Citation: Baldwin CC, Robertson RD (2014) A new *Liopropoma* sea bass (Serranidae, Epinephelinae, Liopropomini) from deep reefs off Curaçao, southern Caribbean, with comments on depth distributions of western Atlantic liopropomins. ZooKeys 409: 71–92. doi: 10.3897/zookeys.409.7249

Abstract

Collecting reef-fish specimens using a manned submersible diving to 300 m off Curaçao, southern Caribbean, is resulting in the discovery of numerous new fish species. The new *Liopropoma* sea bass described here differs from other western Atlantic members of the genus in having VIII, 13 dorsal-fin rays; a moderately indented dorsal-fin margin; a yellow-orange stripe along the entire upper lip; a series of approximately 13 white, chevron-shaped markings on the ventral portion of the trunk; and a reddish-black blotch on the tip of the lower caudal-fin lobe. The new species, with predominantly yellow body and fins, closely resembles the other two “golden basses” found together with it at Curaçao: *L. aberrans* and *L. olneyi*. It also shares morphological features with the other western Atlantic liopropomin genus, *Bathyanthias*. Preliminary phylogenetic data suggest that western Atlantic liopropomins, including *Bathyanthias*, are monophyletic with respect to Indo-Pacific *Liopropoma*, and that *Bathyanthias* is nested within *Liopropoma*, indicating a need for further study of the generic limits of *Liopropoma*. The phylogenetic data also suggest that western Atlantic liopropomins comprise three monophyletic clades that have overlapping depth distributions but different depth maxima (3–135 m, 30–150 m, 133–411 m). The new species has the deepest depth range (182–241 m) of any known western Atlantic *Liopropoma* species. Both allopatric and depth-mediated ecological speciation may have contributed to the evolution of western Atlantic Liopropomini.

Keywords

Liopropoma aberrans, *Liopropoma olneyi*, submersible, Substation Curaçao, Deep Reef Observation Project (DROP), DNA barcoding, phylogeny, modes of speciation

Introduction

Submersible diving to 300 m off Curaçao in the southern Caribbean as part of the Smithsonian Institution's Deep Reef Observation Project (DROP) is expanding our knowledge of the deep-reef Caribbean fish fauna (Baldwin and Robertson 2013, Baldwin and Johnson 2014). Recent collections of fishes included multiple individuals of what we initially identified as *Liopropoma aberrans* (Poey 1860) based on their predominantly golden color pattern. Subsequent analysis of mitochondrial DNA sequences (COI) from those specimens, detailed morphological examination of the preserved voucher specimens, and the discovery of consistent patterns of variation in coloration in photographs of vouchers taken prior to preservation led to the description of some of those individuals as a new species, *L. olneyi* Baldwin & Johnson, 2014. Additional genetic and morphological data indicate that the "golden basses" off Curaçao, in fact, comprise three species, *L. aberrans*, *L. olneyi*, plus one undescribed species. Herein we describe this third species, *Liopropoma santi* sp. n.

Liopropoma (Atlantic and Pacific), *Bathyanthias* (western Atlantic), and the monotypic *Rainfordia* (Indo-Pacific) form the monophyletic epinepheline serranid tribe Liopropomini (Baldwin and Johnson 1993). Twelve species of liopropomins currently are known from the western Atlantic, including the new species described herein: seven species of *Liopropoma*, four species of *Bathyanthias*, and a putative new species of the latter genus that we refer to here. These western Atlantic liopropomin species inhabit both shallow (< 50 m) and deep (to 411 m) reefs in Caribbean and adjacent waters. To compare species depth preferences, we use the known depth maximum and minimum for each species. To investigate how deep and shallow species are interrelated, we use the COI data to hypothesize the phylogeny of the group and then analyze the results in the context of the known depth distributions of the various species. Based on these results, we comment on possible modes of speciation in western Atlantic liopropomins.

Materials and methods

The manned submersible *Curasub* (<http://www.substation-Curacao.com>) was employed to collect fishes and invertebrates during various field periods between 2011 and 2013. Fish specimens were collected using the fish anesthetic quinaldine pumped from a reservoir through a tube attached to one hydraulic arm of the sub and a suction hose (that uses the same pump as the anesthetic-delivery apparatus) attached to the other arm. The latter empties into a vented plexiglass cylinder attached to the outside of the sub. At the surface, the specimens were measured, photographed, tissue sampled (muscle

biopsy from right side) and preserved. They were later x-rayed with a digital radiography system. Counts and measurements included in the description follow Hubbs and Lagler (1958) and Randall and Taylor (1988). Measurements were made to the nearest 0.1 mm with an ocular micrometer fitted into a Wild stereomicroscope (smallest specimen) or with needle-point dial calipers. Institutional abbreviations follow Sabaj Pérez (2012).

Tissue samples for DNA Barcoding were stored in saturated salt-DMSO (dimethyl sulfoxide) buffer (Seutin et al. 1991). DNA extraction, PCR, sequencing cytochrome c oxidase subunit I (COI), and editing COI sequences were performed as outlined by Weigt et al. (2012). A neighbor-joining tree (Saitou and Nei 1987) was generated using PAUP*4.1 (Swofford 2002) on an analysis of Kimura two-parameter distances (Kimura 1980). The neighbor-joining tree shows genetic distances in COI among individuals and how they cluster into genetically distinct lineages, which, in teleost fishes, correspond well with species (e.g. Baldwin and Weigt 2012, Weigt et al. 2012). Interspecific phylogenetic relationships were hypothesized for western Atlantic liopropomins and three Indo-Pacific species of *Liopropoma* based on maximum parsimony analysis of the COI sequences using heuristic searches in PAUP*4.1. Characters were equally weighted and left unordered. The resulting equally parsimonious trees were summarized using the strict consensus method. Outgroups for both analyses were two members of the sister group of the Liopropomini – *Grammistes sexlineatus* (Thunberg, 1782) and *Rypticus carpenteri* Baldwin & Weigt, 2012, of the tribe Grammistini (Baldwin and Johnson 1993), and the trees were rooted on a more distant outgroup, *Scorpaena plumieri* of the family Scorpaenidae. We follow Johnson (1983) and Baldwin and Johnson (1993) in recognizing a monophyletic family Serranidae and subfamily Epinephelinae pending resolution of serranid relationships in light of conflicting hypotheses based on molecular data (e.g., Smith and Craig 2007, Betancur et al. 2013, Near et al. 2013).

The label for each entry on the neighbor-joining tree is an assigned DNA number, and we include that number in the designation of type specimens and in some figure captions. Abbreviations used in DNA numbers are as follows: BAH–Bahamas, BLZ–Belize, CUR–Curacao, FLST–Florida Straits, FWRI–Florida Wildlife Research Institute, MBIO–Moorea Biocode Project, MCgroup–Matthew Craig, MOC–Miguel Oliver Caribbean Cruise, MOOP–Moorea Deep Reef, TOB–Tobago. GenSeq nomenclature for DNA sequences (Chakrabarty et al. 2013) and GenBank information are presented along with museum catalog numbers for voucher specimens in the Appendix.

Results

The neighbor-joining tree (Fig. 1) shows how individual specimens of western Atlantic *Liopropoma* sort into genetic lineages based on similarity in COI sequences. Lineages correlate well with currently recognized species. Genetic distance in COI between pairs of species of western Atlantic *Liopropoma* ranges from 5–18%, and distance between *L. santi* sp. n., and other western Atlantic *Liopropoma* species is 13–18% (Table 1). Average intraspecific variation for western Atlantic *Liopropoma* is 0–0.3%, 0.2% for *L. santi*.

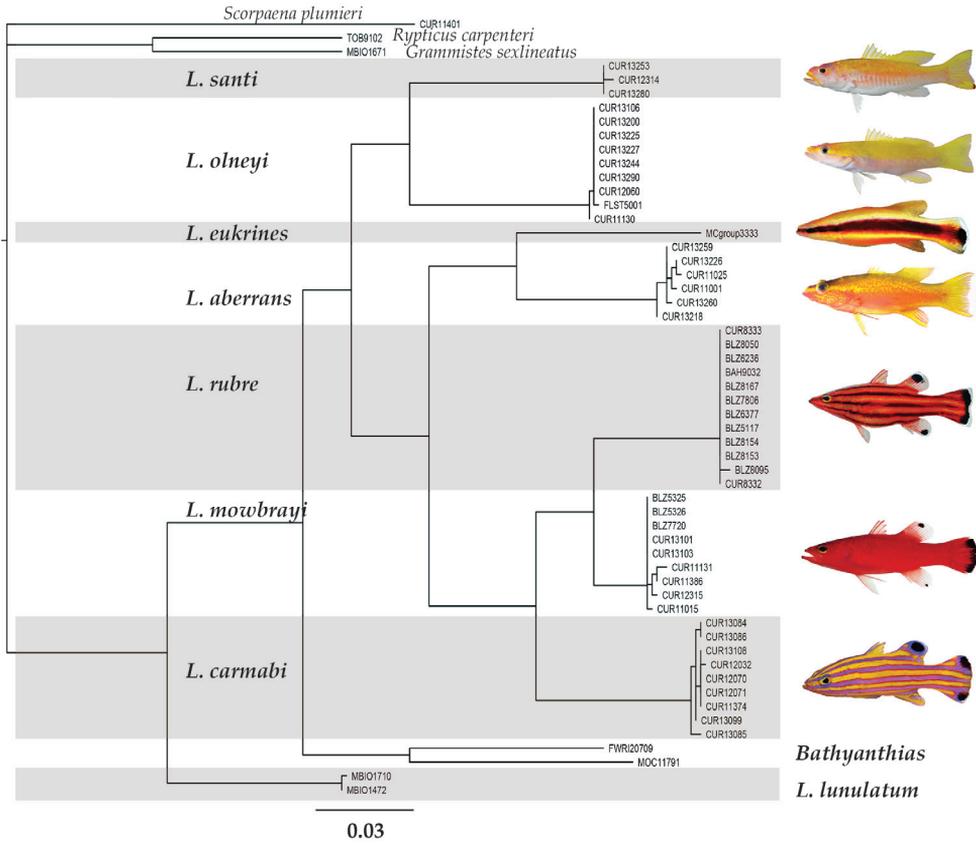

Figure 1. Neighbor-joining tree derived from COI sequences for western Atlantic *Liopropoma*, the Indo-Pacific *L. lunulatum*, and related taxa. The tree was rooted on *Scorpaena plumieri*. Divergence represented by scale bar = 3%. Photographs of *L. rubre* and *L. mowbrayi* by James Van Tassel and Ross Robertson.

southern Caribbean, Curaçao, east of Substation Curaçao downline, near 12°05.069'N, 68°53.886'W, 209 m, 15 Aug 2012, C. C. Baldwin, B. Brandt, B. van Bebbber.

Diagnosis. A liopropomin serranid with the following combination of characters: dorsal fin VIII,13; anal fin III, 8; pectoral fin 15; total gill rakers on first arch (including rudiments) 20–21; lateral-line scales 47–48; length of first dorsal spine 2.9–4.2% SL; margin of spinous dorsal fin moderately indented posteriorly in adults (fourth spine 11–12% SL, fifth and sixth spines only slightly shorter than fourth—6.9–10% SL); depth at origin of dorsal fin 23–26% SL; least depth of caudal peduncle 11–13% SL; orbit diameter 9.4–12% SL; yellow-orange stripe externally on upper lip; series of approximately 13 white, chevron-shaped markings on ventral portion of trunk; reddish-black blotch on distal portion of lower caudal-fin lobe; inhabiting depths of 182–241 m.

Description. Counts and measurements of holotype, if different from those of paratypes, are given in parentheses. Dorsal-fin rays VIII, 13; anal-fin rays III, 8; pectoral-fin rays (both sides) 15; pelvic-fin rays I, 5; principal caudal-fin rays 9+8=17; procurrent caudal-fin rays 9+9=18; pored lateral-line scales 48 (47), two additional pored scales present on base of caudal fin not included in total count; scales from lateral line to dorsal-fin origin 3 or 4 (3); gillrakers on first arch, including rudiments, 6+14-15 (6+14); upper limb with 3 rudiments + 3 rakers, lower limb with 11-13 rakers + 2-3 rudiments, total 20–21 (20); vertebrae 10 + 14.

Body proportions expressed as percentage of SL. Body depth at origin of dorsal fin 23–26 (26); body width just behind gill opening 11–14 (14); head length 37–39 (37); snout length 7.4–9.1 (9.1), relative length increasing with increasing SL; orbit diameter 9.4–12 (9.4) relative diameter decreasing with increasing SL; bony interorbital width 4.5–5.5 (5.5); upper-jaw length 16–18 (18); greatest depth of maxilla 5.0–6.1 (6.1); least caudal-peduncle depth 11–13 (13); caudal-peduncle length 22–24 (23); lengths of dorsal-fin spines: (I) 2.9–4.2 (4.2); (II) 11–12 (12); (III) 13–15 (14); (IV) 11–12 (11); (V) 6.9–10 (10); (VI) 6.9–8.2 (8.2); (VII) 5.0–7.5 (7.5); (VIII) 4.8–6.9 (6.9); longest dorsal soft ray the 11th, length 15–20 (20); length of 3rd anal-fin spine 6.9–9.3 (9.3); longest anal soft ray the 5th, length 15–17 (16); caudal-fin length 23–28 (23), relative length decreasing with increasing SL; pectoral-fin length 27–30 (27), fin reaching vertical between anus and origin of anal fin, falling short of anal fin in all specimens; pelvic-fin length 18–20 (19), fin reaching vertical through base of 6th dorsal-fin spine, well short of anus.

Interorbital region flat to slightly convex; mouth oblique, maxilla reaching vertical beyond posterior border of pupil; prominent bony projection on posteroventral corner of maxilla; lower jaw slightly projecting. Anterior nostril in thin, membranous tube, nostril situated just posterior to groove between tip of snout and premaxilla; posterior nostril a simple opening, nostril situated close to orbit (the distance approximately 1.5 nostril diameters). Lateral line strongly arched above pectoral fin, highest point below fourth and fifth dorsal-fin spines.

Trunk covered with ctenoid scales, scales becoming weakly ctenoid anteriorly and cycloid on head. Head fully scaled except over branchiostegal area. Holotype with

Figure 2. *Liopropoma santi* sp. n., type series: **A** USNM 426811, holotype, 116 mm SL, DNA #CUR 13253 **B** USNM 426813, paratype, 76.2 mm SL, DNA #CUR 13280 **C** USNM 414824, paratype, 42.0 mm SL, DNA #CUR 12314.

short column of scales on dorsal-fin spines III and IV, scales on basal portion of membranes between spines VI and VIII, three rows of scales covering basal portion of soft dorsal fin, and some scales extending distally onto soft dorsal-fin membranes; paratypes with same squamation except no scales present on spinous dorsal fin, and 42.0-mm SL paratype having only basal scale rows on soft dorsal fin. In holotype and larger paratype, anal fin with two or three rows of scales basally and additional scales that extend distally onto fin membranes and cover most of fin. In smaller paratype, scales confined to basal portion of fin. Caudal fin completely scaled in holotype except for

distal tips of rays; larger paratype with scales covering only proximal half of fin; smaller paratype with scales confined to basal portion of fin. Scales present on pectoral-fin base, and elongate scales present on proximal portion of fin. Scales present on pelvic-fin base and on proximal portion of fin; pelvic axillary scales present.

Jaw teeth small and depressible; upper and lower jaws with bands of villiform teeth, bands widest anteriorly, largest teeth in innermost row. Vomer with a chevron-shaped patch of small teeth. Palatines with several rows of small teeth in a long, narrow band. Opercle with three flattened spines, only the middle one conspicuous. Margin of upper limb of preopercle and angle with small serrations, lower limb smooth.

Prior to preservation (Figs 2, 3), background color of upper portions of trunk and caudal peduncle yellow, grading to pale pink around midbody, then to white ventrally; no abrupt transitions between those colors; many individual scales on upper half of body marked with orange spots in adults, densely so in holotype; a series of about 13 narrow, bright-white, chevron-shaped bars that point posteriorly present on lower half of trunk, series extending from just behind pectoral-fin base to vertical through center or posterior portion of anal fin; upper arms of white bars more strongly defined; nape yellow from dorsal midline ventrally to about mid-eye level (with some orange spots on scales in adults), grading anteriorly into an irregularly shaped area of purplish-pink over and behind eye, on upper portion of iris, and on snout; a yellow blotch present behind center of eye (in adults) and a smaller one present on dorsal midline of snout just anterior to orbit; iris mostly orange-yellow, grading to fine inner yellow ring; prominent, mostly deep-yellow (adults) or mostly orange (juvenile) stripe along outside of entire upper lip, this pigment spreading slightly above lip along anterior half of jaw in adults and merging with the pink/orange pigment on snout of juvenile; inside of lower lip with small blotch of yellow pigment in adults, inside of upper lip with stripe of yellow (adults) or orange (juvenile); photographic angle did not permit characterization of pigment on inside of lower lip of juvenile; lower jaw and lower two thirds of head white, with pinkish cast in holotype; in adults, dorsal fin with yellow spines and mostly white inter-spinous membranes; soft dorsal-fin rays yellow, membrane between anterior rays yellow, and membrane between rays of remainder of fin with small to large pale area centrally, size of pale area increasing posteriorly such that membrane between posteriormost rays completely pale; some rays and membranes in posterior portion of soft dorsal fin with pale rose pigment in smaller adult; a thin white margin extending along outer edge of entire dorsal fin, this margin appearing blue-white when fish photographed against black background (Fig. 3); in juvenile, inter-spinous membranes of dorsal fin mostly pale and soft dorsal mostly pale except for yellow stripe at the base and yellow stripe near outer margin of fin; caudal fin mostly yellow in holotype, central portion of fin with pale outer margin and with pale to pinkish-orange membranes between rays; thin pinkish-orange stripe present along dorsal and ventral margins of fin; distal tip of lower lobe with reddish-black blotch, a few thin streaks of black extending proximally from this blotch; pigment on caudal fin of smaller adult similar but with less pinkish-orange pigment, and caudal fin of juvenile mostly clear with a large, oval-shaped, oblique yellow blotch on outer half of both upper and lower

Figure 3. *Liopropoma santi* sp. n., USNM 426811, holotype, 116 mm SL (photographed against a black background).

Figure 4. In-situ photograph of *Liopropoma santi* sp. n., taken from the *Curasub* submersible at 204 m on a reef slope off Jan Theil Bay, Curaçao, 5 Nov 2013. Photo courtesy of Substation Curaçao.

lobes; dark spot on distal portion of ventral caudal lobe relatively larger in juvenile; anal fin white, with faint pinkish-yellow streak on first through fifth rays in holotype, little or no color in smaller adult and juvenile; pelvic fin white; pectoral fin translucent with pale pinkish-orange cast; general coloration most intense in the holotype and least intense in the juvenile.

In alcohol (see Fig. 6A), body pale, the only pigment a dark blotch on distal tip of ventral caudal-fin lobe.

Distribution. Known only from Curaçao, southern Caribbean.

Habitat. Off Curaçao, *L. santi* is found from 182–241 m inhabiting rocky slopes and ledges. It retreats into small caves and crevices when approached and illuminated by the submersible. Figure 4 shows an in-situ photograph taken from the *Curasub* submersible at 204 m on a reef slope off Jan Theil Bay, Curaçao.

Etymology. The specific name honors Roger Sant, who participated in the *Curasub* submersible dive at Playa Forti during which the USNM 426813 paratype was collected. Roger and Victoria Sant have provided generous funding to the Smithsonian Institution’s National Museum of Natural History for ocean-related activities.

Common name. “Spot-tail golden bass” is in reference to the dark spot on the lower lobe of the caudal fin, which, along with other characters, distinguishes *L. santi* from the two other species of western Atlantic *Liopropoma* that have predominantly golden coloration, *L. aberrans* and *L. olneyi*.

Comparisons. Counts and measurements of the three western Atlantic “golden basses” collected off Curaçao, *L. santi*, *L. aberrans*, and *L. olneyi*, are given in Table 2, representative images of the three are provided in Figure 5, and a summary of major differences among them appears in Table 3. An image of a freshly collected specimen of a species of the related genus *Bathyanthias* is also included in Figure 5 for comparative purposes. *Liopropoma santi* is easily distinguished from the others by color in life, especially by the presence of a yellow or orange stripe externally on the upper lip, a series of white chevron-shaped markings on the ventral portion of the trunk, and the reddish-black blotch on the distal portion of the lower caudal-fin lobe. The last also visually distinguishes *L. santi* from *L. aberrans* and *L. olneyi* in preservative. *Liopropoma santi* is further distinguished from both of those species by having more dorsal-fin rays, more gill rakers on the first arch, and usually a larger eye (Table 2). From *L. aberrans*, *L. santi* is further distinguished by having more pectoral-fin rays, a narrower body at the dorsal-fin origin, a narrower caudal peduncle, longer fourth–sixth dorsal-fin spines, and a more shallow indentation in the spinous dorsal fin (Tables 2, 3).

Baldwin and Johnson (2014) discussed the status of *L. aberrans*, which was described from a single specimen collected off Cuba in the 19th century (Poey 1860) and redescribed from a single specimen collected off the Bahamas in the 20th century (Robins 1967). They noted differences in the descriptions of color patterns of the two specimens and numbers of dorsal-fin rays (IX, 12 in Poey’s *L. aberrans*, VIII, 12 in Robins’ *L. aberrans*), and they questioned whether or not the two specimens represent the same species. Specimens of *L. aberrans* collected off Curaçao (“Curaçao *L. aberrans*”) share with the Bahamas *L. aberrans* the same dorsal-fin count, general body shape, and color pattern, although Baldwin and Johnson (2014) noted some differences in the color pattern. Curaçao *L. aberrans* have 17–18 gill rakers on the first arch (Table 2), whereas Robins (1967) reported 14 for the Bahamas specimen; however, as noted by Baldwin and Johnson (2014), Robins’ count only included the rudimentary pads on the upper limb. Examination of the Robins’ Bahamas specimen (UMML 22324) indicates that there are four rudimentary pads on the lower limb, and thus the total number of gill rakers on the first arch is 18.

Table 2. Selected counts and measurements for the type series of *Liopropoma santi* sp. n., *L. aberrans* from Curaçao, and *L. olneyi*. Measurements are in percentages of SL. Data for *L. aberrans* are from Curaçao specimens examined in this study, those for *L. olneyi* are from Baldwin and Johnson (2014).

Table 3. Summary of differences in morphology and depth ranges among the three golden-colored *Liopropoma* species off Curaçao.

Character	<i>L. santi</i> sp. n.	<i>L. olneyi</i>	<i>L. aberrans</i>
Relative body depth	Shallow (23-26% SL)	Shallow (20-24% SL)	Deeper (27-29% SL)
Dorsal fin indentation	Moderate (6 th spine 7-8% SL)	Weak (6 th spine 7-9% SL)	Strong (6 th spine 4-6% SL)
Dorsal-fin rays	VIII, 13	IX, 11	VIII, 12
Gill rakers on first arch	20-21	17-19	17-18
Orbit diameter (% SL)	9.4-12	7.8-9.4	7.4-8.7
White flank chevrons	yes	no	no
Body ground colors	yellow over white	yellow over white	yellow over orange
Yellow stripe through eye	no	yes	yes
Yellow-orange upper lip	yes	no	no
Yellow spots on body	no	adult & juvenile	juvenile only
Dark spot on lower caudal-fin lobe	yes	no	no
Depth range (m)	181-241	133-193	98-149

Curaçao and Bahamas *L. aberrans*, however, appear to have different depth preferences, with Robins' *L. aberrans* occurring deeper—229 m. At Curaçao, *L. aberrans* was collected between 98 and 149 m and observed by us only within that depth range during nearly 100 submersible dives over a three-year period. This is unlikely to be due to effects of differences in habitat availability at the two locations, as *L. santi* and *L. olneyi* occur at deeper depths than *L. aberrans* at Curaçao.

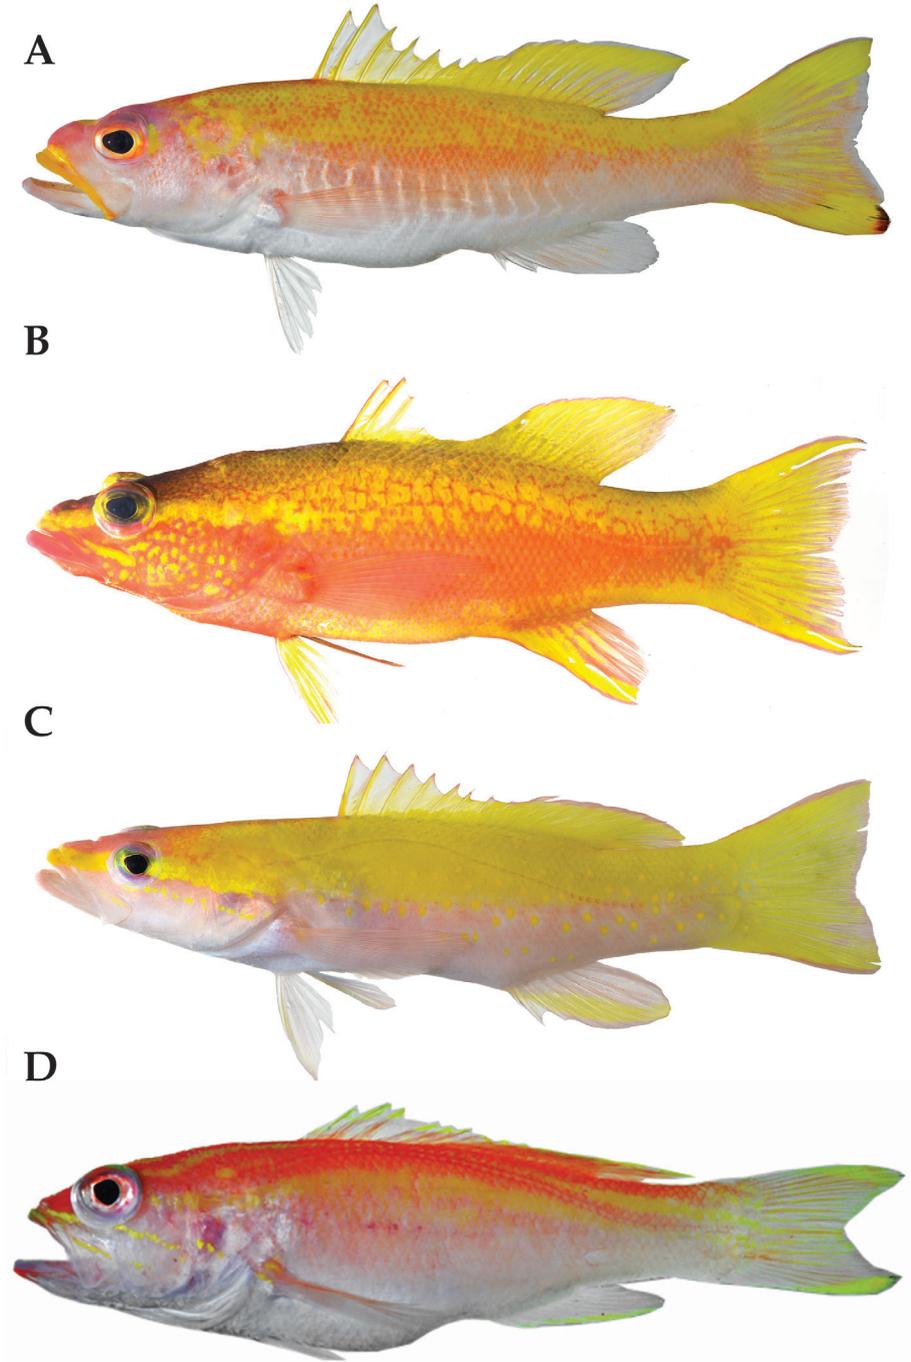

Figure 5. Comparison of the three species of “golden basses” off Curaçao and *Bathyanthias* sp. from Panama: **A** *Liopropoma santi* sp. n., USNM 426811, holotype, 116 mm SL, DNA #CUR 13280 **B** *L. aberrans*, USNM 426807, 102 mm SL, DNA #CUR 12226 **C** *L. olneyi*, USNM 426805, holotype, 84.3 mm SL, DNA #CUR 13200 **D** *Bathyanthias* sp., USNM 407791, 110 mm SL, DNA #MOC 11791.

Figure 6. Comparison of *Liopropoma* and *Bathyanthias*: **A** *L. santi* sp. n., USNM 426811, holotype, 116 mm SL (photographed after preservation) **B** *B. cubensis* (Schultz 1958), USNM 158138, holotype, 80.3 mm SL. Photos by Sandra Raredon.

Poey (1860) did not provide depth data or a gill-raker count for his 115-mm SL specimen from Cuba. Curaçao *L. aberrans* differs from the Cuban *L. aberrans* in dorsal-fin count and certain aspects of color pattern, but fish from those two sites share the presence of yellow spots on the cheek (sometimes lacking in juvenile Curaçao *L. aberrans*), spots that were not mentioned by Robins (1967) for the 112-mm SL Bahamas *L. aberrans*. The whereabouts of the holotype of *L. aberrans* are unknown (Eschmeyer 2013), and, in the absence of additional material from the type locality for comparative purposes, we follow Baldwin and Johnson (2014) in tentatively recognizing the specimens from Cuba, Bahamas, and Curaçao as *L. aberrans*. As noted by Baldwin and Johnson (2014), a digitized copy of a color photograph of a specimen of *L. aberrans* from Jamaica taken and provided by Patrick Colin shows a color pattern nearly identical to that of Curaçao *L. aberrans*. Should Poey's *L. aberrans* prove to be distinct from specimens from the Bahamas, Curaçao, and Jamaica, one or more new species will need to be recognized.

Liopropoma santi differs from Poey's and Robins' *L. aberrans* in number of dorsal-fin rays (VIII, 13 vs. IX, 12 and VIII, 12, respectively) and shape of dorsal fin (with only a moderate indentation in spinous dorsal fin in *L. santi*, deep indentation in the others). It further differs from Robins' *L. aberrans* in numbers of pectoral-fin

Table 4. Dorsal-fin counts of western Atlantic Liopropomini fishes. Data for *Bathyanthias atlanticus*, *B. cubensis*, and *B. mexicanus* are from Schultz (1958); for *Liopropoma aberrans* (Cuba) Poey (1860); for *L. aberrans* (Bahamas) Robins (1967); for *L. carmabi*, *L. eukrines*, *L. mowbrayi*, *L. rubre* Randall (1963); and for *L. olneyi* Baldwin and Johnson (2014).

	SPINES		SOFT RAYS

<i>Liopropoma santi</i> sp. n.	+					+	

¹ As noted by Baldwin and Johnson (1993), Günther (1880) gave IX, 14 as the dorsal-fin count for *B. roseus*, but their examination of a radiograph of the type specimen indicates that it has VIII dorsal spines.

rays (15 vs. 14) and gill rakers on the first arch (20–21 vs. 17–18), and color pattern (presence of diagnostic color features of *L. santi*—see Diagnosis—vs. absence). From other western Atlantic *Liopropoma* (*L. carmabi* [Randall 1963], *L. eukrines* [Starck and Courtenay 1962], *L. mowbrayi* [Woods and Kanazawa 1951], *L. rubre* Poey 1861), *L. santi* differs most notably in color pattern (Fig. 1) and in having VIII, 13 dorsal-fin rays (vs. VIII, 12 in all except one specimen of *L. carmabi* with VIII, 13—Table 4).

Counts of *L. santi* closely match those of *Bathyanthias cubensis* (Schultz, 1958) in having VIII, 13 dorsal-fin rays; III, 8 anal-fin rays; 15 pectoral-fin rays; and 20–21 gill rakers on the first arch. *Liopropoma santi* has 47–49 lateral-line scales, whereas *B. cubensis* has 46–47. The two species are otherwise very different. *Liopropoma santi* has a shallower trunk (body depth 23–26% SL and caudal-peduncle depth 11–13% SL in *L. santi* vs. 28–32% SL and 14–15% SL, respectively, in *B. cubensis*—Schultz, 1958), and *L. santi* has a single blotch of dark pigment on the distal portion of the lower caudal-fin lobe vs. dark pigment on the distal ends of all caudal-fin rays. Like other species of *Bathyanthias*, the dorsal profile of the head in *B. cubensis* is convex (vs. usually straight in *Liopropoma*—although there may be a bump on the snout and the profile may be slightly convex in large specimens of *Liopropoma*); there is little indentation in the margin of the spinous dorsal fin (vs. larger indentation); the posteroventral corner of the maxilla has a weakly developed hook-like process (vs. well developed in *Liopropoma*—see Randall and Taylor [1988] and Baldwin and Johnson [1993]); and in *Bathyanthias*, the anterior portion of the lateral line is broadly curved over the pectoral fin (vs.

sharply curved in *Liopropoma*). Differences between *L. santi* and *L. cubensis* can be seen in Figure 6, and the generic characters listed above can be seen in Figures 5 and 6. The depth range of *B. cubensis* is greater than that of *L. santi*, 183–411 m vs. 182–241 m.

Discussion and conclusions

A combination of morphological and genetic differences supports the recognition of *L. santi* as a valid new species of *Liopropoma*. *Liopropoma santi* inhabits depths of 182–241 m off Curaçao, making it the deepest known *Liopropoma* species in the western Atlantic (Fig. 7). The shallower portion of its depth range overlaps the deeper portion of the depth range of *L. olneyi* (133–193 m), but with the exception of Robins' (1967) specimen of *L. aberrans* from the Bahamas (229 m), no other western Atlantic *Liopropoma* species occur within the depth range of *L. santi*. A preliminary phylogeny of western Atlantic *Liopropoma* based on parsimony analysis of the COI data is shown in Figure 8. In that phylogeny, the three species that inhabit depths of 3–135 m (*L. rubre*, *L. carmabi*, and *L. mowbrayi*) form a monophyletic group that is sister to a clade comprising two species that inhabit depths of 30–150 m (*L. eukrines* and *L. aberrans* from Curaçao). Those clades combined are sister to a clade comprising the deepest western Atlantic *Liopropoma* (*L. olneyi* and *L. santi*, 133–241 m) plus two species of the genus *Bathyanthias* (*B. mexicanus* [Schultz 1958] and a putative new species from Panama) that were collected at 143–259 m. Two additional species of *Bathyanthias*, *B. atlanticus* [Schultz, 1958] and *B. cubensis* (not available for inclusion in the molecular phylogenetic analysis), are known from 82–411 m, and the depth range of non-Curaçao *L. aberrans* (also not available for inclusion in the phylogenetic analysis) is 89–230 m (Robins 1967, Ocean Biogeographic Information System [OBIS] - <http://www.iobis.org/>, Fishnet 2 - <http://www.fishnet2.net/>).

The COI data provide excellent support for the monophyly of species of western Atlantic *Liopropoma* but poor support for clades within the genus (see bootstrap values in Fig. 8). Nevertheless, the strict consensus (Fig. 8) suggests that western Atlantic liopropomins are monophyletic with respect to Indo-Pacific *Liopropoma* (*L. lunulatum*, *L. tonstrinum*, and *L. pallidum* in Fig. 8). A more robust phylogenetic hypothesis is needed that is derived from additional genes and more Indo-Pacific species of *Liopropoma*, but the COI data suggest a relationship between depth and monophyletic clades in western Atlantic Liopropomini that warrants further investigation. Members of the three clades of western Atlantic liopropomins identified in the phylogeny show a tendency to occupy different depth strata (3–135 m, 30–150 m, and 82–411 m). Based on our few specimens, it appears that *L. santi* has larger eyes than its sister species, *L. olneyi* (Table 3), which may represent an adaptation allowing *L. santi* to extend its range to greater depths. Among the three golden basses at Curaçao (*L. aberrans*, *L. olneyi*, *L. santi*), *L. aberrans* has the shallowest range and shows a tendency to have the smallest eyes (Table 3). Adaptation to life at different depths may have been involved in the speciation of this co-occurring species group. It may also be involved in the di-

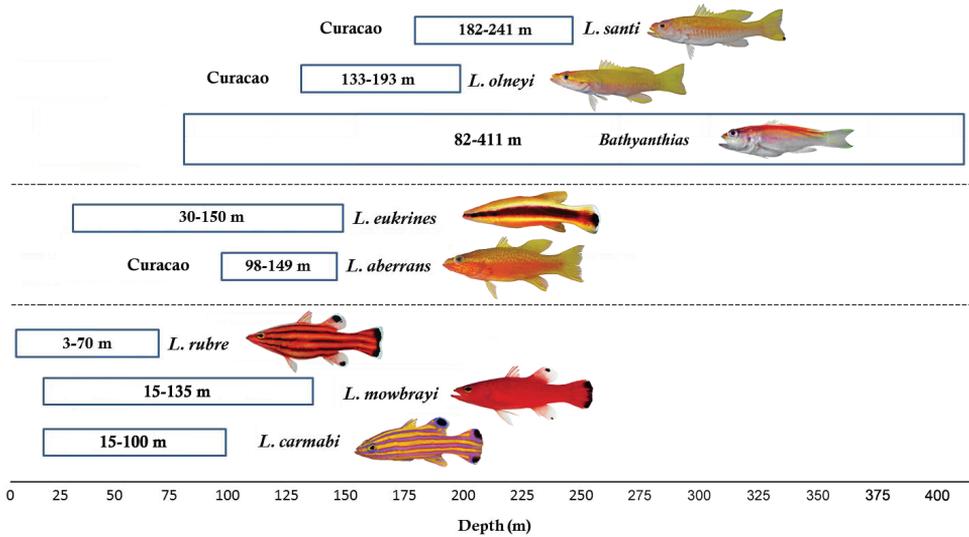

Figure 7. Depth distributions of western Atlantic *Liopropoma* and *Bathyanthias* species that were included in the phylogenetic analysis (see Fig. 8). Photographs of *L. rubre* and *L. mowbrayi* by James Van Tassell and Ross Robertson.

vergence between *L. mowbrayi* and *L. rubre*, which represent sister species that show only partial overlap in their depth ranges (Fig. 7) but broadly overlapping geographic ranges that incorporate most of the Caribbean and adjacent areas. Adaptation to use of different depth strata may also have been involved in the initial diversification of western Atlantic liopropomins into three clades that now occupy the same geographic area. Such parapatric ecological speciation, in which species diverge along environmental gradients, has been proposed for other marine fishes including *Halichoeres* (Rocha et al. 2005) and *Sebastes* (Ingram 2011). In *Sebastes*, Ingram (2011) found a strong signal of speciation evolution in depth habitats and in traits apparently related to life at different depths, such as eye size.

Conversely, the sister species *L. eukrines* and *L. aberrans* overlap substantially in depth range but show a significant amount of geographic separation: *L. eukrines* is largely restricted to the Gulf of Mexico and southeastern USA, whereas *L. aberrans* is primarily Caribbean. However, there is one inconsistency in this pattern of either geographic or depth segregation among members of the same clade: *L. carmabi* and both species in its sister group, *L. rubre* and *L. mowbrayi*, have both geographic- and depth ranges that broadly overlap. Liopropomins have pelagic larvae, and allopatric speciation might be facilitated by larval dispersal to new areas. Possibly both ecological and allopatric speciation have occurred in the group, but, if so, more information on depth and geographic distributions, morphological traits associated with life at different depths, and evolutionary relationships is needed to estimate their relative roles. Depth and morphological information for the three members of the *L. rubre* clade collected at the same geographic location would be highly relevant in this regard. At

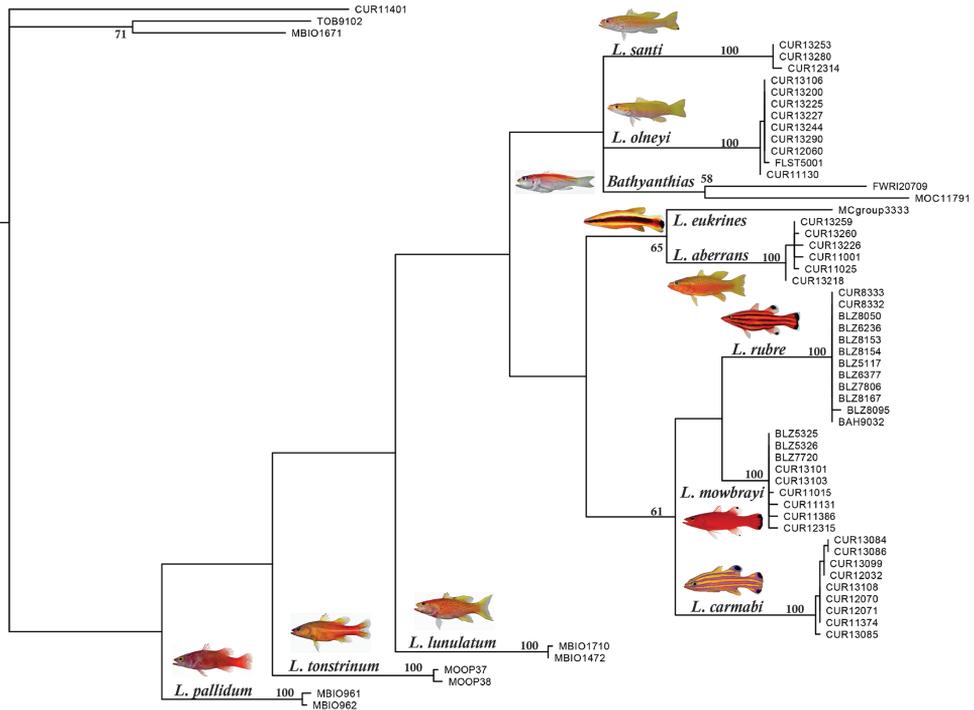

Figure 8. The strict consensus of a maximum parsimony analysis of the COI region among western Atlantic *Liopropoma* and related taxa. The tree was rooted on *Scorpaena plumieri*, (CUR11401), and the non-liopropomini serranids *Rypticus carpenteri* (TOB9102) and *Grammistes sexlineatus* (MBIO1671) were included as additional outgroups. Photographs of *L. rubre* and *L. mowbrayi* by James Van Tassell and Ross Robertson; photos of *L. pallidum* and *L. lunulatum* by Jeffrey Williams (from Encyclopedia of Life); photo of *L. tonstrinum* by Richard Winterbottom (from Encyclopedia of Life).

Puerto Rico all three species in that clade occur on the same mesophotic reefs, where they reach the same maximum depth (Bejarano et al 2014). At Curaçao Adriaan Schrier, who operates Substation Curaçao, has been actively collecting all three species for many years using a combination of traditional SCUBA, mixed gas SCUBA, and the *Curasub*. He provided (personal communication March 2014) the following information for that location: *L. rubre* occurs at 12–55 m, *L. mowbrayi* at 12–135m, and *L. carmabi* at 25–100m. He also noted that while *L. mowbrayi* and *L. carmabi* are found in areas with small-scale coral and rock shelter and rubble, *L. rubre* is restricted to caves in large scale coral structures and is much more secretive than the other two species. These observations indicate that members of the *L. rubre* clade show some degree of depth segregation within a site, as well as microhabitat segregation.

The phylogeny (Fig. 8) further suggests the need to reanalyze generic relationships within the Liopropomini, as *Bathyanthias* is embedded within western Atlantic *Liopropoma*. Morphologically, *L. santi*, *L. olneyi*, and *Bathyanthias* differ from other western

Atlantic *Liopropoma* in having a smaller indentation in the margin of the dorsal fin, and those liopropomins lack body stripes and have similar pale orange/yellow/rose coloration. Four species of *Bathyanthias* have been described – *B. atlanticus* (Schultz, 1860), *B. cubensis* (Schultz, 1860), *B. mexicanus* (Schultz, 1860), and *B. roseus* Günther 1880. Of those, only *B. mexicanus* from the Gulf of Mexico (FWRI 20709) was available for inclusion in our phylogenetic analysis. The other *Bathyanthias* species included, which may represent an undescribed species, is from Central America - Panama (USNM 407791, MOC 11791). Its combination of dorsal-, pectoral, lateral-line, and gill-raker counts do not match any other known species of *Bathyanthias*.

Of the three western Atlantic species of *Liopropoma* with depth distributions entirely below depths accessible using conventional scuba gear – *L. aberrans*, *L. olneyi*, and *L. santi*—two have been discovered only recently through submersible diving to 300 m off Curaçao in the southern Caribbean (*L. olneyi* and *L. santi*). More exploration of western Atlantic tropical mesophotic and other deep-reef depths is needed to fully document fish diversity even in well-studied taxonomic groups such as the Serranidae.

Comparative material

Specimens, color images, or both, were examined of all western Atlantic liopropomin material listed in the Appendix. The following non-Curaçao *L. aberrans* material was examined: UF 222324, 1 specimen, Bahamas; UF 230721, 1, Jamaica; UF 230254, 1, French Guiana.

Acknowledgments

For contributing in various ways to this project, we thank the following (in alphabetical order): Bruce Brandt, Barry Brown, Cristina Castillo, Patrick Colin, Matthew Craig, Tico Christiaan, Dave Johnson, Rob Loendersloot, Dan Mulcahy, Diane Pitassy, Sandra Raredon, Rob Robins, Laureen Schenk, Adriaan Schrier, Ian Silver-Gorges, Raymond Simpson, Jennifer Strotman, Laura Tancredi, Barbara van Bebber, Lee Weigt. Victor Springer provided helpful comments on a draft of the manuscript. Funding for the Smithsonian Institution's *Deep Reef Observation Project* was provided internally by the Consortium for Understanding and Sustaining a Biodiverse Planet to CCB, the Competitive Grants for the Promotion of Science program to CCB and DRR, the Herbert R. and Evelyn Axelrod Endowment Fund for systematic ichthyology to CCB, and externally by National Geographic Society's Committee for Research and Exploration to CCB (Grant #9102-12). This is Ocean Heritage Foundation/Curacao Sea Aquarium/Substation Curacao (OHF/SCA/SC) contribution number 4.
