## ***Methane dynamics in the Belgian coastal zone, a contribution to the BELSPO project "4 decades of Belgian marine monitoring" (4Demon)***

Methane is the second most important greenhouse gas after CO<sub>2</sub>. Yet, there remains an important uncertainty on estimates of the sources and sinks of CH<sub>4</sub>, and how their variations can affect the atmospheric CH<sub>4</sub> growth rate and burden. The open ocean is a very modest source of CH<sub>4</sub> to the atmosphere compared to other natural and anthropogenic CH<sub>4</sub> emissions. Coastal regions are more intense sources of CH<sub>4</sub> to the atmosphere than open oceanic waters. The high CH<sub>4</sub> concentrations in surface waters of continental shelves are due to direct CH<sub>4</sub> inputs from estuaries and from sediments where methanogenesis is sustained by high organic matter sedimentation. Biogenic or thermogenic CH<sub>4</sub> can accumulate in large quantities in sub-surface seabed (gassy sediments) in deep and shallow areas, and can be released as bubbles (gas flares) or by pore water diffusion. We report a data-set of CH<sub>4</sub> concentrations in surface waters of the Belgian coastal zone (BCZ) in spring, summer and fall 2010 and 2011. This is a coastal area with multiple possible sources of CH<sub>4</sub> such as from rivers and gassy sediments. This is a contribution to BELSPO projects BELCOLOUR-II and 4Demon.
