Since the beginning of 2004 MUMM has performed a series of moorings in the Belgian Coastal Zone with a tripod or benthic lander, equipped with a series of oceanographic sensors. Current meters such as an Acoustic Doppler Profiler (ADP) and an Acoustic Doppler Velocimeter (ADV), a CT-sensor capable of measuring temperature and salinity, optical (OBS) and acoustic backscatter sensors (ADP and ADV) to measure suspended sediment concentration, a LISST 100 suspended particle sizer, a passive Cetacean monitoring device (C-PoD, Haelters et al., 2012) and a passive sampling device for chemical monitoring (Monteyne et al., 2013) have ever since been moored for more than 1750 days. From autumn 2009 a permanent coastal observatory has been installed at MOW1, located to the west of the entrance to the Zeebrugge harbor (Backers et al., 2013). Other moorings have been carried out at more offshore locations, such as the Kwintebank, Gootebank, MOWO and the offshore windmill farms and a very nearshore location (Blankenberge). The data collected have increased our understanding of cohesive sediment dynamics in response to tidal and wind-driven flow and this during both good and bad weather conditions and from short (turbulence) to long-term scales (seasonal variations).

The instruments have already recorded several GB worth of data files, but the data need to be processed before they can lead to a large synoptic dataset. This processing includes the transformation from a binary file to a readable ASCII format and is done by proprietary software. The subsequent step consists of the actual processing of the data, the quality control to identify instrument failure or biofouling and calculation of derivative parameters (such as bottom shear stress, turbulent kinetic energy and settling velocity). For this goal a series of MatLab scripts have been created which automate the task. Datasets will be made available through the BMDC website: [http://www.mumm.ac.be/datacentre/](http://www.mumm.ac.be/datacentre/).
