

## Annex 2 Stock annex Celtic Sea Sole

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Sole (division VIIIf,g)

Working Group: Working Group for the Celtic Seas Ecoregion

Date: 7<sup>th</sup> February 2014

Last updated: 7<sup>th</sup> February 2014 – Willy Vanhee and Sofie Nimmegeers

### General

#### Stock definition

A description of the stock definition of sole in the Celtic Sea was given in the leaflet “Fisheries information – cod, sole, plaice and whiting in the south west of the British Isles” published by Cefas under a EU funded project (SAMFISH: EU Study Contract 99-009, Improving sampling of western and southern European Atlantic Fisheries) and is taken over here.

In the coastal waters of western England and Wales, sole are found in greatest abundance in the eastern Celtic Sea. The main spawning areas for sole in the Celtic Sea are in deep waters (40–75 m) off Trevose Head, where spawning usually takes place between March and May. Sole nursery grounds are generally located in shallow waters such as estuaries, tidal inlets and sandy bays. Juvenile sole (0 and 1 year old fish) are found chiefly in depths up to 40 m, and adult sole (fish aged 3 plus) are generally found in deeper water. Spawning and nursery grounds are well defined.

Over 6000 sole were tagged on the nursery grounds of the Bristol Channel and the Irish Sea between 1977 and 1988. The majority of fish tagged in Swansea Bay and Carmarthen Bay were between 15 and 24 cm in length. Most of the recaptures of these tagged fish occurred two or more years after release, which meant that many fish tagged as juveniles were recaptured as adults. The majority of returned fish were reported off the north coasts of Devon and Cornwall, and over a wide area in the eastern Celtic Sea and St George's Channel. These results suggest that once an adult sole has recruited to an area, it tends to remain there, and that there is only limited movement of sole between the Celtic Sea and adjoining areas.

Figure A.1 Nursery and spawning areas of sole in the Celtic Sea (After Coull, K.A., Johnstone, R., and S.I. Rogers. 1998. Fisheries Sensitivity Maps in British Waters. Published and distributed by UKOOA Ltd.)

## Fishery

Fisheries for sole in VIII f, g involve vessels from Belgium, taking approx. three quarters, the UK taking approx. 15%, and France and Ireland taking minimal amounts of the total landings. Nominal landings are available from 1971 onwards. Sole are mainly targeted by beam trawlers and the fishery is concentrated on the north Cornish coast off Trevoise Head and around Lands End. There is an average landing of 1100 tonnes throughout its history (See also figures A.2 and A.3).

Discard information is being collated since 2004 and it seems to be minor. Discarding of sole in the UK (E and W) fleet was estimated to fluctuate between 1% and 9%. Discard rates of sole in the Belgian beam trawl fleet (responsible for the main uptake of this stock) account for about 2%–5% in weight.

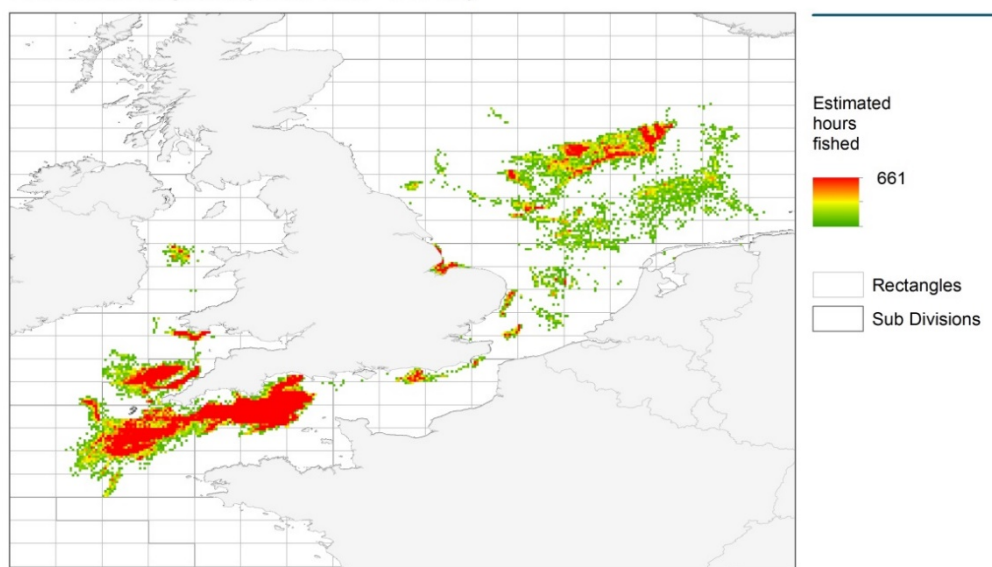

Figure A.2 Effort distribution of the Belgian beam trawl fleet operating in the Celtic Sea (VMS data 2012)

Estimated fishing Activity from VMS - TBB only

Cefas 2014

**Figure A.2 Effort distribution of the UK (E and W) beam trawl fleet operating in the Celtic Sea (VMS data 2012)**

### Management

Celtic Sea sole has been managed by TAC since 1983. Other management measures are technical measures including minimum landing size (24 cm) and minimum mesh sizes (80 mm for beam trawlers).

Furthermore national authorities can impose additional management measures, such as temporal closures, trip catch controls and monthly catch controls.

The area referred to in this report as the Trevoise box, consists of the ICES rectangles 30E4, 31E4 and 32E3.

Council Regulation (EC) No 27/2005, Annex III, part A 12 (b) prohibited fishing in ICES rectangles 30E4, 31E4 and 32E3 during January-March 2005. This prohibition did not apply to Beam trawlers during March.

Council Regulation (EC) No 51/2006, Annex III, part A 4.2; (EC) No 41/2007, Annex III, part A 7.2; (EC) No 40/2008, Annex III, part A 6.2; (EC) No 43/2009, Annex III, part A 6.2 prohibited fishing in ICES rectangles 30E4, 31E4 and 32E3 during February and March 2006-2009 with derogations for vessels using pots, creels or nets with less than 55 mm mesh size. The prohibition does not apply within 6 nautical miles from the baseline.

Council Regulation (EC) No 1288/2009, Article 1 stipulates that the prohibited fishing in ICES rectangles 30E4, 31E4 and 32E3 during February and March referred to in Council Regulation (EC) No 43/2009, Annex III, part A 6.2 shall be applicable until 30 June 2011.

Council Regulation (EC) No 579/2011, Article 2 stipulates that the prohibited fishing in ICES rectangles 30E4, 31E4 and 32E3 during February and March stipulated in Council Regulation (EC) No 43/2009, Annex III, part A 6.2, and prolonged in Council Regulation (EC) No 1288/2009, Article 1, shall be applicable until 31 December 2012.

Council Regulation (EC) No 227/2013, Article 29c of the European Parliament and of the Council of 13 March 2013 amending Council Regulation (EC) No 850/98 for the conservation of fishery resources through technical measures for the protection of juveniles of marine organisms and Council Regulation (EC)

No 1434/98 specifying conditions under which herring may be landed for industrial purposes other than direct human consumption

### **Ecosystem aspects**

The following description of the ecosystem in the Celtic Sea is taken from the MEFEPo atlas (Connolly, P.L., *et al.* 2009).

### **Physics**

**Bathymetry:** Shelf sea south of Ireland, limited to the west by the slope of the Porcupine seabight and the Goban Spur.

**Circulation:** Along the shelf edge, there is a poleward flowing „slope current”; on the shelf a weaker current flows north from Brittany across the mouth of the English Channel. Thermal stratification and tidal mixing generates the Irish coastal current which runs westwards in the Celtic Sea and northwards along the west coast of Ireland. Several rivers discharge freshwater into the ecoregion and influence the circulation patterns. These are notably the River Loire, the Severn and the Irish rivers Lee and Blackwater.

**Fronts:** The Irish Shelf Front is located to the south and west of Ireland (at c. 11°W), and consists of a tidal mixing front existing all year-round. On the shelf, there are the Ushant Front in the English Channel and the Celtic Sea front at the southern entrance to the Irish Sea.

**Temperature:** Sea surface temperatures measured in coastal stations northwest of Ireland since the 1960s show a trend of sustained positive temperature anomalies from 1990. An offshore weather buoy maintained off the southwest coast of Ireland (51.22°N 10.55°W) since mid-2002, indicated that 2003 and 2005 had the warmest summer temperatures of the record while 2007 saw the warmest winter temperatures. Temperatures in 2008 started above the time-series mean (2003–2008) until April and from July onwards, temperatures remained well below the time-series mean (WGOH 2009).

### **Biology**

**Phytoplankton:** Productivity is reasonably high on the shelf with a rapid decrease west of the shelf break. Continuous Plankton Recorder (CPR) data suggests a steady increase in phytoplankton over at least the last 20 years. Toxic algal blooms occur around Irish coasts esp. along the southwest of Ireland.

**Zooplankton:** CPR data suggest an overall decline in the abundance of zooplankton in recent years. *Calanus* abundance is now below the long-term mean.

**Benthos, larger invertebrate, biogenic habitats:** The major commercial invertebrate species is Norway lobster (*Nephrops norvegicus*). Two epibenthic assemblages predominate in the Celtic Sea: one along the shelf edge and the slope, dominated by the anemone *Actinauge richardi* and a more widely distributed assemblage on the continental shelf, dominated by *Pagurus prideaux* and other mobile invertebrates (shrimps and echinoderms).

**Fish Community:** The area is a spawning area for key migratory fish species, notably mackerel *Scomber scombrus* and horse mackerel *Trachurus trachurus*. On the continental shelf the main pelagic species are herring *Clupea harengus*, sardine *Sardina pilchardus* and sprat *Sprattus sprattus*. The groundfish community consists of over a hundred species with the most abundant 25 making up 99% of the total biomass. Surveys revealed a downward trend in the biomass and abundance of cod, whiting and hake.

**Birds, Mammals and Elasmobranchs:** Basking shark (*Cetorhinus maximus*) is seen throughout the area but the stock seems to be severely depleted. Blue sharks (*Prionace glauca*) are found during summer. The Harbour porpoise *hocoena phocoena* is the most numerous cetacean in the region. Bottlenosed dolphins (*Tursiops truncatus*) occur in large numbers while the common dolphin (*Delphinus delphis*) is also widely distributed in the area. White-beaked dolphin and White-sided dolphin (*Lagenorhynchus albirostris* and *L. acutus*) occur over much of the shelf area. Grey seals (*Halichoerus grypus*) are common in many parts of the area. Petrels (fulmar and storm-petrel) dominate the seabird populations in the west of Ireland and Celtic Sea region but there are also large breeding colonies of kittiwake, guillemot and gannet.

**Environmental signals and implications:** Increasing temperature and changes in zooplankton communities are likely to have an impact on the life histories of many species. Cod in the Celtic Sea are at the southern limit of the range of the species in the Northeast Atlantic. It is known that at the southern limits of their range, recruitment tends to decrease in warmer waters (above 8.5°C), and that cod are not found in waters warmer than 12°C. Celtic Sea cod has higher growth rates and mature earlier than other cod stocks. Although it is uncertain, Drinkwater (2005) has predicted that a sustained 1°C rise in seabed temperature, over the course of this century, could result in the disappearance of cod stocks from the Celtic Sea and the English Channel. Already there has been a northward shift in the distribution of some fish with an increase of sea bass *Dicentrarchus labrax* and red mullet *Mullus surmuletus* populations around British coasts. The region also recently experienced an unprecedented increase in the numbers of snake pipefish, *Entelurus aequoreus*. Abundance of herring *Clupea harengus* and pilchard *Sardina pilchardus* occurring off the south-west of England, has been shown to correspond closely with fluctuations in water temperature. Sardines were generally more abundant and their distribution extended further to the east when the climate was warmer, whilst herring were generally more abundant in cooler times. The migration timing of squid (*Loligo forbesi*) and flounder (*Platichthys flesus*) off the south-west of England has also been linked to temperature (Sims *et al.*, 2001; 2004). Zooplankton abundance has declined in the region in recent years and the overall substantial decline in *Calanus* abundance, which is currently below the long-term mean, may have longer term consequences given the fish community shift towards smaller pelagic species feeding on zooplankton.

**Fishery effects on benthos and fish communities:** Temporal analyses of the effects of fishing and climate variation suggest that fishing has had a stronger effect on size-structure than changes in temperature. A marked decline in the mean trophic level of the fish community over time has been documented and this has resulted from a

reduction in the abundance of large piscivorous fish such as cod and hake, and an increase in Nephrops and smaller pelagic species such as boarfish (*Capros aper*) which feed at a lower trophic level. In the Celtic Seas, discarding levels differ between the different fleets but can be as high as two thirds of the total catch with increasing trends in recent years. Discarding of undersized fish is a problem in several fisheries (e.g. cod, haddock, Nephrops and megrim). Improving the selection pattern should benefit the stocks and result in a higher long-term yield. Sole and plaice are predominantly caught by beam trawl fisheries. Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrata and in areas which have been historically exploited by this fishing method. Benthic drop-out panels have been shown to release around 75% of benthic invertebrates from the catches. Information from the UK industry (Trebilcock and Rozarieux, 2009) suggests that uptake in 2008 was minimal. The high mud content and soft nature of Nephrops grounds means that trawling readily marks the seabed, trawl marks remaining visible for some time. Despite the high intensity of fishing (some areas are impacted >7 times/year) burrowing fauna can be seen re-emerging from freshly trawled grounds, implying that there is some resilience to trawling. Cetacean bycatch has been noted in some fisheries, including the pelagic trawl fishery for mackerel and horse mackerel in the SW of Ireland, although the numbers caught were low.

## Data

### Commercial Catch

*Before 2013*

VIIIfg	BEL	IRL*	UK(E and W)	Derivation of international landings in VIIIfg
Length composition	VIIIfg	VIIIfg	VIIIfg	
ALK	VIIIfg	VIIIfg	VIIIfg	
Age Composition	VIIIfg	VIIIfg	VIIIfg	The quarterly national catch numbers-at-age and catch weights at age were raised to the total international landings (including France, Northern Ireland and Scotland).

\* From 2005 to 2009 no Irish Length compositions or ALK's therefore from 2005 to 2009, BEL+UK age composition raised to total international landing

Numbers-at-age 1 in the catch are low in most years, therefore these were not considered to add useful information and are replaced by zeros.

*From 2013 onwards,*

quarterly data (landing numbers and weight at age) from Belgium, Ireland and UK are provided under the ICES InterCatch format on a métier basis. These comprise about 90% of the international landings. Additionally, quarterly total landings from France, Northern Ireland and Scotland can be accessible. Allocation for the unsampled strata is based on a match between gear and mesh size. The remaining unsampled métiers are raised by all original age compositions. All raising is proportional to the catch numbers-at-age. Quarterly stratification has not been taken into account.

#### *WKCELT 2014*

For the period 2003–2005, the catch numbers-at-age and the total international landings were corrected for a substantial misreporting of Belgian landings into VIIj-k.

### **Biological**

#### Weights at Age

##### *Before 2013*

The total international catch weights at age are calculated as the weighted mean of the annual weight at age data supplied by Belgium, UK (E and W) and Ireland, which account for about 95% of the total international landings (weighted by landed numbers).

##### *From 2013 onwards,*

The total international catch weights at age are calculated by applying the weighting algorithm for 'Mean weight weighted by numbers-at-age or length in InterCatch. This means that the mean weights at age of the sampled catches (supplied by Belgium, UK (E and W) and Ireland) and the allocated mean weights at age are weighted by their numbers-at-age. Note that the catch weights at age for the years before 2013 were not updated according to the InterCatch protocol.

In the recent assessments (upon 2013), the catch weights at age were smoothed using a quadratic fit where catch weights at age are mid-year values (age=1.5, 2.5 etc.). Stock weights-at-age were the first quarter catch weights smoothed by fitting a quadratic fit. Catch weights at age and stock weights at age have been scaled to give a SOP of 100%.

For the period 2002–2004 the stock weights at age are the catch weights of the Belgian beam trawl fleet (BEL-BEAM) in the first quarter, smoothed by fitting a Gompertz function. For the period 2005–2007, the stock weights were calculated as the weighted mean of the 1<sup>st</sup> quarter weights at age data supplied by Belgium and UK (E and W) (weighted by landed numbers) and smoothed using a quadratic fit through these points.

Stock and catch weights have no explicit trends. The values for 2001 showed a strange convergence and were replaced by the mean of the 2000 and the 2002 weights.

#### *WKCELT 2014*

For the period 2008-2012, the original total international catch weights at age were used. The stock weights were obtained using the Rivard weight calculator (<http://nft.nefsc.noaa.gov/>) that conducts a cohort interpolation of the catch weights. This protocol should be maintained in future assessments.

#### Natural Mortality and Maturity Ogives

Natural mortality was assumed to be 0.1 for all ages and years. This is consistent with the natural mortality estimates used for other sole stocks (IV, VIId, VIIa, VIIIab) and consistent with estimates of M reported in Horwood (1993).

The maturity ogive applied to all years is, a combined sex maturity ogive taken from area VIIIfg attributed to Pawson and Harley, WD presented to WGSSDS in 1997.

AGE	1	2	3	4	5	6 AND OLDER
	0.00	0.14	0.45	0.88	0.98	1.00

The proportion of M and F before spawning was set to zero.

## Surveys

### Target species

Flatfish species, particularly juvenile plaice and sole. Length data recorded for all finfish species caught; samples for age analysis taken from selected species.

### Period

1988–2012: September (continuing)

### Gear used

Commercially-rigged 4 m steel beam trawl; chain matrix; 40 mm codend liner.

Mean towing speed: 4 knots over the ground. Tow duration: 30 minutes. Tow duration for trips in 1988–1991 was 15 minutes; in 1992 comparative tows of 15 and 30 minutes length were carried out, and subsequent cruises used a standard 30 minute tow. The data from earlier years were converted to 30 minutes tow equivalent using relationships for each species derived from the comparative work in 1992.

Vessel used: RV. *Endeavour* (Cefas).

### Survey design

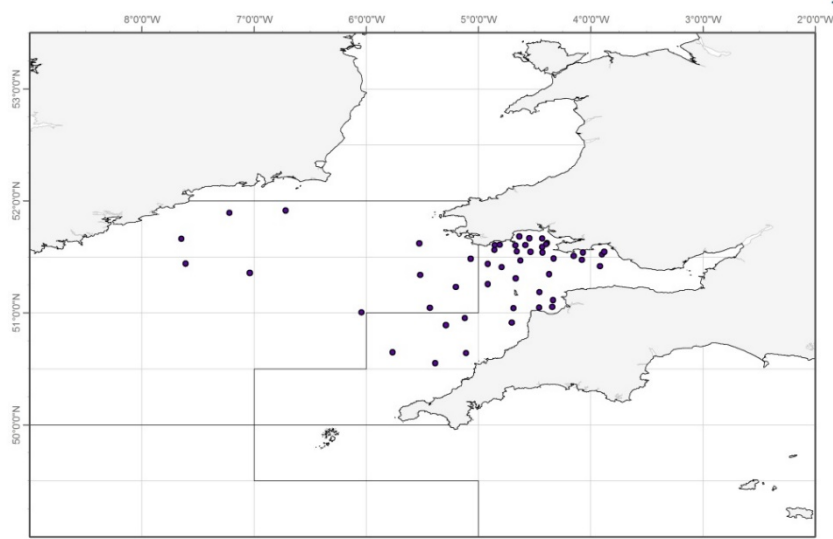

Survey design is stratified by depth band and sector (Depth bands are 0–20, 20–40, 40+). Station positions are fixed. There are 101 core fishing and hydrographic stations distributed around the Irish Sea, Bristol Channel and Celtic Sea between 50 to 55 deg. N and between the English, Welsh and Irish coasts.

### Method of analysis

Raised, standardized length frequencies for each station combined to give total length distribution for a stratum (depth band/sector). Sector age length keys applied to stratum length distributions 1988–1994; stratum age–length keys applied 1995 onwards. Mean stratum cpue (kg per 100 km and numbers-at-age per 100 km) are calculated. Overall mean cpue values are simple totals divided by distance in metres (or hours fished). Population number estimates derived using stratum areas as weighting factors.

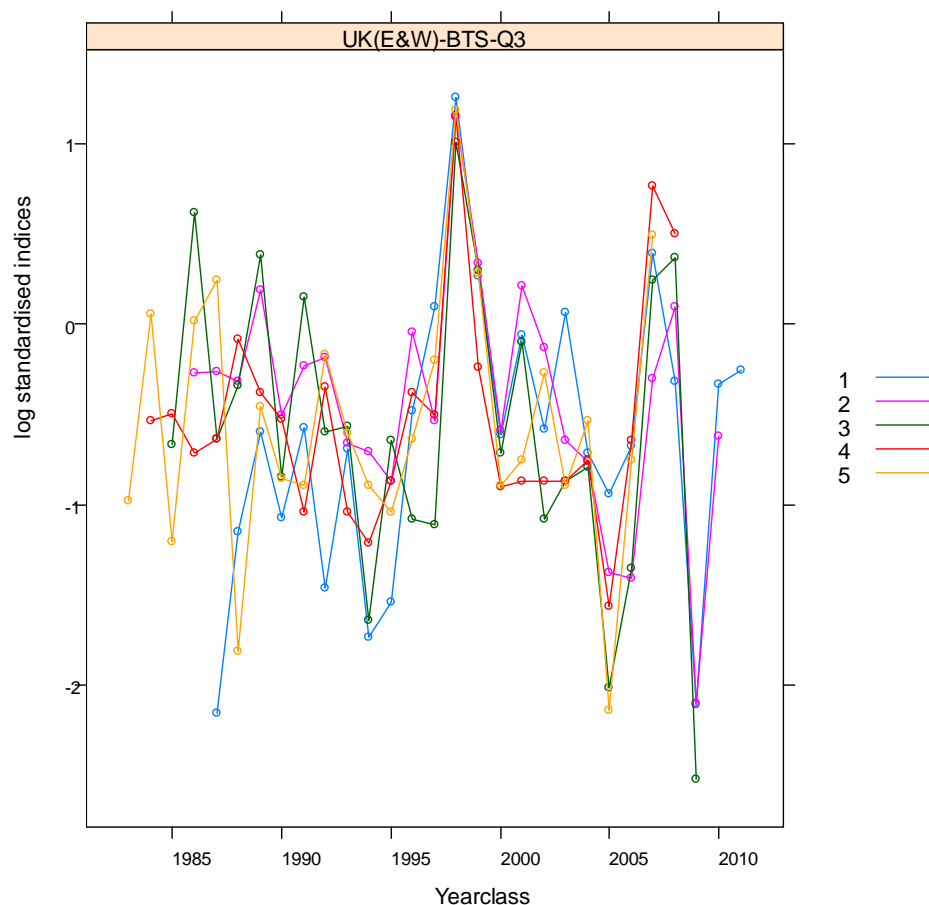

Stations fished on the September 2013 Westerly Beam Trawl survey

Cefas 2014

Abundance indices for all ages used in the assessment (standardized to the mean of the respective ages) are given in the figure below. The figure shows that the survey is able to track the strength of the year classes reasonably well.

The Irish Groundfish survey, held in the 4<sup>th</sup> quarter is available since 2003. The possible inclusion of the Irish Groundfish survey was examined at WKCELT2014, but not retained because the consistency between ages is very poor.

### Commercial cpue

Commercial cpue data are available from the Belgian, the UK (E and W) and the Irish beam trawl fleets, as well as the UK (E and W) and Irish Otter trawl fleets. There is also information on the cpue of the hardly significant Scottish seine fleet for the sole fisheries.

The Belgian and the UK (E and W) beam trawl tuning fleets used for the assessment are described further down in the stock annex. There do exist other tuning data for this stock (e.g. UK otter trawl fleet), but these have not been included in the assessment as they were not considered to be representative for this stock.

### Other relevant data

No information.

## Historical stock development

During the eighties fishing mortality increased for this stock. In the following decades fishing mortality fluctuated around this higher level. However fishing mortality has decreased since the late 1990s and is estimated to be below  $F_{msy}$  (0.31) in 2008–2009. Fishing mortality in 2012 is estimated to be 0.48, above  $F_{pa}$  (0.37).

Recruitment has fluctuated around 5 million recruits with occasional strong year classes. The 1998 year class is estimated to be the strongest in the time series and the 2007 year class to be the second highest for this stock. The 2009 year class is by far the lowest in the time series. The incoming recruitment (year class 2011) is estimated to be above average.

SSB has declined almost continuously from the highest value of 8000 t in 1971 to the lowest observed in the time series in 1998. The exceptional year class of 1998 has increased SSB to above the long-term average. The good recruitment in 2008 and above average recruitment in 2009 and 2012 is predicted to keep SSB well above  $B_{PA}/B_{trigger}$ .

### **Tuning Data**

The tuning data that are used in the assessment are:

Until 2013

- UK Corystes September beam trawl survey (UK(E and W)-BTS-Q3 survey) from 1988 onwards
- Belgium commercial beam trawl fleet (BEL-CBT) from 1971-2003
- UK beam trawl fleet (UK-CBT), Division VIIIf, from 1991 onwards.

*WKCELT2014*

- UK Corystes September beam trawl survey (UK(E and W)-BTS-Q3 survey) from 1988 onwards
- Belgium commercial beam trawl fleet (BEL-CBT) from 1971-1996
- Belgium commercial beam trawl fleet (BEL-CBT) from 1997 onwards
- UK beam trawl fleet (UK-CBT), Division VIIIf, from 1991 onwards.

The Belgian beam trawl tuning fleet was temporally discontinued in 2003. This is due to a change in the calculation of the effort statistics from the official logbooks and sale slip notes. At the 2014 benchmark assessment, a new derivation of the Belgium beam trawl data were available from 1997 onwards. The Belgian tuning series was split into two separate fleets (WKCELT2014 report): one with the original data from 1971 up to 1996 and the new series from 1997 up to 2012. The effort series used to calculate  $cpue$  for the index is HP corrected. For the period 2003–2005, a correction for a substantial misreporting of Belgian landings into VIIj-k, was introduced. For the UK (E and W)-BTS-Q3 tuning series, only ages 1 to 5 were retained.

Celtic Sea sole has been assessed with XSA. An overview of the changes in parameter settings of the XSA are given below:

[illegible]

Fleets	WKCELT2014		
	Years	Ages	$\alpha$ - $\beta$
BEL-CBT commercial 1	71-96	2-9	0-1
BEL-CBT commercial 2	97-asses-year-1	2-9	0-1
UK-CBT commercial	91-asses-year-1	2-9	0-1
UK(E&W)-BTS-Q3 survey	88-asses-year-1	1-5	0.75-0.85
-First data year	1971		
-Last data year	2012		
-First age	1		
-Last age	10+		
Time series weights	None		
-Model	Mean q model all ages		
-Q plateau set at age	7		
-Survivors estimates shrunk towards mean F	5 years / 5 ages		
-s.e. of the means	1.5		
-Min s.e. for pop. Estimates	0.3		
-Prior weighting	None		
Fbar (4-8)			

### Short-term projection

Population numbers for ages 2 and older are taken from the XSA output (estimates of the year = the assessment year minus 1). If age 2, solely assumed by the UK(E and W)-BTS-Q3 survey is substantially high, the estimate is reduced by 23% (calculated as the average reduction from the first year estimate to the converged estimate – 4 years later).

The long-term geometric mean (starting year up to assessment year minus 3) is assumed for age 1 in the forecast.

Standard procedure for setting the fishing mortality in the forecast is to take the mean over the last three years, not rescaled. If a trend occurs in fishing mortality (3 consecutive higher or lower estimates), the Working Group may use a scaled F to the last year.

WKCELT 2014, decided as an interim solution to change the standard procedure for setting the fishing mortality. In case such as in 2012 the estimate of fishing mortality is considered to be uncertain, the fishing mortality should not be rescaled to the last year, but taken as the mean of the last three years.

Weights at age in the catch and in the stock are averaged over the last three years.

### Medium term projections

No medium term projections were done since 2007.

### Yield and biomass per recruit / long-term projections

Population numbers for ages 2 and older are taken from the prediction output (estimates of the year = the assessment year). The long-term geometric mean (starting year up to assessment year minus 3) is assumed for age 1.

Fishing mortality is set at the mean over the last three years, not rescaled. If a trend occur in fishing mortality (3 consecutive higher or lower estimates), the Working Group may use a scaled F to the last year.

Weights at age in the catch and in the stock are averaged over the last three years.

### Biological reference points

Biological reference point values are given in the text table below:

	Type	Value	Technical basis
MSY	MSY Btrigger	2200 t	Bpa
Approach	FMSY	0.31	Provisional proxy based on stochastic simulations
	Blim	Not defined	
Precautionary Approach	Bpa	2200 t	There is no evidence of reduced recruitment at the lowest biomass observed and Bpa can therefore be set equal to the lowest observed SSB.
	Flim	0.52	Flim: Floss.
	Fpa	0.37	This F is considered to have a high probability of avoiding Flim and maintaining SSB above Bpa in 10 years, taking into account the uncertainty of assessments. Fpa: $F_{lim} \times 0.72$ implies a less than 5% probability that $(SSB_{MT} < Bpa)$ .

(Unchanged since: 2010)

## Other Issues

An evaluation of the Trevoise box closure (ICES rectangles 30E4, 31E4 and 32E3) was based on Belgian data that accounts for about 75% of the total international landings. Furthermore, the Belgian fleet is predominantly active in the Trevoise Box (see map in section A.2). This study showed that the cpue substantially increased in the month after the opening of the Trevoise box. The quota uptake also increased substantially in that month, however as the Belgian fleet is subjected to a limited quota uptake by month, the overall uptake levels off at the end of the year. The annual quota has not been exceeded since the introduction of the closure.
