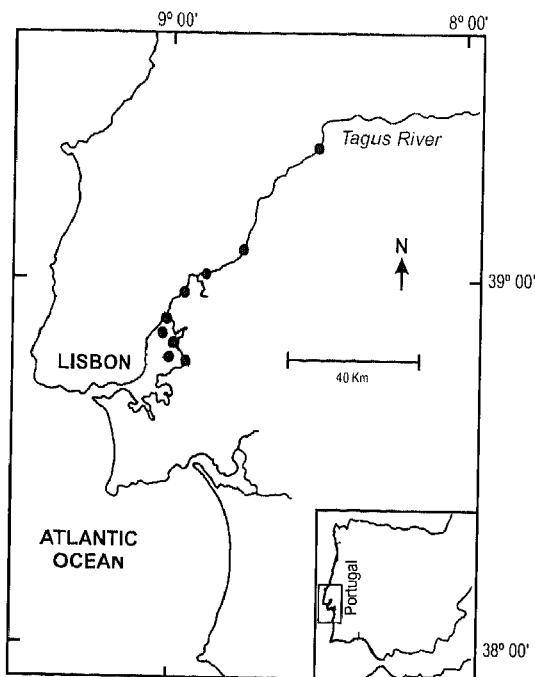

Fig. 1. Occurrence of *Eriocheir sinensis* H. Milne Edwards 1854, in Portugal, within the Tagus estuary and upstream in the river (● = reported occurrence).

mainly as a bycatch in traps used for the eel fishery and the species is considered a pest because it damages nets. However, despite the low abundance at present, this exotic crab is commercially exploited at some localities along the Tagus and it attains higher market prices than some of the most abundant decapod species, namely *Crangon crangon* (L., 1758) and *Carcinus maenas* (L., 1758).

In some European countries there is concern over the burrowing behaviour of *E. sinensis* and over the fact that they may compete with indigenous species, but to date there are no data concerning these issues in Portugal.

Data pertaining to the individuals caught in the Tagus estuary are presented in table I. Some of these showed larger carapace length than the maximum suggested by Falciai & Minervini (1995) and Hayward & Ryland (1995) (respectively, 63 and 62 mm). Adema (1991) gave as largest specimen known from the Netherlands a male with a carapace length of slightly more than 85 mm which is 3 mm shorter than the largest Portuguese crab.
