Fiddler crabs (Ocypodidae) are well known to influence mangrove ecosystem function through their biologically potential of accelerating organic matter decomposition. The anthropogenic impacts of mangrove deforestation on the fiddler crab *Uca annulipes* will be evaluated by analyzing (1) δ¹³C and δ¹⁵N stable isotopes composition and (2) mitochondrial COI DNA sequences. Analysis of δ¹³C and δ¹⁵N stable isotopes in tissues and sediments will help to understand whether there is shift in feeding or foraging ecology of *U. annulipes* while analysis of COI sequences will help to document whether there is shift in genetic diversity due to mangrove deforestation for salt pan development. The study will compare mangrove areas disturbed for salt pan development and relatively undisturbed mangroves. It is expected that the results from this study will be useful for decision makers in planning the management strategies and conservation of both marine flora and fauna in the area and along the Western Indian Ocean.
