Abstract
A new species of free-living marine nematode, *Daptonema macrostoma* sp. nov. from the Yellow Sea, China is described. The new species is characterized by uniquely large buccal cavity, four cephalic setae, amphid circular, S-shaped spicules with a hook at its distal end, gubernaculum invisible and tail conical-cylindrical.

Keywords: Nematode taxonomy, *Daptonema macrostoma* sp. nov., Yellow Sea of China
1. Introduction

In order to study the biodiversity of free-living marine nematodes in the Yellow Sea, China, sediment samples were collected in many sites from the intertidal to the sublittoral region along the Yellow Sea in the past few years. More than 240 species have been identified from these habitats up to now (Huang et al., 2006; Huang & Cheng, 2012). The present paper describes one new species from this region which belong to the genus *Daptonema* Cobb, 1920.

The genus *Daptonema* was established by Cobb in 1920 with the type species *D. fissidens* Cobb, 1920. This genus includes more than 120 species and presents particular difficulty for identification. Wieser (1956) considered *Daptonema* as one of five subgenera of *Theristus*. This subdivision was refuted again by Lorenzen (1977) in a review of the Xyalidae. *Daptonema* species are separated from those of *Theristus* only by the shape of the tail: conico-cylindrical with terminal setae in the former, conical without terminal setae in the latter. Within *Daptonema*, species are distinguished by rather few characters: mainly the relative length of the setae, size and position of the amphids, size and structure of the copulatory apparatus and the shape and length of the tail (Warwick et al., 1998).

So far, more than 120 species of *Daptonema* have been recorded (Gerlach & Riemann, 1973; Tchesunov & Miljutin, 2006; Huang & Zhang, 2010; Electronic databases http://nemys.ugent.be and http://insects.tamu.edu/research/collection/hallan/Nematoda). The new species *D. macrostoma* sp. nov. differs from the other species in this genus by its uniquely large buccal cavity, four short cephalic setae and S-shaped spicules with a hook at its distal end.

2. Materials and Methods

In July 2008, undisturbed sediments were obtained from a grid of 33 sampling stations between 32°N and 38.83°N, 120.34°E and 124.167°E during the Open Research Cruise by R/V KE XUE SAN HAO in the Yellow Sea, China. Undisturbed sediment samples were taken using a 0.1m² improved Gray-O’Hara box, and a 8 cm depth of meiofauna samples were obtained using a sawn-off syringe with a 2.6 cm inner diameter. Samples were fixed with 5% formalin in filtered seawater. In the laboratory, samples were stained with 0.1% Bengal rose for about 24 hours. All the samples were washed to remove the formalin and sieved over two mesh sizes (500 µm and 42 µm) in order to separate the macrofauna (500 µm) from the meiofauna (42 µm). Heavier sediment particles were removed using centrifugation in Ludox-™ with a specific gravity adjusted to 1.15 (Jonge & Bouwman, 1977). Each sample was washed into a lined Petri dish and the meiofauna was sorted under a stereoscopic microscope up to higher taxonomic levels. Nematodes were transferred into a 9:1 (V : V) solution of 50% ethanol : glycerol in block cavity to slowly evaporate ethanol and then mounted in glycerol on permanent slides. The descriptions were made from glycerin mounts using interference contrast microscopy (Nikon, 80i). Drawings were made with a camera lucida. Type specimens have been deposited in the type collections of the Museum of Qingdao Institute of Oceanology, Chinese Academy of Sciences.
Measurements are in µm. Abbreviations are as follows:

de Man a: body length / max. body diameter; a.b.d.: anal body diameter; de Man b: body length / oesophagus length; de Man c: body length / tail length; c.b.d.: corresponding body diameter; h.d.: head diameter; Spic: spicule length along the arc; V: corresponding body diameter of vulva; V %: position of vulva from anterior end expressed as a percentage of total body length.

Order Monhysterida Filipjev, 1929

Family Xyalidae Chitwood, 1951

Genus Daptonema Cobb, 1920.

Daptonema macrostoma sp. nov.

2.1 Type Material

Four males and one female collected from Station 3400-0 and 3400-1.

Holotype: ♂1 on the slide 3400002; Allotype: ♀1 on the slide 3400002; Paratypes: three males on the slides 3400002 and 3400121.

2.2 Type Locality and Habitat

Subtidal muddy sediment in the Yellow Sea. Station 3400-0: 34° N, 120°36´ E, water depth 40.5 m, water temperature at the sediment-water interface 11.6ºC, salinity 33, silt 86%, clay 13%, sand 0.7%, organic matter 0.4%. Station 3400-1: 34°N, 120°48´E, water depth 48 m, water temperature at the sediment-water interface 11.2ºC, salinity 33.2, silt 87%, clay 12%, sand 0.7%, organic matter 0.42%.

2.3 Etymology

This species name refers to its very large buccal cavity.

4. Description

Males. Body slender, gradually tapering towards both extremities. Cuticle with coarse annulations, beginning at base of buccal cavity and ending at tail tip. Labial sensilla not visible. Four short cephalic setae in one circle, 3 µm long. Short somatic setae scattered over body. Buccal cavity very spacious, 15 µm wide, square-rounded, consists of hemispherical cheilostom and conical pharyngostom. Amphids circular, 8 µm in diameter (36% of corresponding body diameter wide), situated at a distance of 15 µm from the anterior end. Excretory pore not obvious. Pharynx cylindrical. Cardia long cordiform. Nerve ring at about 45% of pharyngeal length. Tail conico-cylindrical, 164 µm long (5.3 a.b.d.), tapering with
Aquatic Science and Technology

2013, Vol. 1, No. 1

distal third cylindrical and three terminal setae. Three caudal glands with common opening.

Spicules S-shaped, 28 µm long as arc, slender and tapered with a hook distally. Gubernaculum invisible. No precloacal supplement.

Females. Females have most features in common with males, but are slightly larger. A single anterior outstretched ovary, about 570 µm long. Vulva at 69% of body length from the anterior end.

5. Differential Diagnosis

*Daptonema macrostoma* sp. nov. is characterized by great buccal cavity, four cephalic setae, S-shaped spicules with a hook at the distal end and gubernaculum invisible. This new species is close to *D. deconincki* Sharma, 1985 in the size and structure of the body. Nevertheless, the spicules of the latter species have bifid tips, 49 µm long, the gubernaculum surrounds the distal half of the spicules and with a dorsal apophysis. This new species also resembles *D. setosum* (Bütschli, 1874) Filipjev, 1930, which has a very big and broad gubernaculum and spicules L-shaped, distally bifurcate.
