NOAA Technical Memorandum NMFS

The National Oceanic and Atmospheric Administration (NOAA), organized in 1970, has evolved into an agency which establishes national policies and manages and conserves our oceanic, coastal, and atmospheric resources. An organizational element within NOAA, the Office of Fisheries is responsible for fisheries policy and the direction of the National Marine Fisheries Service (NMFS).

In addition to its formal publications, the NMFS uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series, however, reflect sound professional work and may be referenced in the formal scientific and technical literature.

NOAA Technical Memorandum NMFS

This TM series is used for documentation and timely communication of preliminary results, interim reports, or special purpose information; and have not received complete formal review, editorial control, or detailed editing.

REPORT OF A MARINE MAMMAL SURVEY OF THE CALIFORNIA COASTAL WATERS
ABOARD THE RESEARCH VESSEL McARTHUR
JULY 28 - NOVEMBER 5, 1991

P. Scott Hill
and
Jay Barlow

INTRODUCTION

This paper presents the preliminary results of a three month ship survey of cetaceans in waters off the coast of California. The study was motivated by the need to estimate the size of those populations that are being impacted by gillnet fisheries in this region.

In California, gillnets are used in two quite separate fisheries. In the shark and swordfish fishery, drift gillnets are used in offshore waters from the Mexican border to the Oregon border, typically between 20 and 200 nautical miles from the coast. In the set gillnet fishery, bottom gillnets and trammel nets are used to catch halibut and angel sharks from the Mexican border to approximately Bodega Bay, California. Set gillnets are typically fished only in shallow water (less than 50 fathoms deep). Both types of gillnets take marine mammal species.

The mortality of marine mammals in gillnets came to public attention in the early 1980s. At this time and during the late 1970s, the use of monofilament gillnets increased dramatically with the development of set-netting for halibut and drift-netting for sharks. Swordfish were initially caught incidentally to shark fishing, but soon became a major source of income in the drift-net fishery. Similarly, halibut fishermen found that they could catch angel sharks in the vicinity of the Channel Islands in southern California. Along with these developing fisheries came evidence of marine mammal entanglement. Evidence came in the form of increasing numbers of harbor porpoise washing ashore in the San Francisco area and increasing numbers of sea lions seen with net fragments around their necks at rookeries and haulout areas throughout the state.

Responding to this evidence, the California Department of Fish and Game (CDFG), under a cooperative agreement with the National Marine Fisheries Service (NMFS), began monitoring gillnets by putting observers on gillnet vessels. This on-vessel program depended on voluntary cooperation of the skippers, but CDFG also observed vessels, either from shore with telescopes or from an auxiliary vessel. Beginning with the 1983/84 fishing season, CDFG made yearly estimates of marine mammal mortality in gillnets (until their program ended in 1987). Results from that program indicated that annual fishery by-catch included 2000-4000 California sea lions, 1000-2000 harbor seals, and 200-300 harbor porpoise (Barlow et al. in press). Other marine mammals were also observed to be taken, but in numbers that were too small for accurate mortality rates to be calculated. Other species seen in gillnets

or stranding with gillnet marks included common dolphins, minke whales, northern right whale dolphins, short-finned pilot whales, Pacific white-sided dolphins, bottlenose dolphins, Risso's dolphins, killer whales, Hubb's beaked whales, Cuvier's beaked whales, and gray whales.

Beginning in 1990, NMFS began a mandatory observer program on both drift and set gillnet vessels. Preliminary mortality estimates were made for the last half of 1990 based on these data (Lennert et al. 1991). Estimated mortality for this half-year period was 44 harbor porpoise, 33 sea otters, 234 elephant seals, 415 harbor seals, 937 California sea lions, 203 common dolphins, 68 Pacific white-sided dolphins, 23 short-finned pilot whales, 23 beaked whales, and 23 Dalls porpoise.

The impact of this fishery mortality is easier to measure for pinnipeds than it is for cetaceans. Pinnipeds are counted each year when they haul-out for molting or pupping. The three major species (California sea lions, harbor seals, and elephant seals) are all increasing in abundance despite the fishery mortality (they had all been previously depleted by humans, elephant seals to near extinction). We also know that gray whale populations are growing. Studies of population trends have begun for harbor porpoise using aerial surveys, but insufficient data have been gathered to date to show a definitive trend. For the other species, abundance estimates (if available) are woefully inadequate to estimate trends in abundance and are out of date.

The California coastal marine mammal survey was designed to obtain solid estimates of abundance for the majority of cetacean species which would enable us to judge the significance of incidental fishing mortality. In this report, we describe the design used during the 1991 survey and we present summaries of the distance searched and marine mammals encountered from aboard the NOAA Ship McArthur (Cruise AR-91-02; SWFSC Observer Cruise 1426).

SURVEY OBJECTIVES

The primary objectives of the cruise were to estimate the abundance and understand the distribution of dolphin and whale species which are commonly in California waters and which are killed in U.S. commercial gillnetting operations. The specific objectives were to:

1. collect data for estimating the density, size, and species composition of dolphin and whale aggregations in order to make mean and minimum estimates of their population sizes;
2. collect physical, biological, and oceanographic data regarding the habitat of marine mammals in order to better understand why they are distributed as they are;
3. take individual identification photographs of blue, humpback, right, and sperm whales in order to estimate their population sizes using mark-recapture methods;
4. take biopsy samples from whales and dolphins for future genetic analyses of population structure.

A briefing document for the subsequent Cruise Leaders was compiled by the Chief Scientist during the first leg of the cruise. This document has been included as Appendix A of this report.

MATERIALS AND METHODS

Study Area and Itinerary

The survey called for the McArthur to complete a grid of predetermined tracklines to uniformly cover the California coastal waters out to a distance of approximately 300 nmi (555km) (Figure 1). The grid was chosen arbitrarily without considering known concentrations of cetaceans. A secondary strata was included in the survey design and consisted of circumnavigating each of the Channel Islands at a distance of one nautical mile (1.85 km) from shore. This region was expected a priori to have a higher density of cetaceans. The cruise was conducted from July 28 through November 5, 1991, and included port calls in Eureka, San Diego, and San Francisco. The itinerary of the vessel included four segments or effort legs:

Leg 1.	Departed Arrived	San Diego Eureka	July 28 August 20
Leg 2.	Departed Arrived	Eureka San Diego	August 24 September 15
Leg 3.	Departed Arrived	San Diego San Francisco	September 18 October 7
Leg 4.	Departed Arrived	San Francisco San Francisco	October 13 November 5

Oceanographic data were collected by the McArthur survey department personnel.

Marine Mammal Species Surveyed

During the survey, the observers recorded information on all species of whales and dolphins sighted throughout the cruise. All sightings of pinnipeds encountered more than ten nautical miles (18.5 km) from the nearest point of land were also recorded.

Equipment

The McArthur, commissioned in 1966, is 53.3 m in length, has a beam of 11.6 m, and has a 3.7 m draft. During the surveys, the vessel maintained a cruising speed of approximately 18.5 km/hr (10 knots).

Several pieces of equipment were used to gather data. The geographic position of the vessel was recorded periodically and at the time of a marine mammal sighting using the vessel's Global Positioning System (GPS). Marine mammals were detected with port and starboard pedestal-mounted 25x150 Fujinon¹ binoculars and hand-held 7x50 binoculars. The larger binoculars were mounted on the upper deck approximately 10.7 m above the sea surface. Sea surface temperature and salinity, and temperature versus depth profiles were obtained using a thermosalinograph and expendable bathythermographs (XBTs), respectively. Salinity and temperature profiles were obtained using a conductivity-temperature-depth (CTD) probe. Water samples collected during these casts were analyzed for chlorophyll, salinity, and primary productivity (using a C-14 uptake method).

The bearing and radial distance from the vessel to each sighted marine mammal group was recorded. The bearing from the vessel to the group was recorded by the observers using a 360° graduated ring attached to the base of the 25X binoculars. Distance was determined by utilizing graduated reticles enclosed in the right eyepiece of the 25X binoculars.

A 35 mm F-1 Canon¹ camera with motor drive was used to photograph animals to aid in stock and species identification. The system included 400mm, 70-210mm zoom, 50mm, and 28mm lenses. The photographic identification study of large whales was conducted using a Nikon¹ F-3 camera equipped with a 80-210mm zoom lens and a Canon¹ 630 camera equipped with a 100-300mm autofocus zoom lens. Animals were also recorded on 1.27 cm video tape using a Panasonic¹ VHS camcorder with a telephoto lens.

Duty Stations

The marine mammal observers occupied three duty stations during the survey, with the observers rotating through each station.

1. Left Binocular - The port-side observer used a 25X binocular, mounted on the port side of the vessel, to scan the ocean for marine mammal sighting cues. The major area of responsibility for this observer was from the midpoint of the trackline to abeam the port side of the vessel and outward to the horizon or to the extent possible with prevailing environmental conditions.

2. Right Binocular - The starboard observer used a 25X binocular, mounted on the starboard side of the vessel, to search from the midpoint of the trackline to abeam the starboard side of the vessel, and outward to the horizon or to the extent possible with prevailing environmental conditions. Observers in the left and right positions frequently searched up to 10° on the opposite side of the trackline.

¹Reference to trade name does not imply endorsement by the NMFS.

3. Recorder - The recorder's duties were to enter data on search effort, environmental conditions and sightings using the on-line data acquisition computer system, and to search the trackline adjacent to the vessel by naked eye and with hand held binoculars for groups not detected by the observers on the 25X glasses.

In addition to the regular watch teams, a fourth independent observer, maintained watch in order to detect groups or individual animals missed by the regular observer teams. The independent observer was stationed near the centerline of the vessel on the flying bridge and maintained watch with the naked eye and 7x50 binoculars.

Observer Teams and Rotation

Two teams of three observers each alternately occupied the three duty stations. Each team was on duty for a two-hour shift. During each shift, observers spent approximately equal time occupying each duty station.

Two of the six observers, one on each team, were experts in identifying marine mammals. A rotating watch schedule was developed so the team composition did not remain constant during the entire survey. However, one identification expert was always on watch. Team members rotated between the duty stations and teams rotated on and off duty without interrupting searching effort. Teams alternated standing the first watch of the day.

The independent observer stood watch for no more than two consecutive hours. The cruise leader also occupied the independent observer station as time permitted.

Data Collection Procedures

A typical day's searching activity began at sunrise, approximately 0630 hours local time, and ended at sunset. The searching procedure was initiated when observers were occupying the duty stations and a recorder was in place to record information with the on-line data acquisition computer system. After securing marine mammal sighting effort for the night, the vessel would slow to a minimal speed and stay in the area. An oceanographic station was conducted each morning where the sighting effort was terminated on the previous night. In this manner, the searching effort typically began in the same geographic position as effort was terminated on the previous day.

When a sighting cue (marine mammals, birds, splashes, etc.) was detected, it was determined whether marine mammals were present and if the sighting was appropriate to approach. Generally, all cetacean groups (dolphins and whales) encountered within 5.6 km (3.0 nmi) lateral to the vessel were approached. For these groups, the searching effort was terminated, and the vessel was directed to intersect the group in order for the observers to obtain estimates of group size and species composition. The searching mode was resumed after the vessel returned to its original course and speed, and the observers resumed searching for other sighting cues.

During each marine mammal sighting, the recorder transcribed all the necessary data on the automated data entry system (refer to Appendix B for details concerning this system). Criteria for assigning sun position and sea state conditions are given in Figure 2 and Table 1, respectively. Observers recorded bearing and range to the mammals using the 360° calibrated ring and reticles etched into the right eyepieces of the 25 power binoculars. The reticle measurements were converted to nmi using

$$a = 0.003942 \tan (\arctan (1420.28) - 0.001088 r),$$

where a equals radial distance in nmi and r denotes the number of reticles below the topmost reticle. Values in this equation were calculated by Barlow using an equation presented by Smith (1982) and data collected during previous research vessel cruises.

Each observer who had a good view of the group independently recorded in his or her logbook the high, low, and best estimates of group size and a determination of species composition. At no time were the observers allowed to discuss their estimates of group size and species composition. This procedure assured independence and consistency of each observer's data. Each night the Cruise Leader collected the individual logbooks and transcribed observer estimates of group size and species composition to complete the daily sighting and effort file compiled by the automated data entry system.

All available observers were, however, allowed to discuss species identification and animal behavior, and a consensus was entered on the Research Vessel Sighting Continuation Form (Figure 3) shortly after the time of a sighting. Species identifications were validated when possible by photographing the group at close range using 35 mm and video cameras.

Data Analyses

Sea state conditions were grouped into "calm" conditions, without whitecaps (Beaufort numbers 0-2), or "rough" conditions, with whitecaps (Beaufort numbers 3-5). The presence of whitecaps was important in searching for sighting cues. Animal splashes could not effectively be used as a sighting cue during rough seas because whitecaps were easily confused with the animal splashes.

Visibility conditions were classified into "good" and "poor" categories. Poor visibility conditions were recorded when horizontal sun position was 12 and vertical position was 1, 2, or 3, or when there were clouds together with fog or rain (Holt 1987) or haze. All other conditions were considered good conditions.

The study area was divided into two strata, with the sum of the two strata comprising the total study area. Encounter rate data are presented separately for each stratum and pooled over strata.

The rate of encountering marine mammal groups was determined as the simple ratio of sightings detected per 1000 km searched. Encounter rates were

calculated for all marine mammals detected during Beaufort states 0 through 5. Rates were calculated for all groups detected in the study area and for calm and rough sea conditions, good and poor sun conditions, and individual observers.

Distributions of perpendicular sighting distance for each species were calculated using even intervals of 0.2 nmi out to a total distance of 3.0 nmi from the trackline.

RESULTS

The tracklines surveyed during the entire cruise are depicted in Figure 4. Figures 5 through 11 display those tracklines covered during each leg of the cruise and during the various Beaufort states.

Perpendicular distance groups for on-effort sightings made by the primary observer teams (excluding sightings made by the independent observers) are presented in Table 2.

Information summarized for each marine mammal sighting encountered during the survey is presented in Table 3. Included in this table are off-effort sightings and sightings made by the independent observer. The geographic positions of all groups detected during the survey are presented for each species category (code) in Figures 12 through 46.

Searching effort was conducted during Beaufort 0 through 5 conditions. Effort was terminated once the seas and wind attained a force of Beaufort 6 or when the team leader and the cruise leader determined that conditions were unworkable.

During the entire survey, observers searched 10.353 km and made 822 on-effort marine mammal sightings (plus 7 sightings of unidentified objects, possibly marine mammals). An additional 119 sightings were made off-effort. Dolphins or porpoises were detected in 401 on-effort schools and whales were detected in 185 on-effort pods (of these, 17 groups contained both dolphins and whales). Pinnipeds were detected in 251 groups; in which, they were associated with whales and dolphins on 2 and 9 occasions, respectively. During the survey 7 species of delphinids, 2 species of porpoise, 5 species of other odontocete whales, and 6 species of baleen whales were identified (Table 4). The overall rate of detecting groups in the study area was 74.96 groups/1000 km searched (Table 5).

Sea conditions in the study area were extremely rough. Over 311 hours of searching effort were lost to poor weather, including high winds and seas, rain, and fog. The amount of time lost during each leg varied from 22.0 to 127.5 hours (Table 6). Only 23% of the searching effort was completed in calm seas (Table 5). However, 52% of all groups were detected during calm seas and the rate of detecting groups during calm seas was approximately 3.6 times the detection rate during rough seas.

Poor visibility conditions occurred during 42% of the surveying effort,

during which time 59% of the groups were detected (Table 5). It seems that visibility conditions had little effect on sighting marine mammal groups as the rate of detecting groups during poor conditions was actually higher than the rate of detection during good conditions.

The percentage of groups detected by each of the primary mammal observer ranged from 12 to 24% (Table 5). The rates of detecting marine mammal groups also varied considerably among observers (range of 26.0 to 52.8 groups/1000 km).

SUMMARY

In this report, we have presented data on marine mammal encounter rates, group size, and species composition which meet the primary objectives of the California marine mammal cruise aboard the McArthur. Data on all marine mammal sightings have been summarized. We found that the rate of encountering marine mammal groups was higher during calm seas than during rough seas, and the rate during good visibility conditions was lower than the encounter rate during poor visibility conditions. Encounter rates among observers were variable.

ACKNOWLEDGMENTS

The cruise aboard the NOAA Ship McArthur was successfully executed due to the work of many dedicated professionals. Among those contributing to the success of the cruise were the marine mammal observers who spent many long hours collecting the data and especially the officers and crew of the McArthur who gave their continuous support. Special recognition should be given to the survey department personnel of the McArthur who exceeded our data gathering expectations. Special efforts were provided in procurement by B. Engstrand and B. Watkins. A. Jackson edited the sighting data. We are grateful to I. Barrett, R. Neal, D. DeMaster, T. Gerrodette, and B. Remington for their support during the entire cruise preparation and execution. This manuscript was improved by the careful reviews of DeMaster and T. Gerrodette. Editorial assistance was provided by J. Gilmore.

Table 1. Sea state conditions measured by the Beaufort scale (from Bowditch, 1966).

Wind force (Beaufort)	Knots	Descriptive	Sea Conditions	Probable wave height in feet
0	0- 1	Calm	Sea smooth and mirror-like	-
1	1- 3	Light air	Scale-like ripple without foam crests	1/4
2	4- 6	Light breeze	Small short wavelets; crests have a glassy appearance and do not break	1/2
3	7-10	Gentle breeze	Large wavelets; some crests begin to break; foam of glassy appearance. Occasional white foam crests	2
4	11-16	Moderate breeze	Small waves, becoming longer; fairly frequent white foam crests	4
5	17-21	Fresh breeze	Moderate waves, taking a more pronounced long form; many white foam crests; there may be some spray	6
6	22-27	Strong breeze	Large waves begin to form; white foam crests are more extensive everywhere; there may be some spray	10

Table 2. Perpendicular distance groups for on-effort sightings made by the primary observer team (excluding the independent observer). Distances are estimated as the sine of the sighting angle times the radial sighting distance. Sightings of mixed species are counted in each applicable species category; therefore, the totals will be less than the sum of the columns.

Spp. Code	Total Number of Sightings	Perpendicular Distance Groups in Nautical Miles

Table 3. All marine mammal sightings (including off effort and independent observer sightings) from the 1991 CAMMS cruise ordered by species and sighting number. Mean school sizes are the unadjusted averages of all animals taken from all observers. To obtain the number of the primary species, it is necessary to multiply by the fraction of the school represented by that species. This fraction is also a simple average from all observers.

Table 4. Summary of marine mammal sightings encountered during the 1991 CAMMS cruise. Included are on-effort sightings made by the primary observations team (excluding independent observer sightings). Group sizes are based on simple averages of the product of estimated group size multiplied by the proportion of the given species in the group for each observer.

Species Name (Scientific name)	Species Code	# of Sightings			Average No. per Group
		Total	Pure	Mixed	
(006) Common dolphins (unid.) (<u>Delphinus delphis</u>)	05	10	8	2	75.8
(016) Common dolphins (longbeak) (<u>Delphinus delphis bairdii</u>)	16	13	9	4	183.8
(017) Common dolphins (shortbeak) (<u>Delphinus delphis delphis</u>)	17	129	100	29	97.9
(013) Striped dolphins (<u>Stenella coeruleoalba</u>)	13	24	5	19	43.3
(018) Bottlenose dolphins (<u>Tursiops truncatus</u>)	18	18	0	18	7.7
(021) Risso's dolphins (<u>Grampus griseus</u>)	21	30	14	16	15.7
(022) Pacific white-sided dolphins (<u>Lagenorhynchus obliquidens</u>)	22	12	7	5	24.6

APPENDIX A

CRUISE LEADER INSTRUCTIONS FOR THE 1991 CAMMS CRUISE

As cruise leader, your primary responsibilities are to maintain the integrity of the scientific data collected on your leg and to act as supervisor and coordinator of all scientific research on the vessel. The intent of this document is to give you guidelines for the performance of these duties. If activities are required outside these guidelines, you should make every effort to contact the chief scientist as soon as possible.

The primary mission of this cruise is to estimate the population size of all cetacean species in California coastal waters (out to approximately 300nmi offshore). Methods include 1) line-transect surveys of a uniform grid pattern (see attached figures), 2) a line-transect survey of a separate strata which consists of the region within 2nmi of each of the Channel Islands, 3) mark-recapture estimation of abundance for those whale species for which photographic catalogs are already well developed, and 4) studies of genetic population structure through collection of biopsy tissue samples from those species which are included in our permit. Sufficient time has been allocated to accomplish each of the primary missions. If, due to extraordinarily bad weather, some activities have to be curtailed, the priorities are in the order given above. Each of these facets of the primary mission are covered below in more detail.

A secondary mission is the collection of oceanographic data to help understand the patterns of cetacean distribution. These samples include continuous measurement of sea surface salinity, temperature, and chlorophyll; twice daily expendable bathythermograph XBT probes; and a daily hydrographic station each morning with CTD and water samples for primary productivity. All oceanographic data collection will be run by the ship's survey technical department (with help of Valerie Philbrick on leg 3). As cruise leader, you do not directly supervise the oceanography, but you should be aware of what is going on. Check with chief survey tech Julie every couple of days to see if everything is going smoothly. Another secondary mission is the collection of at-sea pinniped sightings to better establish where the various species are feeding. When pinniped sightings are so frequent that they are interfering with cetacean search, the recording of pinniped sightings should be curtailed or limited to short comments. A guideline that worked on the first leg is that pinnipeds are not considered sightings and are not given sighting numbers when within 10 miles from shore or nearest island. When they are given sighting numbers, pinniped group sizes should be recorded in green books just as with cetaceans. A third secondary mission is the collection of turtle sighting data. This is so rare as to not affect cetacean searching. If a turtle is small enough to be brought aboard, we should try to capture it for life-history data and measurements, and we should tag and release the turtle. A final secondary mission is the dip-netting of surface fish at the end of the day (usually 2100 to 2200). This is lead by Jim Cotton out of his own personal research interest. This work should be permitted, but is not a NMFS mission and is not covered by overtime for Jim.

Several previously scheduled scientific mission have been cancelled, including hydro-acoustic surveys and associated mid-water trawling, bird observations, and manta net tows.

PRIMARY MISSIONS

1) LINE TRANSECT ON UNIFORM GRID

The established cruise tracks cover a uniform grid from the Mexican border to the Oregon border and out 300nmi. Try to stick to these cruise tracks as much as possible. The cruise tracks include several "dead head" transects which are necessary to simply get from the end of one transect to the beginning of the next. I have indicated these on the enclosed figures. Try to cover the "dead head" line by running at night as much as possible. When on a dead line, conduct search during daylight hours as usual, but I want to keep these data separate from the regular uniform grid. Start a new data file whenever you start or end a "dead-head" transect (you close an existing data file using the control-D to escape the program CRUISE and start a new file by restarting the program). In getting from the end of one transect line to the beginning of the next, try to make efficient use of ship time. If you can replicate previous tracklines, do so. If you can search for whales to photo-ID, do so. On leg one, I conducted a survey for harbor porpoise along the 10-20 fathom depth contour (using 5 observers and a recorder, all searching with hand-held binoculars). Additional data of this sort would be useful north of Point Conception (in Beaufort 0-2 only).

On the first leg, I found that given good weather, the time was more than sufficient to complete the scheduled transects. At one point we were weathered-out in one area and headed for shelter near the coast. There we were able to complete about 40nmi of LEG 2 transects in the vicinity of Bodega Head. Also, we were able to complete a sizeable segment of LEG 4 transects in the far northeastern corner of the grid. These added regions are noted in the back of the Cruise Leader Logbook. If you have extra time on your leg, try to cover areas assigned to other legs. Always try to take advantage of good weather when it occurs. There is no need to re-do that which was completed in good weather on a previous leg (even if that area was scheduled originally to be completed on your leg).

On the first leg, we missed a segment of LEG 1 transect (approximately a 1-day run) just southwest of Fort Bragg. Please try to fill in missed segments of previous surveys as time permits. Missed segment of effort should be listed in the back of the cruise leader log-book.

In good weather, you can expect to cover about 80 miles per day in the Southern California Bight, 120 miles per day on the outside (more than 100nmi from land), and an intermediate distance in the northern inshore areas. Originally I planned for 100nmi per day, but on the first leg we averaged more than this. Because I was generous with time, the option exists of sitting-out rough weather or fog rather than just trucking down the trackline and leaving a big hole that has to be filled later. Consider this option if the weather forecast is encouraging. (Note, a phone number of the marine forecaster for the National Weather Service is listed in the front of the Cruise Leader Logbook. You can consult that person directly if you identify

yourself as being on a NOAA dolphin survey.)

LEG-Specific Comments

LEG 2. Leg 2 has a long segment of dead-head on the outside in the far north. Try to cover as much of this at night as possible (even if it means shaving 20 miles off one of the other legs). After this excursion offshore, you will come to shore near Bodega Head. The 20nmi inshore segment of this transect and the 20nmi offshore segment of the next transect were already covered in suitable weather conditions. This area is, however, a hot-bed of whale abundance and has surface swarms of krill. I do not want to bias the survey by double-counting this area, but you might want to conduct a whale hunt for photo-ID in this area. A good option for finding whales might be to travel south approximately 10 miles from shore. The home stretch going into San Diego crosses Mexican waters and is thus a dead-head run. If you have time after completing scheduled lines, try to pick-up another transect line and avoid wasting time transitting Mexican waters.

LEG 3. Leg 3 circumnavigates most of the Channel Islands. See the explicit instructions below for these surveys. We were able to do San Clemente Island on the LEG 1, so skip it. See if you can pick-up San Nicolas or Santa Barbara Islands in its place. You should probably call the Navy long before you try San Nicolas. Once you complete the northern Channel Islands, you have a long "dead-head" line. If weather is good, try to complete the LEG 3 transect that was planned to go from offshore towards Los Angeles in the reverse direction (or replicate adjacent tracklines which head in the same general direction). Take advantage of good weather when you get it. Leave some time for whale photo-ID in the vicinity of Half Moon Bay, on you final run into San Francisco.

LEG 4. Leg 4 is a mop-up leg. In addition to the scheduled tracklines, try to fill-in the holes created by bad weather during the previous Legs. A large section of the LEG 4 transects in the far northeast were completed under good weather on LEG 1 and do not have to be replicated. As time permits, complete one or two of the forays into the far offshore waters to see what cetacean fauna is there. Confer with the chief scientist frequently regarding cruise tracks.

2) LINE-TRANSECT SURVEYS W/IN 2 MILES OF CHANNEL ISLANDS.

During these survey, end the regular transect grid-line at approximately the 10-fathom curve before you begin the special "island stratum". Close the data file and open a new one so that I can keep these data separate in the analyses. You will conduct the surveys at 1 nmi offshore and will not chase sightings that are more than 1 nmi perpendicular to the offshore side of the ship). This will form a strata that consists of waters within 2nmi of the Channel Islands. As with other surveys, you can break effort to conduct whale photo-ID, but if the AR-2 is running well and waters are calm, you may be able to send-out a photo-ID team and continue effort. I especially would like to get picture of the island population of Tursiops.

3) PHOTO-IDENTIFICATION OF WHALES FOR MARK/RECAPTURE POPULATION ESTIMATION.

If whales are cooperative or if weather is rough, this work can be conducted from the McArthur. In general, better photographs can be taken from the launch, AR-2, because of its faster speed (to get in position) and its greater maneuverability. The crew is very fast and efficient at launching and retrieving AR-2. The photo-ID crew usually consists of the team leader who is not on-duty as the primary photographer, the cruise leader (or Sue Kruse who has extensive experience) as data recorder and back-up photographer, and Wes Armstrong for biopsy sampling (see below). Try to rotate in other people if possible, without packing the boat (a practical maximum is 3 scientists and a driver). I am willing to spend up to 3-4 hours at this with a good bunch of whales under good conditions. Read the conditions of the permit and make sure that those conditions are not violated. Species of primary interest are blue whales, humpback whales, killer whales, pilot whales, bottlenose dolphins (inshore or near islands), and right whales. Do not waste time on gray whales.

4) BIOPSY SAMPLES FOR POPULATION IDENTIFICATION

We have an ETP biopsy permit to take samples from some of the species that are found in California coastal waters. A second permit is pending that would include the remaining species. Do not take samples from unauthorized species (including Dalls porpoise and northern right whale dolphins) until the second permit is in-hand. In general, we would like to get samples from a wide variety of authorized species. Of particular interest are common dolphins and humpback whales because existing studies of DNA stock structure are already underway for those species. Wes Armstrong is taking the lead in this project.

INDEPENDENT OBSERVER EXPERIMENT

During the regular survey grid and the island surveys, an independent observer will collect data on the groups of cetaceans and (when more than 10 miles from shore) pinnipeds that are missed by the primary observer team. The independent observer searches primarily with naked eyes but should have a binocular in their hands at all times to verify more distant objects. The stick binoculars are good to hold because they are always raised and the independent observer does not draw inadvertent attention by raising or searching for binoculars. To qualify as missed, the entire group must be past 90 degrees right or left or be at the bow. To know whether a group will be missed, the independent observer must wait without saying anything or cueing the other observers until the school is past. If the independent observer is cueing the other observers, they should be sternly warned by the cruise leader not to do so. If this happens more than twice, you should consider relieving them of duty. The independent observer can call to turn the vessel if they need to verify species or school size, but only after the group has passed abeam. I expect the independent observer to work 4 to 5 hours a day at this job, with watches of not more than 2 consecutive hours. Watches should cover all periods of the day on a rotational basis (animals may be especially likely to be missed near dawn or dusk). The cruise leader should participate as independent observer whenever time permits (subject to the same constraints as the regular independent observer). You will have to

coordinate watch schedules with the independent observer.

APPENDIX B

AUTOMATED DATA ENTRY INSTRUCTIONS FOR CAMMS CRUISE

INTRODUCTION

For the first time on our marine mammal ship surveys, a computerized data entry system will be used to record sighting and effort data. The reasons for using a computer are primarily to increase the accuracy of data recording and to reduce the time between collecting the data and being able to analyze it. An added benefit is a reduced work load for the data recorder. Of course, the Sighting Continuation Form (which is the most time consuming form to fill out) cannot be replaced by computer entry since it requires drawing pictures. The Sighting Form and the Effort Record will not be used on this cruise.

The data entry program (called CRUISE) is a modification of one used extensively on SWFSC aerial surveys. It was designed for very rapid data gathering situations and has been tested under the most trying of circumstances. It may not be bullet-proof, but it is very close.

The basic feature of the program is that it is event-driven. You press a function key to indicate an event. Each function key has a specific assignment (eg. F2 for a sighting, F5 to toggle effort on-or-off, etc.). When you press a function key, the computer notes the time and latitude/longitude of the ship at the moment you pressed the key. You will not have to write down time or position (for the latter, the computer is plugged into a GPS satellite navigation unit). The first event you enter will be noted in the event buffer in the upper left part of the computer screen. You can continue to press other event buttons while the computer is waiting for you to respond with information on the first event. These subsequent events will just stack-up in the buffer and wait for your response. There is never any rush. The time and position of the buffered events has already been recorded.

Most errors that are made in entering data can be easily fixed. If you make an error that cannot be fixed, or if you are unsure you fixed it correctly, it is best to document the problem using a comment statement (F10). If, when you are entering information, that information will not be saved until you press the escape button (ESC). You can continue to make changes, going from one data element to the next, until you get it perfect. If you make a mistake and pressed the wrong event button, you can cancel it by pressing the UNDO button (F1). If you entered a wrong value and already pressed the ESC to save it, you can even go backwards and re-edit these data using the left and right arrow keys on the keyboard. Each of the event buttons and error-recovery functions are documented in more detail below.

As always, it is the recorder's responsibility to see that all data are entered properly. That person should be constantly reviewing weather and sighting conditions and updating them on the computer whenever conditions

change. All conditions must be reviewed at the beginning of each recorder's shift.

At the end of each day, it is the responsibility of the team leaders and the cruise leader to edit the newly created data files to ensure that data are complete and that any missing data have been inserted. Never edit the original copy of the data file. Transfer the data file to hard disk and edit it there. Document any problems with the data in a new comment line.

DATA EVENT FUNCTION KEYS

Information requested by the computer when you press an event button is exactly the same information that would go on the paper forms. There is, however, some differences in format. On paper, yes/no answers are coded as 1/2; on the computer you will answer with the letters "y" or "n". On paper you do not enter the decimal point; on the computer you do. On paper you must supply leading zeros for all data fields; on the computer you do not. Detailed instructions on each data element follow a general summary of the event options. The information you enter will be edited to ensure that it falls within specified ranges. A beep will indicate an invalid entry. You must then enter a correct value before proceeding.

ESC The ESC or escape button is used to save the changes you have made for a specific event button.

F2 Sighting This event indicates that you have seen something (a cue) that may be a marine mammal. The computer will prompt you for initial sighting information (the observer ID number, the type of cue, the method of sighting, the bearing to the cue, the distance to the cue). If you enter reticle distance, the computer will convert this to nautical miles. If the cue pans out to be a marine mammal sighting, then you will also enter a sighting number. The last assigned sighting number is shown in the upper line on the screen. When you are certain that the sighting is a cetacean and have already entered all of the above data, you press ESC to record these data. At this point, the computer will request auxiliary sighting information (the water temperature, whether documented photos were taken or birds were present with the cetacean, and species codes for up to 3 species). Species codes are available from a separate table. If you are unsure of the species, please enter the lowest taxonomic group that you are sure of. These species codes may be edited later based on your continuation sheets. [If more than 3 species are present in a school, hit the sighting button, F2, a second time and enter the additional species. Document what you have done using a comment, F10.]

If a cue does not turn out to be a cetacean, you can

cancel both the first and second page of input by pressing UNDO (F1) and responding yes to the subsequent query.

- F3 Begin** This event begins a day's effort. It sets up a series of events in the event buffer to ensure that when you start effort, all the pertinent information has been recorded. In addition to using this to start effort in the morning, it is good to use it whenever you are starting effort after a long (>30 minute) gap in sighting effort. The only specific information for this event is the cruise number. Pressing this button will, however, stack-up the buffer with events that correspond with F6, F7, F8, and F9.
- F4 Turtle** This event indicates a turtle sighting. Information requested includes the observer ID number, the turtle species, the bearing and distance at first sighting, the number of turtles, and associated objects (jellyfish, floating debris, or red tide). [NOTE that you are also requested to fill out the turtle life history form for each turtle sighting.]
- F5 Effort** Both beginning and ending effort are considered separate events. This one button acts as a toggle switch for both. If you are on-effort, pressing F5 will end it. If you are off-effort, pressing F5 will start it. Always check to see that the screen properly displays "ON" or "OFF". If you have an on-effort sighting, always press the sighting button before logging off-effort.
- F6 ObsvPos** This event indicates a change in observer positions. Use this whenever you rotate positions or begin a new shift. Pressing this button will stack-up the buffer with events that correspond with F7, F8, and F9 so that you can review this information and certify that it is correct.
- F7 ViewCondit'n** This event indicates a change in sea state variables. These include Beaufort code, swell height, swell direction, and water temperature.
- F8 Navigation** This event indicates a change in navigational variables. These include course and speed.
- F9 Weather** This event indicates a change in weather conditions. These include rain/fog/haze code, horizontal sun, vertical sun, wind direction, and visibility code.
- F10 Comment** This event is used to record ancillary information. You are encouraged to insert relevant comments liberally. Whenever you make an error in data entry, it is a good idea to document it. This is absolutely necessary if you are unable to go back and fix the error directly. Each

comment is associated with a time and position, so feel free to record any unusual sightings or observations as comments.

NON-EVENT FUNCTION KEYS

There are several function keys which do not indicate an event. Some of these are activated by pressing the SHIFT key while simultaneously pressing a function key. These non-event keys are documented below.

- ctrl-d** Exit the program by simultaneously pressing the control key (Ctrl) and the letter 'd'.
- F1 Undo** Undo is used to correct errors on the event you are currently editing. It has two levels. First, if you are typing information on a specific data element and you make a mistake and want to go back to the previous, original information you can press F1. If instead you are not adding information but have discovered that you have pressed the wrong event button by mistake, you can press F1 to cancel the event you are currently editing. Similarly you can go back into the data record using the arrow keys (below) and delete a previously entered event. In either case, the computer will prompt you to make sure you want to cancel this event.
- left-arrow** The left-arrow key is used to go back to make corrections on previous events which were recorded incorrectly. Each time you press "left-arrow", you will step one event back through the data file. You will be limited to editing only the most recent data. Undo can be used to delete a previous event. ESC is used to save a corrected event or to return to the most recently event that has not yet been entered. Similarly, the left or right arrow keys will save the corrected event, but these will move you within the buffer and will not return you to the end of the buffer.
- When you back-up to a sighting or a sighting position update, the bearing (rel. true north) and distance to that sighting are displayed. This is not continuously updated (as is the "last sighting position" window), but rather represents the bearing and distance at the time it appeared. If you want to update this, press right-arrow followed by left-arrow.
- right-arrow** The right-arrow will move you around in the event buffer, but cannot be used to by-pass events for which no information has been added. This is to prevent you from

accidentally skipping an event.

up-arrow

The up-arrow is used to move from one data element in the currently displayed event to the element above it.

down-arrow

The down-arrow is used to move from one data element in the currently displayed event to the element below it.

shift

F2 SightPos

To update school position, press Shift-F2 and enter the sighting number and the current course, angle, and distance. There is a window on the screen which indicates the approximate position of the initial sighting cue and the angle and heading to that position. This is based on the position and course at the time of the cue, and the angle and distance entered by the recorder. This information is presented in the hope that it will help find lost schools and to document school movement. Schools do move, and you should update the school's position frequently, at least 2-3 times for distant sightings. As with sightings, if you enter reticle distance, the computer will convert this to nautical miles.

shift

F3 Map

A map of the entire study area or the immediate region (+/- 12 NMI) can be displayed using shift-F3. For the entire area, all on-effort tracklines will also be shown. For the immediate area, all tracklines will be shown. Sighting positions will also be displayed in the latter mode. NOTE: this feature can only be called when there are no events waiting in the buffer. It will be canceled by pressing any key.

shift

F5 Sighting#

A new sighting number can be specified using F5. This is only used if sequential numbering of schools get off track.

SPECIFIC INSTRUCTIONS FOR DATA ELEMENTS

F2 Sighting

Sight# xxxx 4-digit sequential sighting number.

Observer xx 2-digit code assigned to observer who saw the initial cue. See Code Table 15.

1st Cue x 1-digit code: 1=bird, 2=splash, 3=mammals, 4=ships, 5=other or unknown, 6=blow, 7=helo.

SiteCode x 1-digit code: 3=crew, 4=obs 25x, 5=obs not 25x, 6=other or ?, 7=helo, 8=ind.observer.
Bearing xxx 3-digit angle to cue.
Reticle x.x Reticle distance to cue in tenths.
Distance x.x Nautical miles to cue, in tenths.
Temp xx.x Temperature in degrees centigrade to tenths.
PhotoY/N y/n Were photographs taken of the animals and documented on the sighting continuation sheet? Answer "y" or "n".
BirdsY/N y/n Were birds present with sighting? Answer "y" or "n".
Spp1Code xx 2-digit code for 1st mm spp. present.
Spp2Code xx 2-digit code for 2nd mm spp. present.
Spp3Code xx 2-digit code for 3rd mm spp. present.

F3 Begin

Cruise # xxxx 4-digit cruise number.

F4 Turtle

Observer xx 2-digit code assigned to observer who saw the initial cue. See Code Table 15.
Species xx 2-digit code for species of turtle.
Bearing xxx 3-digit initial angle to turtle sighting.
Distance x.x Initial nautical miles to turtle in tenths.
#Turtles x Number of turtles present in the given sighting.
AssocJFR x Up to 3 1-digit codes for associated objects: J=jellyfish, F=floating object, R=redtide

F5 Effort Turn effort on or off.

F6 ObsvPos

Left xx 2-digit code assigned to left 25x observer. See Code Table 15.
Recorder xx 2-digit code assigned to data recorder. See Code Table 15.
Right xx 2-digit code assigned to right 25x observer. See Code Table 15.

Ind.Obs. xx 2-digit code assigned to independent observer (if any).
See Code Table 15.

F7 SeaState

Beaufort x 1-digit code for Beaufort sea state. See Code Table 5.
Swell Ht xx Swell height in feet.
SwellDir xxx Swell direction relative to North.
W. Temp xx.x Water temperature in degrees centigrade.

F8 Navigation

Course xxx Ship heading relative to true north.
Speed xx.x Ship's speed in knots and tenths.

F9 Weather

Rain/Fog x 1-digit code, 1=no rain or fog, 2=fog, 3=rain, 4=rain and fog, 5=haze but not fog or rain.
Horz Sun xx 2-digit code for horizontal sun position.
Vert Sun xx 2-digit code for vertical sun position.
Wind Dir xxx Wind direction relative to true North.
Visbilty xx Distance in nautical miles of visibility.

F10 Comment

Enter written comment up to 142 characters long.

DATA FILES CREATED

The program creates or uses a number of data files; these are described below.

DAShhmm.mdd This is the day's main data file created on the computer's battery-backed RAM-Disk drive D. The name includes a time and day stamp so as to avoid overwriting this file when you restart the computer. In the name, **hhmm** refers to the hour and minute the program was started and **mdd** refers to the month and day (months 10, 11 and 12 are coded A, B, and C, respectively). Data include any edited changes made to the original data during the data gathering. See below for data format.

BAKhhmm.mdd This is the day's backup data file created on the computer's internal battery-backed RAM-Disk drive D. The name includes the same time and date stamp as the above DAS file. It also includes all the same information in the same format as the DAS file. In the backup, however, edited changes have not been made to the original line of data. Instead, a new data line has been created with the same sequence number as the original data line but with the edited data in place of the original data. Using this file, it is possible to find out what was originally entered before any changes have been made or it is possible to reconstruct the DAS file.

POSITION.DAT This file contains information of the ship's position recorded at the beginning and end of each segment of effort. This file is used in MAP function #1 to plot cruise tracks. New information is appended to the end of this file.

COAST.DAT This file contains the California coastline data. The file is used to plot the coast in MAP functions.

SIGHTNUM.DAT This file contains the last sighting number of the previous day.

DESCRIPTION OF DATA OUTPUT FORMAT FOR FILES DAS* AND BAK*

COLUMNS

1-3 3-digit sequence number for the given event. Sequence starts anew each day.

4 1-digit code to indicate the type of event.

S	marine mammal sighting
B	begin effort for the day
t	turtle sighting
R	resume effort
E	end effort
V	sea state viewing conditions
N	navigation information
W	weather information
C	comment
P	observer positions
A	auxiliary sighting information
s	sighting position update
*	automatic position record (every 10 minutes)
1,2,3,4,5,or 6	school size and species proportions

5 period . to indicate on-effort event, otherwise blank

6-11 time (HHMMSS)

12 blank

13-18 date (MMDDYY)

19 blank

20-39 position, latitude and longitude

40 blank

41-44 data field 1

45 blank

46-49 data field 2

50 blank

51-54 data field 3

55 blank

56-59 data field 4

60 blank

61-64 data field 5

65 blank

66-69 data field 6

70 blank

71-74 data field 7

contents of data fields 1-7
depends on type of event (see
column 4)

Event	Data Field Number					
	1	2	3	4	5	6
B	Cruise#	Spp	Bearing	DistNMI	#turtles	AssocJFR
t	ObsID					
R						
E	Beauf	SwHght	SwDir	W.Temp.		
V	Course	Speed				
N	Rain/Fog	HorzSun	VertSun	WindDir	Visibility	
W	LtObsID	RecordID	RtObsID	IndObsID		
P	Sight#	Bearing	Reticle	DistNMI	Course	
S						
*						
S	Sight#	ObsID	Cue	SCode	Bearing	Reticle
A	Sight#	W.Temp	PhotoY/N	Birdsy/N	Spp1Code	Spp2Code
1,2,3,4,	ObsID	BestSS	HighSS	LowSS	%Spp1	%Spp2
5, or 6						
C						DistNMI
C						Spp3Code
						%Spp3

Comments are continuous lines across all the data fields and may wrap around to subsequent comment lines.

Event	Description
B	begin effort for the day
t	turtle sighting
R	resume effort
E	end effort
V	sea state viewing conditions
N	navigation information
W	weather information
C	comment
P	observer positions
S	marine mammal sighting
A	auxiliary sighting information
S	sighting position update
*	automatic position record (every 10 minutes)
1,2,3,4,5,or 6	school size and species proportions for up to 6 observers

RECENT TECHNICAL MEMORANDUMS

Copies of this and other NOAA Technical Memorandums are available from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22167. Paper copies vary in price. Microfiche copies cost \$4.50. Recent issues of NOAA Technical Memorandums from the NMFS Southwest Fisheries Science Center are listed below:

- NOAA-TM-NMFS-SWFSC- 159 Report of a marine mammal survey of the eastern tropical Pacific aboard the research vessel *McArthur*,
P.S. HILL, A. JACKSON and T. GERRODETTE
(May, 1991)
- 160 Report of ecosystem studies conducted during the 1990 eastern tropical Pacific dolphin survey on the research vessel *David Starr Jordan*.
V.A. PHILBRICK, P.C. FIEDLER, S.B. REILLY, R.L. PITMAN, L.T. BALLANCE, G.G. THOMAS and D.W. BEHRINGER
(May, 1991)
- 161 Report of ecosystem studies conducted during the 1990 eastern tropical Pacific dolphin survey on the research vessel *McArthur*.
V.A. PHILBRICK, P.C. FIEDLER, S.B. REILLY, R.L. PITMAN, L.T. BALLANCE and D.W. BEHRINGER
(May, 1991)
- 162 Predicting sablefish age using otolith characteristics.
A. McBRIDE and J.E. HIGHTOWER
(August, 1991)
- 163 CHARTOPS: simulating short-term use of the tuna purse-seine fleet to survey dolphin schools in the eastern tropical Pacific Ocean.
E.F. EDWARDS and P. KLEIBER
(August, 1991)
- 164 Results of the southern California sportfish economic survey.
C.J. THOMSON and S.J. CROOKE
(August, 1991)
- 165 Status of Pacific oceanic fishery resources of interest to the USA for 1991.
STAFF OF THE SOUTHWEST FISHERIES SCIENCE CENTER
(September, 1991)
- 166 Methods used to identify pelagic juvenile rockfish (Genus *Sebastes*) occurring along the coast of central California.
EDITED BY T.E. LAIDIG and P.B. ADAMS
(November, 1991)
- 167 Spatial and temporal variability in growth of widow rockfish (*Sebastes entomelas*)
D.E. PEARSON and J.E. HIGHTOWER
(December, 1991)
- 168 Documentation of three computer programs used to assess daily age from the hard structures of animals.
T.E. LAIDIG and D.E. PEARSON
(June, 1992)
