5 CELTIC SEA AND WEST OF SCOTLAND .....  .1
5.1 Ecosystem Overview .....  1
5.2 The human impacts on the ecosystem .....  1
5.2.1 Fishery effects on benthos and fish communities .....  1
5.3 Assessments and advice .....  1
5.3.1 Assessments and advice regarding protection of biota and habitats .....  1
5.3.2 Assessment and advice regarding fisheries .....  1
5.3.3 Special requests ..... 10
5.3.3.1 NEAFC request on Rockall haddock MP evaluation ..... 10
5.4 Stock summaries ..... 13
5.4.1 Cod in Division VIIa (Irish Sea) ..... 13
5.4.2 Cod in Divisions VIIe-k (Celtic Sea cod) ..... 24
5.4.3 Haddock in Division VIIa (Irish Sea). ..... 35
5.4.4 Haddock in Divisions VIIb-k ..... 41
5.4.5 Whiting in Division VIIa (Irish Sea) ..... 47
5.4.6 Whiting in Divisions VIIe-k ..... 53
5.4.7 Plaice in Division VIIa (Irish Sea) ..... 60
5.4.8 Plaice in Divisions VIIf,g (Celtic Sea) ..... 66
5.4.9 Plaice in Division VIIe (Western Channel) ..... 73
5.4.10 Plaice in Divisions VIIh-k (Southwest of Ireland) ..... 81
5.4.11 Plaice in Division VIIb,c (West of Ireland) ..... 86
5.4.12 Sole in Division VIIa (Irish Sea). ..... 89
5.4.13 Sole in Divisions VIIf,g (Celtic Sea) ..... 96
5.4.14 Sole in Division VIIe (Western Channel) ..... 103
5.4.15 Herring in Division VIIa North of $52^{\circ} 30^{\prime} \mathrm{N}$ (Irish Sea) ..... 110
5.4.16 Herring in Divisions VIIa South of $52^{\circ} 30^{\prime} \mathrm{N}$ and VIIg,h,j,k (Celtic Sea and South of Ireland) ..... 115
5.4.17 Herring in Divisions VIa (South) and VIIb,c ..... 124
5.4.18 Sprat in Division VIa and Subarea VII (Celtic Sea and West of Scotland) ..... 129
5.4.19 Megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d ..... 133
5.4.20 Anglerfish (Lophius piscatorius and L. budegassa) in Divisions VIIb-k and VIIIa,b,d ..... 136
5.4.21 Cod in Division VIa (West of Scotland) ..... 142
5.4.22 Cod in Division VIb (Rockall) ..... 152
5.4.23 Haddock in Division VIa (West of Scotland) ..... 155
5.4.24 Haddock in Division VIb (Rockall) ..... 165
5.4.25 Whiting in Division VIa (West of Scotland) ..... 173
5.4.26 Whiting in Division VIb (Rockall) ..... 179
5.4.27 Saithe in Subarea VI (West of Scotland and Rockall) ..... 182
5.4.28 Sprat in Subarea VI and Divisions VIIa-c and f-k (Celtic Sea and West of Scotland). ..... 183
5.4.29 Anglerfish (Lophius piscatorius and L. budegassa) in Divisions IIa and IIIa, and Subareas IV and VI ..... 192
5.4.30 Herring in Division VIa North ..... 204
5.4.31 Norway pout in Division VIa (West of Scotland) ..... 212
5.4.32 Sandeel in Division VIa ..... 214
5.4.33 Nephrops in Division VIa ..... 216
5.4.33.1 Nephrops in North Minch (FU 11) ..... 223
5.4.33.2 Nephrops in the South Minch (FU 12) ..... 230
5.4.33.3 Nephrops in the Firth of Clyde + Sound of Jura (FU 13) ..... 237
5.4.34 Nephrops in Division VII ..... 246
5.4.34.1 Nephrops in Irish Sea East (FU14) ..... 253
5.4.34.2 Nephrops in Irish Sea West (FU 15) ..... 259
5.4.34.3 Nephrops on Porcupine Bank (FU 16) ..... 267
5.4.34.4 Nephrops on Aran Grounds (FU 17) ..... 275
5.4.34.5 Nephrops off the south-eastern and south-western coasts of Ireland (FU 19) ..... 283
5.4.34.6 Nephrops in the Celtic sea (FU 20-22) ..... 289
5.4.35 Sole in Division VIIh-k ..... 296
5.4.36 Sole in Division VIIb,c (West of Ireland) ..... 301
5.4.37 Demersal elasmobranchs in the Celtic Sea and West of Scotland ..... 305
5.4.38 Megrim (Lepidorhombus spp) in Subarea IV (North Sea) and Division VIa (West of Scotland) ..... )307
5.4.39 Megrim (Lepidorhombus spp) inDivision VIb (Rockall) ..... 314
5.4.40 Pollack in SubareasVI and VII (Celtic Sea and West of Scotland) ..... 320

### 5.1 Ecosystem overview

This Section has not been updated in 2011. The most recent ecosystem overview is available in ICES Advisory Report 2008, Section 5.1. This overview can also be found on the ICES website:
http://www.ices.dk/committe/acom/comwork/report/2008/2008/5.1-5.2\ Celtic $\% 20$ Sea $\% 20$ ecosystem $\% 20$ overview.pdf.

### 5.2 Human impacts on the ecosystem

### 5.2.1 Fishery effects on benthos and fish communities

This Section has not been updated in 2011. The most recent description on Fishery effects on benthos and fish communities is available in ICES Advisory Report 2008, Section 5.2. This description can also be found on the ICES website: http://www.ices.dk/committe/acom/comwork/report/2008/2008/5.1-5.2\ Celtic $\% 20$ Sea $\% 20$ ecosystem $\% 20$ overview.pdf.

### 5.3 Assessments and Advice

### 5.3.1 Assessment and advice regarding protection of biota and habitats

In 2010, ICES has not provided advice regarding protection of biota and habitats for this area.

### 5.3.2 Assessments and Advice regarding fisheries

## Mixed fisheries and fisheries interactions

This Section has not been updated in 2011. The most recent description on mixed fisheries and fisheries interactions is available in ICES Advisory Report 2008, Section 5.3. This description can also be found on the ICES website: http://www.ices.dk/committe/acom/comwork/report/2008/2008/5.3\ Celtic\ Seas\ advice\ overview.pdf

The state and advice of the individual stocks are presented in the stock sections．The state of stocks and advice（according to the Section 1.2 ）are summarized in the table below．
Table 5．3．2．1 State of the stock and advice for 2012 in the Celtic Seas ecoregion．

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 （in tonnes or effort） |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\mathrm{MSY}}$ | Fishing  <br> mortality $\quad$ in  <br> relation to  <br> precautionary  <br> limits $\left(F_{\mathrm{PA}} / F_{\text {lim }}\right)$  | Spawning  <br> biomass in <br> relation to <br> MSY $B_{\text {trigger }}$  | Spawning biomass in relation to precautionary limits $\left(\mathbf{B}_{\mathrm{PA}} / \mathbf{B}_{\text {lim }}\right)$ | MSY approach （within the precautionary approach） | Precautionary approach considerations | Management plan |  |
| Anglerfish <br> （L．piscatorius and <br> L．budegassa）in Divisions VIIb－k and VIIIa，b | Unknown ？ | Unknown ？ | Unknown ？ | Unknown ？ | － | Catches should be reduced | － | Precautionary considerations： catches should be reduced． |
| Anglerfish <br> （L．piscatorius and <br> L．budegassa）in Division IIa，IIIa， Subarea IV，and Subarea VI | Unknown ？ | Unknown ？ | Unknown ？ | Unknown ？ | － | Catches should be reduced | － | Precautionary considerations：catches should be reduced． |
| Cod in Division VIa （West of Scotland） | Unknown ？ | Unknown ？ | Below trigger | Below $\mathrm{B}_{\text {lim }}$ | Catches（mainly discards）of cod should be reduced to the lowest possible level． | Zero catch | － | Precautionary considerations：reduced to the lowest possible level． |
| Cod in Division VIb （Rockall） | Insufficient information ？ | Insufficient information ？ | Insufficient information ？ | Insufficient information ？ | － | No increase of the catch | － | Precautionary considerations：no increase of the catch． |
| Cod in Division VIIa （Irish Sea） | Above target | Harvested unsustainably | Below trigger | Reduce reproductive capacity | Zero catch | Zero catch | TAC and associated effort reduction of at least $25 \%$ | MSY approach：zero catch． |
| Cod in Divisions VIIe－k | Above target | Harvested sustainably | Above trigger | Full reproductive capacity | Landings less than 10000 t | Landings less than 14700 t | － | MSY approach：landings less than 10000 t ． |
| Haddock in Division VIa（West of Scotland） | At target | Harvested sustainably | Below trigger | Reduced reproductive capacity | Landings less than 10200 t | Landings less than 15700 t | TAC of 2506 t | MSY approach：landings more than 10200 t ．Selection pattern should be improved in the Nephrops（TR2）fleet． |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\text {MSY }}$ | Fishing  <br> mortality $\quad$ in  <br> relation to  <br> precautionary  <br> limits $\left(F_{P A} / F_{\text {lim }}\right)$  | Spawning  <br> biomass in <br> relation to <br> MSY $B_{\text {trigger }}$  | Spawning biomass in relation to precautionary limits ( $\left.\mathbf{B}_{\mathrm{PA}} / \mathbf{B}_{\mathrm{lim}}\right)$ | MSY approach (within the precautionary approach) | Precautionary approach considerations | Management plan |  |
| Haddock in Division VIb (Rockall) | Below target | Harvest sustainably | Above trigger | Full reproductive capacity | Landings of less than 3300 t | Landings less than 3800 t | - | MSY approach: landings no more than 3300 t . |
| Haddock in Division VIIa (Irish Sea) | Unknown $?$ | Unknown ? | Unknown ? | Unknown ? | - | Catches should be reduced, and uptake of further technical measures reduce discards | - | Precautionary considerations: catches should be reduced, and uptake of further technical measures to reduce discards. |
| Haddock in Divisions VIIb-k | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | No increase in catches. Fishing effort should not be allowed to increase and technical measures should be introduced to reduce discards | - | Precautionary considerations: no increase in catch and technical measures to reduce discards rates. |
| Herring in VIa south and VIIb,c | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches should be reduced | - | Precautionary considerations: catches should be reduced. |
| Herring in Division VIa North | Above target | Undefined ? | Undefined ? | Above limit | Landings less than 22900 t | - | TAC of 22900 t | Management plan: 22900 t . |
| Herring in Division VIIa South of $52^{\circ} 30^{\prime}$ N and VIIg,h,j,k (Celtic Sea and South of Ireland) | Below target | Undefined | Undefined | Full reproductive capacity | Landings less than 26900 t | - | TAC of 17160 t | MSY approach: landings no more than 26900 t . |
| Herring in Division VIIa North of $52^{\circ}$ $30^{\prime} \mathrm{N}$ (Irish Sea) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches should not be allowed to increase | - | Precautionary considerations: catches should not be allowed to increase. |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 （in tonnes or effort） |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\mathrm{MSY}}$ | Fishing mortality in $\quad$ in relation to precautionary limits $\left(F_{\text {PA }} / F_{\text {lim }}\right)$ | Spawning  <br> biomass in <br> relation to <br> MSY $B_{\text {trigger }}$  | Spawning <br> biomass in <br> relation to <br> precautionary <br> limits <br> $\left(B_{\mathrm{PA}} / B_{\mathrm{lim}}\right)$ | MSY approach （within the precautionary approach） | Precautionary approach considerations | Management plan |  |
| Megrim <br> （Lepidorhombus whiffiagonis）in Divisions VIIb－k and VIIIa，b，${ }^{1}$ | Unknown ？ | Unknown ？ | Unknown ？ | Unknown ？ | Catch and effort reduction | No increase in catch and effort | － | MSY considerations：Catch and effort reduction． |
| Megrim <br> （Lepidorhombus spp） in Divisions IVa and VIa） | Unknown ？ | Unknown ？ | Unknown ？ | Unknown ？ | － | Catches should not be allowed to increase | － | Precautionary considerations：catches should not be allowed to increase． |
| Megrim <br> （Lepidorhombus spp） in ICES Division Vlb （Rockall） | Unknown ？ | Unknown ？ | Unknown ？ | Unknown ？ | － | Catches should not be allowed to increase | － | Precautionary <br> considerations：catches should not be allowed to increase |
| Nephrops in Division VIa，North Minch （FU11） | Below target | Undefined $?$ | Above trigger ${ }^{2}$ | Undefined ${ }^{4}$ ？ | Landings than 3200 t $\quad$ less | － | － | MSY approach：landings should be no more than 3200 t |
| Nephrops in Division VIa，South Minch （FU12） | Below target | Undefined ？ | Above trigger ${ }^{4}$ | Undefined $^{4}$ ？ | Landings than 5500 t $\quad$ less | － | － | MSY approach：landings should be no more than 5500 t |
| Nephrops in the Firth of Clyde＋Sound of Jura（FU 13） | Firth of Clyde： <br> Above target <br> Sound of Jura： <br> Below target | Firth of Clyde： Undefined ？ <br> Sound of Jura： Undefined $?$ | Firth of Clyde： <br> Above trigger ${ }^{4}$ <br> Sound of Jura： Undefined ${ }^{4}$ | Firth of Clyde： Undefined ${ }^{4}$ ？ <br> Sound of Jura： Undefined ${ }^{4}$ ？ | Firth of Clyde： in landings of less than 4200 t <br> Sound of Jura： <br> in landings of less than 900 t | － | － | MSY approach：landings should be no more than $5100 \mathrm{t}(4200 \mathrm{t}$ for Firth of Clyde and 900 t for Sound of Jura）． |
| Nephrops in Irish Sea East（FU14） | Below target | Undefined ？ | Undefined $^{4}$ ？ | Undefined ${ }^{4}$ ？ | Landings than 960 t $\quad$ less | － | － | MSY approach：landings should be no more than 960 t |
| Nephrops in Divisions VIIa FU 15 | Below target | Undefined ？ | Above trigger ${ }^{4}$ | Undefined $^{4}$ ？ | Landings than 9800 t less | － | － | MSY approach：landings should be no more than 9800 t |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathbf{F}_{\mathrm{MSY}}$ | Fishing mortality in relation to precautionary limits $\left(F_{P_{A}} / F_{\text {lim }}\right)$ | Spawning  <br> biomass in <br> relation to <br> MSY B  <br>   | Spawning biomass in relation to precautionary limits ( $\mathrm{B}_{\mathrm{PA}} / \mathrm{B}_{\mathrm{lim}}$ ) | MSY approach (within the precautionary approach) | Precautionary approach considerations | Management plan |  |
| Nephrops in Sub-area <br> VII: Porcupine bank <br> (FU 16) | Undefined ? | Undefined ? | Undefined ? | Undefined ? | - | Catches should not increase to allow the stock to rebuild | - | Precautionary considerations: should not increase |
| Nephrops in Sub-area <br> VII: Aran Grounds <br> (FU 17) | Below target | Undefined $?$ | Undefined ? | Undefined ? | Landings less <br> than $1100 t$  | - | - | MSY approach: landings should be no more than 1100 t . |
| Nephrops off the south-eastern and south-western coasts of Ireland (FU 19) ${ }^{1}$ | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches should be reduced | - | Precautionary considerations: that catches should be reduced. |
| Nephrops in the Celtic Sea (FU 20-22) ${ }^{1}$ | FU 20-21: <br> Unknown ? <br> FU 22: <br> Appropriate | FU 20-21: <br> Unknown ? <br> FU 22: <br> Unknown ? | FU 20-21: <br> Unknown ${ }^{4}$ ? <br> FU 22: <br> Unknown ${ }^{4}$ ? | FU 20-21: <br> Unknown ? <br> FU 22: <br> Unknown ${ }^{4}$ | FU 20-21: landings of less than 2300 t | FU 22: catches should be reduced | - | FU 20-21: MSY approach: landings should be no more than 2300 t . <br> FU 22: precautionary considerations: landings should be reduced |
| Norway pout in Division VIa | Insufficient information ? | Insufficient information ? | Insufficient information ? | Insufficient information ? | - | No increase of the catches | - | Precautionary considerations: no increase of the catches should take place unless there is evidence that this will be sustainable |
| Plaice in VIIa (Irish Sea) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches of plaice should not increase and technical measures should be introduced to reduce discard rates. | - | Precautionary considerations: catches should not increase and technical measures should be introduced to reduce discard rates. |
| Plaice West of Ireland (Division VIIb,c) | Insufficient information ? | Insufficient information ? | Insufficient information ? | Insufficient information $?$ | - | No increase of the catch unless there is evidence that this will be sustainable. | - | Precautionary considerations: no increase of the catch should take place unless there is evidence that this will be sustainable |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathbf{F}_{\mathrm{MSY}}$ | Fishing mortality $\quad$ in relation to precautionary limits $\left(F_{P A} / F_{\text {lim }}\right)$ | Spawning  <br> biomass in <br> relation to <br> MSY $B_{\text {trigger }}$  | Spawning biomass in relation to precautionary limits ( $\mathbf{B}_{\mathrm{PA}} / \mathbf{B}_{\mathrm{lim}}$ ) | MSY approach (within the precautionary approach) | Precautionary approach considerations | Management plan |  |
| Plaice in Division VIIe (Western Channel) | Above target | Undefined ? | Above trigger | Undefined ? | Landings less | - | - | MSY transition: that landings in 2012 should be no more than 1440 t . |
| Plaice in the Celtic Sea (Divisions VIIf and g) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | Less than 500 t | Catches of plaice should be reduced and measures to reduce discards should be introduced. | - | Precautionary considerations: catches should be reduced. Discards exceed landings and technical measures should be introduced to reduce discard rates |
| Plaice Southwest of Ireland (VIIh-k) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Reduce catches | - | Precautionary considerations: catches should be reduced |
| Pollack in Subareas VI and VII (Celtic Sea and West of Scotland) | Insufficient information ? | Insufficient information ? | Insufficient information ? | Insufficient information ? |  | Catches should not be allowed to increase. |  | Precautionary consideration: catches should not be allowed to increase |
| Sandeel in Division VIa | Insufficient information ? | Insufficient information ? | Insufficient information ? | Insufficient information | - | No increase of the catches should take place unless there is evidence that this will be sustainable. | - | Precautionary considerations: no increase of the catches should take place unless there is evidence that this will be sustainable. |
| Sole VIIa | Above target | Harvested sustainably | Below trigger | Reduced reproductive capacity | Landings of 200 t | Zero catch | - | MSY approach: landings should be no more than 200 t . |
| Sole West of Ireland (Division VIIb,c) | Insufficient information ? | Insufficient information ? | Insufficient information ? | Insufficient information ? | - | No increase of the catch should take place unless there is evidence that this will be sustainable. | - | Precautionary considerations: no increase of the catch should take place unless there is evidence that this will be sustainable. |
| Sole in Division VIIe (Western Channel) | Appropriate | Undefined ? | Below trigger | Undefined ? | Landings than 740 t | - | TAC of 777 t | MSY approach: landings should be less than 740 t |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\text {MSY }}$ | Fishing  <br> mortality $\quad$ in  <br> relation to <br> precautionary  <br> limits $\left(F_{\mathrm{FA}_{\mathrm{A}}} / \mathrm{F}_{\text {lim }}\right)$  | Spawning  <br> biomass in <br> relation to <br> MSY $B_{\text {trigger }}$  | Spawning biomass in relation to precautionary limits ( $\left.\mathbf{B}_{\mathrm{PA}} / \mathbf{B}_{\mathrm{lim}}\right)$ | MSY approach (within the precautionary approach) | Precautionary approach considerations | Management plan |  |
| Sole in the Celtic Sea (Divisions VIIf and g) | Appropriate | Harvest sustainably | Above trigger | Full reproductive capacity | Landings than 1060 t less | Landings of less than 1230 t | - | MSY approach: landings should be no more than 1060 t |
| Sole Southwest of Ireland <br> (Division VIIh-k) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches should not be allowed to increase | - | Precautionary considerations: catches should not increase. |
| Sprat in Subarea VI and Divisions VIIa-c and f-k (Celtic Sea and West of Scotland) | Insufficient information $?$ | Insufficient information ? | Insufficient information ? | Insufficient information ? | - | Catches should not be allowed to increase | - | Precautionary considerations: catches should not be allowed to increase. |
| Sprat in divisions VII d, e | Insufficient information ? | Insufficient information $?$ | Insufficient information $?$ | Insufficient information $?$ | - | Catches should be reduced. | - | Precautionary considerations: catches should be reduced. |
| Whiting in Division VIIa | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches (mainly <br> discards) should <br> be reduced to the <br> lowest possible <br> levels. <br> Management measures should be introduced in the Irish Sea to reduce discarding of small whiting in order to maximize their contribution to future yield and SSB. | - | Precautionary <br> considerations: catches should be reduced to the lowest possible levels and uptake of further technical measures to reduce discards. |

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathbf{F}_{\text {MSY }}$ | Fishing  <br> mortality $\quad$ in  <br> relation to <br> precautionary  <br> limits $\left(F_{\text {PA }} / F_{\text {lim }}\right)$  | Spawning  <br> biomass in <br> relation to <br> MSY $_{\text {trigger }}$  | Spawning biomass in relation to precautionary limits $\left(B_{\mathrm{PA}^{\prime}} / B_{\text {lim }}\right)$ | MSY approach (within the precautionary approach) | Precautionary approach considerations | Management plan |  |
| Whiting in Divisions VIIe-k | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | Catches should not be allowed to increase. Technical measures re to minimise discards should be considered with urgency. | - | Precautionary considerations: catches should not be allowed to increase and technical measures should be introduced to reduce discard rates |
| Whiting West of Scotland | Unknown ? | Unknown ? | Unknown ? | Unknown ? | Lowest possible catch and reduce discards | Lowest possible catch | - | Precautionary considerations: catches should be reduced. The selection pattern should be improved in the Nephrops (TR2) fleet. |
| Whiting in Division VIb (Rockall) | Unknown ? | Unknown ? | Unknown ? | Unknown ? | - | No increase of the catch should take place unless there is evidence that this will be sustainable. | - | Precautionary considerations: no increase of the catch should take place unless there is evidence that this will be sustainable |

Table 5.3.2.2 State of the stock and advice for 2012 in theCeltic Sea ecoregion, for stocks with biennial advice (advice from 2010, valid for 2011 and 2012).

| Stock | State of the stock |  |  |  | Outlook options for 2012 |  |  | ICES advice for 2012 (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\mathrm{MSY}}$ | Fishing mortality in relation to precautionary limits $\left(F_{P A} / F_{\text {lim }}\right)$ | Spawning biomass in relation to MSY $\mathbf{B}_{\text {trigger }}$ | Spawning  <br> biomass in <br> relation to <br> precautionary  <br> limits $\left(B_{P A} / B_{\text {lim }}\right)$  | MSY approach  <br> (within the <br> precautionary  <br> approach)  | Precautionary approach considerations | Management plan |  |
| Demersal elasmobranchs in the Celtic Sea and West of Scotland: Skates and Rays ${ }^{34}$ | Unknown | Unknown | Unknown | Unknown | Landings less than 9900 t for the main species | No target fishery on Raja undulata and Dipturus batis complex | - | Landings less than 9900 t for the main species. |
| Demersal elasmobranchs in the Celtic Sea and West of Scotland: Scyliorhinus canicula (Lesser-spotted dogfish ${ }^{1}$ | Unknown | Unknown | Unknown | Unknown | Maintain catch at recent level | Maintain catch at recent level | - | Maintain catch at recent level. |

Table 5.3.2.3 Summary of the state of the stock and advice in the Celtic Sea and West of Scotland ecoregion.
In this ecoregion, 49 stocks or stock complexes are given advice for, of which ICES provides advice on the basis of a forecast for 17 stocks ( $35 \%$ ).

| State of stock | Criteria | Number of stocks for which criteria are defined | Percentage of stocks for which criteria are met |
| :---: | :---: | :---: | :---: |
| Stocks fished at or below MSY level | $\mathrm{F}_{2010} \leq \mathrm{F}_{\text {MSY }}$ | 17 | 71\% |
| Stocks fished precautionary | $\mathrm{F}_{2010} \leq \mathrm{F}_{\text {PA }}$ | 6 | 83\% |
| Stocks above MSY ${ }_{\text {trigger }}$ biomass | $\mathrm{SSB}_{2011} \geq \mathrm{MSY} \mathrm{B}_{\text {trigger }}$ | 13 | 62\% |
| Stocks above precautionary biomass | $\mathrm{SSB}_{2011} \geq \mathrm{B}_{\text {PA }}$ | 9 | 56\% |
|  |  |  |  |
| Stocks within safe biological limits | $\mathrm{F}_{2010} \leq \mathrm{F}_{\mathrm{PA}}$ and SSB2011 $\geq \mathrm{B}_{\text {PA }}$ | 6 | 50\% |
|  |  |  |  |
| Stocks without a forecast for which the advice is "do not allow catches to increase" | Trends based assessment with nonreduction advice | 21 | 43\% |

## ECOREGION Celtic Sea and West of Scotland SUBJECT haddock

## Advice Summary

ICES examined the proposed harvest control rules (HCRs) of a long-term management plan for Rockall haddock but the analyses are preliminary and incomplete. ICES, therefore, is unable to assess if the proposed HCRs are consistent with the precautionary approach. ICES notes, however, that the proposed harvest control rules would provide an improvement over recent management approaches, but the rules need to be further evaluated.

## Request

NEAFC requests ICES to evaluate the following proposal for the harvest control component of a long-term management plan for Rockall haddock and in particular to consider whether the plan is consistent with the precautionary approach and will provide for the sustainable harvesting of the stock. ICES will also suggest an alternative approach if necessary.

Draft EU-Russia proposal for harvest control component of a long-term management plan for haddock at Rockall
In the following, the TACs refer to total catches, not just landings.

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than Bpa and a minimum level of SSB greater than Blim.
2. For [20XX] and subsequent years the Parties agreed to set a TAC to be consistent with a fishing mortality rate of no more than [either Fpa (0.4) or Fmsy (0.3)] for appropriate age-groups, when the SSB in the end of the year in which the TAC is applied is estimated above $B_{p a}$.
3. The Parties agree that the TAC that results from the application of the fishing mortality referred to in paragraph 2 will be adjusted according to the following formula:

$$
\text { a. } \quad T A C y=T A C f+0.2 *(T A C y-1-T A C f)
$$

where TACy is the TAC that is to be set by the management plan, TACy-1 is the TAC that was fixed the previous year and TACf is the TAC resulting from the provisions in paragraphs 1 and 2.
4. Where the SSB referred to in paragraph 2 is estimated to be below Bpa but above Blim the TAC shall not exceed a level, which will result in a fishing mortality rate equal to $0.3-0.2 \times(B p a-S S B) /\left(B_{p a}-B_{l i m}\right)$. This consideration overrides paragraph 3.
5. Where the SSB referred to in paragraph 2 is estimated to be below Blim the TAC shall be set at a level corresponding to a total fishing mortality rate of no more than 0.1. This consideration overrides paragraph 3.
6. No later than 31 December [20XX], the parties shall review the arrangements in paragraphs 1 to 5 in order to ensure that they are consistent with the objective of the plan. This review shall be conducted after obtaining inter alia advice from ICES concerning the performance of the plan in relation to its objective.

## Elaboration on the Advice

ICES reviewed analyses of the proposed harvest control rules (HCRs) of a long-term management plan for Rockall haddock, but the simulations carried out were insufficient to determine whether or not the HCRs are consistent with the precautionary approach. The analyses suggested that the proposed HCR with an $\mathrm{F}_{\text {target }}=0.3$ had a low risk of the SSB falling below $\mathrm{B}_{\text {lim }}$. In one of the analyses, the proposed HCR with an $\mathrm{F}_{\text {target }}=0.4$ had a greater than $10 \%$ risk of the SSB falling below $\mathrm{B}_{\text {lim }}$. ICES considers that the analyses of both HCRs underestimate the risk that SSB will be less than $\mathrm{B}_{\text {lim }}$ because scenarios, consistent with the characteristics of the stock and fisheries, were not fully examined (see the Results and conclusions section).

Nevertheless, ICES notes that the proposed HCRs are an improvement compared to the management approaches implemented in recent years because the TAC would now account for total catches (landings and discards) from all sources, including the international fishery.

The proposed HCRs include two target fishing mortality proposals ( 0.3 and 0.4 ). When the estimated SSB value, referred to in Paragraph 2, is between $B_{l i m}$ and $B_{p a}$, Paragraph 4 is invoked. In this circumstance, if $F_{\text {target }}=0.4$, there is a discontinuity in the $F$ to be used in setting the TAC, depending on whether the SSB is just above or below $B_{p a}$. If the estimated SSB is below $\mathrm{B}_{\mathrm{pa}}$, an immediate drop to $\mathrm{F}=0.3$ is required, leading to large fluctuations in TAC and making
the application of this HCR very sensitive in situations where SSB is estimated to be around $\mathrm{B}_{\mathrm{pa}}$. ICES considers that the formula for determining the fishing mortality rate in Paragraph 4 should provide continuity with respect to the target $F$ defined in Paragraph 2.

In the past, discards percentages of certain trawl fleets from the European Union have been observed to be as high as $52 \%$ to $87 \%$ by numbers. The discarding percentage is highly dependent on the abundance of incoming recruitment. The proposed HCRs specify that TACs refer to total catch, not just landings. ICES considers that controlling total catch is the only way to control fishing mortality. Closer monitoring of actual catches (instead of just landings) is required. The long-term management plan needs to specify how this will be accomplished. ICES previously advised (ICES, 2011a) that it would be beneficial to develop and introduce fisheries practices and measures aimed at preventing discards of haddock.

## Suggestions

Because the stock-recruitment relationship for this stock is poorly defined (as is the case for many other stocks and particularly so for haddock), a more complete evaluation of the HCRs requires conducting simulations under low recruitment conditions, as have been observed in recent years. Analyses including implementation errors (for example, catch exceeding the TAC), and explorations of the impact of errors in catch data on the assessment and of variations in the fishery selection pattern (due to fleet variability) would also be useful.

The TAC adjustment foreseen in Paragraph 3 could induce large percentage changes in TAC from year to year. This could simply result from strong recruitment. The performance of this, and other TAC constraints, should be examined in subsequent analyses.

Potential benefits, both to the industry and the stock, of improving the fishery selection pattern should also be evaluated.

## Basis of advice

## Background

The haddock stock at Rockall is a separate stock from that on the continental shelf of the British Isles. Rockall haddock have lower growth rates and reach a lower maximum size than other haddock populations in the Atlantic. There does not appear to be a significant stock-recruitment relationship for this stock, which is typical for haddock stocks. For example, recruitment for the last four years has been very low despite a moderately large SSB.

Discussions between the European Union (EU) and the Russian Federation (RF) on possible joint management measures for the Rockall haddock fishery have taken place for over ten years. Changes in the shape of the EU Exclusive Economic Zone in 1999 led to a renewal of the RF Rockall haddock fishery, making it clear that joint management would be desirable although potentially difficult to implement. Meetings involving both scientists and fisheries managers from the EU and the RF have been held on an almost annual basis since 2001 to determine what is known about these fisheries, and how such information can best be used to develop a productive and sustainable management system.

Building on the history of Rockall fisheries and the supporting scientific work presented by Newton et al. (2008) and Filina et al. (2009), the EU-RF Working Group on Rockall haddock met several times during 2008-2010 and produced a state-of-the-art review of available data and scientific analyses pertaining to Rockall haddock [(EU-RF, 2011) documents the first three of these meetings]. At the fourth meeting in Edinburgh during September 2010, a proposal for a joint EU-RF management plan for Rockall haddock was drafted. Following further refinements, a final version was presented to the appropriate NEAFC plenary meeting towards the end of 2010. The decision was taken there to forward the HCRs proposal to ICES for evaluation.

## Results and conclusions

The results of the analyses (ICES, 2011b) are preliminary, but ICES considers that the risk of the SSB falling below $\mathrm{B}_{\mathrm{lim}}$ is underestimated and the simulations do not properly account for potential future conditions:

- The assumed stock-recruitment relationship makes the simulations very unlikely to reproduce a period of low recruitments under moderately high SSB , as experienced in recent years (even with the random variability assumed around the stock-recruitment relationship);
- The evaluation follows the example of the ICES stock assessment in not allowing explicitly for the presence of two fleets (EU and RF) with very different characteristics, especially in terms of fishing pattern. The relative catches of these two fleets have been highly variable in the past. Using a constant selection pattern in the simulations is unlikely to reflect future conditions;
- The analyses assumed perfect implementation, i.e. the set TAC is not exceeded.

## Methods

Two different management strategy evaluation (MSE) analyses were conducted to investigate the properties of the proposed HCRs (ICES, 2011b). Both MSE analyses were based on the ICES assessment of this stock, which uses an XSA model, with catch (landings and discards) numbers-at-age data and an abundance index provided by a Scottish survey conducted annually in Division VIb. In the ICES assessment, recruitment is at age 1, and the same age at recruitment was used in the MSE analyses.

The first analysis used the R library FLR (Kell et al., 2007) and the XSA version provided within FLR, using the historical assessment data until 2009 with the same settings as in the ICES assessment. The assessment was rerun 500 times, assuming each time a random alteration of the original abundance index values. This produced 500 "true" population abundance values at the start of 2010 for each age older than 1. Recruitment in 2010 and subsequent years was derived from a stock-recruitment relationship, based on the fit to the historical data and incorporating random noise. The catch in 2010 was assumed equal to the EU TAC, and the proposed HCRs were used in setting the TACs in 2011-2030. This first analysis corresponds to a "standard" MSE, incorporating variability in recruitment, assessment error, and no implementation error.

The second analysis shares many methodological features with the first one; it was carried out using Excel, instead of the FLR software. This analysis used the most recent ICES assessment, leading to a single "true" population abundance value at the start of 2011 for each age older than 1 . Recruitment in 2011 and subsequent years was derived from a stock-recruitment relationship, incorporating random variability based on the residuals from the fit to the historical data ( 100 recruitment values were simulated each year). Status quo F was used to calculate the catch in 2011 and the proposed HCRs were used in setting the TACs in 2012-2039. This second analysis also provides an MSE, incorporating variability in recruitment, assessment error (although following less standard procedures than in the first analysis), and no implementation error.

Both analyses used a Ricker stock-recruitment relationship, but the fits were slightly different. Both MSEs used a constant selection pattern and a constant discarding ratio at age, assumed perfect implementation, and evaluated F targets of 0.3 and 0.4. The second analysis investigated further changes in the HCRs, and also examined F targets of 0.2 and 0.5 .

### 5.4.1

## ECOREGION STOCK <br> Celtic Sea and West of Scotland Cod in Division VIIa (Irish Sea)

## Advice for 2012

ICES advises on the basis of MSY approach that zero catches be taken in 2012.

## Stock status

Fishing mortality (age 2-4)

Recruitment

Figure 5.4.1.1 Cod in Division VIIa (Irish Sea). Summary of stock assessment (weights in tonnes) Landings: solid lines are reported landings; filled squares are landings incorporating sample-based estimates at three ports; circles are total removals estimates in excess of $\mathrm{M}=0.2$ with $90 \%$ confidence intervals from B-Adapt. Recruitment, fishing mortality, and SSB: dotted lines are $5^{\text {th }}$ and $95^{\text {th }}$ bootstrap percentiles. Top right: SSB and F over the years.
The fishing mortality in recent years is uncertain, but total mortality remains very high. The spawning stock biomass has declined ten-fold since the late 1980s and has had reduced reproductive capacity since the mid-1990s. The spawning stock biomass remains well below $\mathrm{B}_{\text {lim }}$. With the exception of the 2009 year class, recruitment has been low for the last 9 years.

## Management plans

A long-term plan has been agreed by the EU in 2008 (Council Regulation (EC) 1342/2008) which results in a TAC of 380 t and effort reduction of $25 \%$. ICES $(2009 \mathrm{a}, \mathrm{b})$ evaluated the plan and considers the management plan not to be in accordance with the precautionary approach.

## Biology

Due to the aggregating behaviour of cod it is still possible to find areas of high cod density even at low abundance. This can lead to high catches in localised areas and low levels of fishing effort causing high mortality on the stock is possible. Recent tagging experiments have shown migrations of cod out of the Irish Sea into the north Channel, and also migrations south through the deeper Channel into the Celtic Sea.

## Environmental influence on the stock

There is evidence that the reduction in cod recruitment observed in the Irish Sea since the 1990s may be due to a combination of small spawning-stock biomass and poor environmental conditions, coinciding with a shift towards above-average sea temperatures.

## The fisheries

The Irish Sea cod fishery has traditionally been carried out by otter trawlers targeting spawning cod in spring and juvenile cod in autumn and winter, and cod are also taken as a bycatch in fisheries for Nephrops, plaice, sole and rays. Available data indicates that until 2009 discarding was mainly a function of minimum landing size (MLS) and largely restricted to catches of 0 and 1 years old cod. In 2010 there appears to be a shift towards also discarding 2 years old fish. ICES estimates of the landing in 2010 were the lowest on record and $\sim 30 \%$ below the TAC. The targeted whitefish fishery that developed during the 1990 using semi-pelagic trawls has continued to decline during 2010 to only four vessels mainly using the gear.

Catch by fleet Total catch (2010) is unknown, landings estimated at 460 t , official landings were $28 \%$ higher, due to inaccurate area reporting. Accurate discard estimates are not available.

## Effects of the fisheries on the ecosystem

Cod is taken in mixed demersal fisheries and there are no impacts specific to the catching of cod.

## Quality considerations

The model estimates of total removals continue to vary around 2 to 3 times the reported landings, despite more accurate catch reporting and lack of evidence for significant highgrading of cod. There is currently very little direct evidence to evaluate the potential source(s) of this and how much is due to fishing in Division VIIa or elsewhere. Discard estimates are not currently integrated into the assessment.

| $\mathrm{~F}_{\max }$ | 0.40 | 1.74 | 4.84 |
| $\mathrm{~F}_{0.1}$ | 0.21 | 1.60 | 8.16 |
| $\mathrm{~F}_{\text {med }}$ | 1.00 | 1.53 | 1.84 |

## Outlook for 2012

No short term forecast is provided because recent mortality values are highly uncertain due to unaccounted mortality. However, assuming a $25 \%$ reduction in mortality in 2011, the spawning stock biomass is expected to increase in 2012 due to the higher recruitment estimated in 2009. Given the uncertainty in the F estimation the MSY results below should be treated with caution. Current landings (i.e. TAC), effort, and spatial management of fisheries catching cod in Division VIIa are not controlling mortality levels.

## Management plan(s)

Following the cod long term management plan (EC 1342/2008) the stock is considered data poor which implies using article 9(a). This results in a TAC and associated effort reduction of at least $25 \%$. ICES considers that article 10(2) may also apply.

ICES (2009a,b) evaluated the plan and considers the management plan not in accordance with the precautionary approach.

## MSY approach

Fishing mortalities in the range $0.25-0.54$ are consistent with maximising long-term yield for cod in Division VIIa. This is consistent with the management plan target fishing mortality of 0.4. Given the low SSB and low recruitment it is not possible to identify any non zero catch which would be compatible with the MSY transition scheme. This implies no targeted fishing should take place on cod in Division VIIa. Bycatches including discards of cod in all fisheries in Division VIIa should be reduced to the lowest possible level and uptake of further technical measures to reduce discards

## PA considerations

No targeted fishing should take place on cod in Division VIIa. Bycatches including discards of cod in all fisheries in Division VIIa should be reduced to the lowest possible level.

## Additional considerations

## Management considerations

Both the recruitment and reproductive capacity of this stock have become severely impaired in recent years. Recruitment has been below average for the past eighteen years and eight of the last nine years of recruitment are amongst the lowest on record. The stock has been harvested unsustainably since the late 1980s. The fishing mortality in recent years is uncertain, but total mortality rates remain very high despite the establishment of a spawning closure since 2000, reductions in fishing effort and TAC reduction per year since 2006.

The 2009 year class is estimated to be more abundant, consequently additional measures to protect it are essential to ensure that it contributes to the rebuilding of the stock. It will be necessary to reduce all sources of fishing mortality on cod to as close to zero as possible if the stock is to recover above $\mathrm{B}_{\text {lim }}$ as quickly as possible. STECF (2010) data show that the main gear types catching cod in the Irish Sea in 2009, based on official landings data, were otter trawls and seines with $100 \mathrm{~mm}+$ mesh ( $56 \%$ of cod landings), otter trawls with $70-99 \mathrm{~mm}$ mesh (mainly Nephrops gears; 29\%), fixed nets ( $12 \%$ ), and beam trawls ( $3 \%$ ). Recent discard estimates available for some fleets indicate a potential shift from discarding mostly younger age 0 and 1 cod, to discarding age 2 fish also in 2010. It is not yet known if this is a long term change. Estimates of discarding are not used in the assessment due to the short time-series and variable quality of the data.

To minimize the impact of cod recovery measures on fisheries not targeting cod, there will be a need for gear designs and cod avoidance measures that can be proven effective in reducing by-catches of cod to as close to zero as possible. Council Regulation (EC) 1342/2008 states that Member States should introduce new mechanisms (developed in cooperation with the fishing industry) to encourage fishermen to engage in cod-avoidance programmes, and to exercise their power to allocate access to fishing for cod stocks so as to encourage their fishermen to fish in ways that result in more selective fishing and are less harmful to the environment. However it is necessary to quantify the impact of such measures, and they should be accompanied by appropriate monitoring and data collection schemes to determine if they are achieving their stated aims. This includes ensuring accurate data on quantities and composition of fishery removals from all sources.

Egg production surveys since 2006 (see Figure 5.4.1.4 for 2010 results) show that $\sim 30-50 \%$ of the spawning took place in the eastern Irish Sea which is not included in the spring spawning closure, indicating that the design of the closure is not optimal.

There is evidence of substantial misreporting in the past, but observations at the ports indicate that the implementation of the Registration of Buyers and Sellers regulations since 2006 in the UK and Ireland has improved the accuracy of landings reporting.

In recent years, Irish landings of cod reported from ICES rectangles immediately north of the Irish Sea - Celtic Sea boundary have been re-allocated into the Celtic Sea as they represent a combination of inaccurate area reporting and catches of cod considered to be part of the Celtic Sea stock.

The ability to implement a management plan for this stock will remain compromised until all sources of significant unaccounted mortality are identified

## Regulations and their effects

The regulations have had the following effects on Irish Sea cod and fisheries taking cod:
In 2000, a cod closure was introduced into Irish Sea, initially covering both cod spawning areas in the east and west of the Irish Sea, subsequently amended to only include the western Irish Sea. Derogations for Nephrops trawlers using separator panels was included. STECF (2007) was unable to determine the extent to which the closure has reduced fishing mortality STECF advised that a comprehensive evaluation of how fleet activities have been affected by the closure and other regulations and factors is required to evaluate the cod closure.

The cod recovery plan introduced a system for limiting fishing effort by adjusting the number of fishing days allowed for various vessel categories deploying gears with various mesh sizes. STECF, 2010 reported that

- '"Nominal effort ( $k W^{*}$ days-at-sea) within the Irish Sea has decreased by $36 \%$ since 2000 . The overall trend indicates historical effort was relatively stable until 2003, after which effort declined. Overall effort within the Irish Sea has declined by $\sim 40 \%$ since 2003. An 11\% decline occurred between 2008 and 2009."
- "Over the time series available, Irish Sea fisheries have been dominated by demersal trawling and seining (TR category). This category accounts for around $60 \%$ of overall effort, mirroring the overall declining effort trend. Beam trawling has declined over time, now accounting for $<10 \%$ in the last two years. All other regulated gears account for $<1 \%$ combined."

## Changes in fishing technology and fishing patterns

The introduction of the effort control elements of the cod long term plan (LTP) is expected to lead to changes in fishing effort in different "effort groups". This and the introduction of more selective gears are likely to change exploitation patterns in 2011. The impact of these is currently difficult to quantify. Four Irish vessels have gained exemption from the effort regulation by using a sorting grid to maintain cod catches below $1.5 \%$. The use of grids in the Nephrops fishery should be promoted to reduce capture of cod, or selectivity devices that achieve equivalent or better improvements.

## Data and methods

The quality of the commercial data for this stock deteriorated in the 1990s. ICES has attempted to improve the accuracy of the landings data by replacing the reported landings figures in 1991-1999 from three major Irish Sea ports by estimates derived from a sampling scheme.

The sampling scheme had insufficient coverage in some subsequent years, and the assessment model (B-Adapt) implements a procedure for estimating any unaccounted removals of cod since 2000. All removals prior to 2000 are assumed to be accounted for, apart from discards which are not included in the assessment. The procedure estimates the quantity of total removals since 2000 needed for catch-based estimates of abundance to follow the same trends over time given by several series of survey indices. The model estimates of removals since 2000 are up to three times larger than reported landings for those years. The existence of substantial unaccounted removals can explain the lack of any improvement in age structure of cod and the continuation of an apparently high mortality rate well in excess of the precautionary approach reference points.

Discard estimates prior to 2010 indicate a variable, but high discard rate for 0 - and 1 -year-old cod. Some 2010 data indicate a shift into discarding the larger 2 -year-old cod along with the younger fish. Estimates of discarding are not used in the assessment due to the short time-series and variable quality of the data.

## Information from the fishing industry

The UK Fisheries-Science Partnership surveys of the Irish Sea cod spawning grounds in spring 2005-2011, carried out using commercial trawlers, indicated a widespread distribution of cod mostly at low density but with some localized aggregations. The time-series of SSB indices shows a downward trend similar to the trends shown by the other surveys used in the assessment. The surveys also indicate a highly truncated age composition of cod, which supports the ICES assessment, indicating continuing high mortality rates.

## Uncertainties in assessment and forecast

The assessment indicates additional, unaccounted removals from the stock in recent years, which are not explained from the recent observation of reported landings.

A large but variable proportion of the catch of 1-year-old cod is discarded and 2010 data suggests an increase number of discarded 2-year-old fish are discarded. Discards are not included in the assessment, leading to an underestimate of the mortality at this age

Comparison with previous assessment and advice.
The perception of the stock has not changed since last year's assessment. The basis for the advice is the same as last year.

## Annex 5.4.1

The European Commission has enacted a Council Regulation ((EC) No. 1342/2008) which establishes measures for the recovery and long term management of cod stocks. The stated objective of the plan is to ensure the sustainable exploitation of the cod stocks on the basis of maximum sustainable yield while maintaining a fishing mortality of 0.4. Articles 7-9, describing aspects of the plan relevant for Irish Sea cod, are reproduced below:

## Article 7

## Procedure for setting TACs for cod stocks in the Kattegat the west of Scotland and the Irish Sea

1. Each year, the Council shall decide on the TAC for the following year for each of the cod stocks in the Kattegat, the west of Scotland and the Irish Sea. The TAC shall be calculated by deducting the following quantities from the total removals of cod that are forecast by STECF as corresponding to the fishing mortality rates referred to in paragraphs 2 and 3: (a) a quantity of fish equivalent to the expected discards of cod from the stock concerned; (b) as appropriate a quantity corresponding to other sources of cod mortality caused by fishing to be fixed on the basis of a proposal from the Commission.
2. The TAC shall, based on the advice of STECF, satisfy all of the following conditions: (a) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be below the minimum spawning biomass level established in Article 6, the fishing mortality rate shall be reduced by $25 \%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year; (b) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be below the precautionary spawning biomass level set out in Article 6 and above or equal to the minimum spawning biomass level established in Article 6, the fishing mortality rate shall be reduced by $15 \%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year; and (c) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be above or equal to the precautionary spawning biomass level set out in Article 6, the fishing mortality rate shall be reduced by 10 $\%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year.
3. If the application of paragraph 2(b) and (c) would, based on the advice of STECF, result in a fishing mortality rate lower than the fishing mortality rate specified in Article 5(2), the Council shall set the TAC at a level resulting in a fishing mortality rate as specified in that Article.
4. When giving its advice in accordance with paragraphs 2 and 3, STECF shall assume that in the year prior to the year of application of the TAC the stock is fished with an adjustment in fishing mortality equal to the reduction in maximum allowable fishing effort that applies in that year.
5. Notwithstanding paragraph 2(a), (b) and (c) and paragraph 3, the Council shall not set the TAC at a level that is more than $20 \%$ below or above the TAC established in the previous year.

Article 9

## Procedure for setting TACs in poor data conditions

Where, due to lack of sufficiently accurate and representative information, STECF is not able to give advice allowing the Council to set the TACs in accordance with Articles 7 or 8 , the Council shall decide as follows: (a) where STECF advises that the catches of cod should be reduced to the lowest possible level, the TACs shall be set according to a $25 \%$ reduction compared to the TAC in the previous year; (b) in all other cases the TACs shall be set according to a $15 \%$ reduction compared to the TAC in the previous year, unless STECF advises that this is not appropriate.

## Article 10

## Adaptation of measures

1. When the target fishing mortality rate in Article 5(2) has been reached or in the event that STECF advises that this target, or the minimum and precautionary spawning biomass levels in Article 6 or the levels of fishing mortality rates given in Article 7(2) are no longer appropriate in order to maintain a low risk of stock depletion and a maximum sustainable yield, the Council shall decide on new values for these levels.
2. In the event that STECF advises that any of the cod stocks is failing to recover properly, the Council shall take a decision which: (a) sets the TAC for the relevant stock at a level lower than that provided for in Articles 7, 8 and 9; (b) sets the maximum allowable fishing effort at a level lower than that provided for in Article 12; (c) establishes associated conditions as appropriate.

## ECOREGION Celtic Sea and West of Scotland STOCK Cod in Divisions VIIe-k (Celtic Sea cod)

## Advice for 2012

The strong 2009 year class is expected to bring the SSB above MSY $\mathrm{B}_{\text {trigger }}$. Based on the MSY framework, ICES advises that F in 2012 be set at $\mathrm{F}_{\mathrm{MSY}}=0.40$, resulting in landings of 10000 t in 2012.

## Stock status

Figure 5.4.2.1 Cod in Divisions VIIe-k (Celtic Sea Cod). Summary of stock assessment (weights in thousand tonnes). Top right: SSB and $F$ over the years.

More than $80 \%$ of the landings consist of 3 age groups (1-3) over the available time-series (Figure 5.4.2.4). Therefore the stock is highly dependent on incoming recruitment. Various sources indicate that the recruitment of the 2009 year class is the strongest since 2000. SSB is above $\mathrm{B}_{\mathrm{pa}}$ and is expected to increase to a high level in the near future because of decreasing fishing mortality and strong incoming recruitment. However, it is known that discard rates have increased in some fleets in 2010, and this discard information is incomplete in the assessment; this means that the assessed and predicted stock size may be overestimated. Fishing mortality has been substantially decreasing since the late 1990s while landings are stable and close to their lowest historical levels. Current fishing mortality is above the potential proxy for $\mathrm{F}_{\mathrm{MSY}}$.

## Management plans

There are no specific management objectives or a management plan for this stock, but a plan is under development by the NWWRAC.

## Biology

Celtic Sea cod has higher growth rates and mature earlier than other cod stocks. There is a potential for a high yield if the fishing mortality can be reduced.

## Environmental influence on the stock

Cod in the Celtic Sea are at the southern limit of the range of the species' distribution in the Northeast Atlantic. It is known that recruitment tends to decrease in warmer waters at the southern limits of the range.

## The fisheries

Cod is caught in a range of fisheries, including gadoid trawlers, Nephrops trawlers, otter trawlers, beam trawlers, and gillnetters. Landings are made throughout the year, but are generally more abundant during the first semester. The TACs have constrained catches since 2003 and the impact of the Trevose Head Closure applied since 2005 has resulted in landings being spread across the year.

## Catch by fleet

Not available, but discard estimates are $>500 \mathrm{t}$ in 2010. Total landings $(2010)=3200 \mathrm{t}$ ( $76 \%$ otter trawl, $12 \%$ beam trawl, $4 \%$ gillnets, and $8 \%$ other gears).

## Quality considerations

In previous assessments, the major sources of uncertainties were discard estimates (including highgrading) and misreporting. These problems occurred in 2003 and subsequent years, when quotas became increasingly restrictive. The magnitude of highgrading and misreporting has decreased since 2008. Estimates of highgrading have been included in this assessment. Landings have been revised to include misreporting from the southern part of the Irish Sea. Lpue for the French fleets for 2009 and 2010 are not available.

Weights in ' 000 tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012.
${ }^{2)}$ Landings 2012 relative to TAC 2011.

## MSY approach

The strong 2009 year class is expected to bring the SSB above MSY $\mathrm{B}_{\text {trigger }}$. Based on the MSY framework, ICES advises that F in 2012 be set at $\mathrm{F}_{\mathrm{MSY}}=0.40$, resulting in landings of 10000 t in 2012. This is expected to lead to an SSB of 21900 t in 2013.

Following the transition scheme towards the ICES MSY framework implies that F in $2012\left(\mathrm{~F}_{2010}{ }^{*} 0.6+0.4 * \mathrm{~F}_{\mathrm{MSY}}\right)$ is 0.47 , resulting in landings of 11300 t in 2012. This is expected to lead to an SSB of 20400 t in 2013.

## Precautionary considerations

The fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings of less than 14700 t in 2012. This is expected to keep SSB above $B_{p a}$ in 2013.

## Additional considerations

## Management considerations

Because of the large 2009 year class is now entering the fishery, which was not anticipated in last year's advice or TAC, there will be a large inconsistency between the TAC set for 2011 ( 4023 t ) and the predicted landings for that year, assuming the current fishing mortality ( 10500 t ). Therefore, in the absence of any effort limitation and/or TAC revision, high discarding will occur.

A truncated age structure has been observed in landings of this stock over many years. The historical dynamics of Celtic Sea cod have been "recruitment driven", i.e. the stock increased in response to good recruitments and decreased rapidly during times of poor recruitment. Recruitment in recent years has been poor except for the 2009 year class, which is estimated to be the strongest since 2000 (Figure 5.4.2.1). Fishing mortality should be reduced in the longer term to maximize the contributions of recruitment to future SSB and yield. This will result in reduced risk to the stock.

In recent years, Irish landings of cod reported from ICES rectangles immediately north of the Irish Sea-Celtic Sea boundary have been re-allocated into the Celtic Sea as they represent a combination of inaccurate area reporting; these catches of cod are considered to be part of the Celtic Sea stock.

Cod in Divisions VIIe- k are caught in a range of fisheries, including gadoid trawlers, Nephrops trawlers, otter trawlers, beam trawlers, and gillnetters. Other commercial species that are caught by these fisheries include haddock, whiting, Nephrops, plaice, sole, anglerfish, hake, megrim, and elasmobranchs.

In the recent past, there have been indications of underreporting of cod landings in some fleets. The introduction of the "buyers and sellers" legislation in the UK and Ireland may have reduced this, but may also have increased discards. Measures aimed at reducing discarding and improving the fishing pattern should be encouraged. These might include spatial and temporal changes in fishing practices or technical measures, such as grids. These measures would need to be evaluated in the context of other species caught in mixed fisheries.

The displacement of effort from areas with existing effort control regimes (Division VIIa, Subareas VI and IV) could have a detrimental effect on measures to reduce the mortality of cod in the Celtic Sea.

Recent tagging studies using data storage and conventional tags have shown movement of cod between the estuaries on the south coast of Ireland (officially in Division VIIa) and their offshore feeding grounds in the Celtic Sea (mainly Division VIIg). Irish landings from the southern part of Division VIIa are included in the assessment for the Celtic Sea stock. Tagging shows some dispersal of cod tagged north of $53^{\circ}$ in the Irish Sea into the deeper offshore waters of the Celtic Sea, but the proportion of the Irish Sea stock migrating into the Celtic Sea is unknown. There is also seasonal movement of fish tagged in Division VIIe to feeding grounds in Division VIIg.

## The effects of regulations

Fishing effort for the main fleets targeting gadoids have significantly decreased in the last 5-10 years. This is particularly the case for the French fleets for which the number of vessels involved in the fishery has been reduced, partly due to a decommissioning scheme. The estimated decline in fishing mortality since 2003 is consistent with this decrease in effort for the main fleets exploiting this stock.

Since 2005, ICES rectangles 30E4, 31E4, and 32E3 have been closed during the first quarter (Council Regulations $27 / 2005,51 / 2006$, and $41 / 2007,40 / 2008$, and $43 / 2009$ ) with the intention of reducing the fishing mortality of cod. STECF (2007) concluded that the closure is a potentially effective measure for displacing fishing activities away from spawning aggregations off North Cornwall and hence making vessels less efficient at catching cod. The major impact of the closure appears to have been on French trawlers that historically have taken a large proportion of the cod landings in Divisions VIIe-k. The effectiveness of the closed rectangle off the Irish coast is less evident due to its lesser importance as a fishing ground for the EU whitefish fleets and the poorer knowledge of the distribution of cod spawning activity off the southeast coast of Ireland. The quantitative impact of this closure was evaluated by ICES in 2007 in response to a special request from the EC and it could not be quantitatively disentangled from other factors.

Technical measures applied to this stock are a minimum mesh size for beam and otter trawlers in Subarea VII and a minimum landing size (MLS) of 35 cm . For Belgian trawlers that land in Belgium the MLS has been 50 cm since 2008. Minimum landing sizes do not prevent cod from being discarded, but might prevent the targeting of juvenile cod. Recent sampling programmes in countries exploiting this stock indicate that discarding is high and variable. They may account for $40-60 \%$ by number of all fish caught. These discards were mainly under the MLS until recently, when highgrading became more prominent in the fishery.

The most pertinent changes to the fishing pattern for cod have been the increased highgrading and discarding in response to restrictive quotas since 2002. Highgrading has occurred in French fisheries since 2003 and has also been apparent in UK fisheries since 2007. Highgrading has decreased in the major fleets catching cod since 2008.

## Data and methods

The assessment methodology for this stock has been benchmarked in 2009 (ICES, 2009), but this process failed to develop an assessment procedure on account of recent deterioration in the quality of assessment input data for this stock. The major sources of uncertainties lie in the assessment of discard practices estimates (discards and highgrading) and landings misreporting. These problems occurred in 2003 and subsequent years, as quotas became increasingly restrictive. The magnitude of highgrading and misreporting has decreased since 2008. Estimates of highgrading have been included in this assessment. Landings have been revised to include misreporting from the southern part of the Irish Sea. The previous model (XSA) and settings (ICES, 2008) have been used this year pending new guidance from the next Benchmark, scheduled for 2012.

Self-sampling datasets obtained since 2008 have been applied to estimate the French highgrading, assuming that the discarding practices in 2006-2007 were the same as the practice observed in the self-sampling of the main fleet in 2008. However, applying this procedure back to 2003 was considered inappropriate.

## Information from the fishing industry

The industry has cooperated in a number of scientific endeavours with regards to improving the information base for this stock.

The French industry has been involved in a self-sampling project since 2008 and has proved to be efficient in providing quarterly estimates of discarding. The representatives of Fishers' Organisations at the WKROUND 2009 have indicated that the discarding level was probably not the same in earlier years as seen in recent years, and that this is linked to the level of TAC. French highgrading has decreased from 592 t in 2007 to 7 t in 2010.

In 2010 the Marine Institute and the Federation of Irish Fishermen initiated an annual Q1 fishery-independent survey for Celtic Sea cod. The data from the first survey have been presented to the expert group in 2011 and reveal an age structure similar to the one from the commercial catches.

## Uncertainties in assessment and forecast

Misreporting, discard practices, and highgrading were the main cause of uncertainty affecting the assessment (WKROUND, 2009), especially in the 2003-2008 period when quotas were particularly restrictive. Most of these issues have been quantified and included in this year's assessment. Another source of uncertainty is the the lack of usable effort data for France in 2009 and 2010, and thus of lpues indices for the French commercial fleets for these two years.

The uncertainties in the forecasts are associated with the strength of the incoming and the assumed recent recruitment estimates.

## Comparison with previous assessment and advice

This year the advice is based on an age-based assessment. Last year the advice to reduce catches was based on indicators in the catch-at-age, recruitment, and survey indices. This year, the advice takes into account the large increase in stock size due to the estimated outstanding 2009 year class.

## Assessment and management area

From 2009 onwards the TAC covers Divisions VIIb,c,e-k, Subareas VIII, IX, and X, and EU waters of CECAF 34.1.1 (a separate TAC was established for Division VIId). The exclusion of the ICES Division VIId in the TAC area since 2009 brings the management area more in line with the boundaries of the stock.

## ECOREGION Celtic Sea and West of Scotland STOCK <br> Haddock in Division VIIa (Irish Sea)

## Advice for 2012

ICES advises based on precautionary considerations, that catches in 2012 should be reduced, and uptake of further technical measures to reduce discards.

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  |  | 2008-2010 |
| MSY ( $\mathrm{F}_{\text {MSY }}$ ) |  | Unknown |
| Precautionary $\operatorname{approach}\left(\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{lim}}\right)$ | $?$ | Unknown |

| SSB (Spawning-Stock Biomass) |  |  |
| :---: | :---: | :---: |
|  |  | 2009-2011 |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | ? | Unknown |
| Precautionary approach ( $\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}$ ) | $?$ | Unknown |
| Qualitative evaluation | (x) | Below poss. reference points |

Figure 5.4.3.1 Haddock in Division VIIa (Irish Sea). Summary of trends in ICES estimates of landings (in tonnes, 2003 sampling was inadequate to derive catch age compositions), recruitment, total mortality (Z, empirical total mortality values from one survey are also shown for illustrative purposes), and spawning-stock biomass. Dotted lines are $\pm 1$ standard error.

The assessment is indicative of trends only. Stock trends indicate an increase in SSB over the time-series, but a decrease since 2008. The strength of the 2010 year class is uncertain and the response to SSB is unknown due to the dependence on incoming year classes.

## Management plans

No specific management objectives are known to ICES.

## Biology

Recruitment is highly variable and the biomass increases rapidly after good recruitment. Density dependent growth is also evident by year-class, which will have an effect on the overall yield of abundant year classes

## The fisheries

Haddock in Division VIIa are taken in Nephrops and mixed demersal trawl fisheries, using mid-water trawls and otter trawls. Landings are made throughout the year, but are generally more abundant during the third quarter. Discarding is high and additional technical measures should be introduced, for example the use of sorting grids or large square mesh ( $>120 \mathrm{~mm}$ ) panels in Nephrops fisheries. Discard estimates are very variables and estimates are large in some years.

Catch by fleet Total catch (2010) is unknown; 840 t landings ( $44 \%$ Nephrops otter trawl, $26 \%$ midwater otter trawl, $7 \%$ seine, $1 \%$ beam, and $22 \%$ other gears), with discards data not raised to fleet level.

## Quality considerations

This assessment is based on survey trends only, as recent levels of catch are uncertain. This has been attributed to poor discard sampling, which however has improved considerably in the last two years.

| Scientific basis |  |
| :--- | :--- |
| Assessment type | Surba analysis based on survey information, considered indicative of trends only. |
| Input data | 1 trawl survey (NIGFS-WIBTS-Q1). |
| Discards and bycatch | Not included in the assessment. |
| Indicators | NIGFS-WIBTS-Q4, NIMIK, UK FSP survey, Irish Sea AEPM survey. |
| Other information | None. |
| Working group report | WGCSE |

(unchanged since: 1998)

## Outlook for 2012

The assessment is indicative of trends only. The main reason why no full analytical assessment is presented is uncertainty in absolute levels of recent catch. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

The exploitation status is unknown and SSB is fluctuating widely considering the full time series. Therefore catches should be reduced.

Management by TAC is inappropriate for this stock because landings - but not catches - are controlled. Management measures should be introduced in the Irish Sea to reduce discarding of small haddock in order to maximize their contribution to future yield and SSB.

## Additional considerations

## Management considerations

Discarding is a serious problem for this stock. The discard rates for all fleets in 2010 were $92-100 \%$ for one-year-olds; $22-96 \%$ for two-year-olds and $3-68 \%$ for three-year-olds by number.

An increase in mesh size to reduce discarding will be beneficial to this stock and could increase future yield. Reduced selectivity on younger ages would reduce discarding and promote stock increase when strong year classes occur. Some fleets are using 80 mm mesh to target Nephrops, 90 mm mesh in mixed fisheries and $100+\mathrm{mm}$ to target gadoids and other species. Recent gear trials have shown that square mesh panels can significantly reduce discards of undersized haddock (BIM, 2009). In order to minimise discards, a square mesh panel of at least 120 mm should be introduced for all fleets or selectivity devices that achieve equivalent or better improvements.

The Annual Egg Production (AEMP) survey estimates of haddock SSB confirm the trend in SSB from the assessment (Fig. 5.4.3.2). The absolute estimates in 2006 and 2008 ( 8.8 kt and 9.4 with CV of $32 \%$ and $24 \%$, respectively) are very large compared to the WG landings of 650 and 870 t for these years. Even when discard estimates at age $2+$ are taken into account the total catch estimates are $\sim 1000-1200 t$ during this period. This would imply a much lower mortality than given by the age profile in the survey used in the assessment. There is, however, no evidence from any fishery data for an age composition that would reflect low mortality. The AEMP estimate for 2010 is in contrast to the 2006 and 2008 estimates, substantially lower at 870 t (CV of $26 \%$ ) corresponding to landing of 940 t and catch estimates of $\sim 1100 \mathrm{t}$.

Current TAC management measures are not responsive enough considering the dynamic nature of changes in stock abundance. The increase in abundance from 2005-2008 created increased catch opportunities. During this period the TAC remained relatively constant and resulted in increased discarding of older fish (particularly in 2007). The TAC for 2009 was increased based on the increasing trend of stock abundance, in spite of evidence of weaker recruitment and possible decreasing abundance.

Landings data have not been used in the assessment. Landings data for this stock are uncertain because of species misreporting, which has been estimated from quayside observations in one country only. Restrictive quotas for some countries caused extensive misreporting during the 1990s prior to the introduction of a separate TAC allocation for the Irish Sea. Estimates of misreporting have been included in the estimates of landings, except for 2003. The recent implementation of UK Buyers and Sellers legislation has improved the quality of the landings data and there is little evidence of misreporting since 2006.

## Regulations and their effects

EU has adopted a long-term plan for cod stocks and the fisheries exploiting those stocks (Council Regulation (EC) 1342/2008). The long-term management plan for cod implemented in the Irish Sea from 2008 will affect catches of species caught in related fisheries, including haddock.

## Changes in fishing technology and fishing patterns

The introduction of effort regulation has effectively encouraged vessel operators to reduce mesh size and shift to other fisheries, particularly to Nephrops trawling, in order to gain more days at sea. This has implications for catch compositions and the selectivity of the fishery. Four Irish vessels targeting Nephrops are now using selective grids and are exempted from the effort control regime. Grids have been shown to reduce haddock catches to negligible levels.

## Uncertainties in the assessment

An assessment was carried out based on survey information only and is considered to be indicative of trends only. Both total mortality and SSB estimates are relative as survey catchabilities at age are not known. Recruitment estimates for the 2010 year class is uncertain with conflicting signals from the surveys.

## Information from the fishing industry

The UK Fishery Science Partnership Irish Sea roundfish survey 2004-2009, which was carried out using commercial trawlers, indicated similar year-class signals to research vessel surveys. This survey supports the conclusions of the assessment.

## Comparison with previous assessment and advice

The perception of the stock has not changed since last year's assessment. The most recent SSB estimate indicates that the stock has declined since 2008. Last year the SSB was expected to remain at stable or increase; this year the SSB is expected to remain at current levels or decrease depending on the strength of recruitment.

The basis for the advice is the precautionary considerations.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Haddock in Divisions VIIb-k

## Advice for 2012

Abundance of haddock is increasing due to a large recruiting year class, but exploitation status is unknown; therefore, ICES advises no increase in catch and technical measures to mitigate the increased discarding of the recruiting year class.

Standard short-term projections imply a TAC increase of around $300 \%$ for 2012 compared to 2011, under status quo F, although the precision is expected to be poor. Discarding rates will be high unless technical measures are implemented in 2011. During 2011 new data from surveys and the industry will be coming in that will improve the estimate of the year-class strength, and this may allow changes in management in 2012.

Figure 5.4.4.1 Haddock in Divisions VIIb-k. Summary of stock trends: Top right: SSB/F over the years. Y-axis starting at 0 .
The assessment is indicative of trends only. SSB shows an increasing trend over the time-series. Recruitment is highly variable and in the past the SSB and catches have increased after good recruitment. Recruitment of the 2009 year class appears to be exceptionally good, and catches have increased in 2010. However, most of the increase in catch was discarded because these fish were under the minimum landing size. As these fish become of marketable size from age 2 onwards, they are likely to be discarded due to a restrictive TAC. Fishing mortality has been stable over the recent years.

## Management plans

No specific management objectives are known to ICES.

## Biology

Adult haddock appear to be continuously distributed from the north of Biscay along the Irish coasts and the west of Scotland into the North Sea. It is not clear from their distribution if the Divisions VIIb-k stock is distinct from the surrounding areas.

## The fisheries

Haddock are caught in mixed demersal fisheries. Some fleets are using 80 mm mesh to target Nephrops, 90 mm mesh in mixed fisheries, and 100 mm to target gadoids and other species.

Catch by fleet Total catch $(2010)=22.2 \mathrm{kt}$, of which $44 \%$ are landings (all fleets combined) and $56 \%$ discards.

## Quality considerations

There is considerable uncertainty around the estimated discard numbers-at-age due to the diverse fishing (and discarding) practices and relatively low numbers of discard samples. However, the estimates of F and trends in recruitment and SSB do not appear to be sensitive to the inclusion of the age classes at which the discarding takes place in the assessment.

Scientific basis

| Assessment type | Age-analytical assessment (XSA) considered for trends only. |

## ECOREGION Celtic Sea and West of Scotland STOCK Haddock in Divisions VIIb-k

## Reference points

No reference points have been defined for this stock.

## Outlook for 2012

A trends-only assessment is presented for this stock. The main reason why no full analytical assessment is presented is uncertainty in absolute levels of recent discards. Therefore, fishing possibilities cannot be projected.

A short-term forecast, used in relative terms, illustrates the drastic changes expected in yield and SSB at different levels of exploitation in relation to current F (Fig. 5.4.4.3). The landings in 2012 are expected to be $300 \%$ of the TAC (Divisions VIIb-k and Subareas VIII, IX, and X) in 2011. The high recruitment in 2009 is expected to account for a large proportion of the projected landings in 2012 and SSB in 2013. TACs will control landings, but not catches. A high level of discarding is therefore expected in 2011 and 2012.

## Precautionary considerations

The underlying data do not support the provision of estimates of $\mathrm{F}_{\text {MSY }}$. The exploitation status is thus unknown. Fishing mortality has been stable over the recent years. Therefore, there should be no increase in catches.

Future catches and SSB will be highly dependent on the strength of incoming year classes and their discard mortality. With the higher incoming recruitment of the 2009 year class, the stock should be managed by ensuring that fishing effort is not allowed to increase and technical measures should be introduced to reduce discards.

## Additional considerations

Management by TAC is inappropriate for this stock because landings, and not catches, are controlled. Haddock are caught in a mixed fishery, so TAC management can lead to discarding of over-quota fish in addition to the already considerable discarding of undersized fish.

Discarding is a serious problem for this stock; over the last 10 years $70 \%$ of the catch has been discarded ( $45 \%$ by weight). The TAC has not been restrictive in recent years, but since 2009 the national quotas of Ireland and Belgium appear to have become restrictive. The catches are increasing as the 2009 year class enters the fishery; and despite a moderate increase in TAC in 2011, the quota are likely to become restrictive for all countries, resulting in increased levels of discarding.

An analysis of Irish landings and discards by metier (Anon., in prep.) indicates that although the Nephrops fleets have very high discarding rates of haddock ( $>70 \%$ by weight), in absolute terms these fleets only contribute $10 \%$ of the Irish haddock discards in the Celtic Sea. The demersal otter bottom trawl (OTB) and Scottish seine (SSC) fleets in Divisions VIIgj contribute $82 \%$ of the haddock discards.

Technical measures can reduce discarding and could increase the yield considerably. Improved selectivity on younger ages will reduce discarding and promote stock increase when strong year classes occur. ICES recommends that an escape panel and minimum mesh size for the demersal fleet should be increased substantially and an analysis should be performed to estimate appropriate mesh size.

Comparison with previous assessment and advice
The basis for the assessment and the advice is the same as last year.

## Assessment and management area

The TAC for haddock is set for all of Divisions VIIb-k and Subareas VIII, IX and X, which does not correspond to the stock assessment area (Division VIIb-k). However, official international landings from Subareas VIII, IX, and X have been less than $2 \%$ of all landings in the TAC area in most years since 1973.

Figure 5.4.4.2 Haddock in Divisions VIIb-k. TAC area in the boxes outlined in red (Divisions VIIb-k and Subareas VII, IX, and X), assessment area in blue shading (Divisions VIIb-k).

Figure 5.4.25.1
Whiting in Division VIIa (Irish Sea). Landings reported to the WG (in thousand tonnes, 1991-2002 estimates include sampled-based estimates of landings at a number of Irish Sea ports), and mean standardised: SSB, total mortality $(\mathrm{Z})$, and recruitment estimates, from single fleet SURBA analysis.

The state of the stock is uncertain. Long-term information on the historical yield and catch composition indicate that the present stock size is extremely low and likely to be well below previously defined $\mathrm{B}_{\text {lim. }}$. Landings have seen a declining trend since the early 1980s, reaching lowest levels in the 2000s. The survey results indicate a decline in relative SSB. Total mortality has been variable over the time series. Current fishing mortality is likely to be above possible MSY targets.

## Management plans

No specific management objectives are known to ICES.

## Biology

The degree of mixing between this stock and other adjacent stocks is unclear and whiting in Division VIIa may be a component of a larger stock.

## The fisheries

There is no targeted whiting fishery in the Irish Sea. Whiting are bycatch (and discarded) within in the main Irish Sea fisheries. Otter trawlers utilising $70-90 \mathrm{~mm}$ mesh sizes are the primary gear associated with whiting landings. This incorporates the Nephrops fishery, which shows high discard rates of whiting. Discard rates are very high likely due to the low market value of this species, particularly for smaller sizes.

Catch by fleet Total catch (2010) is unknown. Total landings $0.1 \mathrm{kt},>1.0 \mathrm{kt}$ estimated discards.

## Quality considerations

Since 2003 the low landing levels have resulted in poor sampling coverage of the stock and no reliable estimates of catch numbers-at-age. Discard estimation and raising procedures are problematic and discard estimates may be imprecise. Survey data are consistent with increasing F and low stock size.

## ECOREGION Celtic Sea and West of Scotland STOCK Whiting in Division VIIa (Irish Sea)

Reference points

|  | Type | Value | Technical basis |
| :---: | :---: | :---: | :---: |
| MSY <br> Approach | MSY $\mathrm{B}_{\text {trigger }}$ | Undefined |  |
|  | $\mathrm{F}_{\text {MSY }}$ | Undefined |  |
| Precautionary | $\mathrm{B}_{\text {lim }}$ | 5000 t | $\mathbf{B}_{\text {loss }}$ (1998); the lowest observed SSB as estimated in previous assessment. There is no clear evidence of reduced recruitment at the lowest observed SSBs. |
|  | $\mathrm{B}_{\mathrm{pa}}$ | 7000 t | $\mathbf{B l o s s}^{*}$ * 1.4; considered to be the minimum SSB required to ensure a high probability of maintaining SSB above its lowest observed value, taking into account the uncertainty of assessments. |
| Approach | $\mathrm{F}_{\text {lim }}$ | 0.95 | The fishing mortality above which stock decline has been observed. |
|  | $\mathrm{F}_{\mathrm{pa}}$ | 0.65 | This F is considered to have a high probability of avoiding $\mathrm{F}_{\text {lim. }}$ It implies an equilibrium SSB of 10.6 kt , and a relatively low probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}(=7 \mathrm{kt}$ ), and is within the range of historic Fs. |

(unchanged since: 1998)

## Outlook for 2012

No reliable assessment can be presented for this stock. The main cause of this is the limited data on discards. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

SSB has declined to a very low level. The underlying data do not support the provision of estimates of $\mathrm{F}_{\mathrm{MSY}}$. However, it is likely that current F is above $\mathrm{F}_{\mathrm{MSY}}$. Therefore, catches (mainly discards) of whiting should be reduced to the lowest possible levels.

Management by TAC is inappropriate for this stock because landings - but not catches - are controlled. Further management measures should be introduced in the Irish Sea to reduce discarding of small whiting in order to maximize their contribution to future yield and SSB.

## Additional considerations

Management by TAC is inappropriate for this stock because landings, not catches, are controlled.
Catches of whiting have substantially reduced from the 1980s. Discarding remains a substantial problem for this stock, with almost all whiting caught being discarded. Of the onboard observer trips carried out in 2010 by the UK (E\&W), UK (NI) and Ireland, negligible fish were retained on board while thousands of small fish were discarded. Raised discards from the main national fleets landing whiting show over 22 million whiting, greater than $1000 t$ in weight, were discarded in 2010. This focused on the two youngest ages, and to a lesser extent age 2 . In some years up to age 4 fish are discarded.

Any measure to reduce discarding and to improve the fishing pattern should be actively encouraged. These might include spatial and temporal changes in fishing practises or technical measures such as increased codend mesh size, square mesh panels, separator trawls, and increased top sheet mesh in towed gears. These measures would also need to be evaluated in the context of other species caught in these mixed fisheries. In late 2009, a number of Irish vessels operating within the Irish Sea Nephrops fishery incorporated a Swedish grid into otter trawls, as part of the cod long term management plan. It is expected that this will reduce the whiting catches of these vessels by $60 \%$ in weight. Further more, a small number of vessels began utilizing an inclined separator panel expected to reduce whiting catch by $76 \%$ in weight.

## Regulations and their effects

Various technical measures have been introduced in the past to mitigate bycatch of whiting, particularly in the Nephrops fishery, which operates on the whiting nursery grounds. It has proven difficult to evaluate the success of measures, such as the mandatory use of square mesh panels in Nephrops trawls since 1994. A minimum landing size of
$\geq 27 \mathrm{~cm}$ is applied to this stock, however, discard data shows that individuals in excess of that size are also discarded. In addition to area and species related minimum mesh size restrictions applicable to mixed demersal fisheries.

Due to the bycatch of cod in fisheries taking whiting, the regulations affecting Division VIIa whiting remain linked to those implemented under the Irish Sea cod long term management plan, including effort restrictions. Although vessels catching whiting will be affected by this regulation at present it is not believed that the effort limitations will prove beneficial to the whiting stock.

The closure of the western Irish Sea to whitefish fishing from mid-February to the end of April, designed to protect cod, has been continued, though it is not clear to what extent these measures will protect whiting.

## Uncertainty in the assessment

The primary deficiency is the limited availability of discard time series data. There are no reliable estimates of catch numbers-at-age since 2003 due to the low landings levels of whiting in recent years resulting in poor sampling. Discard estimation and raising procedures are problematic and discard estimates may be imprecise. Additionally, the stock structure of whiting in the Irish Sea is uncertain.

Comparison with previous assessment and advice
The basis for the assessment is the same as last year. The advice is the same as last year.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Whiting in Divisions VIIe-k

Advice for 2012
ICES advises based on precautionary considerations, that catches should not be allowed to increase and technical measures should be introduced to reduce discard rates.

## Stock status

Fishing Mortality

Figure 5.4.6.1
Whiting in Divisions VIIe-k. Summary of stock trends assessment.
The state of the stock is uncertain and the assessment is indicative of trends only. The stock is estimated to have declined since the mid 1990s and has recently increased to the long term average. SSB is highly dependent on incoming recruitment. Fishing mortality estimates are variable and recent trends suffer in precision due to lack of discard data in the assessment. Surveys indicate that the 2008 and 2009 year classes may be above average.

## Management plans

No specific management objectives are known to ICES.

## The fisheries

Celtic Sea whiting are taken in mixed species fisheries. Discard rates are very high due to the low market value of this species, particularly for smaller sizes. Otter trawlers are the primary gear associated with whiting landings from the Celtic Sea

Catch by fleet Total catch (2010) is unknown. Total landings 8.4 kt (\% by gear unavailable), discard estimates are high ( $8-82 \%$ by weight depending on metier).

## Quality considerations

The main quality consideration is the non-inclusion of discard data in the assessment, which biases recruitment estimates and may explain changing catchabilities in commercial fleets observed throughout the assessment period. Surveys used in the assessment are prone to year effects, and often give very different estimates of the incoming year classes. The lack of French effort and lpue data for 2009 and 2010 is an additional uncertainty.

(unchanged since: 1998)

## Outlook for 2012

No reliable assessment can be presented for this stock. The main cause of this is high and uncertain discards which are not included in the assessments. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

The SSB estimates show an increase since 2007 and the exploitation status is unknown. Therefore, catches should not be allowed to increase.

Management by TAC is inappropriate for this stock because landings - but not catches - are controlled. Recruitment in 2008 and 2009 appears to be above average. Catches and SSB may increase in 2011 if effort remains constant. Technical measures to minimise discards should be considered with urgency.

## Additional considerations

Discarding of this stock for different fleets is substantial and highly variable ( $9-82 \%$ by weight and $18-90 \%$ by number of total catch). Any measure to reduce discarding and to improve the fishing pattern as advised for haddock in Divisions VIIb-k would be beneficial to the whiting stock (see section 5.4.4). These might include spatial and temporal changes in fishing practises or technical measures such as increased cod-end mesh size, square mesh panels, separator trawls, and increased top sheet mesh in towed gears. These measures would also need to be evaluated in the context of other species caught in these mixed fisheries. ICES suggest that a square mesh panel of at least 120 mm should be introduced for the Nephrops fleet and a minimum mesh size of at least 100 mm with a square mesh panel of at least 110 mm for all other fleets or selectivity devices that achieve equivalent or better improvements.

## Regulations and their effects

The stock is managed by a TAC and technical measures. The TAC has not been restrictive or approached restriction since the mid 1990s, a period of strong recruitment. Uptake since 2002 has been on average around $40 \%$.

A closure of the three rectangles in the Celtic Sea has been in place annually during the first quarter, since 2005 to protect the cod stock. The impact of this on the whiting stock remains unclear. Whiting landings from these rectangles are lower than the surrounding area and remaining quarters.

## Changes in fishing technology and fishing patterns

There have been major changes in fleet dynamics over the period of the assessment. Effort in the majority of fleets has been declining since the late 1990s or early 2000s. The exception to this is the Irish otter trawl fleet in Division VIIg which showed increased effort, due to activity shifting into the area from Division VIIj. During this period, fleet modernisation has occurred, replacing old inefficient vessels with newer more efficient vessels. Since the early 2000s a number of decommissioning schemes have been carried out by several nations including France, UK and Ireland, to reduce fleet capacity. A number of schemes have been aimed at reducing whitefish fleet capacity. However, this has not always been as effective because of low participation rates in such schemes by vessels targeting whiting or targeting other species groups.

## Comparison with previous assessment and advice

The basis for the assessment and advice is the same as last year.

## Assessment and management area

The assessment area of this stock (Divisions VIIe-k) does not correspond to the TAC area (VIIb,c,d,e,f,g,h,j and k). Whiting in Divisions VIIb,c are not assessed and whiting in Division VIId is considered to be part of the North Sea stock (Subarea IV and Division VIId) (section 6.4.5). Division VIIj was without TAC constraint, from 2008-2010, but included again in 2011. Whatever management measures are implemented, they must be consistent with the assessment area.

Figure 5.4.6.2 Whiting in Divisions VIIe-k. TAC Area in the boxes outlined in red, assessment area in blue shading.

## ECOREGION Celtic Seas and West of Scotland STOCK Plaice in Division VIIa (Irish Sea)

## Advice for 2012

ICES advises on the basis of precautionary considerations that catches of plaice should not increase and technical measures should be introduced to reduce discard rates.

## Stock status

Figure 5.4.7.1 Plaice in Division VIIa. Estimated catch, landings and discards, Recruitment (age 1), Fishing mortality (ages 3-6) and SSB trends (Central trend lines are mean estimated values per year, surrounding lines are $90 \%$ confidence intervals. Horizontal lines in standardised plots are mean of the time series). Top right: SSB and F over the years.

The assessment is indicative of trends only. The SSB trends show an increase in stock size since the mid-1990s to a stable level. Fishery-independent estimates of plaice SSB from Annual Egg Production Method (AEPM) surveys increased from 9 kt in 1995 to $14-15 \mathrm{kt}$ since 2006. Absolute estimates of SSB from the assessment are very uncertain but are $>20 \mathrm{kt}$ since 2003. Fishing mortality from the assessment shows a declining trend since the early 1990s to a stable level. The recent F is likely to be very low as the estimates of total catch (landings and discards) since 2006 are only around $15 \%$ of the AEPM estimates of SSB over this period, and the catches also include immature plaice. Recruitment has been slightly lower than average in recent years.

## Management plans

No specific management objectives are known to ICES.

## Biology

There are considered to be three main spawning areas of plaice in the Irish Sea: one off the Irish coast, another northeast of the Isle of Man towards the Cumbrian coast, and the third off the north Wales coast. Cardigan Bay in St. George's Channel has also been identified as a spawning ground for plaice in the Irish Sea. The level of mixing between the eastern and western components of the Irish Sea stock appears small. Males are smaller than females and mean length at age of both sexes has generally declined since the mid 1990s. Survey data indicate that males of ages 1-5 and females of age 1-3 are generally below minimum landing size (MLS).

## Environmental influence on the stock

Time series of recruitment estimates for all plaice stocks in waters around the UK (Irish Sea, Celtic Sea, western and eastern Channel, North Sea) show a high degree of synchrony and significant negative relationships with sea surface temperature.

## The fisheries

A very high proportion of the catch is discarded. In the eastern Irish Sea plaice are caught by the mixed demersal fishery, largely UK otter trawlers, and as a bycatch in targeted sole beam trawl fisheries, dominated by Belgian trawlers. Total effort (hours fished) in the UK fleets targeting plaice have declined to the lowest levels recorded. Total effort by the Belgian beam trawl fleet has declined steadily from a peak in 2002. In the western Irish Sea, plaice are caught by the Irish and UK Nephrops fisheries: effort by these fisheries is greater than in the mixed demersal and beam fisheries combined. The regulations affecting plaice and other demersal stocks in Division VIIa remain linked to those implemented under the Irish Sea cod long-term management plan.

Catch by fleet Catch (2010) 2892 t where $13 \%$ landings, $87 \%$ discards. Landings: 377 t where $36 \%$ beam trawl and $64 \%$ otter trawl. ICES estimates of discards: 2516 t where $13 \%$ beam trawl and $87 \%$ otter trawl.

## Effects of the fisheries on the ecosystem

A proportion of the plaice catch is caught by beam trawl fisheries. Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates and in areas which have been historically exploited by this fishing method.

## Quality considerations

Up to 2010 ICES carried out an assessment using landings-at-age data. Discard sampling studies have indicated variable discarding rates up to $80 \%$ by number. This year, an assessment model that includes discard data since 2004, was used, and considered appropriate to assess SSB and fishing mortality trends. The discard data are noisy and the 2010 estimate will be revised when complete age data from observer trips become available. The high discard and catch estimates for 2007 and 2010 are downscaled by the assessment model. Estimation of partial fishing mortalities due to the landed and discarded component indicates that the fraction of F due to discarding has increased since 2004 (Figure 5.4.7.4).

## Scientific basis

| Assessment type | Trends only based on Aarts \& Poos (2009) assessment model |
| :--- | :--- |
| Input data | 3 survey indices (UK (E\&W)-BTS-Q3, NIGFS-WIBTS-Q1, NIGFS-WIBTS-Q4) |
| Discards and bycatch | Discards included in the assessment (2004-2010) |
| Indicators | Annual egg production survey of spawning stock size |
| Other information | This stock was benchmarked in 2011 (WKFLAT 2011) |
| Working group report | WGCSE |

## ECOREGION Celtic Sea and West of Scotland STOCK Plaice in Division VIIa (Irish Sea)

## Reference points

No reference points are defined for this stock. Previous precautionary reference points (2010) are no longer considered appropriate.

## Outlook for 2012

No reliable forecast can be presented for this stock, because the assessment is only indicative of trends and the absolute level of stock size is uncertain.

## Precautionary considerations

The exploratory assessment shows that SSB is stable at a high level above possible reference points. At the same time F is stable at a low level and considered to be below possible reference points. Therefore, catches of plaice should not increase and technical measures should be introduced to reduce discard rates.

## Additional considerations

The high level of discarding (typically up to $80 \%$ in number) in this fishery indicates a mismatch between the minimum landing size and the mesh size of the gear being used. Measures, such as the introduction of grids to Nephrops trawlers, which reduce discardings will result in increased future yield potentials. Gear selectivity trials and monitoring from four Irish Nephrops trawlers using grids since 2009 indicate a potential $75 \%$ drop in fish bycatch (BIM, 2009). The absolute level of catch estimates compared to independent estimates of spawning stock biomass using the Annual Egg Production Method, confirm that plaice in the Irish Sea is lightly exploited. SSB estimates for 2006-2010 were 14-15 kt (Fig. 5.4.7.3) compared to catch estimates $2-3 \mathrm{kt}$ (which also include significant amount of discarded juvenile fish),

## Regulations and their effects

Technical measures in force are minimum mesh sizes and minimum landing size ( 27 cm ).
Considering the high level of discarding observed in this stock, gear selectivity regulations have had little effect. The closures of cod spawning-grounds that have been in force since 2000 are unlikely to have had a significant impact on catches by the plaice fishery. In 2000, the closure covered the western and eastern Irish Sea. Since then, the closure has been mainly in the western part, whereas the majority of the plaice fishery has taken place in the eastern part of the Irish Sea.

## Changes in fishing technology and fishing patterns

Fishing effort in the Irish Sea beam trawl fleet declined significantly in 2008 and remained at a low level in 2009 and 2010. Fishing effort in larger mesh ( $>100 \mathrm{~mm}$ ) otter trawl fleets declined substantially since 2002 with the introduction of the cod recovery plan. Total effort (hours fished) in these fleets has declined to the lowest level since 1979.

## Data and methods

The benchmark investigated several assessment methods to explore options for incorporating a short time-series of discard observations into the assessment. None of the approaches examined proved to be entirely satisfactory. The group concluded that the Aarts and Poos (2009) method, developed initially for North Sea plaice, could be used as a trends only assessment for the provision of management advice but could not be used as a basis for predicting future catch options.

## Comparison with previous assessment and advice

Last year's assessment was based on survey trends. This year, an assessment using a new assessment model incorporating discard data from 2004 was performed and used as indicative of trends. Last year the SSB trends showed an increase in stock size since the mid-1990s to a stable level and this perception did not change this year. Last year's
total mortality showed a declining trend since the early 1990s. This year assessment shows a declining trend in fishing mortality since the early 1990s to a stable level.

The advice last year was based on precautionary considerations, extended with the MSY approach. This year's advice is based on precautionary considerations, considering the qualitative evaluation of trends in F and SSB and independent indicators of total spawning stock biomass.

## ECOREGION Celtic Sea and West of Scotland STOCK Plaice in Divisions VIIf,g (Celtic Sea)

## Advice for 2012

ICES advises on the basis of the precautionary considerations that catches should be reduced. Discards exceed landings and technical measures should be introduced to reduce discard rates.

## Stock status

|  | F (Fishing Mortality) |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

Total fishing mortality (ages 3 to 6 )

Figure 5.4.8.1
Plaice in Divisions VIIfg. Estimated catch, landings and discards; Recruitment (age 1); Fishing mortality (ages 3-6); and SSB trends (Central trend lines are the mean estimated values per year, surrounding lines are $90 \%$ confidence intervals. Horizontal lines in standardized plots are the mean of the time series).

The assessment is indicative of trends only. SSB has increased since 2004 to a stable level, but is considered to be well below historic levels. Fishing mortality shows a declining trend since 2002, but is considered to be above levels that would increase SSB and achieve high long term yields. Catch rates by commercial fleets and research surveys are well below historic levels and the stock is considered at a low level (Figure 5.4.8.2). Recruitment has been fluctuating without clear trend in recent years.

## Management plans

No specific management objectives are known to ICES.

## Biology

Plaice aggregate at spawning grounds of the North Cornwall coast in the $1^{\text {st }}$ quarter of the year. The condition factor for plaice is highest in summer/autumn on the more dispersed feeding grounds.

## Environmental influence on the stock

Juvenile plaice are distributed inshore and migrate offshore at maturity. The recruitment of Celtic Sea plaice and neighbouring stocks appear to be related to sea temperature changes.

## The fisheries

The mixed plaice and sole fishery is dominated by beam trawls and otter trawls, with bycatch of both commercial and non-commercial species. The main fishery occurs in the spawning area off the north Cornish coast, at depths greater than 40 m , about 20 to 25 miles offshore. Although plaice are taken throughout the year, the larger landings occur during February-March after the peak of spawning, and again in September. There is a high rate of discarding in both beam and otter trawl fisheries.

Catch by fleet Catch (2010) 1133 t where $38 \%$ landings, $62 \%$ discards. Landings (2010) 433 t (of which 48\% beam trawl, $42 \%$ otter trawl and $10 \%$ other), discards (2010) 700 t where $58 \%$ beam trawl and $39 \%$ otter trawl and $1 \%$ other

## Effects of the fisheries on the ecosystem

Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates and in areas which have been historically exploited by this fishing method.

## Quality considerations

Discards are substantial and have ranged from $30 \%$ to $70 \%$ in number (mainly below the minimum landing size). In 2011 discards were been included in the assessment for the first time, although the time series of discard data available is short and consequently the revised assessment estimates are considered relative. Estimation of partial fishing mortalities due to the landed and discarded component indicates that the fraction of F due to discarding has increased since 2004 (Figure 5.4.8.3).

## ECOREGION Celtic Sea and West of Scotland STOCK Plaice in Divisions VIIf,g (Celtic Sea)

## Reference points

No reference points are defined for this stock. Previous precautionary reference points (2010) are no longer considered appropriate.

## Outlook for 2012

No reliable forecast can be presented for this stock because the assessment is only indicative of trends and the absolute level of stock size is uncertain.

## Precautionary considerations

The stock is considered to be below any possible reference points, while the exploitation rate is deemed too high to improve this and thus above possible reference points. Therefore, catches of plaice should be reduced and measures to reduce discards should be introduced.

## Additional considerations

## Management considerations

Discard rates are high for this stock in some seasons/fleets. The high level of discarding indicated in this mixed fishery would suggest a mismatch between the mesh size employed and the size of the fish landed. Increases in the mesh size of the gear will result in fewer discards and in increased yield from the fishery. The use of larger-mesh gear should be encouraged in this fishery in instances where mixed fishery issues allow for it.

## Regulations and their effects

Plaice in the Bristol Channel and Celtic Sea (ICES Divisions VIIf,g) are managed by TAC and technical measures. Technical measures in force for this stock are minimum mesh sizes, minimum landing size, and restricted areas for certain classes of vessels. The minimum landing size for plaice in Divisions VIIf,g is 27 cm .

Since 2005, ICES rectangles $30 \mathrm{E} 4,31 \mathrm{E} 4$, and 32 E 3 have been closed during the first quarter with the intention of reducing the fishing mortality of cod. There is evidence that this closure has redistributed effort to other areas. The effect this had on fishing mortality of plaice is uncertain.

## Information from the fishing industry

The UK Fisheries Science Partnership investigations conducted in the Eastern Celtic Sea and Bristol Channel during 2005 confirmed the presence of spawning aggregations off the north Cornwall coast. The main issues for the fishery in Divisions VIIf,g were displacement of effort due to the cod recovery zone; and the restrictions on the use of 80 mm mesh west of $7^{\circ}$ west.

## Data and methods

The benchmark investigated several assessment methods to explore options for incorporating a short time-series of discard observations into the assessment. None of the approaches examined proved to be entirely satisfactory. The group concluded that the Aarts and Poos (2009) method, developed initially for North Sea plaice, could be used as a trends only assessment for the provision of management advice but could not be used as a basis for predicting future catch options.

## Comparison with previous assessment and advice

Last year there was a full analytical assessment and forecast. The stock was benchmarked this year, new assessment model was used and discards were included. However, the assessment including discards could only be used as indicative of trends. The basis for the advice is the precautionary considerations, and catch options cannot be provided.

## ECOREGION Celtic Sea and West of Scotland STOCK Plaice in Division VIIe (Western Channel)

## Advice for 2012

ICES advises on the basis of the transition to the MSY approach that landings in 2012 should be no more than 1440 t .

## Stock status

Figure 5.4.9.1 Plaice in Division VIIe (Western Channel). Summary of stock assessment (weights in ' 000 tonnes). Estimates are shaded. Top right: SSB and F over the years.

The large reduction of F in 2009 and subsequent increase in 2010 reflects the recent changes in fishing effort. Fishing mortality is well above $\mathrm{F}_{\text {MSY }}$. SSB has increased to above MSY $\mathrm{B}_{\text {triger }}$ in last two years. The 2008 year class was well above average.

## Management plans

No specific management objectives are known to ICES.

## Biology

Plaice aggregate at spawning grounds in the $1^{\text {st }}$ quarter of the year. The condition factor for plaice is highest in summer/autumn on the more dispersed feeding grounds. Tagging studies show spawning migrations from Division VIId to VIIe during the $1^{\text {st }}$ quarter of the year. It is assumed that $15 \%$ of the $1^{\text {st }}$ quarter plaice catch in Division VIId consists of fish from VIIe. Suitable sites for nurseries are located in shallow waters, close to fresh and cool seasonal water input.

## The fisheries

Plaice are taken as a bycatch in the beam trawl fishery mainly targeting sole and anglerfish, and as part of a mixed demersal fishery by otter trawlers. The main fishery is south and west of Start Point. Although plaice are taken throughout the year, the larger landings are usually during February, March, October, and November. Discarding appears to be higher in quarters 1 and 2 in this fishery, but is low compared to other plaice stocks.

Catch by fleet Landings in 2010 were 1078 t ( $57 \%$ beam, $31 \%$ otter (dem), $3 \%$ gillnets, $2 \%$ otter (mol) and $7 \%$ other (mostly caught by the above gears, but not available separately by all countries). In addition, 149 t landed from division VIId are included in the assessment reflecting the $15 \%$ Q1 migration correction (unknown gear).

## Effects of the fisheries on the ecosystem

Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates and in areas which have been historically exploited by this fishing method. Some beam trawlers are experimenting with benthic drop-out panels that release about $75 \%$ of benthic invertebrates from the catches. Full square mesh codends are being tested in order to reduce the capture of benthos further and improve the selection profile of gadoids.

## Quality considerations

There is uncertainty about the stock structure due to migration between this area and the Eastern Channel during the spawning period, which is now partially corrected for in the assessment by an added element of VIId catches and age information to account for migration (ICES 2010). There is a heavy reliance on the age composition data derived from UK $(\mathrm{E}+\mathrm{W})$ sample data. Discards are not included in the assessment. Discard rates of plaice in Division VIIe are much lower compared to other plaice stocks and their omission is unlikely to significantly alter SSB and mortality trends.

Figure 5.4.9.2 Plaice in Division VIIe (Western Channel). Historical assessment results (final year recruitment estimates included).

Weights in tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012.

## MSY approach

Following the ICES MSY framework implies fishing mortality to be reduced to 0.19 (at $\mathrm{F}_{\text {MSY }}$ as SSB in 2012 is above MSY $B_{\text {trigger }}$ ), resulting in landings of 840 t in 2012. This is expected to lead to an SSB of 4620 t in 2013.

Following the transition scheme towards the ICES MSY framework implies fishing mortality of 0.35 for 2012. This results in landings of $1440 t$ in 2012. This is expected to lead to an SSB of $4030 t$ in 2013.

## Additional considerations

## Management considerations

The catch of plaice in Division VIIe is managed by a TAC applied to Division VIId (Eastern Channel) and VIIe combined. Consequently the TAC management does not control F on the Division VIIe stock. Splitting the TAC area into separate components will ignore the migration of the VIIe stock into VIId where they are taken in the first quarter spawning fishery. Whatever management measures are implemented, they must be effective at controlling F in both stocks. A spawning migration correction assumes that a constant $15 \%$ of quarter 1 catches in Division VIId to originate from VIIe, based on historical tagging information.

In addition to the days-at-sea regulations there has been a recent UK decommissioning scheme that has reduced the number of beam trawlers in the southwest fleet. Fishing mortality declined in 2009 and stayed at this level in 2010 and this is consistent with the recent development in effort in the main fleet exploiting this stock.

## Regulations and their effects

Technical measures include mesh size and MLS ( 27 cm ) for this species. There is some discarding, in particular of fish below the MLS in the first two quarters, but this is relatively low compared to other plaice stocks.

Effort management is implemented for beam trawlers ( $>80 \mathrm{~mm}$ ) and for static demersal nets including gillnets, trammel nets, and tangle nets on an annual basis in the EC TAC regulations. Otter trawlers contribute to a large proportion of the landings, but are not under effort restrictions.

Council Regulation (EC) No 509/2007 establishes a multi-annual plan for the sustainable exploitation of sole in Division VIIe. Reductions in fishing mortality for sole will likely also reduce fishing mortality in plaice. The UK has introduced a single area licensing scheme in November 2008 which appears to be effective at enforcing the required reductions in effort.

## Information from the fishing industry

The fisheries science partnership (FSP) conducted cooperatively with Cefas and the UK industry has provided some evidence for the widespread distribution and broad age distribution for this stock.

## Uncertainties in the assessment

There is a heavy reliance on the age composition data derived from UK $(\mathrm{E}+\mathrm{W})$ sample data. Discards are not included in the assessment, but discard rates of plaice in Division VIIe are much lower compared to other plaice stocks. The proportion of discards in number ranges from 5 to $40 \%$ depending on the season and fishery. Both the UK-WEC BTS and the FSP-7e UK (E\&W) surveys are spatially restricted to the same area as the commercial tuning fleets and little information exists on stock dynamics on the French coast.

## Comparison with previous assessment and advice

The assessment is similar to the previous assessment in terms of F , with a downward revision of $3 \%$ in $\mathrm{F}(2009)$, but there is a $21 \%$ upwards revision in SSB (2010). The estimate of the 2008 year class has been revised upwards by $>500 \%$ in this assessment as a result the additional year's survey data being included.

The basis for the advice is the same as last year.

## Assessment and management area

Stock is assessed for ICES Division VIIe, but is managed for ICES Divisions VIId and VIIe combined. The advice for Division VIId plaice can be found in Section 6.4.8 of the ICES 2011 advice.

## ECOREGION <br> STOCK

## Celtic Sea and West of Scotland

 Plaice in Divisions VIIh-k (Southwest of Ireland)Advice for 2012
ICES advises on the basis of precautionary considerations that catches in 2012 should be reduced.

Figure 5.4.10.1

Plaice in Divisions VIIh-k. Official landings (tonnes).
There is no accepted analytical assessment for this stock and the state of the stock is unknown. However, exploratory estimates of mortality suggest that recent fishing mortality for the major component of the catch is greater than a proxy for $\mathrm{F}_{\mathrm{MSY}}$.

## Management plans

No specific management objectives are known to ICES.

## The fisheries

Plaice in Division VIIh-k are mainly taken by inshore fisheries in Division VIIj.

## Outlook for 2012

No reliable assessment can be presented for this stock. The main cause of this is that catch numbers-at-age are only available for Irish landings. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

The state of the stock is unknown, but exploratory estimates of mortality suggest that recent fishing mortality for the landings component of the catch is greater than $\mathrm{F}_{\max }$ which is used as a proxy for $\mathrm{F}_{\mathrm{MSY}}$ (Figure 5.4.10.3). Therefore, catches should be reduced.

## Additional considerations

A proxy for total mortality $(Z)$ was estimated from the Irish catch numbers at age in Division VIIj-k (Figure 5.4.10.2). Exploratory estimates of mortality suggest that the current fishing mortality in the VIIj-k part of the stock is greater than $\mathrm{F}_{\text {MSY }}$ estimated from a yield per recruit analysis. The estimated levels of Z are quite high compared to other plaice stocks. There is a possibility that this can be the consequence of migration. If young fish are highly concentrated in inshore areas and have a higher catchability than older fish, which might be distributed more widely further offshore, this could result in apparent high levels of $Z$.

The only data available for Division VIIh are landings data.
Comparison with previous assessment and catch options
The assessment is based on a catch curve through landings-at-age data for plaice in Division VIIj-k, which is the same as last year. Exploratory estimates of mortality and $\mathrm{F}_{\mathrm{msy}}$ are similar to last year. The basis for the advice is the same as last year.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Sole in Division VIIa (Irish Sea)

## Advice for 2012

ICES advises on the basis of the transition to the MSY approach that landings in 2012 should be no more than 200 t .

## Stock status

Figure 5.4.12.1 Sole in Division VIIa. Summary of stock assessment (weights in ' 000 t ). Estimates are shaded. Top right: SSB and F over the years.

SSB has continuously declined since 2001 and dropped below $\mathrm{B}_{\text {lim }}$ since 2006. In 2009 SSB reached the lowest level. The fishing mortality shows a declining trend since the mid 1980s to a stable level in recent years. Recent recruitment levels have been lower than earlier in the time-series, with the incoming recruitment being the lowest in the time series.

## Management plans

No specific management objectives are known to ICES.

## The fisheries

Sole are predominantly caught by beam trawl fisheries. Sole is caught in a mixed fishery with other flatfish as well as gadoids. Information from observer trips indicates that the discarding of sole is between 0 and $8 \%$ in weight.

Catch by fleet Landings $(2010)=275 \mathrm{t}(92 \%$ beam trawlers, $8 \%$ otter trawlers, $<1 \%$ other gears $)$. Beam trawl discards between $0 \%$ and $8 \%$ in weight.

## Effects of the fisheries on the ecosystem

Although discard rates of sole are low in these fisheries, discard rates of other (commercial and non-commercial) species can be considerable. Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates.

## Quality considerations

Given the low stock size, predictions become more dependent on the assumed incoming recruitment. $30 \%$ of the predicted landings in 2012 and $45 \%$ of the predicted SSB in 2013 are based on the assumed geometric mean recruitment.

Weights in tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012
${ }^{2)}$ Landings 2012 relative to TAC 2011.

## MSY approach

Following the ICES MSY framework implies fishing mortality to be reduced to 0.07 ( $56 \%$ lower than $\mathrm{F}_{\text {MSY }}$ because SSB is $56 \%$ below MSY $\mathrm{B}_{\text {triger }}$ ), resulting in landings of less than 80 t in 2012. This is expected to lead to a SSB of 1520 t in 2013.

Following the transition scheme towards the ICES MSY framework implies fishing mortality of 0.19 for 2012. This results in landings of 200 t in 2012. This is expected to lead to an SSB of 1390 in 2013.

## PA approach

Given the low SSB and low recruitment since 2000, it is not possible to identify any non-zero catch which would be compatible with the precautionary approach.

## Additional considerations

## Regulations and their effects

Technical measures in force are minimum mesh sizes and minimum landing size ( 24 cm ).
Since 2000, a spawning closure for cod has been in force. The first year of the regulation the closure covered the Western and Eastern Irish Sea. Since then, closure has been mainly in the Western part whereas the sole fishery takes place mainly in the Eastern part of the Irish Sea. No direct impact on the sole stock is expected from this closure.

## Changes in fishing technology and fishing patterns

Beam trawl effort has decline by $75 \%$ between 2003 and 2010. Fishing mortality has reduced over the same period, but to a lesser extent.

## Comparison with previous assessment and advice

The poor biological sampling coverage of sole in VIIa was the main issue that has been addressed on the WKFLAT 2011. The resulting changes from the benchmarked assessment) did not affect the consistency of the trends in SSB and fishing mortality. F values for 2009 have been revised upwards by $28 \%$, and SSB in 2010 has been revised downwards by $14 \%$.

Last year's advice was based on the precautionary and MSY approach. This year the basis is the MSY approach.

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 1060 t .

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  | 20082009 | 2010 |
| MSY ( $\mathrm{F}_{\text {MSY }}$ ) | ( $\downarrow$ | ( Appropriate |
| Precautionary approach $\left(\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{lim}}\right)$ | $\checkmark>$ | - Harvest sustainably |
| SSB (Spawning Stock Biomass) |  |  |
|  | 20092010 | 2011 |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | $\checkmark>$ | - Above trigger |
| Precautionary approach $\left(\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}\right)$ | ( $\downarrow$ | - Full reproductive capacity |

Figure 5.4.13.1 Sole in Divisions VIIf,g. Summary of stock assessment. Top right: SSB and F over the years.
The spawning stock biomass has been above MSY $\mathrm{B}_{\text {trigger }}$ since 2001. Fishing mortality has decreased from $\mathrm{F}_{\text {lim }}$ in 2003 to the lowest levels in the time series and is now below $\mathrm{F}_{\mathrm{MSY}}$. The 2007 year class is estimated to be above average while the 2009 year class is the lowest of the time series.

## Management plans

No specific management objectives are known to ICES.

## Biology

The main spawning areas for sole in the Celtic Sea are in waters $40-75 \mathrm{~m}$ deep, off Trevose Head. Spawning usually takes place between February and April. Juvenile sole are found in relatively high abundance in depths up to 40 m , while adult sole (fish aged 3 plus) are generally found in deeper water. Spawning and nursery grounds are well defined. The results of recent tagging experiments suggest that there is only limited movement of sole between the Bristol Channel (Division VIIf) and adjacent areas (Division VIIg).

## The fisheries

Sole are taken mainly in a beam trawl fishery that started in the early 1960s and, to a lesser extent, in the longer established otter trawl fisheries. In the 1970s, the fishery was mainly carried out by Belgian beam trawlers and Belgian and UK otter trawlers. The use of beam trawls increased during the mid-1970s, and the Belgian otter trawlers have now been almost entirely replaced by beam trawlers. In the Celtic Sea, the beam and otter trawl fleets also take other demersal species such as plaice, cod, rays, brill, turbot, and anglerfish.

## Catch by fleet <br> Total landings (2010) were 862 t - (of which $91 \%$ beam trawlers - $8 \%$ otter trawlers - $1 \%$ Other gear). Beam trawl discards about $5 \%$ in weight.

## Effects of the fisheries on the ecosystem

Although discard rates of sole are low in beam trawl fisheries (about 5\% in weight), discard rates of other (commercial and non-commercial) species can be considerable. Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates and in areas which have been historically exploited by this fishing method. Benthic drop-out panels have been shown to release around $75 \%$ of benthic invertebrates from the catches.

## Quality considerations

Incoming recruitment of very strong year classes at age 1 may be overestimated and needs to be adjusted in accordance with the historical performance of the assessment. However, this year the incoming recruitment is low. The research beam trawl survey and commercial indices show divergent signals on year class strength. Discards are currently not included in the assessment, but given the low discard rates of sole it is unlikely that the inclusion of discards would change the perception of the stock.

Weights in tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012.
${ }^{2)}$ Landings 2012 relative to TAC 2011.

## MSY approach

Following the ICES MSY framework implies fishing mortality to be 0.31 , resulting in landings of 1060 t in 2012. This is expected to lead to an SSB of 3600 t in 2013.

## PA approach

The fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}$ corresponding to landings of less than 1230 t in 2012. This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013.

## Additional considerations

Sole are mainly taken in a beam trawl fishery as part of a mixed demersal fishery with plaice and, to a lesser extent, cod. Both of the latter stocks require a reduction in fishing mortality.

The Celtic Sea is an area without days-at-sea limitations for demersal fisheries. In the past this has resulted in increased effort in the Celtic Sea as a direct result of restrictive effort in other areas. This was particularly the case in 2004-2005 when effort in the sole fishery increased because of restrictive days at sea in the eastern channel (Division VIId). The removal of the restrictive days-at-sea EU regulation in Division VIId prior to 2006 resulted an area shift of the Belgian beam trawl fleet back to Division VIId and a strong decrease in effort deployment in the Celtic Sea by that fleet.

Benthic drop-out panels have been shown to release around $75 \%$ of benthic invertebrates from the catches. Information from the UK industry (Trebilcock and Rozarieux, 2009) suggests that use of the panels in 2008 was minimal.

## Factors affecting the fisheries and the stock

The fisheries for sole in the Celtic Sea and Bristol Channel involve vessels from Belgium taking two thirds, the UK one quarter, and France and Ireland taking minimal amounts of the total landings. The sole fishery is concentrated on the northern Cornish coast off Trevose Head and around Lands End. Effort of the two main fleets (Belgian and UK beam trawl fleets) has decreased substantially over the last few years.

## Regulations and their effects

Since 2005, ICES rectangles 30E4, 31E4, and 32E3 have been closed during the first quarter (in EU Council Regulations for TACs) with the intention of reducing the fishing mortality of cod. The effects of the closure on sole are not known although there have been spatial and temporal changes in the distribution of effort.

## Changes in fishing technology and fishing patterns

Beam trawlers account for the majority of the vessels targeting sole. High fuel costs contributed to a reduction in effort in Divisions VIIf,g since 2008 . In addition, several vessels of this fleet segment are developing methods to reduce fuel costs.

## Comparison with previous assessment and advice

Trends in SSB and fishing mortality are consistent with last year's assessment. F values for 2009 have been revised upwards by $20 \%$, and SSB in 2010 has been revised downwards by $12 \%$.

Last year the advice was based on the precautionary and MSY approach. This year the basis is the MSY approach.

| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | * 3 | * Below trigger |
| Precautionary approach $\left(\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}\right)$ | ? | ? Undefined |

Fishing Mortality

Figure 5.4.14.1 Sole in Division VIIe (Western Channel). Summary of stock assessment. Estimates are shaded. Top right: SSB and F over the years.

The significant reduction of F in 2009 reflects the reduction in fishing effort. SSB is around the lowest observed values in the time series. Recruitment has been fluctuating without trend.

## Management plans

Council Regulation (EC. No. 509/2007) establishes a multi-annual plan for the sustainable exploitation of Division VIIe sole. This results in a TAC of 777 t in 2012. This plan has not been evaluated by ICES.

## The fisheries

The principal gears used for this stock are beam trawls, otter trawls, and gillnets. Sole is the target species of an offshore beam trawl fleet, which is concentrated off the south Cornish and Devon coast. This fishery also takes substantial catches of plaice, anglerfish, lemon sole, and cuttlefish. Otter trawlers and gillnetters take sole mainly as a bycatch fishery, and a targeted fishery at spawning time. Discarding of sole is considered small.

## Catch by fleet Landings in 2010 were 688 t ( $52 \%$ beam, $16 \%$ otter, $8 \%$ gillnets, $3 \%$ dredge, $21 \%$ other (mostly caught by the above gears, but not available separately by all countries)

## Effects of the fisheries on the ecosystem

Beam trawling, especially using chain-mat gear, is known to have a significant impact on the benthic communities, although less so on soft substrates. Discard rates of non-commercial species and commercial species of unmarketable size are substantial. Some beam trawlers are experimenting with benthic drop-out panels that release about $75 \%$ of benthic invertebrates from the catches. Full square mesh codends are being tested in order to reduce the capture of benthos further and improve the selection profile of gadoids.

## Quality considerations

Key uncertainties with regards to the data quality / assessment quality of this stock are the uncertainty regarding the degree of mixing between this and adjacent stocks, particularly with regards to recruitments, and the fact that the survey covers only part of the stock. The 2009 yearclass was estimated to be strong by the assessment, but has been replaced in the assessment with $\mathrm{GM}_{69-08}$ due to uncertainties. This precautionary outlook is to some degree balanced by a likely underestimate of $\mathrm{F}_{\mathrm{sq}}$ for 2011 which is the rescaled $\mathrm{F}_{2010}$ as neither $\mathrm{F}_{08-10}$ nor a TAC constraint could be scientifically supported.

Figure 5.4.14.2 Sole in Division VIIe (Western Channel). Historical assessment results (final year recruitment estimate has been replaced by the $\mathrm{GM}_{69-08}$ ). Note that the age range for F changed from 3-7 to 3-9 in 2009.

## Management plan

Council Regulation (EC) No. 509/2007 establishes a multi-annual plan for the sustainable exploitation of Division VIIe sole. Years 2007-2009 were deemed a recovery plan, with subsequent years being deemed a management plan. For 2010, 2011, and 2012 the TAC shall be set at the highest value resulting from either a $15 \%$ reduction in F compared to average F (2007-2009) or an F of 0.27 , with a maximum TAC variation of no more than $15 \%$.

Following the agreed management plan implies an F for 2011 of 0.27 ( $\mathrm{F}_{\mathrm{MP}}$, the management plan long-term target), suggesting a TAC of 777 t in 2012 which is less than the $15 \%$ TAC increase cap in the plan. This is expected to lead to a SSB increase of $5 \%$ in 2013. This plan has not been evaluated by ICES.

## MSY approach

Following the ICES MSY framework implies fishing mortality to be at 0.26 ( $6 \%$ lower than $\mathrm{F}_{\text {MSY }}$ because SSB is $6 \%$ below MSY $\mathrm{B}_{\text {trigger }}$ ). This implies landings of less than 740 t in 2012.

## Additional considerations

## Management considerations

Sole are widespread and usually taken in conjunction with other species to varying degrees, dependent on location and season. Fisheries with beam trawls can target sole, anglerfish and cuttlefish depending on season and vessel size. The most productive sole fishery grounds are located close to ports, while the highest catches of anglerfish for example are taken further south and west in Division VIIe. Therefore, effort restrictions and/or high fuel costs will have a tendency to increase F in sole and reduce F in anglerfish. Area-misreported landings between Divisions VIId and VIIe have been a problem in the past, but the problem has largely been eliminated in recent years.

## Regulations and their effects

In addition to the days-at-sea regulations there has been a recent UK decommissioning scheme that has reduced the number of beam trawlers in the southwest fleet. Fishing mortalities from 2009 onwards are estimated to have declined which is consistent with the decline in effort in the main fleet exploiting this stock.

Management of this stock is mainly by TAC, which has largely been ineffective at regulating the fishery prior to 2009. In 2005 effort restrictions were implemented for beam trawlers in this fishery in order to enforce the TAC and improve data quality. These restrictions were not been limiting this fishery despite a decommissioning scheme, in part due to the large numbers of days available, but also because in the UK fleet there appears to be some latent effort / over capacity in the beam trawl fleet. Since November 2008 the UK has been enforcing a single area licensing scheme which has been highly effective in reducing UK catches.

Technical measures applied to this stock include a minimum landing size ( 24 cm ) and minimum mesh size of 80 mm for beam trawlers. Local regulations restricting certain gear and vessel types are also in place.

Discarding in the towed gears using 80 mm mesh sizes, which are responsible for the large majority of the landings, is very small ( $<5 \%$ by number) by number and small ( $5-10 \%$ ) for the much smaller gillnet fishery. Other spatially or temporally restricted métiers show higher values of discarding ( $10-40 \%$ averaged over years) have very limited effort and hence contribute only a very small percentage to the landings $(<5 \%)$. The gears used to target sole are highly selective for fish above the minimum landing size, and only a few sporadic cases of high-grading (included in the numbers above) have been observed.

## Information from the fishing industry

The fisheries science partnership, conducted cooperatively between CEFAS and the UK industry has provided evidence for the wide dispersal and broad age distribution for this stock.

## Comparison with previous assessment and advice

The F2009 is revised up by $2 \%$ and SSB2010 is revised up by $15 \%$ compared to last years assessment. These revisions are partly influenced by a $12 \%$ upward revision of the 2009 catch.

The basis for the advice this year is the same as last year and was based on the MSY framework.

## ECOREGION Celtic Seas <br> STOCK <br> Herring in Division VIIa North of $\mathbf{5 2}^{\mathbf{0}} \mathbf{3 0} \mathbf{} \mathbf{N}$ (Irish Sea)

## Advice for 2012

ICES advises on the basis of precautionary considerations that catches in 2012 should not be allowed to increase.

Figure 5.4.15.1 Herring in Division VIIa North of $52^{\circ} 30^{\prime} \mathrm{N}$ (Irish Sea). Summary of stock trends from exploratory assessment with standardised values, landings in tonnes. Top right: Trend in acoustic SSB estimate in Subdivision VIIaN since 1994.

The assessment is indicative of trends only. The catches have been close to TAC levels and the main fishing activity has not varied considerably. The 2010 acoustic survey estimates suggest that SSB is at its highest abundance in the 18 year time-series. Recruitment in recent years has been stable close to average recruitment in the time series. Increasing SSB and stable catches suggests decreasing exploitation.

## Management plans

No specific management objectives are known to ICES.

## Biology

Herring are an important prey species in the ecosystem and also one of the dominant planktivorous fish. This autumn spawning stock is considered a part of the Malin Shelf Stock Complex. A component of the VIIaN herring stock is known to mix seasonally with herring in Subarea VI, but the extent is unknown. Juvenile herring from the Celtic Sea herring stock are present in the Irish Sea.

## Environmental influence on the stock

There are irregular cycles in the productivity of herring stocks (weights-at-age and recruitment). It is thought that the environment plays an important role (through transport, prey, and predation).

## The fisheries

The fishery has not changed in recent years. A pair of UK pair trawlers takes the majority of catches during the $3^{\text {rd }}$ and $4^{\text {th }}$ quarters. A small local fishery continues to record landings on the traditional Mourne herring grounds during the $4^{\text {th }}$ quarter. Herring fisheries tend to be clean with little bycatch of other fish. There are no estimates of discarding or slippage in the Irish Sea fisheries that target herring. Discarding however is not thought to be a feature of this fishery.

Catch by fleet Total catch $(2010)=4.9 \mathrm{kt}$, of which $97 \%$ are from pair-trawlers and $3 \%$ gillnet.

## Effects of the fisheries on the ecosystem

The human consumption fisheries for herring are considered relatively clean, with little bycatch of other fish.

## Quality considerations

The exploratory assessment is indicative of recent trends only. The present assessment model is sensitive to the annual changes in fishing pattern.

## Scientific basis

Unchanged since 2004
Outlook for 2012
No analytical assessment is available for this stock and no forecast is possible.

## Precautionary considerations

Recent SSB trends show an increase in herring biomass. Current exploitation appears to be declining but the exploitation status is unknown. Therefore the catches should not be allowed to increase.

## Additional considerations

The catches have been close to TAC levels and the main fishing effort has not varied considerably.
2010 Acoustic survey estimates suggest that SSB is at its highest abundance in the 18 year time-series. 1-ringer+ biomass is also high. Estimates from an enhanced acoustic survey series in 2007 to 2009 indicate and confirm the significant increase in $1+$ herring biomass. The acoustic survey provides estimates of numbers-at-age, however the 1 to 3 -ringers in the area are a mixture of at least two adjacent stocks, (Celtic Sea and VIIa(N)). Splitting the current acoustic spawning stock biomass estimates according to season of origin, does not change the perception of a significant increase in Irish Sea "autumn" spawning biomass.

Herring are an important prey species in the ecosystem and also one of the dominant planktivorous fish. The stock identity of herring west of the British Isles was reviewed by the EU-funded project WESTHER. This identified Division VIaN as an area where catches comprise a mixture of fish from Divisions VIaN, VIaS, and VIIaN. In 2008 ICES began to evaluate management for this Division VIa(South) and VIIa (North). It will be a number of years before ICES can provide a fully operational integrated strategy for these units. In this context ICES recommends that a management plan for Division VIIa (North) should be developed.

## Uncertainties in the assessment

Results of exploratory assessments are not considered reliable for absolute values of SSB and F during the recent period. The exploratory analysis suggests an increasing trend in SSB. There is evidence from acoustic surveys that recent recruitment has been high.

There is a seasonal closed area east of the Isle of Man since 1973. The fleet sometimes is able to fish spawning aggregations if they occur outside the closed area. The effect of this is that the age structure of the catches from year to year can vary widely.

## Comparison with previous assessment and advice

The basis for the assessment is the same as last year. The advice for 2012 is based on precautionary considerations.

STOCK

## Herring in Division VIIa South of $\mathbf{5 2}^{\circ} \mathbf{3 0}{ }^{\prime} \mathbf{N}$ and VIIg,h,j,k (Celtic Sea and South of Ireland)

## Advice summary for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 26900 t .

## Stock status

Figure 5.4.16.1 Herring in Divisions VIIa (South of $52^{\circ} 30^{\prime} \mathrm{N}$ ) and VIIg,h,j,k (Celtic Sea and South of Ireland). Summary of stock assessment. Estimates are shaded. Top right: F and SSB over the years.

The current assessment shows the stock continues to improve. SSB is at the highest level since the 1960s and continues to increase. F is well below $\mathrm{F}_{\text {msy }}$. There are three recent strong year classes (2003/4, 2005/6, and 2007/8).

## Management plans

A long-term management plan has been agreed by the Irish industry in 2011 (Annex 5.4.16). This plan has a target $\mathrm{F}=0.23$ and a $30 \%$ constraint in TAC change. This plan results in a TAC of 17200 t for 2012. ICES has not yet evaluated the plan.

A rebuilding plan has been in place since 2009 although it has not yet been formally adopted in law (Annex 5.4.16). The target F is equal to 0.19 and no TAC constraint applies. The rebuilding plan implies a TAC of 21100 t in 2012 .

## Biology

This stock can be divided into autumn and winter spawning components. Spawning begins in October and can continue until February. A proportion of this stock, mainly juveniles is present in the Irish Sea and return to spawn in the Celtic Sea. The spawning grounds for herring in the Celtic Sea are located inshore close to the coast and consist of either gravel or flat stone. ICES has consistently advised that activities that perturb herring spawning grounds should be avoided.

## Environmental influence on the stock

Temperatures in this area have been increasing over the last number of decades, and indications are that salinity is also increasing. Recruitment in this stock has fluctuated widely, although studies to date have not been able to demonstrate any relationship to environmental changes.

## The fisheries

There has been considerable efficiency creep in the fishery since the 1980s with a greater ability to locate fish. Under the current management regime the quality of the catch data has improved.

Catch by fleet Total catch (2010/2011): 8.37 kt of which $98 \%$ caught by pelagic trawl, $2 \%$ by drift nets.

## Effects of the fisheries on the ecosystem

The human consumption fisheries for herring are considered relatively clean, with little bycatch of other fish.

## Quality considerations

There is a large uncertainty in estimation of 1-ringers. As these contribute to the SSB ( $50 \%$ mature) this influences estimates and forecasts. There is uncertainty in the 2010 acoustic survey due to the substitution of the sounder frequency from 38 kHz to 18 kHz .

Figure 5.4.16.2 Herring in Division VIIa South of $52^{\circ} 30^{\prime} \mathrm{N}$ and VIIg,h,j,k (Celtic Sea and South of Ireland). Historical assessment results (final year predicted SSB and recruitment estimates included).

## Management plan

A rebuilding plan has been proposed by the Irish industry in 2008 (Annex 5.4.16). The stock has been above $\mathrm{B}_{\mathrm{pa}}$ ( 44000 t ) for three consecutive years and the target of the rebuilding plan has thus been met. This plan has not been formally adopted in EU legislation. Under the terms of this rebuilding plan it should be replaced by a long term management plan in 2012. The rebuilding plan implies a TAC of 21100 t in 2012.

In 2011 the Irish Industry has agreed a new proposed long term management plan (Annex 5.4.16). This plan has a target $\mathrm{F}=0.23$ and a $30 \%$ constraint in TAC change. This TAC constraint prevents sudden changes of the TAC and accounts for uncertainties in the assessment and forecast in case of strong incoming recruitment. This would lead to a $30 \%$ increase in TAC to 17160 t . This plan has not yet been evaluated by ICES, but evaluation by the Irish Marine Institute concluded it to be precautionary.

## MSY approach

Following the ICES MSY framework implies fishing mortality be increased to 0.25 which is higher than current F (0.14), resulting in landings of less than 26900 t in 2012. This is expected to lead to an SSB of 92000 t in 2013.

## PA approach

The SSB is well above $B_{p a}$ and $F_{p a}$ is undefined but current $F$ is well below $F_{M S Y}$. ICES does not advise to use $B_{p a}$ as a target in 2012.

## Additional considerations

The spawning grounds for herring in the Celtic Sea are located inshore close to the coast and consist of either gravel or flat stone. Spawning grounds tend to be vulnerable to anthropogenic influences such as dredging, sand and gravel extraction, dumping of dredge spoil and waste from fish cages. There have been several proposals for extraction of gravel and to dump dredge spoil in recent years. Many of these proposals relate to known herring spawning grounds. ICES has consistently advised that activities that perturb herring spawning grounds should be avoided. There may also be proposals to build wind farms on known spawning grounds. Other negative impacts may include benthic fishing and marine energy construction projects.

## Regulations and their effects

There is evidence that closure of Division VIIaS, under the rebuilding plan, has helped to reduce fishing mortality substantially. This closed area has been the dominant spawning area, and before the closure a large proportion of the catch was taken from it. There is no evidence that this closure has led to improved recruitment, however, this area, particularly the area off Dunmore East, is important for recruit spawners. Under the terms of the rebuilding plan the stock is considered to have recovered and this area will be partially reopened in January 2012.

## Revisions in data and methodologies

There were no changes to the methods used in 2011. A full analytical assessment was accepted in 2009. The assessment was an extension of the benchmark carried out in 2007, with some revisions of the input data. Since 2007 a longer timeseries of reliable surveys was available. Therefore, in 2009, the unreliable surveys (pre-2002) were removed. The plus group was reduced to account for smaller numbers at older ages. In 2009, the plus group was further reduced on this basis and led to much improved model fitting.

## Uncertainties in assessment and advice

Estimation of F is considered quite precise in recent years. There is uncertainty in estimation of 1-ring recruits. As these contribute to the SSB ( $50 \%$ mature) this means that there is some uncertainty in SSB.

The 2010 acoustic survey estimate was compromise because of transducer failure. Therefore, data from a transducer of different frequency ( 18 instead of 38 kHz ) had to be substituted. This departure from standard procedures will be further evaluated by ICES. Consequently, there is uncertainty in the 2010 acoustic survey estimate.

## Comparison with previous assessment and advice

The 2011 assessment shows an upward revision in SSB 2010 by $52 \%$, while F for 2009 is estimated to be rather similar. The basis for the advice is the MSY approach.

## Annex 5.4.16

Rebuilding Plan proposed by the Celtic Sea Management Advisory Committee, Ireland, for this stock.

1. For 2009 , the TAC shall be reduced by $25 \%$ relative to the current year (2008).
2. In 2010 and subsequent years, the TAC shall be set equal to a fishing mortality of $\mathrm{F}_{0.1}$.
3. If, in the opinion of ICES and STECF, the catch should be reduced to the lowest possible level, the TAC for the following year will be reduced by $25 \%$.
4. Division VIIaS will be closed to herring fishing for 2009, 2010 and 2011.
5. A small-scale sentinel fishery will be permitted in the closed area, Division VIIaS. This fishery shall be confined to vessels, of no more than 65 feet length. A maximum catch limitation of $8 \%$ of the Irish quota shall be exclusively allocated to this sentinel fishery.
6. Every three years from the date of entry into force of this Regulation, the Commission shall request ICES and STECF to evaluate the progress of this rebuilding plan.
7. When the SSB is deemed to have recovered to a size equal to or greater than $B_{p a}$ in three consecutive years, the rebuilding plan will be superseded by a long-term management plan

Long Term Management Plan for Herring in the Celtic Sea and Division VIIj proposed by Celtic Sea Management Advisory Committee, Ireland, in 2011, to supersede the rebuilding plan above.

1. Every effort shall be made to maintain a minimum level of Spawning Stock Biomass (SSB) greater than $41,000 \mathrm{t}$, the level below which recruitment becomes impaired.
2. Where the SSB, in the year for which the TAC is to be fixed, is estimated to be above $61,000 \mathrm{t}\left(\mathrm{B}_{\text {trigger }}\right)$ the TAC will be set consistent with a fishing morality, for appropriate age groups, of 0.23 ( $\mathrm{F}_{\text {target }}$ ).
3. Where the SSB is estimated to be below 61,000 tonnes, the TAC will be set consistent with a fishing mortality of:

SSB * $0.23 / 61,000$
4. Where the rules in paragraphs 2 and 3 would lead to a TAC which deviates by more than $30 \%$ from the TAC of the preceding year, the TAC will be fixed such that it is not more than $30 \%$ greater or $30 \%$ less than the TAC of the preceding year.
5 Where the SSB is estimated to be below 41,000 tonnes, Subdivision VIIaS will be closed until the SSB has recovered to above 41,000 tonnes.
6. Where the SSB is estimated to be below 41,000 tonnes, and Sub-Division VIIaS is closed, a small-scale sentinel fishery will be permitted in the closed area. This fishery will be confined to vessels, of no more than 50 feet in registered length. A maximum catch limitation of $8 \%$ of the Irish quota will be exclusively allocated to this sentinel fishery.
7. Notwithstanding paragraphs 2,3 and 4 , if the SSB is estimated to be at or below the level consistent with recruitment impairment $(41,000 \mathrm{t})$, then the TAC will be set at a lower level than that provided for in those paragraphs.
8. No vessels participating in the fishery, if requested, will refuse to take on-board any observer for the purposes of improving the knowledge on the state of the stock. All vessels will, upon request, provide samples of catches for scientific analyses.
9. Every three years from the date of entry into force of this Regulation, the Commission will request ICES and STECF to review and evaluate the plan.
10. This arrangement enters into force on 1st January, 2012.

## ECOREGION Celtic Seas <br> STOCK <br> Herring in Divisions VIa (South) and VIIb,c

## Advice summary for 2012

ICES advises on the basis of precautionary considerations that landings in 2012 should be reduced.

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  |  | 2008-2010 |
| MSY ( $\mathrm{F}_{\text {MSY }}$ ) | ? | Unknown |
| Precautionary approach ( $\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\text {lim }}$ ) | (?) | Unknown |
| Qualitative evaluation | (x) | Above poss. reference points |

| SSB (Spawning-Stock Biomass) |  |  |
| :---: | :---: | :---: |
|  |  | 2008-2010 |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | $?$ | Unknown |
| Precautionary approach ( $\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}$ ) | (?) | Unknown |
| Qualitative evaluation | (x) | Below poss. reference points |

Figure 5.4.17.1
Herring in Divisions VIa (South) and VIIb,c. ICES estimates of catches ('000 tonnes) and trends in recruitment, SSB and fishing mortality, with fishing mortality in 2010 assumed between $0.2-0.6$. Y-axis for recruitment, F and SSB are arbitrary scales and all start at 0 .

The assessment is indicative for trends only. Recent F is unknown, but is likely to be above $\mathrm{F}_{\text {MSY }}(0.25)$. The current level of SSB is uncertain, but is likely to be below possible reference points. Recruitment has been low since 2000.

## Management plans

There is no explicit management plan for this stock.

## Biology

This autumn and winter/spring-spawning stock is considered a part of the Malin Shelf Stock Complex. The stock identity is complex as the juveniles mix with those from the west of Scotland and the adults mix with those from the Irish Sea and Division VIaN over the shelf areas to the west of Scotland after spawning. Fish of this stock are expected to mix with VIa North herring in that area. This could lead to catches and acoustic survey registration of this stock in VIa North.

## The fisheries

The fisheries take place using pelagic trawls in quarter 1 and 4 . The low TAC has lead to a much shorter fishing season now consisting of only a few days.

Catch by fleet $\quad$ Catch $(2010)=10241 \mathrm{t}, 100 \%$ pelagic trawls.

## Effects of the fisheries on the ecosystem

The human consumption fisheries for herring are considered relatively clean, with little bycatch of other fish

## Quality considerations

The exploratory assessment is uncertain as it is based on catch at age data only. The spatially and temporally truncated fishing season results in catch at age data that may be less informative of overall population age structure. The current survey series (2008-2010) is too short to be used in tuning the assessment. There is some evidence of a stronger (2008) cohort recruiting to the stock, but until another observation is available from the 2011 acoustic survey, it is not possible to estimate its strength.

## Scientific basis

| Assessment type | Trends-based exploratory assessment (Separable VPA). |
| :--- | :--- |
| Input data | Commercial catch--at age data. |
| Discards and bycatch | Not considered relevant. |
| Indicators | None. |
| Other information | Survey data from MSHAS_S is not used in the assessment yet. |
| Working group report | HAWG |

## ECOREGION Celtic Seas

STOCK

## Herring in Divisions VIa (South) and VIIb,c

## Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY <br> Approach | MSY B $_{\text {trigger }}$ | Undefined. | Under development. |
|  | $\mathrm{F}_{\text {MSY }}$ | 0.25 | Stochastic simulations on segmented regression stock recruit <br> relationship, under different productivity regimes. |
|  | $\mathrm{B}_{\text {lim }}$ | 81000 t | Lowest reliable estimate. |
|  | $\mathrm{B}_{\mathrm{pa}}$ | 110000 t | $1.4 \mathrm{~B}_{\text {lim }}$ |
|  | $\mathrm{F}_{\text {lim }}$ | 0.33 | $\mathrm{~F}_{\text {loss }}$ |
|  | $\mathrm{F}_{\mathrm{pa}}$ | Undefined. |  |

(unchanged since 2011)
Outlook for 2012
No reliable assessment can be presented for this stock. The main cause of this is the lack of sufficiently long survey data series. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

The stock trend is uncertain in recent years, but the stock is considered below possible reference points. Exploitation is considered to be above $\mathrm{F}_{\text {MSY }}$. Therefore, catches should be reduced.

## Additional considerations

## Information from the fishing industry

The pelagic RAC does not accept ICES interpretation of the poor status of this stock. The industry is concerned that, due to the change in fishing pattern because of restrictive quota, an incomplete account is being taken of the stock structure. The pelagic RAC has encouraged the Irish authorities, the industry and the scientists to work together to resolve the problem with the assessment. Quota restrictions result in only one or two principal grounds off Glen Head and off Tory Island being exploited at present. The traditional grounds in VIIb, for instance, are not being fished very much in recent years. Fleets fishing in this fishery have reported that there are large and increasing quantities of herring on the grounds particularly in the northern part of the area in the last four years.

## Ecosystem changes

A recent study (Hammond and Harris, 2006) of seal diets off western Scotland revealed that grey seals may be an important predator for herring in this area. The numbers of seals in Division VIaN is thought to have increased over the last decades. Because the consumption of herring by seals is estimated with great uncertainty, the impact on the stock cannot be estimated accurately.

## Uncertainty in the assessment

The exploratory assessment is only capable of evaluating long term trends, and is not suitable for determining recent trends in fishing mortality and abundance. The overall decline trend in spawning stock since the 1980s and increase in fishing mortality is probably robust to choice of assessment model.

Fishery catch data for this specific population may be affected by mixing with neighbouring stocks. The effect of mixing in the acoustic surveys in this and especially in VIaN contribute to uncertainty in the assessment of both stocks.

## Comparison with previous assessment and advice

The basis for the assessment is the same as last year. The advice this year is based on the ICES precautionary considerations for stocks without forecasts.

## ECOREGION <br> STOCK <br> Celtic Seas / North Sea <br> Sprat in Divisions VIId,e

Advice 2012
ICES advises based on precautionary considerations that catches should be reduced.

## Stock status

Figure 5.4.18.1
Sprat in Divisions VIId,e. ICES landings in tonnes.
As last year, the information available is insufficient to evaluate stock trends and exploitation.

## Management plans

No specific management objectives are known to ICES.

## Quality considerations

This advice sheet is not dedicated to a 'stock', it relates to sprat in the English Channel (Division VIId, e) where data are available. The stock structure of sprat populations in the Celtic Seas eco-region is not clear (Section 5.4.38). ICES does not necessarily advocate that Division VIId,e constitutes a management unit for sprat, and further work is required.

Given discrepancies between national and official landings data, further scrutiny of some of the landings data is required.

Scientific basis

| Assessment type | No assessment |
| :--- | :--- |
| Input data | Catch statistics |
| Discards and bycatch | Not available |
| Indicators | None |
| Other information | Time-series of midwater trawl lpue |
| Working group report | HAWG |

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Sprat in Divisions VIId,e

## Reference points

No reference points are defined.

## Outlook for 2012

The available landings and lpue data are not reliable indicators of sprat abundance in Divisions VIId,e. Stock structure in relation to appropriate management units is unknown. Therefore, fishing opportunities cannot be projected.

## Precautionary considerations

No information is available on stock trends and exploitation status. Therefore, catches should be reduced.

## Additional considerations

It is unclear what the appropriate stock units should be and how these relate to management units. Work is ongoing to understand stock structure in the Celtic Sea eco region (Section 5.4.38).

Most of sprat landings in this area are taken by the English fleet and are used for human consumption. In recent years the fishery has been managed by applying the "use it or lose it" policy whereby TACs have been cut simply because catches have been "low". The UK has a history of taking their quota, but sprat is found by sonar search and sometimes the shoals have been too far offshore for sensible economic exploitation. Skippers then go back to other trawling activity.

Landings per unit effort (lpue) series are available based on the data from the English trawlers targeting sprat and for all midwater trawlers. Although lpue data should be interpreted with caution when based on landings from a shoaling species such as sprat, the data suggest that sprat in this area hast fluctuated over time with a slight increasing trend.

## ECOREGION <br> STOCK

Celtic Sea and West of Scotland

Advice for 2012
New data from 2010 do not change the perception of the stock status. The advice for the fishery in 2012 is therefore the transition to the MSY approach given in 2010 for the 2011 fishery: "Catch and effort reduction".

This stock is scheduled to be benchmarked in 2012.

Figure 5.4.20.1
Anglerfish (L. piscatorius and L. budegassa) in Divisions VIIb-k and VIIIa,b,d. Bay of Biscay and Celtic Sea (EVHOE-WIBTS-Q4) indices: biomass (top line, $\mathrm{kg} / 30 \mathrm{~min}$ ) and total abundance (middle line, number/30 min ). Error bars indicate $\pm 2$ s.d. Lower panel: landings (' 000 tonnes, 2010 and 2009 data are preliminary).

Survey data (biomass and abundance indices, length distribution) give indication that the biomass of both species has been increasing until 2008 as a consequence of the good recruitment. After 2008, biomass of the two species has decreased. For L. piscatorius there is evidence of good recruitments in 2008-2010, whereas the last strong recruitment for L.budegassa occurred in 2008.

## Management plans

No specific management objectives are known to ICES.

## Biology

Lophius budegassa has a more southern distribution than L. piscatorius. Though ICES considers different anglerfish stocks in different area for each species, the boundaries are not based on biological criteria.

## The fisheries

The majority of the anglerfish catch consists of young fish. There are indications that discarding has increased in recent years. There has been an expansion of the French gillnet fishery in the Celtic Sea and in the north of the Bay of Biscay in the last decade, mainly by vessels landing in Spain and fishing in medium-to-deep waters.

Catch by fleet Total preliminary landings (2010) = 29.7 kt , with L. piscatorius $19.5 \mathrm{kt}: 65 \%$ otter trawl, $17 \%$ gillnet, $13 \%$ beam trawl, and $2 \%$ Nephrops trawl; and L. budegassa 10.2 kt : $86 \%$ otter trawl, 6\% beam trawl, 4\% Nephrops trawl, and 2\% gillnet.

## Quality considerations

The increase in discarding in recent years has resulted in uncertainties in recent levels of catch. The 2009 and 2010 French landings are preliminary

Improved sampling of length composition and accurate estimates of growth parameters are needed to facilitate the development of an analytical assessment. An ageing exchange study for L.piscatorius is taking place in 2011 to compare the different approaches that are used (otoliths and illicia).

| Working group report | WGHMM |

## ECOREGION Celtic Sea and West of Scotland STOCK <br> Anglerfish (L. piscatorius and L. budegassa) in Divisions VIIb-k and VIIIa,b,d

## Reference points

There are no reference points defined for these stocks. As a consequence of recently identified problems with growth estimates, previous reference points are not considered to be valid.

## Outlook for 2012

No analytical assessment is available for this stock. The main cause of this is the lack of discard data and the low quality of other parameters (ageing). Therefore, no forecast can be presented

## Precautionary considerations

Stock trends from survey data are stable over the long term, although they show a decrease in the most recent years (particularly for L.budegassa). The exploitation status is unknown. Therefore, catches should be reduced.

## Additional considerations

Improved sampling of length composition and accurate estimates of growth parameters are needed to facilitate the development of an analytical assessment.

Reliable estimates of discards are not available. The increase in discarding may be related to larger year classes recruiting in the fishery. Information from research surveys indicates an increase in smaller fish on the fishing grounds in recent years. Discarding is also known to be partly dependent on market conditions and TAC restrictions.
L. piscatorius and L. budegassa are both caught on the same grounds and by the same fleets and usually are not separated in the landings. Management measures for both species must be considered together and in conjunction with other species caught in these fisheries (sole, cod, rays, megrim, Nephrops, and hake).

## Regulations and their effects

There is no minimum landing size for anglerfish but an EU Council Regulation (No. 2406/96) laying down common marketing standards for certain fishery products fixes a minimum weight of 500 g for anglerfish. Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in DivisionsVIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002).

## Information from the fishing industry

The quota has been restrictive for some fleets and substantial underreporting of landings is known to have occurred. Information from the Irish fishery indicates that underreporting of total landings has been a problem before 2005, due to restrictive individual vessel quotas. Since 2005 specific anglerfish licences have been introduced in Ireland to improve compliance. There has been an increased enforcement on anglerfish quotas.

## Comparison with previous assessment and advice

The basis for the assessment and advice is the same as last year. The perception of the stocks has changed from last year, since a decline in biomass indices in recent years is now more evident.

## Assessment and management area

Two separate TACs are set for both species combined. There is a TAC for Subarea VII and a TAC for Divisions VIIIa,b,d,e. The advice applies to a smaller area (Divisions VIIb-k and VIIIa,b,d) than the management area. However, the advice covers the majority of the area as recent landings in Division VIIa have been relatively small compared to the total TAC.

## ECOREGION Celtic Sea and West of Scotland STOCK Cod in Division VIa (West of Scotland)

## Advice for 2012

ICES advises on the basis of the precautionary considerations that catches in 2012 should be reduced to the lowest possible level.

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  | 2008-2010 |  |
| MSY ( $\mathrm{F}_{\text {MSY }}$ ) | (?) | Unknown |
| Precautionary $\operatorname{approach}\left(\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{lim}}\right)$ | ? | Unknown |
| Qualitative evaluation | 3 | Above poss. reference points |

Figure 5.4.21.1 Cod in Division VIa (West of Scotland). Summary of stock assessment (weights in thousand tonnes). Removals: open circles $=$ observed catches, lines $=$ estimated removals. Dashed lines are $95 \%$ confidence bounds. The vertical line in each plot delineates the last year of the historical assessment (2010); estimates to the right of these lines are forecasts. Top right: SSB and total mortality- 0.2 over the years.

Total mortality is high, but cannot be accurately partitioned into fishing mortality and natural mortality. The spawningstock biomass continues to increase from an all time low in 2006, but remains well below $\mathrm{B}_{\mathrm{lim}}$. Recruitment has been estimated to be low over the last decade. The 2005 and 2008 year classes are estimated to be the largest since 1997 and comparable with the long-term geometric mean.

## Management plans

In the cod long-term management plan (EC 1342/2008) the stock is considered data poor. Article 9(a) implies a TAC and associated effort reduction of $25 \%$, translating to a TAC of less than 137 t . ICES considers that article 10(2) may also apply. ICES cannot yet evaluate if the management plan is in accordance with the precautionary approach.

## Biology

Cod are known to be a hyper-aggregating species, so at low abundance it is still possible to find areas of high cod density. This can lead to high catches in localized areas, with the possibility of low levels of fishing effort causing high mortality on the stock. Occasional large catches cause greater uncertainty in survey abundance indices. Relatively stable aggregations on timescales of several weeks are consistent with management by temporary spatial closures.

## Environmental influence on the stock

Grey seal abundance has increased between $30 \%$ and $160 \%$ (dependant on estimation model) west of Scotland over the recent decades (Thomas and Harwood, 2009). Seals are known to feed on cod, among other species. The contribution of seal predation to total cod mortality is likely to be significant and likely to have increased in recent years. This may impair the ability of the cod stock to recover. A negative impact on recruitment with rising sea temperature has been shown for cod in the warmer waters of this species' range, including cod west of Scotland.

## The fisheries

The $>100 \mathrm{~mm}$ otter trawl gear vessels targeting finfish (TR1) take roughly $80 \%$ of the cod catch and the $70-99 \mathrm{~mm}$ Nephrops fleet (TR2) takes $15-20 \%$ of the catch. A proportion of the landings come from vessels using TR1 gear, fishing west of the line defined in the cod long-term management plan. Discards reported to ICES (all fleets combined) are five times greater than landings, making catch (landings + discards) six times greater than landings.

```
Catch by fleet Total catch (2010) = 1400t, where 17% are reported landings (76% TR1, 1% TR2, and 23%
    other gears) and 83% discards (86% TR1 and 14% TR2).
```

## Effects of the fisheries on the ecosystem

Cod is taken in mixed demersal fisheries and there are no impacts specific to the catching of cod.

## Quality considerations

Quantities of landings and discards are not included in the model (only weights-at-age information) because of concerns over unreliability in the historical commercial data. Mortality estimates arising from this assessment - based on survey data - are poorly estimated. Because of uncertainties in the level and trend of natural mortality it is not possible to predict landings estimates from the forecast, only removals associated with both fishing and unaccounted natural mortality. There have been changes to the survey design and gear and the impact on the assessment is unknown.

## ECOREGION Celtic Sea and West of Scotland STOCK Cod in Division VIa (West of Scotland)

## Reference points

|  | Type | Value | Technical basis |
| :---: | :---: | :---: | :---: |
| MSY <br> Approach | MSY $\mathrm{B}_{\text {trigger }}$ | 22000 t | $\mathrm{B}_{\mathrm{pa}}$ |
|  | $\mathrm{F}_{\text {MSY }}$ | 0.19 | Provisional proxy by analogy with North Sea cod $\mathrm{F}_{\text {max }}$. Fishing mortalities in the range $0.17-0.33$ are consistent with $\mathrm{F}_{\mathrm{MSY}}$. |
| Precautionary <br> Approach | $\mathrm{B}_{\text {lim }}$ | 14000 t | $\mathrm{B}_{\text {lim }}=\mathrm{B}_{\text {loss }}$, the lowest observed spawning stock estimated in previous assessments. |
|  | $\mathrm{B}_{\mathrm{pa}}$ | 22000 t | Considered to be the minimum SSB required to ensure a high probability of maintaining SSB above $\mathrm{B}_{\mathrm{lim}}$, taking into account the uncertainty of assessments. This also corresponds with the lowest range of SSB during the earlier, more productive historical period. |
|  | $\mathrm{F}_{\text {lim }}$ | 0.8 | Fishing mortalities above this have historically led to stock decline. |
|  | $\mathrm{F}_{\mathrm{pa}}$ | 0.6 | This F is considered to have a high probability of avoiding $\mathrm{F}_{\text {lim }}$. |

(unchanged since: 2010)

## Outlook for 2012

No short-term forecast is provided because recent mortality values are highly uncertain due to unaccounted mortality.

## Management plan

The stock is considered data poor under the definitions of article 9 (EC 1342/2008). Following the cod long-term management plan (EC 1342/2008) article 9(a) implies a TAC and associated effort reduction of $25 \%$. This translates to a TAC of less than 137 t . ICES considers that article 10(2) may also apply. Because it is not possible at present to assess unaccounted mortality accurately, ICES cannot yet evaluate if the management plan is in accordance with the precautionary approach.

## MSY approach

Estimates of $\mathrm{F}_{\mathrm{MSY}}$ for this stock are uncertain because of the absence of fisheries data in the assessment since 1994. However, the estimates are consistent with the proposed $\mathrm{F}_{\mathrm{MSY}}$ for the neighbouring North Sea cod stock. There is no estimate of the current fishing mortality for this stock. However, it is likely that the current F is above $\mathrm{F}_{\text {MSY }}$. SSB has declined to a very low level. Therefore, catches (mainly discards) of cod should be reduced to the lowest possible level.

## PA considerations

Given the low SSB and low recruitments in recent years, it is not possible to identify any non-zero catch which would be compatible with the precautionary approach. No targeted fishing should take place on cod in Division VIa. Bycatches, including discards of cod in all fisheries in Division Via, should be reduced to the lowest possible level.

The 2008 year class is estimated to be more abundant and consequently additional measures (such as real-time closures) to protect it are essential to ensure that it contributes to the rebuilding of the stock. It will be necessary to reduce all sources of fishing mortality on cod to as close to zero as possible if the stock is to recover above $\mathrm{B}_{\mathrm{pa}}$ as quickly as possible.

## Additional considerations

Management considerations
The stock is suffering impaired recruitment. SSB is very low. It is necessary to reduce all sources of fishing mortality to recover the stock above $B_{p a}$ as quickly as possible. Management measures taken thus far have not recovered the stock.

The previous cod recovery plan did not apply west of a line known as the west of Scotland management line. The cod long-term management plan (EC 1342/2008) includes a west of Scotland management line that follows the 200 m depth contour. Fleets fishing at depths less than 200 m (i.e. within the cod recovery zone) are subject to the effort restrictions
of the management plan and new gear technical measures specified in EC 53/2010. Vessels fishing to the west of the management line are still subject to effort restrictions, but may apply for additional effort up to the point where fleetaggregated effort equals that from the previous year (if fleet effort allowances were cut). Some landings from this stock are taken west of the line defined in EC $1342 / 2008$. Some vessels using $>100 \mathrm{~mm}$ otter trawl (TR1) gear have larger cod landings from west of the line than from within the cod recovery zone.

Grey seal abundance, in west of Scotland, has increased from between $30 \%$ and $160 \%$ (dependant on estimation model) over the recent decades (Thomas and Harwood, 2009). Seals are known to feed on cod, among other species, and the mortality of cod due to seal predation is likely to have increased in recent years. The contribution of seal predation to total cod mortality is likely to be significant (Pope and Holmes, 2008). This may impair the ability of the cod stock to recover.

## Management plan evaluations

In 2009 the EU adopted a long-term plan for cod stocks and the fisheries exploiting those stocks (Council Regulation (EC) $1342 / 2008$, see Annex 5.4.21). This regulation has the objective of ensuring the sustainable exploitation of the cod stocks on the basis of maximum sustainable yield, while maintaining a target fishing mortality of 0.4 on specified age groups.

In 2009 ICES evaluated this revised long-term plan for cod (Council Regulation (EC) 1342/2008) in relation to the precautionary approach. This evaluation concluded that assuming TAC and effort constraints would lead to rapid declines in fishing mortality, the stock would recover by 2015. Given the recent changes in discarding in response to a moderate year class and the difficulty in partitioning the total mortality into that attributable to landings, discards, other causes due to fishing, and natural mortality in excess of the assumed 0.2 , ICES could not conclude the plan was precautionary.

ICES has previously commented on the appropriateness of $\mathrm{F}=0.4$ as a target for this stock. Based on the yield-perrecruit analysis, which estimates $\mathrm{F}_{\max }=0.22$ and the positive relationship of SSB and recruitment, the long-term target fishing mortality of 0.4 is not expected to achieve the management objective of maximum sustainable yield.

## Regulations and their effects

The fishery is managed by a combination of TAC, area closures, technical measures, and effort restrictions. Current landings (i.e. TAC) effort and spatial management of fisheries catching cod in Division VIa are not controlling mortality levels. Catch (landings + discards) is six times the reported landings.

## Area closures

- Clyde Sea area closure - STECF (2007) noted that the Clyde closure includes the main spawning area of a reproductively isolated aggregation of cod and concluded that the closure is likely to have a positive effect in reducing targeting of high densities of mature cod.
- Windsock closed area - STECF (2007) concluded that the extent of the Windsock closure is unlikely to be large enough to greatly reduce fishing mortality on cod, and its boundaries should be reconsidered. However, its removal would not help improve cod recovery.
- Since 2009, the Irish authorities introduced a seasonal closure in Division VIa. The closure covers ICES statistical rectangle 39E3 and is in force from October 31 to March 31. Historically, over 40\% of Irish cod landings from ICES Division VIa are from the closed area. For contrast, standardized cpue rates observed from a dedicated survey conducted inside the closed area in 2006 were on average $26.8 \mathrm{~kg} \mathrm{hr}^{-1}$ while cpue rates estimated from observer trips outside the closure gathered in the same period were $0.015 \mathrm{~kg} \mathrm{hr}^{-1}$. STECF (2010) concluded that, in accordance with the provisions of article 13 (1342/2008), the partial cod mortality associated with the Irish fleet had declined considerably ( $>50 \%$ ) since the introduction of the cod closure and other measures, although it is not possible to disentangle the effects of the Cape closure from other measures.

## Mesh sizes and catch composition rules

- Catch composition rules related to days-at-sea allowances (Reg. (EC) 850/1998 Annex I and Reg. (EC) 2056/2001) - These rules legislate for landings compositions, but do not restrict discards.
- Emergency measures introduced in EC regulation 43/2009 (Annex III) (and rolled forward into 2010 and 2011) prohibited all fishing activity to the east of the West of Scotland Management (French) line in Division VIa with the exception of a number of derogated fisheries. For demersal otter trawlers targeting whitefish this required an increase in mesh size to 120 mm and the inclusion of a 120 mm square-meshed panel (SMP). Vessels targeting Nephrops also require the 120 mm SMP or a sorting grid. More stringent catch composition
rules have also been introduced. For Nephrops-directed fisheries, no more than $10 \%$ of the retained catch can consist of cod, haddock, and whiting, where the limit is no more than $30 \%$ for whitefish targeted vessels.
- The latest assessment for Division VIa haddock suggests the emergency measure catch composition rules will be restrictive for haddock and may lead to discarding..

## Effort limitations

- Between 2003 and 2009 STECF (2010) reported that the fishing effort (in kW-days) of trawlers using $>100 \mathrm{~mm}$ mesh declined by $43 \%$. These vessels primarily targeted roundfish, including cod. Over the same period effort for trawlers using $70-99 \mathrm{~mm}$ mesh declined by $26 \%$. These vessels primarily target Nephrops.
- Further effort reductions have been implemented since February 2011 under Annex IIa of Reg. (EC) 57/2011. This includes a $25 \%$ reduction in effort for all trawl fleets relative to a recent average effort. 'Buy back' of this effort reduction is possible after adoption of cod avoidance measures or proof of operating west of the cod management line.

## Supply chain traceability

U.K. "Buyers and Sellers" regulation and Irish "Sales Note" regulation - Unreported landings are expected to have reduced under these regulations. Observer data, however, show an increase in discards starting in 2006. The amount of discards relative to landings has increased and the age pattern of discarding has changed. Currently discards of fish aged 3 and above are being recorded.

## Cod avoidance measures

In 2008, Scotland introduced a voluntary programme known as "Conservation Credits", which involved seasonal closures, real-time closures (RTCs), and various selective gear options. This was designed to reduce mortality and discarding of cod. The number of RTCs west of Scotland were 4 in 2008, 20 in 2009, and 19 in 2010, representing $27 \%$, $14 \%$, and $12 \%$ of the total RTCs in each year. RTCs are determined by lpue, based on fine-scale VMS data and daily logbook records, and also by on-board inspections. The low number of RTCs west of Scotland result from few instances of high lpue in the area. Early indications are that the scheme has not so far been as effective as in the North Sea, with discard rates remaining high in Division VIa.

## Changes in fishing technology and fishing patterns

The implementation of the cod long-term plan effort controls (Annex IIa of Reg. (EC) 43/2009) and other technical measures including gear restriction in Division VIa (Annex III of Reg. (EC) 43/2009) was expected to lead to large changes in fishing patterns starting in 2009. Analysis is not yet available to evaluate this.

## Uncertainties in assessment and forecast

Survey information shows that the total removal of cod in Division VIa may have been underestimated in the past decade relative to earlier periods. In an attempt to remove bias in the assessment a catch-at-age model was used that ignored landings and discard numbers from 1995 onwards, relying on survey data for this later period. It is, however, considered that mortality estimates arising from this assessment heavily or wholly based on survey data are poorly estimated. In contrast, historical trends in spawning biomass and recruitment appear to be robust measures of stock dynamics, see Figure 5.4.21.1.

Some changes have been made to the survey design in the past, but surveys are considered to be a reasonable indicator of stock trends from the mid-1990s. The survey gear changed in 2011 to bring it in line with other surveys in the area so that these can be combined in future to provide a more robust and precise survey index. The opportunity was also taken to improve the survey design at this time: it is now random-stratified. This only affects our perception of stock metrics in 2011 and does not influence the basis for the advice.

Because of uncertainties in the level and trend of natural mortality it is not possible to predict landings estimates from a forecast, only removals associated with both fishing and unaccounted natural mortality.

## Comparison with previous assessment and advice

The basis for the assessment is the same as last year. The advice is the same as last year.

### 5.4.21 Annex

The European Commission has adopted a Council Regulation ((EC) No. 1342/2008) which establishes measures for the recovery and long-term management of cod stocks. The stated objective of the plan is to ensure the sustainable exploitation of the cod stocks on the basis of maximum sustainable yield while maintaining a fishing mortality of 0.4. Articles 7-9, describing aspects of the plan relevant for west of Scotland cod, are reproduced below:

## Article 7

## Procedure for setting TACs for cod stocks in the Kattegat the west of Scotland and the Irish Sea

1. Each year, the Council shall decide on the TAC for the following year for each of the cod stocks in the Kattegat, the west of Scotland and the Irish Sea. The TAC shall be calculated by deducting the following quantities from the total removals of cod that are forecast by STECF as corresponding to the fishing mortality rates referred to in paragraphs 2 and 3: (a) a quantity of fish equivalent to the expected discards of cod from the stock concerned; (b) as appropriate a quantity corresponding to other sources of cod mortality caused by fishing to be fixed on the basis of a proposal from the Commission.
2. The TAC shall, based on the advice of STECF, satisfy all of the following conditions: (a) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be below the minimum spawning biomass level established in Article 6, the fishing mortality rate shall be reduced by $25 \%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year; (b) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be below the precautionary spawning biomass level set out in Article 6 and above or equal to the minimum spawning biomass level established in Article 6, the fishing mortality rate shall be reduced by $15 \%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year; and (c) if the size of the stock on 1 January of the year of application of the TAC is predicted by STECF to be above or equal to the precautionary spawning biomass level set out in Article 6, the fishing mortality rate shall be reduced by 10 $\%$ in the year of application of the TAC as compared with the fishing mortality rate in the previous year.

If the application of paragraph 2(b) and (c) would, based on the advice of STECF, result in a fishing mortality rate lower than the fishing mortality rate specified in Article 5(2), the Council shall set the TAC at a level resulting in a fishing mortality rate as specified in that Article.
4. When giving its advice in accordance with paragraphs 2 and 3, STECF shall assume that in the year prior to the year of application of the TAC the stock is fished with an adjustment in fishing mortality equal to the reduction in maximum allowable fishing effort that applies in that year.
5. Notwithstanding paragraph 2(a), (b) and (c) and paragraph 3, the Council shall not set the TAC at a level that is more than $20 \%$ below or above the TAC established in the previous year.

Article 9

## Procedure for setting TACs in poor data conditions

Where, due to lack of sufficiently accurate and representative information, STECF is not able to give advice allowing the Council to set the TACs in accordance with Articles 7 or 8, the Council shall decide as follows: (a) where STECF advises that the catches of cod should be reduced to the lowest possible level, the TACs shall be set according to a $25 \%$ reduction compared to the TAC in the previous year; (b) in all other cases the TACs shall be set according to a $15 \%$ reduction compared to the TAC in the previous year, unless STECF advises that this is not appropriate.

## Article 10

## Adaptation of measures

1. When the target fishing mortality rate in Article 5(2) has been reached or in the event that STECF advises that this target, or the minimum and precautionary spawning biomass levels in Article 6 or the levels of fishing mortality rates given in Article 7(2) are no longer appropriate in order to maintain a low risk of stock depletion and a maximum sustainable yield, the Council shall decide on new values for these levels.
2. In the event that STECF advises that any of the cod stocks is failing to recover properly, the Council shall take a decision which: (a) sets the TAC for the relevant stock at a level lower than that provided for in Articles 7, 8 and 9; (b) sets the maximum allowable fishing effort at a level lower than that provided for in Article 12; (c) establishes associated conditions as appropriate.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Cod in Division VIb (Rockall)

## Advice for 2012

There is insufficient information to evaluate the status of the stock. Therefore, based on precautionary considerations, ICES advises that no increase of the catch should take place unless there is evidence that this will be sustainable.

## Stock status

| SSB (Spawning-Stock Biomass) |  |  |  |
| :--- | :---: | :---: | :---: |
|  | 2008-2010 |  |  |
| Qualitative evaluation | $?$ |  |  |

Figure 5.4.22.1 Cod in Division VIb (Rockall). ICES estimates of landings.
The information available is insufficient to evaluate stocks trends and exploitation.

## Management plans

No specific management objectives are known to ICES.

## The fisheries

Cod in Division VIb are taken in otter trawl fisheries targeting haddock or anglerfish.

## Catch by fleet Not available.

Quality considerations
Available data provides information on landings.

## Scientific basis

| Assessment type | No assessment. |
| :--- | :--- |
| Input data | Landings statistics. |
| Discards and bycatch | Not included in the assessment. |
| Indicators | None. |
| Other information | Lpue from Irish and Scottisch otter trawl fleet available since 2010 and 2011 respectively. |
| Working group report | WGCSE |

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Cod in Division VIb (Rockall)

## Reference points

No reference points are defined for this stock.

## Outlook for 2012

No analytical assessment is available for this stock. The main cause of this is lack of data. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

There is insufficient information to evaluate the status of the stock. Therefore, based on precautionary considerations, ICES advises that no increase of the catch should take place unless there is evidence that this will be sustainable.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Haddock in Division VIa (West of Scotland)

## Advice for 2012

ICES advises on the basis of the MSY framework that landings in 2012 should be no more than 10200 t. The selection pattern should be improved in the Nephrops (TR2) fleet to reduce its high proportion of discards.

## Stock status

Figure 5.4.23.1 Haddock in Division VIa (West of Scotland). Summary of stock assessment (weights in ' 000 tonnes). Predicted values are shaded. Top right: SSB and F over the years.

The 2009 year class is strong relative to others in the recent period, but still below the long-term average. Nevertheless, this year class contributes to the rise of the SSB in 2011 estimated at 20.8 thousand tonnes. F has been above $\mathrm{F}_{\mathrm{pa}}$ in most years since 1987, but dropped below $\mathrm{F}_{\mathrm{pa}}$ in 2007 has been and at $\mathrm{F}_{\text {MSY }}$ since 2008.

## Management plans

A management plan is under development (See Annex 5.4.23). Following the annex would result in a 2012 TAC of 2506 t and a decrease in F of $77 \%$. The aim of this plan is to keep the SSB above 30000 tonnes with a fishing mortality no more than 0.3 . The main elements in the plan are a $25 \%$ constraint on TAC change between years and lower fishing mortality rates whenever the SSB is lower than 30000 t .

Early in 2010, ICES evaluated an earlier version of the plan (with a $+/-15 \%$ TAC constraint applied only when SSB was greater than $\mathrm{B}_{\mathrm{pa}}$ ) and concluded that it was in accordance with the precautionary principle. The revised plan (with a TAC constraint of $+/-25 \%$ ) has not yet been fully evaluated.

## Biology

Haddock are widely distributed across the continental shelf from the North Sea to the Celtic Sea. There is some connectivity with the haddock stock in the North Sea, which is assessed as a different stock. The stock-recruit relationship for haddock is characterized by sporadic high recruitments. There may be periods of low recruitment at any stock size.

## The fisheries

Haddock in Division VIa is caught mainly by Scottish and Irish bottom trawlers, which target mixed demersal fish assemblages. Catches are widely distributed and are concentrated in several areas, e.g. Butt of Lewis and on the shelf west of the Outer Hebrides. The total catch for haddock is estimated to be 5830 tonnes; $51 \%$ of these are discards. Splitting discards by fleet shows that Nephrops vessels (TR2) are responsible for $\sim 88 \%$ of all discards while landing only 21 tonnes, less than $1 \%$ of the total landings (2882 tonnes).

Catch by fleet Total catch $(2010)=5830 \mathrm{t}$, where the demersal fish fleet (TR1) contributes $3217 \mathrm{t}(2861 \mathrm{t}$ landed, 356 t discarded) and the Nephrops fleet ( TR2) 2613 t ( 21 t landed, 2592 t discarded).

## Quality considerations

In 2010 the catch-at-age data from 2006 onwards were re-introduced to the assessment, based on evidence from the improved accuracy of landing statistics. The survey design and gear were changed in the Scottish west coast survey (ScoGFS-WIBTS-Q1 and ScoGFS-WIBTS-Q4) in the first quarter of 2011(and the changes will be maintained hereafter). The impact on the assessment is unknown, although survey-based analyses suggest that the catchability of the new survey configuration for haddock may be higher for all ages. For these reasons the 2011 data for the Q1 survey (ScoGFS-WIBTS-Q1) were not used in the assessment until further analysis can be made. No survey data for the 2010 Q4 (ScoGFS-WIBTS-Q4) were available due to a ship breakdown.

[*] $\mathrm{F}_{\max }$ is not well defined.

## $\stackrel{\rightharpoonup}{\infty} \quad$ Outlook for 2012

The short-term forecast is presented in terms of total removals. These are then divided into landings ( $55 \%$ ), discards ( $36 \%$ ), and unallocated removals ( $9 \%$ ), using the most recent assessment to calculate the average proportions of these catch components over the last three years.

Basis: $\mathrm{F}(2011)=\mathrm{F}_{\mathrm{sq}}=\mathrm{F}(2008-2010)=0.29 ; \operatorname{SSB}(2012)=31.3 ; \mathrm{R}(2012)=\mathrm{TSA}$ model estimate $=105.1$ million, $\mathrm{R}(2013)=\mathrm{GM}=82.7$ million; Removals $(2011)=8.21$.

Weights in ' 000 tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012.
${ }^{2)}$ Total removals 2012 relative to TAC 2011.
${ }^{3)}$ Human consumption landings 2012 relative to TAC 2011. Note: this is the percentage TAC change as it was used in the management plan evaluation.

## Management plan

A management plan is under development (See Annex 5.4.23). Following the annex would result in a $25 \%$ increase in landings. This would result in removals from the stock of 4600 tonnes, and landings of 2506 tonnes in 2012. This is expected to lead to an SSB of 50000 tonnes in 2013.

The management plan is not yet in operation and has not yet been fully evaluated by ICES. Therefore, the advice is not based on this plan.

## MSY approach

Following the ICES MSY framework implies a fishing mortality less than 0.3, resulting in landings of 10200 tonnes in 2012. This is expected to lead to an SSB of 40700 tonnes in 2013. Haddock is caught in a mixed fishery where other species such as cod and whiting are present.

## PA approach

The fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings of less than 15700 t in 2012. This is expected to keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2013.

## Additional considerations

EU emergency measures were implemented in 2009 in Division VIa. These measures include inter alia quite strict bycatch limits ( $30 \%$ cod, haddock, and whiting combined). The improving stock condition and associated advice assuming the management plan or the MSY approach will lead to increased catches of haddock for which the current bycatch arrangements will be inappropriate.

## Management considerations

ICES recommends a management plan which would offer maximum protection to the haddock, recognizing that it is caught in a mixed fishery. Special attention needs to be given to the sporadic nature of the haddock recruitment and how to manage periods of low recruitment interspersed with large, occasional pulses. In recent years around $50 \%$ of the total catch in weight has been discarded, so restricting landings alone may not achieve the necessary increase in SSB.

One-year-olds comprised the largest proportion ( $\sim 82 \%$ ) of total numbers of haddock caught in 2010 and the majority of these were discarded in the Nephrops fleet (TR2). Any measure to reduce discarding and to improve the fishing pattern should be actively encouraged. Such measures should include the adoption of a sorting grid as well as appropriately located square-meshed panels.

Effort data 1998-2010 from UK vessels (one of the main countries fishing in the area) suggests that overall, effort has declined in recent years in Division VIa, and that declines in particular categories have not been compensated for by rises in other categories. Larger-meshed whitefish demersal trawls were the most important gears in Division VIa prior to 2002, but since then there has been a marked decline in kW-days by this category. Single-rig Nephrops trawls in the $70-99 \mathrm{~mm}$ mesh category are the other major gears in use and effort by these seems to have been maintained at a fairly stable level throughout the time-series.

The management of haddock will be strongly linked to that of cod, for which a management plan is currently in force.

## Impacts of fisheries on the ecosystem

In general, the impact of the fisheries concerns the effects of bottom trawling on benthos, poor selectivity of gear acting on mixed fish assemblages, and the practice of discarding in response to, for example, available quota or market prices.

## Regulations and their effects

The fishery is managed by a combination of TAC and technical measures, and in addition, the cod recovery plan measures (including effort restrictions and closed areas) are also expected to affect haddock. A detailed description of the effects of cod recovery measures and regulations and can be found in the Division VIa cod advice (Section 5.4.21).

The UK "Buyers and Sellers" regulation and Irish "Sales Note" regulation have reduced unreported landings. Discard rates have, however, remained stubbornly high.
Data and methods

The analytical assessment is based on landings-at-age data, discard-at-age data, and indices from research vessel surveys. Due to uncertainties in landings for several years, commercial catch numbers from 1995-2005 were not used in the assessment. In 2010 fishery landings and catch-at-age data from 2006 onwards were re-introduced in the assessment, based on the perception of improved accuracy of landing statistics.

## Uncertainties in assessment and forecast

The main uncertainty in the forecast is the strength of the 2009 year class. The various surveys and discard sampling information have indicated that the 2009 year class is strong relative to others in the recent period, but still below the long-term average. The absolute magnitude of the year class will have a strong impact on the catch predictions.

The ScoGFS-WIBTS-Q4 did not take place in 2010. However, due to the introduction of catch-at-age data this has less affect on the quality of the assessment than previously when the recent catch was excluded. There have been changes to the survey design and gear in the ScoGFS-WIBTS-Q1 in 2011 and the impact of this is unknown. For that reason the survey data for the first quarter of 2011 was not used in the assessment until further analysis can be made.

## Comparison with previous assessment and advice

Last year's assessment indicated that the SSB would continue to decline as the 1999 and 2005 year classes move out of the population. Last year's assessment forecasted a small increase in the recruitment for 2010. The 2010 year class has been estimated as stronger than expected, resulting in an increase in SSB to 20800 tonnes. The recruitment forecast for the 2011 year-class is estimated to be $\sim 15$ million higher than in 2010 .

The basis for the advice is the same as last year.

## Annex 5.4.23

Option for a harvest rule for the management of haddock in zones VIa and EC waters of Vb:

1. For 2010 and subsequent years the TAC will be set consistent with a fishing mortality rate of no more than 0.3 for appropriate age-groups, when the SSB in the end of the year in which the TAC is applied is estimated to be above 30,000 tonnes ( $B_{p a}$ ).
2. Where the SSB referred to in paragraph 1 is estimated to be below $B_{p a}$ but above 22,000 tonnes (Blim) the TAC shall not exceed a level which will result in a fishing mortality rate equal to 0.3-0.2*( $\left.B_{p a}-S S B\right) /\left(B_{p a}-B_{\text {lim }}\right)$.
3. Where the SSB referred to in paragraph 2 is estimated to be below Blim the TAC shall be set at a level corresponding to a total fishing mortality rate of no more than 0.1.
4. Where the rules in paragraphs 1-3 would lead to a TAC which deviates by more than $25 \%$ from the TAC of the preceding year, the TAC will be set that is no more than $25 \%$ greater or $25 \%$ less than the TAC of the preceding year. This consideration overrides paragraphs 1-3.
5. In the event that STECF advises that changes are required to the precautionary reference points $B_{p a}(30,000 t)$ or Blim, (22,000t) paragraphs 1-4 shall be reviewed.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Haddock in Division VIb (Rockall)

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 3300 t .

## Stock status

| F (Fishing Mortality) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

| Precautionary $\operatorname{approach}\left(\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{lim}}\right)$ |  |  |  | Harvest sustainably |
| SSB (Spawning-Stock Biomass) |  |  |  |  |
|  | 2009 | 2010 |  | 2011 |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | $\cdots$ | $\checkmark$ |  | Above trigger |
| Precautionary approach $\left(\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}\right)$ |  |  |  | Full reproductive capacity |

Figure 5.4.24.1
Haddock in Division VIb (Rockall). Summary of stock assessment (weights in ' 000 tonnes). Predicted values are shaded. Top right: SSB and F over the years.

Spawning biomass has increased in recent years as a result of the 2001 and 2005 year classes. SSB has been above $\mathrm{B}_{\text {pa }}$ since 2003. Fishing mortality has declined over time and is now below $\mathrm{F}_{\mathrm{MSY}}$. Recruitments since 2007 are estimated to be extremely weak and there is a high probability that SSB will decrease to levels below $\mathrm{B}_{\mathrm{pa}}$ in 2013.

## Management plans

A management plan is under development and is currently being evaluated.

## Biology

The haddock stock at Rockall is an entirely separate stock from that on the continental shelf of the British Isles. Rockall haddock have lower growth rates and reach a lower maximum size than other haddock populations in the Atlantic.

## Environmental influence on the stock

Recruitment for the last four years has been low despite a large SSB. This may be related to rising seawater temperature on the Rockall bank.

## The fisheries

Haddock in Division VIb are caught in a directed fishery and as a bycatch in demersal and gillnet fisheries. Haddock are mostly taken in fisheries deploying otter trawls, but also by pair trawlers and gillnetters. Last years the discards are significantly reduced as a result of the small number of young haddock in the population.

Catch by fleet Total catch $(2010)=3.7 \mathrm{kt}$, where $92 \%$ are landings $(93 \%$ otter trawl, $5 \%$ pair trawl, and $2 \%$ other gears) and $8 \%$ discards.

## Effects of the fisheries on the ecosystem

In order to protect cold water corals, four areas (North West Rockall, Logachev Mounds, West Rockall Mounds, and Empress of British Banks) have been closed since 2007.

## Quality considerations

An improved time-series of landings and discard is needed for this assessment. The survey area coverage has been reviewed and will be extended into deeper waters in 2011. The survey used in the assessment was not carried out in 2010 and therefore the only additional data used this year compared to last year are catch-at-age data for 2010. This makes this year's assessment more uncertain than in the past years.

Figure 5.4.24.2 Haddock in Division VIb (Rockall). Historical assessment results (final year recruitment estimates included).

Weights in ' 000 tonnes.
${ }^{1)}$ SSB 2013 relative to SSB 2012.
${ }^{2)}$ Human consumption landings 2012 relative to TAC 2011.
Total catches have been divided into landings and discards using the average ratio of discards to catches over the period 1999-2009.

## MSY approach

A fishing mortality of $0.3\left(=\mathrm{F}_{\mathrm{MSY}}\right)$ corresponds to landings of less than 3300 t in 2012 and is expected to lead to an SSB of 9600 t .

Because F in 2010 is below $\mathrm{F}_{\mathrm{MSY}}$, no transition scheme is necessary.
Further management measures should be introduced to reduce discarding of small haddock in order to maximize their contribution to future yield and SSB.

## PA approach

A fishing mortality of $0.4\left(=F_{p a}\right)$ corresponds to landings of $4200 t$ in 2012 and is expected to lead to an SSB of $8600 t$ which will be below $B_{p a}$ in 2013. To keep SSB above $B_{p a}$, landings in 2012 should be less than 3800 t .

## Additional considerations

The European Community and the Russian Federation have proposed a draft plan for the harvest control component of a long-term management plan for haddock at Rockall. NEAFC requests ICES to evaluate this component of the longterm management plan for Rockall haddock.

In 2012 SSB is at $\mathrm{B}_{\mathrm{pa}}$ but the incoming recruitment for the last five years has been low There is a high probability that the SSB will decrease to levels below $\mathrm{B}_{\mathrm{pa}}$.

The TAC only applies to catches in the EU zone. The TAC should apply to all areas and countries having fisheries for this stock. Since 1999 part of Division VIb has been in international waters where non-EU vessels are not subject to TAC. This allows for an unregulated fishery in the Rockall area. In addition, misreporting and discarding can lead to removals that exceed the TAC.

The forecast predicts future catches disaggregated into landing and discard components. The discard ratio is around $47 \%$ in 1991-2009 and $34 \%$ in the recent period (1999-2009). Some countries land the whole catch while others discard part of the catch. For countries which discard part of the catch the discard rate in the past was as high as $52-$ $87 \%$ by numbers by results of discards trips. It would be beneficial to develop and introduce into fisheries practices
measures aimed at preventing discards of haddock. Elaboration of such measures comply with recommendations under the UNGA Resolution 61/105 that urge states to take action to reduce or eliminate fish discards (UNGA Resolution 61/105, 2007, Chapter VIII, item 60).

Haddock is taken in a mixed fishery together with monk and megrim. Some of the fisheries include substantial catches of blue whiting and non-assessed species such as grey gurnard.

## The effects of regulations

Following the NEAFC agreement in March 2001, an area of the NEAFC zone around Rockall was closed to fishing. In spring 2002, part of the shallow water in the EU component was also closed to trawling. The main goal of the ban was to protect young haddock distributed in shallow water. Effort in the rectangle containing the closure declined when the closure came into effect. There was also a decline in UK effort across the bank as a whole at this time, but an increase of effort in other areas of Division VIb. Spawning biomass has increased since 2003, and the fishing mortality has decreased since 2004. In 2006 and 2010, mortality reached the lowest estimates for the last 15 years. Fishing mortality has decreased for small individuals (ages 1 and 2) since 2001. However, it is difficult to determine the extent to which this may be caused by the effort made to protect juveniles in the closed area.

## Data and methods

The assessment is based on catch numbers-at-age and one survey index (Rock-WIBTS-Q3). Discarding occurs in part of the fishery and has been estimated and used in the assessment.

## Uncertainties in assessment and forecast

A main uncertainty in the assessment and forecast is the estimates of discards in the EU fleets. In some years these are directly estimated from sampling aboard Scottish and Irish vessels, and in other years are inferred using survey length frequencies, average fishery selectivity and discarding ogives, and length frequencies from port sampling. In 2010 there was no discard sampling or survey, and average discard rates were applied.

The survey covers only part of the currently known distribution area of haddock that raises uncertainty of an assessment. The survey area coverage has been reviewed and will be extended into deeper waters in 2011. The survey used in the assessment was not carried out in 2010.

## Comparison with previous assessment and advice

Fishing mortality in 2009 has been revised upward by $4 \%$, and SSB in 2010 has been revised downward by $23 \%$, when compared with last year's assessment.

The basis for the advice is the same as last year, but extended by MSY considerations.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Whiting in Division VIa (West of Scotland)

## Advice for 2012

ICES advises on the basis of the precautionary considerations that catches in 2012 should be reduced. The selection pattern should be improved in the Nephrops (TR2) fleet.

|  |  | $?$ |

Figure 5.4.25.1 Whiting in Division VIa (West of Scotland). Comparison of trends-based assessment final run outputs (SURBA) with exploratory analytical assessment (TSA) estimates. Recruitment, fishing mortality, and biomass are mean-standardized over 1985-2010 (the length of the tuning series used in TSA).

The state of the stock is unknown, but long-term information on the historical yield and catch composition, a surveybased assessment, and an exploratory analytical assessment covering the more recent period, all indicate that the present stock size is at a historical low. Fishing mortality estimates have declined since around 2005. Recruitments in the most recent years are estimated to be very low, although there are several indications that recruitment increased in 2010 (year class 2009).

## Management plans

No specific management objectives are known to ICES.

## Biology

Whiting occur throughout northeast Atlantic waters, in a wide range of depths, from shallow inshore waters down to 200 m . Adult whiting are widespread throughout Division VIa, while high numbers of juvenile fish occur in inshore areas. There may be a degree of mixing of adult fish between Division IVa whiting and the Division VIa component off the northwest of Scotland.

## The fisheries

Whiting has never been a particularly valuable species and is primarily taken as a bycatch with other species, such as haddock, cod, and anglerfish. Whiting in Division VIa are caught mainly by $80-120 \mathrm{~mm}$ trawlers. Since 2000 there has been a big reduction in the large-meshed (TR1) trawl and seine effort, but no reduction by smaller-meshed (TR2) gears. At present a higher proportion of the overall effort is by relatively small-meshed trawls. There has been a tendency to shift from the use of heavy groundgear (like rockhopper) to lighter groundgear.

## Catch by fleet Total catch $(2010)=1193 \mathrm{t}$, where TR1 takes $451 \mathrm{t}(301 \mathrm{t}$ landed, 150 t discarded) and TR2

 742 t (6t landed, 736 t discarded).
## Quality considerations

An exploratory analytical assessment was presented this year that indicates increasing catchability of the survey over the time-series. The mean weights-at-age in the catch are also quite variable in recent years because of low and patchy sampling levels. An increase in the mesh size of the TR1 fleet affects the fishing selectivity for $38 \%$ of the catch. There have been changes to the survey design and gear and the impact on the exploratory assessment is unknown.

## Scientific basis

| Assessment type | Trends-based assessment and an exploratory analytical assessment (SURBA and TSA.) <br> Landings and discards 1965 to 1994 and 2006 to 2010; <br> Input data |
| :--- | :--- |
| one survey index (ScoGFS-WIBTS-Q1, years 1985-2011). |  |
| Discards and bycatch | Included in the TSA exploratory assessment. |
| Indicators | ScoGFS-WIBTS-Q4, IGFS-WIBTS-Q4. |
| Other information | The stock is planned to be benchmarked in 2012. |
| Working group report | WGCSE |

## ECOREGION Celtic Sea and West of Scotland STOCK Whiting in Division VIa (West of Scotland)

## Reference points

|  | Type | Value | Technical basis |
| :---: | :---: | :---: | :---: |
| MSY <br> Approach | MSY $\mathrm{B}_{\text {trigger }}$ | Not defined. |  |
|  | $\mathrm{F}_{\mathrm{MSY}}$ | Not defined. |  |
| Precautionary | $\mathrm{B}_{\text {lim }}$ | 16000 t | Blim = Bloss(1998), the lowest observed spawning stock estimated in previous assessments. |
|  | $\mathrm{B}_{\mathrm{pa}}$ | 22000 t | $\mathrm{B}_{\mathrm{pa}}=\mathrm{B}_{\lim }$ * 1.4. This is considered to be the minimum SSB required to have a high probability of maintaining SSB above Blim, taking into account the uncertainty of assessments. |
| Approach | $\mathrm{F}_{\text {lim }}$ | 1.0 | Flim is the fishing mortality above which stock decline has been observed. |
|  | $\mathrm{F}_{\mathrm{pa}}$ | 0.6 | $\mathrm{F}_{\mathrm{pa}}=0.6$ * Flim. This F is considered to have a high probability of avoiding Flim. |

(unchanged since: 1998)
A yield-per-recruit analysis using the results from the exploratory assessment indicates a reasonably well defined $\mathrm{F}_{\text {max }}$, which is where the current fishing mortality is estimated to be.

## Outlook for 2012

No reliable assessment can be presented for this stock. The main cause of this is due to historic uncertainties in the reported landings. However, based on the recent decline in trends of fishing mortality and the increased abundance of the 2009 year class, the stock would be expected to increase if the 2009 year class does not continue to be discarded at the rate observed in 2010.

## Precautionary considerations

The stock trend is considered to be close to the historically low level; the qualitative evaluation suggests that fishing mortality has declined and is now close to its historically lowest value, but this is uncertain. Catches should be reduced. The selection pattern should be improved in the TR2 fleet.

## Additional considerations

There are strong indications that management control is not effective in limiting the catch. The proportion of fish discarded is very high and appears to have increased in recent years. More than half of the annual catch weight comprises undersized or low-value whiting which are discarded. $83 \%$ of these discards come from the TR2 (Nephrops) fishery. Measures to reduce discards and to improve the exploitation pattern would be beneficial to the stock and to the fishery, particularly when there are indications that the 2009 year class is relatively strong. Such measures should include the adoption of a sorting grid as well as appropriately located square-meshed panels.

## Regulations and their effects

The fishery is managed by a combination of TAC and technical measures, and in addition, the cod recovery plan measures (including effort restrictions and closed areas) are also expected to affect whiting. A detailed description of the effects of cod recovery measures and regulations and can be found in the Division VIa cod advice (Section 5.4.21).

Unreported landings are expected to have reduced under the UK "Buyers and Sellers" regulation, the Irish "Sales Note" regulation and other measures to improve compliance. Discard rates have, however, remained high.

## Changes in fishing technology and fishing patterns

Whiting in Division VIa are caught mainly by Scottish trawlers. There has been a reduction in trawl and seine effort, but with a more moderate reduction by Nephrops trawlers. At present a higher proportion of the overall effort is by relatively small-meshed trawls. There has been a tendency to shift from the use of heavy groundgear (like rockhopper) to lighter groundgear.

Effort data 1998-2010 from UK vessels (one of the main countries fishing in the area) suggests that overall, effort has declined in recent years in Division VIa, and that declines in particular categories have not been compensated for by rises in other categories. Larger-meshed whitefish demersal trawls were the most important gears in Division VIa prior to 2002, but since then there has been a marked decline in kW-days by this category. Single-rig Nephrops trawls in the $70-99 \mathrm{~mm}$ mesh category are the other major gears in use and effort by these seems to have been maintained at a fairly stable level throughout the time-series.

Numerous other gears make generally small contributions to the overall effort and the pattern in most of these has been either a downward trend (e.g. seine nets and midwater trawls) or a fluctuation without trend (e.g. fixed nets).

## Uncertainties in assessment and forecast

Some changes have been made to the survey design in the past, but surveys are considered to be a reasonable indicator of stock trends from the mid-1990s. The survey gear changed in 2011 to bring it in line with other surveys in the area so that these can be combined in future to provide a more robust and precise survey index. The opportunity was also taken to improve the survey design at this time; it is now random-stratified. This only affects our perception of SSB in 2011 and does not influence the basis for the advice.

## Comparison with previous assessment and advice

Last year's assessment provided trends only for the stock; a new exploratory assessment this year gives similar trends. The advice is based on precautionary considerations.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Whiting in Division VIb (Rockall)

## Advice for 2012

There is insufficient information to evaluate the status of the stock. Therefore, based on precautionary considerations, ICES advises that no increase of the catch should take place unless there is evidence that this will be sustainable.

## Stock status

Figure 5.4.26.1
Whiting in Division VIb (Rockall). Official landings in tonnes.

The available information is insufficient to evaluate the stocks trends and exploitation. Landings of whiting from Division VIb are negligible ( 18 t in 2010).

## Management plans

No specific management objectives are known to ICES.

## Scientific basis

| Assessment type | No assessment |
| :--- | :--- |
| Input data | Catch statistics |
| Discards and bycatch | Not included in the assessment |
| Indicators | None |
| Other information | - |
| Working group report | WGCSE |

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Whiting in Division VIb (Rockall)

## Reference points

No reference points are defined for this stock.

## Outlook for 2012

No analytical assessment is available for this stock. The main cause of this is lack of data. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

There is insufficient information to evaluate the status of the stock. Therefore, based on precautionary considerations, ICES advises that no increase of the catch should take place unless there is evidence that this will be sustainable.

## ECOREGION Celtic Sea and West of Scotland <br> Saithe in Subarea VI (West of Scotland and Rockall)

This stock has now been combined with saithe in Subarea IV (North Sea), Division IIIa (Skagerrak), and Subarea VI (West of Scotland and Rockall) and can be found in Book 6 North Sea, Section 6.4.12.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Sprat in Subarea VI and Divisions VIIa-c and f-k (Celtic Sea and West of Scotland)

## Advice for 2012

This is the first time that ICES analyses data for sprat in the Celtic Sea and West of Scotland. Currently there is no TAC for this species in this area, and it is not clear whether there should be one or several management units. There is insufficient information to evaluate the status of sprat in this area. Therefore, based on precautionary consideration, ICES advises that catches should not be allowed to increase in 2012.

## State of the stock

SSB (Spawning Stock Biomass)

Figure 5.4.28.1 Sprat in the Celtic Sea and West of Scotland. ICES landings (in tonnes) by area.
The information available is insufficient to evaluate stock trends and exploitation.

## Management plans

No specific management objectives are known to ICES.

## Biology

Sprat is a relatively short lived species that shows large inter-annual variations in biomass mainly driven by recruitment variability. Multispecies investigations in the North Sea have demonstrated that sprat is one of the important prey species in the North Sea ecosystem, for both fish, seabirds, and sea mammals. At present, there are no data available on the total amount of sprat taken by these predatorts in this area. The Celtic Sea is a feeding ground for several species of large baleen whales that prey largely on herring and sprat.

## The fisheries

Most sprat in the Celtic Seas ecoregions are caught by small pelagic vessels that also target herring, mainly Irish and Scottish vessels. In Ireland, many multi-purpose vessels target sprat on an opportunistic basis. At other times these boats target a large variarity of other species. Targeted fishing takes place when there are known sprat abundances.

## Quality considerations

This advice is not dedicated to a 'stock'. It relates to a species in a wider region where data are available. The stock structure of sprat populations in this eco-region is not clear. ICES does not necessarily advocate that VI and VII constitutes a management unit for sprat, and further work is required.

Given discrepancies between national and official landings data further scrutiny of some of the landings data is required.

Scientific basis

|  | None |
| Other information | HAWG |

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Sprat in Subarea VI and Divisions VIIa-c and f-k (Celtic Sea and West of Scotland)

## Reference points

No reference points have been defined.

## Outlook for 2012

No reliable assessment can be presented for sprat in this Ecoregion and stock structure in relation to appropriate management units is unknown. Therefore, fishing opportunities cannot be projected.

## Precautionary considerations

This is the first time that ICES analyses data for sprat in the Celtic Sea and West of Scotland. Currently there is no TAC for this species in this area, and it is not clear whether there should be one or several management units. There is insufficient information to evaluate the status of sprat in this area. Therefore, based on precautionary consideration, ICES advises that catches should not be allowed to increase in 2012.

## Additional considerations

It is unclear what the appropriate stock units should be and how these relate to management units. Work is ongoing to understand stock structure in the Celtic Sea eco region. The relationship between sprat in VIId,e (Section 5.4.18) and the wider Celtic Sea ecoregion is unclear.

Sprat landings are used for both human consumption and fish meal. No sprat quotas exist for the management areas in this ecoregion with the exception of sprat in Divisions VIId,e which is subject to a TAC and a separate advice is provided in section 5.4.18 of this report.

## ECOREGION STOCK

## Celtic Sea and West of Scotland + North Sea

Anglerfish (Lophius piscatorius \& L. budegassa) in Divisions IIa and IIIa, and Subareas IV and VI

## Advice for 2012

ICES advises on the basis of precautionary considerations that catches in 2012 should be reduced.

Figure 5.4.29.1 Anglerfish (Lophius piscatorius and L. budegassa). Left: Official landings ('000 t). Middle and right: Total abundance and stock biomass index from the Scottish and Irish anglerfish and megrim industry science survey for the Northern shelf (black filled circles with $95 \%$ confidence limits), with breakdown by area: Subarea IV (red squares), Division VIa (blue open circles), and Division VIb (green triangles).

Recent dedicated anglerfish surveys (SCO-IV-VI-AMISS-Q2) in Division IVa and Subarea VI indicate a decline in trends of abundance in 2007-2009 and stable biomass in recent years.

## Management plans

No specific management objectives are known to ICES.

## Biology

Anglerfish mature at large size, resulting in a large proportion of the catch consisting of immature fish. This makes the stock susceptible to recruitment overfishing and management measures are required to ensure sufficient numbers to survive to spawning size. Catches of anglerfish on the northern shelf (from Division VIb to IIIa) come from the same biological stock. Spawning appears to occur largely in deep water off the edge of the continental shelf, although mature females are rarely encountered.

## The fisheries

Anglerfish are caught in a targeted anglerfish fishery and as a bycatch in other demersal fisheries, including roundfish fisheries in Division VIa, the haddock fishery on Rockall Bank, Nephrops fisheries, and fisheries in deeper waters. In the North Sea, anglerfish are caught mainly as a bycatch in demersal fisheries for mixed roundfish and Nephrops and to a lesser extent in small-meshed Pandalus fisheries. A Norwegian large-meshed gillnet fishery targeting fish over 60 cm has developed along the Norwegian coast since the early 1990s; in Division IIa this fishery has expanded in recent years.

Catch by fleet Total catch value is not available; official total landings in 2010 were 9000 t in Division IIIa and Subarea IV; 4000 t in Subarea VI, and 5400 t in Division IIa. Discards from the Scottish fleet were minimal in 2010 ( $<1 \%$ ).

## Effects of the fisheries on the ecosystem

The directed fishery takes place in deep water on the continental shelves in areas where cold water corals (Lophelia $s p p$.) occur, particularly at Rockall. However, demersal trawling is prohibited in several large areas at Rockall, and near the Wyville-Thomson ridge, which affords protection for corals in those areas.

## Quality considerations

Improved landing and effort data are needed. Accurate estimates of growth parameters are needed to facilitate the development of an analytical assessment. An anglerfish ageing exchange study is planned in 2011 to compare the different approaches that are used (otoliths and illicia). A dedicated Scottish and Irish industry/science anglerfish survey has operated from 2005-2010. However, the survey does not cover the eastern part of the North Sea and Skagerrak, where significant fisheries take place, which adds uncertainty to the stock trends perception.

## ECOREGION Celtic Sea and West of Scotland+ North Sea STOCK <br> Anglerfish (Lophius piscatorius \& L. budegassa) in Divisions IIa and IIIa, and Subareas IV and VI

## Reference points

No reference points have been defined for these stocks. Because of recently identified problems with growth estimates, previous reference points are no longer considered to be valid.

## Outlook for 2012

No analytical assessment can be presented for this stock. Because of major uncertainties concerning catch-at-age and effort data for anglerfish as well as limited knowledge about population dynamics, a forecast cannot be presented.

## Precautionary considerations

Recent trends in abundance and biomass have shown different results, from reductions to relatively stable. The available information is insufficient to evaluate exploitation status. Therefore, catches should be reduced.

## Additional considerations

The distribution of anglerfish in the North Sea, Kattegat, and Skagerrak is associated with the distribution to the west of Scotland (Divisions VIa and VIb). It is likely that catches from these areas come from the same biological stock. Genetic studies have found no evidence of separate stocks and particle-tracking studies have indicated interchange of larvae between areas.

## Regulations and their effects

The current EU-agreed TAC for Subarea IV and the EC waters of Division IIa as well as the EU-Norway-agreed TAC for the Norwegian North Sea EEZ do not include Division IIIa: no internationally agreed management rules for anglerfish appear to exist in Division IIIa.

Information from several fisheries indicates that underreporting of total landings has been a problem in recent years due to restrictive individual vessel quotas. In 2005 the TACs of the North Sea Subarea VI were raised to countermand underreporting practices, but the extent to which this has resolved the reporting problems in this fishery is not known. However, improved compliance and the registration of "buyers and sellers" legislation in Scotland and Ireland, should make it more difficult to make unreported landings of this species (and others). The legislation came into effect at the beginning of 2006. There has been increased enforcement on anglerfish quotas since 2006. This is expected to have lead to improved data on total catches of anglerfish.

Estimates accounting for area misreporting indicate that the percentage of the catch in the years 1993-2002 averaged $60 \%$ from Division IIIa and Subarea IV, and $40 \%$ from Divisions VIa and VIb. In previous years, these proportions have been used to allocate TAC between these areas. The ratio in biomass between ICES Subareas IV and VI from recently developed surveys was approximately $52: 48 \%$ (IV:VI) in 2010, although the survey does not cover all of Subarea IV.

Ghost fishing and discarding of fish not suitable for consumption due to long soaking times are considered to be a problem in some offshore gillnet fisheries carried out by "flag-vessels" targeting anglerfish in Subareas IV, VI, and VII. How effective the regulations (Council Regulation (EC) No. 43/2009) on gear length and soak time have been in mitigating this phenomenon is unknown.

## Changes in fishing technology and fishing patterns

Until the mid-1980s, anglerfish was taken mainly as a bycatch in bottom-trawl groundfish fisheries. Restrictive TACs for other species in Division VIa led to increased fishing pressure on anglerfish in that area, where they are now caught in a targeted anglerfish fishery and as a bycatch in other demersal fisheries.

The fishery has expanded into deeper waters since the mid-nineties, areas believed to have been a refuge for adult anglerfish, so this fishery increases the vulnerability of the stock to overexploitation. Immature fish are subjected to exploitation for a number of years prior to first maturity.
Comparison with previous assessment and advice
The basis for the assessment (analysis of survey trends) has not changed since last year. The abundance has decreased since 2009, but the biomass has remained relatively stable in the last two years However, the provision of the 2011 survey data will be important in validating recent trends. The basis for the advice is the same as last year.

## Assessment and management area

Two TACs are set: one TAC for EC waters of Division IIa and Subarea IV, and one for Division $\mathrm{Vb}(\mathrm{EC})$ and Subareas VI, XII, and XIV.

Figure 5.4.29.2 ${ }^{-15}$ Anglerfish (Lophius piscatorius $\stackrel{-5}{-5}^{-10}$ L. budegassa) ${ }^{0}$. Map of the European Northern Shelf showing the distribution of reported landings of anglerfish for 2010 from Scotland, Ireland, France, Denmark, Norway, and England \& Wales. The circles are centred on each ICES rectangle and segmented according to the landings of each country according to the legend (top left). The legend is divided according to the total reported landings of each country. The area of each circle is proportional to the landings in tonnes relative to the maximum as indicated. The Scottish data have been corrected according to certain assumptions about area misreporting.

## ECOREGION Celtic Seas <br> STOCK <br> Herring in Division VIa (North)

## Advice summary for 2012

ICES advises on the basis of the agreed west of Scotland herring management plan that the TAC for 2012 should be set at 22900 t .

## Stock status

Figure 5.4.30.1 Herring in Division VIa (North). Summary of stock assessment (weights in ' 000 tonnes). Estimates are shaded Top right: SSB and F over the years.

ICES considers that the stock over recent years has been fluctuating at a low level. Fishing mortality has fluctuated around $\mathrm{F}_{\text {MSY }}$ in recent years. Recruitment has been low since 2003.

## Management plans

A management plan has been adopted by the EU in 2008 (Council Regulation (EC) 1300/2008). ICES has evaluated the plan and concludes that it is in accordance with the precautionary approach.

## Biology

This autumn-spawning stock is considered a part of the Malin Shelf Stock Complex. Components of the neighbouring herring stocks to the south are known to be present seasonally in Division VIa (North). Studies are ongoing to evaluate the level of mixing in the acoustic survey. The effect of mixing in the fishery is expected to be lower than in previous years, but is unknown.

## Environmental influence on the stock

Temperatures and salinity in this area have been increasing over recent decades. It is known that similar environmental changes have affected the North Sea herring. There has been a reduction of the productivity of the Division VIa (North) stock since the late 1980s.

## The fisheries

Fisheries take place in pair trawlers in shallow, coastal waters, and single trawls, purse seiners and freezer trawlers offshore. Prior to 2006 there was a fairly even distribution of effort, both temporally and spatially. Since 2006 the majority has been fished in the northern part of Division VIa (North) in the $3^{\text {rd }}$ quarter.

## Catch by fleet

$$
\text { Catch }(2010)=19877 \mathrm{t}(68 \% \text { pelagic freezer trawlers and } 32 \% \text { pelagic RSW trawlers })
$$

## Effects of the fisheries on the ecosystem

Herring fisheries tend to be clean with little bycatch of other fish. Scottish discard observer programmes since 1999 indicate that discarding of herring in these directed fisheries are at a low level. These discard observer programmes have recorded occasional catches of seals and zero catches of cetaceans.

## Quality considerations

The assessment is considered to be noisy, but unbiased. Area misreporting continues to be a problem, with almost all countries taking catches of herring in other areas and reporting it into Division VIa (North). However, routine use of VMS has reduced the problem.

Figure 5.4.30.2 Herring in Division VIa North. Historical assessment results (final year recruitment estimates included).

| Zero catch | 0 | 98.9 | $\mathrm{~F}=0$ | 0 | 120.8 | $+22 \%$ | $-100 \%$ |
| Status quo | 18.0 | 88.3 | $\mathrm{Fsq}_{\mathrm{sq}} * 0.725$ | 0.193 | 94.3 | $+7 \%$ | $-20 \%$ |
|  | 22.5 | 85.6 | $\mathrm{~F}_{\mathrm{sq}}{ }^{*} 0.925$ | 0.246 | 88.3 | $+3 \%$ | $0 \%$ |
|  | 27.0 | 82.8 | $\mathrm{~F}_{\mathrm{sq}} * 1.14$ | 0.303 | 82.3 | $-1 \%$ | $+20 \%$ |

Weights in ' 000 tonnes.
${ }^{1)}$ For autumn-spawning stocks, the SSB is determined at spawning time and is influenced by fisheries between 1 January and spawning.
${ }^{2)}$ SSB 2013 relative to SSB 2012.
${ }^{3)}$ Landings 2012 relative to TAC 2011.

## Management plan

The EU management plan (Council Regulation (EC) 1300/2008) is based on the following rule;

| SSB in the year of the TAC | Fishing mortality | Maximum TAC variation |
| :---: | :---: | :---: |
| SSB $>75000 \mathrm{t}$ | $\mathrm{F}=0.25$ | $20 \%$ |
| $\mathrm{SSB}<75000 \mathrm{t}$ | $\mathrm{F}=0.2$ | $20 \%$ |
| $\mathrm{SSB}<62500 \mathrm{t}$ | $\mathrm{F}=0.2$ | $25 \%$ |
| $\mathrm{SSB}<50000 \mathrm{t}\left(\mathrm{B}_{\mathrm{lim}}\right)$ | $\mathrm{F}=0$ | - |

Following the agreed management plan implies a TAC of 22900 t in 2012 which is expected to lead to a TAC increase of $2 \%$.

A similar management plan was evaluated by ICES in 2005 and found to be consistent with the precautionary approach. In 2008 ICES checked that the recent changes in stock dynamics and the changes to the plan had not significantly increased the risks.

## MSY approach

Following the ICES MSY framework implies fishing mortality at $\mathrm{F}_{\text {MSY }}=0.25$, resulting in landings of less than 22900 t in 2012. This is expected to lead to an SSB of 87700 t in 2013 . As no MSY $\mathrm{B}_{\text {trigger }}$ has been identified for this stock, the ICES MSY framework has been applied with $\mathrm{F}_{\mathrm{MSY}}$ without consideration of SSB in relation to $\mathrm{MSY} \mathrm{B}_{\text {triger }}$.

## Additional considerations

## Ecosystem changes

A recent study (Hammond and Harris, 2006) of seal diets off western Scotland revealed that grey seals may be an important predator for herring in this area. The numbers of seals in Division VIaN is thought to have increased over the last decades. Because the consumption of herring by seals is estimated with great uncertainty, the impact on the stock cannot be estimated accurately.

## Fishing patterns and fishing technology changes

Prior to 2006 there was a fairly even seasonal and spatial distribution of effort. Since 2006 the majority of the fishery takes place in quarter 3 north of the Hebrides and to the north of Scotland.

## Uncertainties in assessment and catch options

The assessment is noisy, leading to annual revisions of SSB and F. The management plan has been designed to cope with this by applying a constraint on year-on-year change in TAC. Revisions in SSB can be upwards or downwards, so it is important to maintain the restrictions on change in TAC both when the stock is revised upwards or downwards. Asymmetrical responses have not been tested and may be significantly more risky.

The stock identity of herring west of the British Isles was reviewed by the EU-funded project WESTHER. This identified Division VIa (North) as an area where catches comprise a mixture of fish from Divisions VIa (North), VIa (South) and VIIb,c, and VIIaN. If there is an increasing catch on the mixed fishery in Division VIa (North), this should be considered in the management of the Division VIaS and VIIb,c component, which is in a depleted state. In 2008 ICES began to evaluate management for this Division VIa (South) and VIIb,c and VIIa (North). ICES is working to achieve an assessment take mixing into account.

## Comparison with previous assessment and advice

$\operatorname{SSB}(2010)$ was revised downwards by $35 \%$ and $\mathrm{F}(2009)$ upwards by $6 \%$ this year compared to last year.
The basis for the advice is the same as last year.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK Norway pout in Division VIa

## Advice for 2012

There is insufficient information to evaluate the status of stock. Therefore, based on precautionary considerations, ICES advises that no increase of the catches should take place unless there is evidence that this will be sustainable.

## Stock status

| $\qquad$ F (Fishing Mortality) |  |

## ECOREGION STOCK

## Celtic Sea

Nephrops in Division VIa
Nephrops are limited to a muddy habitat. This means that the distribution of suitable sediment defines the species distribution and the stocks are therefore assessed as three separate functional units (FU) (Figure 5.4.33.1),

| Section | FU no. | Name | ICES area | Statistical rectangles |
| :--- | :--- | :--- | :--- | :--- |
| 5.4 .33 .1 | 11 | North Minch | VIa | $44-46$ E3-E4 |
| 5.4 .33 .2 | 12 | South Minch | VIa | $41-43$ E2-E4 |
| 5.4 .33 .3 | 13 | Firth of Clyde + Sound of Jura | VIa | $39-40$ E4-E5 |

Figure 5.4.33.1 Nephrops functional units in Subarea IV and Division VIIa (see Section 5.4.34).

## Advice for 2012

The advice for Nephrops stocks is given by functional units in Sections 5.4.33.1-3. A summary can be found in Table 5.4.33.1.

There is no information available on the trends in the stock or exploitation status for the rectangles outside the FUs ('other rectangles') for which ICES provides advice. Advice for the FUs in Division VIa has slightly increased. On the basis of precautionary considerations, ICES advises that the catches in the other rectangles should not increase.

Table 5.4.33.1 Nephrops in Division VIa. Summary of ICES advice by functional unit plus other rectangles.

| Year | Predicted landings corresponding to ICES advice |  |  |  |  |  | $\begin{aligned} & \text { Agreed } \\ & \text { TAC }^{1)} \end{aligned}$ | ICES landings |

${ }^{2)}$ Effort should not be increased.
${ }^{3)}$ ICES advises that stocks should be managed by functional unit.
${ }^{4)}$ ICES advises that the catches in the other rectangles should not increase.

## Biology

Nephrops is limited to a muddy habitat and requires sediment with a silt and clay content of between $10 \%$ and $100 \%$ to excavate its burrows. This means that the distribution of suitable sediment defines the species distribution. Adult Nephrops only undertake very small scale movements (a few 100 m ), but larval transfer may occur between separate mud patches in some areas. Catches typically consist of a lower proportion of females than males due to the lower burrow emergence (resulting in lower catchability) of females during the egg bearing. It is likely that maximum stock size and fishery potential is constrained by the available space since the species competes for space and there are upper limits on density.

## Environmental influence on the stock

Temperature and hydrographic factors are critical to recruitment success in Nephrops, particularly during the larval phase. Different environmental factors such as sediment type and hydrography result in very different population structure, productivity, and vulnerability to fishing.

## Effects of the fisheries on the ecosystem

There is a bycatch of other species in the Nephrops fisheries in Division VIa. This bycatch reflects the species associated with muddy sediments. Estimates of discards of whiting and haddock are high in Division VIa. Bycatches of cod are low and the Scottish Conservation Credits Scheme is in place to minimize cod catches. The use of creels for Nephrops fishing has increased in inshore areas in Division VIa FUs. Discards and bycatch in the creel fisheries are considered to be low. The high mud content and soft nature of Nephrops grounds means that trawling readily marks the seabed, with trawl marks remaining visible for some time. Burrowing fauna can be seen re-emerging from freshly trawled grounds, implying that there is some resilience to trawling.

## Additional considerations

## MSY approach for stocks with UWTV surveys

No precautionary reference points have been defined for Nephrops. Under the new ICES MSY framework, exploitation rates which are likely to generate high long-term yield (and low probability of overfishing) have been evaluated and proposed for each functional unit. Owing to the way Nephrops are assessed, it is not possible to estimate $\mathrm{F}_{\text {MSY }}$ directly and hence proxies for $\mathrm{F}_{\text {MSY }}$ have been determined. Three stock-specific candidates for $\mathrm{F}_{\text {MSY }}\left(\mathrm{F}_{0.1}, \mathrm{~F}_{35 \% \text { SPR }}\right.$, and $\left.\mathrm{F}_{\max }\right)$ were derived from a length-based per recruit analysis (these may be modified following further data exploration and analysis). Then an appropriate $\mathrm{F}_{\mathrm{MSY}}$ candidate was selected for each functional unit independently, taking into account the following factors: observed burrow density, harvest rates, stability in stock size, knowledge of biological parameters (including factors affecting recruitment), and the nature of the fishery. The table below illustrates the framework against which stocks were evaluated and appropriate $\mathrm{F}_{\text {MSY }}$ proxies chosen. In general, $\mathrm{F}_{35 \% \text { SPR }}$ was used unless there were stockspecific justifications for either higher or lower harvest ratios.

|  |  | Burrow density (average burrows $\mathrm{m}^{-2}$ ) |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\begin{aligned} & \text { Low } \\ & <0.3 \end{aligned}$ | Medium $0.3-0.8$ | $\begin{gathered} \text { High } \\ >0.8 \end{gathered}$ |
| Observed harvest rate or landings compared to stock status | $\begin{aligned} & \hline>\mathrm{F}_{\max } \\ & \mathrm{F}_{\max }-\mathrm{F}_{0.1} \\ & <\mathrm{F}_{0.1} \\ & \text { Unknown } \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline \mathrm{F}_{35 \% \text { SPR }} \\ & \mathrm{F}_{0.1} \\ & \mathrm{~F}_{0.1} \\ & \mathrm{~F}_{0.1} \\ & \hline \end{aligned}$ | $\mathrm{F}_{\text {max }}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ <br> $\mathrm{F}_{0.1}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ | $\mathrm{F}_{\text {max }}$ <br> $\mathrm{F}_{\text {max }}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ |
| Stock size estimates | Variable Stable | $\begin{aligned} & \mathrm{F}_{0.1} \\ & \mathrm{~F}_{0.1} \\ & \hline \end{aligned}$ | $\begin{aligned} & \mathrm{F}_{0.1} \\ & \mathrm{~F}_{35 \% \mathrm{SPR}} \\ & \hline \end{aligned}$ | $\begin{aligned} & \mathrm{F}_{35 \% \mathrm{SPR}} \\ & \mathrm{~F}_{\max } \\ & \hline \end{aligned}$ |
| Knowledge of biological parameters | Poor <br> Good | $\begin{aligned} & \hline \mathrm{F}_{0.1} \\ & \mathrm{~F}_{35 \% \text { SPR }} \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline \mathrm{F}_{0.1} \\ & \mathrm{~F}_{35 \% \mathrm{SPR}} \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline \mathrm{F}_{35 \% \mathrm{SPR}} \\ & \mathrm{~F}_{\max } \\ & \hline \end{aligned}$ |
| Fishery history | Stable spatially and temporally <br> Sporadic <br> Developing | $\begin{aligned} & \mathrm{F}_{35 \% \mathrm{SPR}} \\ & \mathrm{~F}_{0.1} \\ & \mathrm{~F}_{0.1} \\ & \hline \end{aligned}$ | $\mathrm{F}_{35 \% \text { SPR }}$ <br> $\mathrm{F}_{0.1}$ <br> $\mathrm{F}_{35 \% \mathrm{SPR}}$ | $\mathrm{F}_{\text {max }}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ <br> $\mathrm{F}_{35 \% \text { SPR }}$ |

There may be strong difference in relative exploitation rates between the sexes in many stocks. To account for this, values for each of the candidates have been determined individually for males, females, and the two sexes combined. The combined sex $\mathrm{F}_{\text {MSY }}$ proxy should be considered appropriate, provided that the resulting percentage of virgin spawner-per-recruit for males or females does not fall below $20 \%$. If this happens a more conservative sex-specific $\mathrm{F}_{\text {MSY }}$ proxy should be picked instead of the combined proxy.

Where possible, a preliminary MSY $\mathrm{B}_{\text {triger }}$ was proposed based on the lowest observed UWTV abundance.

## Management considerations

The overriding management consideration for these stocks is that management should be at the functional unit rather than the ICES Subarea/Division level. Management at the functional unit level should provide the controls to ensure that catch opportunities and effort are compatible and in line with the scale of the resources in each of the stocks defined by the functional units. Current management of Nephrops in Subarea VI (both in terms of TACs and effort) does not provide adequate safeguards to ensure that local effort is sufficiently limited to avoid depletion of resources in functional units. In the current situation vessels are free to move between grounds, allowing effort to develop on some grounds in a largely uncontrolled way and this has historically resulted in inappropriate harvest rates from some parts.

Following changes to UK legislation in 2006, the reliability of UK landings data is considered to have significantly improved. Provided this is true and that it continues in the future, assessment scientists will eventually have data which could be used to parameterize dynamic stock assessment models, which in turn will allow direct estimation of $\mathrm{F}_{\text {MSY }}$ rather than having to rely on proxies. Until this point, the decision of which $\mathrm{F}_{\mathrm{MSY}}$ proxy is suitable for which FU will inherently be a subjective process, but the process outlined above should provide sufficient justification to support the decision.

There are also Nephrops catches in "other rectangles" in Division VIa, e.g. from offshore areas adjacent to Stanton Bank where Irish fishers frequently operate from the shelf edge. To provide some guidance on appropriate future landings for these areas, ICES advises that the catches in the other rectangles should not increase.

There are no functional units in ICES Division VIb, but occasional small Nephrops landings occur (Table 5.4.33.4).

## Factors affecting the fisheries and the stock

## Regulations and their effects

The minimum landing size for Nephrops is 20 mm carapace length (CL), and usually very few of the landed animals are under this size. The average discard rate of Nephrops by number over the last five years is $20 \%$. In 2009 the mesh size was increased from 70 mm to 80 mm .

Under the Scottish Conservation Credits Scheme and the west coast emergency measures, Nephrops trawlers are required to use more selective gears. However, these gears are designed to release fish and do not significantly improve selectivity of Nephrops. Under the EU Cod Recovery Plan, trawl effort in Division VIa has declined significantly. So far this has mainly affected effort in the larger mesh gears ( $>100 \mathrm{~mm}$ ) and effort in the Nephrops fisheries has been relatively stable.

## Scientific basis

## Data and methods

The assessment and advice for Nephrops stocks in Division VIa is primarily based on abundance estimates from underwater TV (UWTV) surveys together with fishery landings data and estimates of quantities of discards. Additional indicators of changes in stocks are derived from trends in length compositions and sex ratio in the catches. The assessment procedure involves the following steps:

- Total population numbers are estimated from the UWTV surveys, including adjustments for a range of biases associated with the method. WKNEPH (ICES, 2009) proposed that the UWTV surveys provide abundance estimates for Nephrops of 17 mm carapace length and over.
- Historical harvest ratios are calculated as the ratio of total catch numbers (landings and dead discards) to population numbers from the UWTV survey in each year.
- Recent fishery length compositions (landings and dead discards) are analysed using a length-based assessment model to estimate population numbers and fishing mortality at length for Nephrops of 17 mm carapace length and over. This method assumes that the length compositions are representative of a population at equilibrium. The analysis is done separately for males and females using stock-specific growth and maturity parameters.
- Yield-per-recruit and spawning biomass per recruit curves are derived for male and female Nephrops, based on fishery selectivity parameters from the length-based assessment model. The harvest ratios associated with potential $\mathrm{F}_{\text {MSY }}$ proxies (e.g. $\mathrm{F}_{0.1}, \mathrm{~F}_{\mathrm{MAX}}, \mathrm{F}_{35 \% \text { SPR }}$ ) are computed for males and females individually, and for both sexes combined. These are conditional on a fishery selectivity pattern that includes fishing mortality due to discarding of dead Nephrops in the years covered by the assessment model.

Catch options tables for 2011 are derived for a range of $\mathrm{F}_{\mathrm{MSY}}$ and other options by applying the appropriate harvest ratios to the population numbers estimate from the most recent UWTV survey. This assumes that population numbers remain stable in the interim year. Landings are derived from the resultant total catch numbers after multiplying by the recent average of proportion retained and the mean weight in the landings.

## Uncertainties in assessment and forecast

There is a gap of 18 months between the survey and the start of the year for which the assessment is used to set management levels. It is assumed that the stock is in equilibrium during this period (i.e. recruitment and growth balance mortality) although this is rarely the case. The effect of this on the accuracy of the catch forecast has not been investigated. The calculations of MSY proxies are all based on yield-per-recruit analyses from a length-based agestructured population model. These analyses utilize average length frequency data taken over a 3-year period and therefore assume that the stock is in equilibrium. However, it is unlikely that the Nephrops stocks to which the approach has been applied are actually in equilibrium due to variable recruitment. MSY proxies estimates may vary in time due to changes in selection pattern.

Stock monitoring continues, and enhanced work on observer trips on-board commercial vessels should furnish additional data which will be beneficial in further developing assessment approaches. Vessel monitoring data from satellite (VMS) are being successfully used to match survey and fishery areas for vessels $>15 \mathrm{~m}$.

The overall area of the ground is estimated by contoured sediment data. New VMS data linked to landings (through interrogation of the Scottish FIN system) suggest that not all areas are covered in the current UWTV approach and as such, the absolute abundance estimate for this ground is likely to be an underestimate. In the North Minch, the survey area in 2010 was extended to include the VMS distribution of fishing effort.

In the provision of catch options based on the absolute survey estimates additional uncertainties related to mean weight in the landings and the discard rates also arise. A three-year average of discard rates (2008-2010) has been used in the calculation of catch options. The discard rates for some stocks in Division VIa have been quite variable.

There were concerns over the accuracy of historical landings and effort data prior to 2006 when the "buyers and sellers" legislation was introduced and the reliability began to improve. Because of this the final assessment adopted is independent of official statistics. Harvest ratios since 2006 are also considered more reliable due to more accurate landings data reported under new legislation. The incorporation of creel length compositions since the 2010 assessment has also improved estimates of harvest ratios.

## ECOREGION Celtic Sea <br> STOCK

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 3200 t .
To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  | 20082009 | 2010 |
| MSY ( $\mathrm{F}_{\text {MSY }}$ ) | * 3 | ( Below target |
| Precautionary $\operatorname{approach}\left(\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\text {lim }}\right)$ | (?) | ? Not defined |
| SSB (Spawning-Stock Biomass) |  |  |
|  | 20092010 | 2011 |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | $\checkmark>$ | ( Above trigger |
| Precautionary approach $\left(\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}\right)$ | ? ? | ? Not defined |

Figure 5.4.33.1.1
Nephrops in North Minch (FU 11). Landings (tonnes), UWTV survey abundance (millions; SSB proxy), and harvest rate (fishing mortality proxy). Harvest rates before 2006 may be unreliable due to underreporting of landings. Green dashed lines represent MSY $\mathrm{B}_{\text {trigger }}$ and $\mathrm{F}_{\text {MSY }}$ harvest ratios.

The harvest ratios (dead removals/TV abundance) has fluctuated around the $\mathrm{F}_{\text {MSY }}$ proxy. The stock has been above MSY $B_{\text {trigger }}$ for more than 10 years.

## Management plans

No specific management objectives are known to ICES.

## Biology

The general biology of Nephrops is discussed in the overview (Section 5.4.33). The North Minch stock consistently exhibits medium densities compared to other stocks.

## The fisheries

The fishery has been fairly stable over the time-series, but a $35 \%$ drop in landings has been observed in 2010 which seems to be mainly related to market conditions. It is an all-year-round fishery and creel fishing takes place mainly in the sea-loch areas, but has recently extended also to further offshore. Overall effort in creel numbers is not known and measures to regulate the fishery are not in place.

Catch by fleet Total catch $(2010)=2384 \mathrm{t}$, where 2263 t are landings $(76 \%$ Nephrops trawl, $24 \%$ creel $)$ and 121 t discards.

## Effects of the fisheries on the ecosystem

There is a bycatch of other species, particularly haddock and whiting, in Nephrops fisheries in the North Minch.

## Quality considerations

Harvest ratios since 2006 are considered reliable due to more accurate landings data reported under new legislation. Incorporation of length compositions of creel catches has also improved estimates of harvest ratios. The survey area in 2010 was extended and now corresponds to the VMS distribution of fishing effort.

## Scientific basis

| Assessment type | UWTV and trends. |
| :--- | :--- |
| Input data | One survey index (UWTV-FU11). |
| Discards and bycatch | Discards included in the assessment. |
| Indicators | Size structure of catches. |
| Other information | Latest benchmark was performed in 2009. |
| Working group report | WGCSE |

ECOREGION Celtic Sea
STOCK
Nephrops in North Minch (FU 11)
Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY B trigger | 465 million <br> individuals | Bias-adjusted lowest observed UWTV survey estimate of <br> abundance |
|  | $\mathrm{F}_{\text {MSY }}$ | $12.5 \%$ harvest rate | Equivalent to $\mathrm{F}_{35 \% \text { SpR }}$ combined sex in 2010 |
|  | Not agreed |  |  |
|  | Not agreed |  |  |

(unchanged since: 2011)
MSY $B_{\text {trigger }}$ was revised to take account of VMS area and rescaling of the historic abundance estimates in 2011.
Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | :--- | :--- | :--- |
| $\mathrm{F}_{\max }$ | 12.2 | 37.2 | 16.6 |
| $\mathrm{~F}_{0.1}$ | 7.4 | 19.8 | 8.7 |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | 8.7 | 21.7 | 12.5 |

For this FU, the absolute density observed on the UWTV survey is medium ( $\sim 0.59$ burrow $/ \mathrm{m}^{2}$ ). Historical harvest ratios in this FU have been above that equivalent to fishing at $\mathrm{F}_{\text {max }}$ and landings have been relatively stable in the last thirty years. $\mathrm{F}_{35 \% \mathrm{SpR}}$ (combined between sexes) is expected to deliver high long term yield with a low probability of recruitment overfishing and therefore is chosen as a proxy for $\mathrm{F}_{\mathrm{MSY}}$.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate and MSY $\mathrm{B}_{\text {trigger }}$ values remain preliminary and may be modified following further data exploration and analysis.

Outlook for 2012
Basis: $\quad \mathrm{F}_{2011}=\mathrm{F}_{2010}=7.6$ \%; Bias corrected survey index $(2010)=1115$ million; Mean weight in landings $(08-10)=$ 26.16 g ; Dead discard rate $($ by number $)=11.2 \%$; Survey bias $=1.33$.

|  | Harvest <br> rate | Landings (tonnes) |
| :--- | :---: | :---: |
| $\mathrm{F}_{\mathrm{MSY}}$ | $12.5 \%$ | 3200 |
| $\mathrm{~F}_{2011}$ | $7.6 \%$ | 2000 |
| $\mathrm{~F}_{0.1}$ | $8.7 \%$ | 2300 |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | $12.5 \%$ | 3200 |
| $\mathrm{~F}_{\max }$ | $16.6 \%$ | 4300 |

## MSY approach

Following the ICES MSY framework implies the harvest ratio for the North Minch Functional Unit to be less than $12.5 \%$, resulting in landings less than 3200 t in 2012.

## Additional considerations

Mean sizes in the length compositions of catches (of individuals $>35 \mathrm{~mm} \mathrm{CL}$ ) are stable (Figure 5.4.33.1.2). Recent work using VMS has refined the estimate of the area. However, the survey should still be considered as a minimum estimate since areas of suitable sediment in the sea lochs are not included.

## Change in the fisheries

The Nephrops (TR2) fleet has been observed to have extremely high discard rates of haddock and whiting in recent years. The selectivity for this fleet needs to be improved.

In 2009, under the west coast emergency measures a square-meshed panel of 120 mm was required in the Nephrops trawlers and the minimum mesh size is now 80 mm . Twin-rig vessels tend to use a 200 mm square-meshed panel (with a 100 mm codend). This means that they do not catch bulk quantities and this leads to Nephrops of larger average size and quality suitable for storage using 'individual tubing'. Reported effort by all Scottish Nephrops trawlers has shown a gradual decreasing trend since 2002.

## Data and methods

Underwater TV (UWTV) surveys have been conducted for this stock since 1994, with annual surveys available since 1998. There is a gap of 18 months between the survey and the start of the year for which the assessment is used to set management levels. It is assumed that the stock is in equilibrium during this period (i.e. recruitment and growth balance mortality) although this is rarely the case. The effect of this assumption on precision of the catch forecast has not been investigated.

Anecdotal evidence from the fishing industry that some areas outside the "Sediment area" could be suitable ground for Nephrops were confirmed by new VMS data linked to landings and as such, the absolute abundance estimate was likely to be an underestimate. To account for this, the VMS area in the North Minch was used to generate the sampling stations for the 2010 survey and the burrow densities were raised accordingly. A correction ratio calculated as 1.41 (VMS area / Sediment area) was applied to back-calculate the abundance estimates in previous years.

## Uncertainties in the assessment and forecast

The discard rate has been highly variable in recent years and a large decline in discard rates in 2010 was observed. This introduces uncertainties in $\mathrm{F}_{\text {MSY }}$ estimates and catch forecast. The cumulative bias estimates for empty burrows for FU 11 are largely based on expert opinion. The precision of these bias corrections cannot yet be characterized.

As the VMS areas are calculated only for vessels of 15 m and over, the inclusion of vessels smaller than 15 m would likely increase the fished area in some of the inshore locations. It is known that most of the sea lochs have areas of mud substrate and are typically fished by creel boats. In recent years, limited TV surveys have taken place in some of the sea lochs and attempts are being made to utilize these data to improve estimates of mud area and Nephrops abundance.

## Comparison with previous assessment and advice

The basis for the advice is the same as last year. The survey area in 2010 was based on the VMS distribution of fishing effort (rather than the British Geological Survey sediment area estimate). Last year's advice was based on a transition to a $\mathrm{F}_{\text {MSY }}$ proxy, this year the harvest rate is below $\mathrm{F}_{\text {MSY }}$ and the advice is based on the MSY framework.

## ECOREGION Celtic Sea <br> STOCK <br> Nephrops in South Minch (FU 12)

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 5500 t .
To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

Figure 5.4.33.2.1 Nephrops in South Minch (FU 12). Long-term trends in landings (tonnes), UWTV survey (millions; SSB proxy; Confidence intervals $95 \%$ ), and harvest rate (fishing mortality proxy). Harvest rates before 2006 may be unreliable due to underreporting of landings. Green dashed lines represent MSY $\mathrm{B}_{\text {trigger }}$ and $\mathrm{F}_{\text {MSY }}$ harvest ratios.

The harvest ratios (dead removals/TV abundance) has fluctuated around the $\mathrm{F}_{\text {MSY }}$ proxy. The stock has been above MSY $\mathrm{B}_{\text {trigger }}$ the full time-series.

## Management plans

No specific management objectives are known to ICES.

## Biology

The general biology of Nephrops is discussed in the overview (Section 5.4.33). The South Minch stock consistently exhibits medium densities (compared to other stocks).

## The fisheries

Trawling is the predominant fishing method and fishing takes place all year round. The fishery has been fairly stable for the time-series and the recent decrease in landings seems to be mainly related to market conditions. Inshore trawlers are mainly small, but in the offshore areas of this FU larger boats operate. Creel fishing takes place mainly in inshore areas (including the sea-lochs), but has extended further offshore in recent years. Overall effort in creel numbers is not known and measures to regulate the fishery are not in place.

Catch by fleet Total catch $(2010)=3852 \mathrm{t}$, where 3725 t are landings ( $76 \%$ trawl, $24 \%$ creel ) and 127 t discards from the trawl fleet. Discards from the creel fishery are considered to be very low.

## Effects of the fisheries on the ecosystem

There is a bycatch of other species, particularly haddock and whiting, in the Nephrops fisheries in the South Minch. Bycatches of cod are low and the Scottish Conservation Credits Scheme is in place to minimize cod catches.

## Quality considerations

Harvest ratios since 2006 are considered reliable due to more accurate landings data reported under new legislation. Incorporation of creel length compositions has also improved estimates of harvest ratios.

## Scientific basis

| Assessment type | UWTV and trends. |
| :--- | :--- |
| Input data | One survey index (UWTV-FU12). |
| Discards and bycatch | Discards included in the assessment. |
| Indicators | Size structure of catches. |
| Other information | Latest benchmark was performed in 2009. |
| Working group report | WGCSE |

ECOREGION Celtic Sea
STOCK Nephrops in South Minch (FU 12)

Reference points

|  | Type | Value | Technical basis |
| :---: | :---: | :---: | :---: |
| MSY | MSY $\mathrm{B}_{\text {trigger }}$ | $\begin{array}{ll}1016 & \text { million }\end{array}$ | Bias-adjusted lowest observed UWTV survey estimate of abundance. |
| Approach | $\mathrm{F}_{\mathrm{MSY}}$ | 12.3\% harvest rate. | Equivalent to $\mathrm{F}_{35 \% \mathrm{SPR}}$ combined sex. |
| Precautionary | Not agreed. |  |  |
| Approach | Not agreed. |  |  |

(unchanged since: 2010)

Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | :--- | :--- | :--- |
| $\mathrm{F}_{\max }$ | 13.3 | 26.8 | 16.1 |
| $\mathrm{~F}_{0.1}$ | 7.8 | 13.8 | 8.7 |
| $\mathrm{~F}_{35 \%}$ | 9.6 | 18.3 | 12.3 |

For this FU, the absolute density observed on the UWTV survey is medium ( $\sim 0.44$ burrows $\mathrm{m}^{-2}$ ). The fishery in this area has been in existence since the 1960s. Historical harvest ratios in this FU have been variable, but generally around the $\mathrm{F}_{35 \% \text { SPR }} . \mathrm{F}_{35 \% \text { SPR }}$ (combined between sexes) is expected to deliver high long-term yield with a low probability of recruitment overfishing and is therefore chosen as a proxy for $\mathrm{F}_{\mathrm{MSY}}$.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate and MSY $\mathrm{B}_{\text {trigger }}$ values remain preliminary and may be modified following further data exploration and analysis.

## Outlook for 2012

Basis: $\quad \mathrm{F}_{2011}=\mathrm{F}_{2010}=7.4 \%$; Bias-corrected survey index $(2010)=2076$ million; Mean weight in landings (2008-2010) $=24.47 \mathrm{~g}$; Dead discard rate $($ by number $)=11.8 \%$; Survey bias $=1.32$.

|  | Harvest <br> rate | Landings (tonnes) |
| :--- | :--- | :---: |
| $\mathrm{F}_{\mathrm{MSY}}$ | $12.3 \%$ | 5500 |
| $\mathrm{~F}_{2011}$ | $7.4 \%$ | 3300 |
| $\mathrm{~F}_{0.1}$ | $8.7 \%$ | 3900 |
| $\mathrm{~F}_{35 \% \mathrm{SPR}}$ | $12.3 \%$ | 5500 |
| $\mathrm{~F}_{\max }$ | $16.1 \%$ | 7200 |

## MSY approach

Following the ICES MSY framework implies the harvest ratio for the South Minch functional unit to be less than $12.3 \%$, resulting in landings of less than 5500 t in 2012.

## Additional considerations

Mean sizes in the length compositions of catches (of individuals $>35 \mathrm{~mm} \mathrm{CL}$ ) are stable. Recent work comparing the area based on VMS and on sediment showed only a small difference between them and the original area of ground has been retained. However, the survey should still be considered as a minimum estimate since areas of suitable sediment in the sea lochs are not included.

## Change in the fisheries

The Nephrops (TR2) fleet has been observed to have extremely high discard rates of haddock and whiting in recent years. The selectivity for this fleet needs to be improved.

In 2009, under the west coast emergency measures a square-meshed panel of 120 mm was required in the Nephrops trawlers and the minimum mesh size is now 80 mm . Twin-rig vessels tend to use a 200 mm square-meshed panel (with a 100 mm codend), and some of them are slightly bigger than that. This means that they do not catch bulk quantities and this leads to Nephrops of larger average size and quality suitable for storage using 'individual tubing'. Reported effort by all Scottish Nephrops trawlers has shown a gradual decreasing trend since 2001.

## Data and methods

Underwater TV surveys have been conducted for this stock every year since 1995. Confidence intervals for the abundance estimates are on average greater in the most recent years, when abundance estimates have been slightly higher. The overlap of confidence intervals makes it difficult to determine which population changes are significant.

In the 2010 assessment, length frequencies from the trawl and creel components of the fishery were incorporated for the first time.

## Uncertainties in the assessment and forecast

The recent observed discard rate shows a decline in discards from 2008 coincident with an increase in the survey abundance and a further decrease in harvest rates in 2010. The cumulative bias estimates for FU 12 are largely based on expert opinion. The precision of these bias corrections cannot yet be characterized.

The overall area of the ground is estimated from the available British Geological Survey contoured sediment data and at present is considered to be a minimum estimate although the problem is less severe than in the North Minch. On average the area estimates for the sediment maps exceed those estimated for the VMS by a factor of around 1.1. The inclusion of vessels smaller than 15 m would likely increase the VMS area. On the other hand, it is known that most of the sea lochs have areas of mud substrate and are typically fished by creel boats, but not by the trawl fleet.

## Comparison with previous assessment and advice

The basis for the advice and the assessment method is the same as last year. Last year's advice was based on a transition to a $\mathrm{F}_{\text {MSY }}$ proxy, this year the harvest rate is below $\mathrm{F}_{\text {MSY }}$ and the advice is based on the MSY framework.

## ECOREGION Celtic Sea <br> STOCK

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 5100 t ( 4200 t for Firth of Clyde and 900 t for Sound of Jura).

Management of Nephrops should be implemented at the Functional Unit level. In this FU the two Subareas imply that additional controls maybe required to ensure that the landings taken in each Subarea are in line with the landings advice.

## Stock status

Figure 5.4.33.3.1 Nephrops in the Firth of Clyde (FU 13). Long-term trends in landings (tonnes), UWTV survey (in millions; SSB proxy), and harvest rate (fishing mortality proxy). Harvest rates before 2006 may be unreliable due to underreporting of landings. Green dashed lines represent MSY $B_{\text {trigger }}$ and $\mathrm{F}_{\text {MSY }}$ harvest ratios.

Harvest rates for Nephrops in the Firth of Clyde have been above the proposed $\mathrm{F}_{\text {MSy }}$ proxy since 2007 . UWTV abundance remains well above the MSY $\mathrm{B}_{\text {trigger }}$.

Figure 5.4.33.3.2
Nephrops in the Sound of Jura (FU 13). Long-term trends in landings (tonnes), UWTV survey (millions; SSB proxy), and harvest rate (fishing mortality proxy). Harvest rates before 2006 may be unreliable due to underreporting of landings. Green dashed line represents $\mathrm{F}_{\text {MSY }}$ harvest ratios.

Harvest rates for Nephrops in the Sound of Jura have been well below the proposed $\mathrm{F}_{\text {MSY }}$ proxy in recent years. UWTV abundance remains higher than observed at the start of the series, but the series is too short and patchy to propose a MSY $B_{\text {trigger }}$.

## Management plans

No specific management objectives are known to ICES.

## Biology

The general biology of Nephrops is discussed in the overview (Section 5.4.33). The Firth of Clyde stock consistently exhibits high densities (over 0.8 burrows $\mathrm{m}^{-2}$ ) compared with other stocks. The habitat in Firth of Clyde is a relatively continuous patch of muddy sediment apart from the sea lochs, while the Sound of Jura consists of a single patch of muddy sediment.

## The fisheries

Trawling is the predominant fishing method and fishing takes place all year round. The fishery has been fairly stable over the time-series. An increasing number of creel boats operate in the Clyde due to temporal and area bans on trawling. Nephrops discard rates from trawl fleets in this functional unit are high ( $33 \%$ by number on average over the past 10 years).

Catch by fleet Total catch (2010) in Firth of Clyde + Sound of Jura $=6161 \mathrm{t}$, where 5701 t are landings $(97 \%$ trawl, $3 \%$ creel) and 460 t discards from the trawl fleet. Discards from the creel fishery are considered to be very low.

## Effects of the fisheries on the ecosystem

There is a bycatch of other species, including cod, haddock and whiting in the Nephrops trawl fisheries in this functional unit. Bycatches of cod in the Clyde are generally low, but are higher than in other Division VIa FUs. This is an important area for cod spawning.

## Quality considerations

Harvest ratios since 2006 are considered reliable due to more accurate landings data reported under new legislation. Incorporation of creel length compositions has also improved estimates of harvest ratios.

| MSY | MSY $\mathrm{B}_{\text {trigger }}$ | 579 millions. | Lowest observed abundance estimate. |
| Approach | $\mathrm{F}_{\text {MSY }}$ | 16.4\% harvest rate. | Equivalent to $\mathrm{F}_{\text {max }}$ combined sex. |
| Precautionary | Not agreed. | Not defined. |  |
| Approach | Not agreed. | Not defined. |  |

(unchanged since 2010)
Reference points - Sound of Jura

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY <br> Approach | MSY B $_{\text {trigger }}$ | Not defined. |  |
|  | $\mathrm{F}_{\text {MSY }}$ | $14.5 \%$ harvest rate. | Equivalent to $\mathrm{F}_{35 \% \text { SPR }}$ combined sex. |
|  | Not agreed | Not defined. |  |
| Approach | Not agreed | Not defined. |  |

(unchanged since 2010)
Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | :--- | :--- | :--- |
| $\mathrm{F}_{\max }$ | 13.6 | 34.0 | 16.4 |
| $\mathrm{~F}_{0.1}$ | 8.7 | 21.1 | 9.7 |
| $\mathrm{~F}_{35 \%}$ | 10.7 | 25.7 | 14.5 |

For the Firth of Clyde subarea of this FU, the absolute density observed in the UWTV survey is generally high (over 0.8 burrows $\mathrm{m}^{-2}$ for the entire series and around 1.0 burrows $\mathrm{m}^{-2}$ for the last 5 years), suggesting that the stock has relatively high productivity. The fishery in this area has been in existence since the 1960s and the population and biological parameters have been studied numerous times. Historical harvest ratios in this FU have been generally high at or above $\mathrm{F}_{\text {max }} . \mathrm{F}_{\text {max }}$ is considered an appropriate $\mathrm{F}_{\text {MSY }}$ proxy and is expected to deliver high long-term yield with a low probability of recruitment overfishing.

For the Sound of Jura subarea of this FU, the absolute density observed on the UWTV survey is generally high (over 0.8 burrows $\mathrm{m}^{-2}$ for the entire series and around 1.0 burrows $\mathrm{m}^{-2}$ for the last 5 years), suggesting that the stock has relatively high productivity. The fishery in this area has been sporadic over its history and effort and landings have been low in the last decade. The population and biological parameters have been studied numerous times, but the time-series of UWTV data are more fragmented and sampling is at a relatively low level. A more cautious $\mathrm{F}_{35 \% \mathrm{SPR}}$ is considered an appropriate $\mathrm{F}_{\text {MSY }}$ proxy for this stock.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate values and MSY $\mathrm{B}_{\text {trigger }}$ remain preliminary and may be modified following further data exploration and analysis.

## Outlook for 2012

## Firth of Clyde

Basis: $\quad \mathrm{F}_{2011}=\mathrm{F}_{2010}=17.5 \%$; Bias-corrected survey index $(2010)=1750$ million; Mean weight in landings $(2008-2010)=18.56 \mathrm{~g}$; Discard rate (by number) $=$ $25.3 \%$; Survey bias $=1.19$.

|  | Harvest <br> rate | Landings (tonnes) |
| :--- | :---: | :---: |
| $\mathrm{F}_{\text {MSY }}$ | $16.4 \%$ | 4000 |
| $\mathrm{~F}_{\text {MSY transition }}$ | $17.1 \%$ | 4200 |
| $\mathrm{~F}_{0.1}$ | $9.7 \%$ | 2400 |
| $\mathrm{~F}_{35 \% \text { SPR }}$ | $14.5 \%$ | 3500 |
| $\mathrm{~F}_{\max }$ | $16.4 \%$ | 4000 |
| $\mathrm{~F}_{2010}$ | $17.5 \%$ | 4200 |

## Sound of Jura

Basis: $\quad \mathrm{F}_{2011}=\mathrm{F}_{2010}=1.1 \%$; Bias-corrected survey index $(2010)=376$ million; Mean weight in landings $(2008-2010)=21.44 \mathrm{~g}$; Discard rate (by number) $=$ $25.3 \%$; Survey bias $=1.19$.

|  | Harvest <br> rate | Landings (tonnes) |
| :--- | :---: | :---: |
| $\mathrm{F}_{\mathrm{MSY}}$ | $14.5 \%$ | 900 |
| $\mathrm{~F}_{0.1}$ | $9.7 \%$ | 600 |
| $\mathrm{~F}_{35 \% \text { SPR }}$ | $14.5 \%$ | 900 |
| $\mathrm{~F}_{\max }$ | $16.4 \%$ | 1000 |
| $\mathrm{~F}_{2010}$ | $1.1 \%$ | 70 |

## MSY approach

Following the ICES MSY framework implies the harvest ratio for the Firth of Clyde subarea to be reduced to less than $16.4 \%$, resulting in landings of less than 4000 t in 2012. Following the transition scheme towards the ICES MSY framework implies the harvest ratio for the Firth of Clyde should be reduced to less than $17.1 \%$ ( 0.6 x harvest $\operatorname{ratio}\left(\mathrm{F}_{2010}\right)+0.4 \mathrm{x}$ harvest ratio $\left.\left(\mathrm{F}_{\mathrm{MSY}}\right)\right)$, resulting in landings of less than 4200 t in 2012.

Following the ICES MSY framework implies the harvest ratio for the Sound of Jura subarea to be less than 14.5\%, resulting in landings of less than 900 t in 2012. For the Sound of Jura no transition is needed as the harvest rate is already below the $\mathrm{F}_{\text {MSY }}$ proxy.

## Additional considerations

An increasing number of creel boats operate in the Clyde. Creeling activity often takes place during the weekend when the trawlers are not allowed to fish. One third of the creelers operate throughout the year, the rest prosecute a summer fishery.

A seasonal closure to protect spawning cod is in place, but there is derogation for the Nephrops fleet and the Scottish Conservation Credits Scheme is in place to minimize cod catches.

## Data and methods

Underwater TV surveys have been conducted for the Firth of Clyde subarea every year since 1995. Confidence intervals around the abundance estimates are stable throughout the series and relatively low compared with other FUs in Division VIa. Underwater TV surveys for the Sound of Jura subarea have been more fragmented and sampling is at a relatively low level; confidence intervals are larger.

In the 2010 assessment, length frequencies from the trawl and creel components of the fishery were incorporated for the first time.

## Uncertainties in assessment and forecast

Discard rates have fluctuated over the time-series and are in 2010 estimated to be at the lowest level in the last 10 years. Mean weight has fluctuated without trends over the time-series. These uncertainties are not taken into account in the forecast. The cumulative bias estimates for the FU 13 Clyde and Jura component are largely based on expert opinion. The precision of these bias corrections cannot yet be characterized.

Yield-per-recruit analysis is not yet available for the Sound of Jura subarea, therefore F proxies from the Firth of Clyde have been used.

The overall area of the ground is estimated from the available British Geological Survey contoured sediment data and at present may be a minimum estimate. However, examination of VMS data shows close correspondence with the area estimated by sediment. In the Clyde, the underestimated sea loch areas are relatively small, when compared with other FUs of Division VIa.

## Comparison with previous assessment and advice

The basis for the advice and the assessment method is consistent with last year.

## ECOREGION STOCK

## Celtic Sea

## Nephrops in Subarea VII

Nephrops are limited to a muddy habitat and the distribution of suitable sediment defines the species distribution. The stocks are assessed as six separate Functional Units (FU) as shown in Figure 5.4.34.1. There are also some smaller catches from areas outside these Functional Units.

| Section | FU no. | Name | ICES <br> Divisions | Statistical rectangles |
| :--- | :--- | :--- | :--- | :--- |
| 5.4 .34 .1 | 14 | Irish Sea East | VIIa | $35-38 \mathrm{E} 6 ; 38 \mathrm{E} 5$ |
| 5.4 .34 .2 | 15 | Irish Sea West | VIIa | $36 \mathrm{E} 3 ; 35-37$ E4-E5; 38E4 |
| 5.4 .34 .3 | 16 | Porcupine Bank | VIIb,c,j,k | $31-35$ D5-D6; 32-35 D7-D8 |
| 5.4 .34 .4 | 17 | Aran Grounds | VIIb | $34-35$ D9-E0 |
| 5.4 .34 .5 | 19 | Ireland SW and SE coast | VIIa,g,j | $31-33$ D9-E0; 31E1; 32E1-E2; 33E2-E3 |
| 5.4 .34 .6 | $20-21$ and 22 | Celtic Sea | VIIg,h | $28-30$ E1; 28-31 E2; 30-32 E3; 31 E4 |

Figure 5.4.34.1
Nephrops Functional Units in Subarea VII (around Ireland). The TAC for Subarea VII applies to the area bounded by the red line. The FUs within the TAC area are shaded.

## Advice for 2012

The advice for Nephrops stocks is given by functional units in sections 5.4.34.1-6. A summary can be found in table 5.4.34.1.

There is no information available on the trends in the stock or exploitation status for FU18 and the rectangles outside the FUs ('other rectangles') for which ICES provides advice. Advice for the FUs in Subarea VIa have slightly increased. On the basis of precautionary considerations, ICES advises that the catches in the FU18 and other rectangles should not increase.

${ }^{6}$ ICES advises that the catches in the FU18 and other rectangles should not increase.

## Biology

Nephrops is limited to muddy habitat, and requires sediment with a silt and clay content of between $10-100 \%$ to excavate its burrows. This means that the distribution of suitable sediment defines the species distribution. Adult Nephrops only undertake very small scale movements (a few 100 m ) but larval transfer may occur between separate mud patches in some areas. This makes some stocks, particularly those with lower average density, vulnerable to localised depletion. Catch rates and composition vary daily and seasonally between different areas and sexes due to different emergence patterns and underlying population densities. After the onset of maturity male Nephrops grow faster and attain a large size than female. Density limits growth and grounds with high Nephrops density ( $>0.7 / \mathrm{m}^{2}$ ) have smaller average size that those with low density.

## Environmental influence on the stock

Temperature and hydrographic factors, particularly during the larval phase are critical to recruitment success in Nephrops. Some stocks in Division VII such as FU15 have well known and understood larval retention mechanisms (i.e. Western Irish Sea Gyre). Other stocks such as the Porcupine Bank have less well understood larval retention mechanisms. This results in very different population structure, productivity and vulnerability to fishing. Increasing water temperature leading to shorter larval development times is thought to improve recruitment in areas such as the Irish Sea. Increased storminess related to the NAO has also been linked to reduced recruitment and low catch rates several years later on the Porcupine Bank.

## Effects of the fisheries on the ecosystem

Trawling for Nephrops results in bycatch and discards of other commercial species, including cod, haddock, whiting, hake, monkfish, and megrim. Given that 80 mm is the predominant mesh size used in Nephrops fisheries the resulting discard rates of small Nephrops and fish can be high.

The high mud content and soft nature of Nephrops grounds means that trawling readily marks the seabed, trawl marks remaining visible for some time. Despite the high intensity of fishing (some areas are impacted $>7$ times/year) burrowing fauna can be seen re-emerging from freshly trawled grounds, implying that there is some resilience to trawling.

## Additional considerations

The overriding management consideration for these stocks is that management should be at the Functional Unit rather than the ICES Subarea/Division level. Management at the Functional Unit level should provide the controls to ensure that catch opportunities and effort are compatible and in line with the scale of the resources in each of the stocks defined by the Functional Units.

Current management of Nephrops in Subarea VII (both in terms of TACs and effort) does not provide adequate safeguards to ensure that local effort is sufficiently limited to avoid depletion of resources in separate Functional Units. The current situation allows for catches to be taken anywhere in the TAC area and this could imply inappropriate harvest rates in some FUs. This appears to have been a particular problem in the Porcupine Bank where a large increase in effort occurred from 2002 up to 2007 and the stock declined substantially.

Landings from the northwest coast of Ireland NW (FU 18) have previously been treated as a separate Functional Unit although landings have been negligible in recent years and there is no major Nephrops fishery in that area. There are also Nephrops catches in other rectangles outside Functional Units in Subarea VII. There is no information available on the trends in the stock or exploitation status for FU18 and the rectangles outside the FUs ('other rectangles') for which ICES provides advice. Advice for the FUs in Subarea VII has slightly increased. On the basis of precautionary considerations, ICES advises that the catches in the other rectangles and FU18 should not increase.

Landings in recent years have been well below the TAC due to low uptake by France and Spain, whereas the UK and Irish landings are close to the quota.

## MSY approach

There are no precautionary reference points defined for Nephrops. Under the new ICES MSY framework, exploitation rates which are likely to generate high long-term yield (and low probability of stock overfishing) have been explored and proposed for each functional unit. Owing to the way Nephrops are assessed, it is not possible to estimate $\mathrm{F}_{\text {msy }}$ directly and hence proxies for $\mathrm{F}_{\mathrm{MSY}}$ are determined. Three candidates for $\mathrm{F}_{\mathrm{MSY}}$ are $\mathrm{F}_{0.1}, \mathrm{~F}_{35 \% \mathrm{SpR}}$ and $\mathrm{F}_{\text {max }}$. There may be strong difference in relative exploitation rates between the sexes in many stocks. To account for this, values for each of the candidates have been determined for males, females and the two sexes combined. The appropriate $\mathrm{F}_{\text {MSY }}$ candidate has been selected for each Functional Unit independently according to the perception of stock resilience, factors affecting recruitment, population density, knowledge of biological parameters and the nature of the fishery (relative exploitation of the sexes and historical harvest rate $v s$ stock status).

A decision making framework based on the table below was used in the selection of preliminary stock specific $\mathrm{F}_{\text {MSY }}$ proxies. These may be modified following further data exploration and analysis. The combined sex $\mathrm{F}_{\mathrm{MSY}}$ proxy should be considered appropriate provided that the resulting percentage of virgin spawner per-recruit for males or females does not fall below $20 \%$. In such a case a more conservative sex specific $\mathrm{F}_{\text {MSY }}$ proxy should be picked over the combined proxy.

|  |  | Burrow Density (average burrow/ $\mathrm{m}^{2}$ ) |  |  |

Preliminary MSY $\mathrm{B}_{\text {trigger }}$ reference points were proposed at the lowest observed UWTV abundance. However, the time series of surveys in Subarea VII are too short for that. For FU 15 where a longer series of survey trawl cpue was available this has been used to estimate a preliminary MSY $\mathrm{B}_{\text {trigger }}$.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Landings by some fleets prior to 2007 are thought to have been underreported. The implementation of the 'Buyers and Sellers' legislation in the UK in 2006 and 'sales notes' in Ireland in 2007, coupled with the increased TAC in 2007, is thought to have improved the reliability of reported landings data. The transition has been accompanied by a large change in reported landings and a significant recent increase in landings per unit effort (lpue) for some countries that cannot completely be attributed to changes in the stock.

## Scientific basis

## Data and methods

The assessments and advice for Nephrops stocks in Functional Units 14 and 15 (Irish Sea), 17 (Aran), and 22 (the Smalls) are primarily based on abundance estimates from under-water TV (UWTV) surveys together with fishery landings data and estimates of quantities of discards. Additional indicators of changes in stocks are derived from trends in length compositions and sex ratio in the catches, fishery lpue, and (for FU15) trawl survey catch rates. The assessments and advice for FU 16 (Porcupine Bank) and FU 20-21 (Celtic Sea) are based on a range of indicators of stock trends including fishery lpue, trawl survey catch-rates, size compositions and sex ratio.

For FUs 14, 15, 17, and 22, the following procedure is adopted for providing assessment and advice based on UWTV survey estimates:

- Total population numbers are estimated from the UWTV surveys, including adjustments for a range of biases associated with the method. WKNEPH (ICES, 2009) proposed that the UWTV surveys provide abundance estimates for Nephrops of 17 mm carapace length and over.
- Historical harvest ratios are calculated as the ratio of total catch numbers (landings and dead discards) to population numbers from the UWTV survey in each year.
- Recent fishery length compositions (landings and dead discards) are analysed using a length-based assessment model to estimate population numbers and fishing mortality at length for Nephrops of 17 mm carapace length and over. This method assumes that the length compositions are representative of a population at equilibrium. The analysis is done separately for males and females using stock-specific growth and maturity parameters.
- Yield-per-recruit and spawning biomass-per-recruit curves are derived for male and female Nephrops, based on fishery selectivity parameters from the length-based assessment model. The harvest ratios associated with potential $\mathrm{F}_{\mathrm{MSY}}$ proxies (e.g. $\mathrm{F}_{0.1}, \mathrm{~F}_{\max }, \mathrm{F}_{35 \% \mathrm{SPR}}$ ) for males, females and both sexes combined are computed. These are conditional on a fishery selectivity pattern that includes fishing mortality due to discarding of dead Nephrops in the years covered by the assessment model.

Catch options tables for 2012 are derived for a range of $\mathrm{F}_{\text {MSY }}$ and other options by applying the appropriate harvest ratios to the population numbers estimate from the most recent UWTV survey. This assumes the population numbers
remain stable in the interim year. Landings are derived from the resultant total catch numbers after multiplying by the recent average value for proportion retained and mean weight in the landings.

## Uncertainties in assessment and forecast

ICES expert groups in preparation of the benchmark of UWTV assessments (ICES, 2009) have worked to reduce uncertainty and increase precision in the interpretation of survey data. Despite these improvements, there remains a requirement for expert knowledge in the production of bias factors applied to UWTV abundance estimates and these were last estimated in 2009. As further research is conducted and better understanding of the UWTV process is gained, these bias estimates will require revision.

In the provision of catch options based on the survey estimates additional uncertainties related to mean weight in the landings and to the discard rates also arise. The procedure outlined in WKNEPH (ICES, 2009) is to use a multi-annual average to dampen variability. The variability in mean weight and discarding is a key uncertainty in the derivation of catch options. Improved quality of fishery data and knowledge of growth rates are needed for development of analytical assessment models and improvement of MSY reference points.

There is a gap of 16-18 months between the survey and the start of the year for which the assessment is used in management advice. It is assumed that the stock is in equilibrium during this period (i.e. recruitment and growth balance mortality) although this is rarely the case. The effect of this assumption on realised harvest rates has not been investigated. The calculations of harvest ratio and reference points $F_{0.1}$ and $F_{\max }$ are all based on yield-per-recruit analyses. In addition, important assumptions are made on growth, natural mortality and discard rates in the derivation of reference points.

Trends in lpue data are subject to uncertainties as a measure of stock abundance due to changes in fishing practices.

## ECOREGION Celtic Sea <br> STOCK <br> Nephrops in Irish Sea East (FU14)

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 960 t .
To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

Landings - International

Figure 5.4.34.1.1 Nephrops, Irish Sea East (FU14): Long-term trends in landings (in tonnes), UWTV survey abundance with $95 \%$ confidence limits (in millions; SSB proxy) and harvest rate (green dashed line is $\mathrm{F}_{\text {MSY }}$ proxy).

There is not a long enough time series to determine a candidate for MSY $\mathrm{B}_{\text {trigger }}$. Current harvest rate is below the $\mathrm{F}_{\text {MSY }}$ proxy.

## Management plans

No specific management objectives are known to ICES.

## Biology

The Eastern Irish Sea stock is of a relatively low mean density ( $\sim 0.3$ burrows $/ \mathrm{m}^{2}$ ) and is limited to two discrete areas of muddy sediment. The main part of the stock sits between the Isle of Man and the Cumbrian coast of England with a smaller patch in Wigtown Bay off the south coast of Scotland. Whilst females are carrying their eggs their emergence rate from burrows is much reduced. Males are limited in their geographical range for finding mates, hence low densities of males can have a significant impact upon stock spawning potential.

## The fisheries

The fleet is made of around 30 English vessels almost entirely single otter trawling and around 40 generally larger Northern Irish vessels over half of which fish multi-rig trawls. The multi riggers take around $1 / 3$ of the landings. 80 mm cod ends are commonly used for both types of trawl. The fishery takes place mainly in spring and early summer, when male Nephrops predominate.

Catch by fleet Total landings (2010): 563 t ( $32 \%$ twin rig otter trawls, $67 \%$ single otter trawl). Additional discards estimated at $28 \%$ by number.

## Effects of the fisheries on the ecosystem

The Nephrops trawl fishery takes bycatches of other species, especially plaice, but also, whiting and cod.

## Quality considerations

The survey series commenced in 2007. Because of reduced discard sampling in 2009 the discard rate and catch composition for 2009 is uncertain. No reliable length composition is available from 2010.

## ECOREGION Celtic Sea

STOCK

## Nephrops in Irish Sea East (FU14)

## Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY <br> Approach | MSY B $_{\text {trigger }}$ | Not defined | No available reference. UWTV time series too short. |
|  | $\mathrm{F}_{\text {MSY }}$ | Harvest <br> ratio $9.8 \%$ | Equivalent to $\mathrm{F}_{0.1}$ for combined sexes. |
| Precautionary <br> Approach | Not defined |  |  |

(unchanged since: 2011)

Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | ---: | ---: | ---: |
| $\mathrm{F}_{\max }$ | $15.8 \%$ | $17.4 \%$ | $16.4 \%$ |
| $\mathrm{~F}_{0.1}$ | $9.6 \%$ | $10.2 \%$ | $9.8 \%$ |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | $12.5 \%$ | $13.5 \%$ | $13.0 \%$ |

Compared to other Nephrops stocks in the ICES area the absolute population density of this stock appears relatively low (around $0.3 / \mathrm{m}^{2}$ ) in a highly seasonal male dominant fishery. The area covered by this fishery is relatively small and the confidence intervals for the abundance estimate are large for a geostatistical survey. The annual variability of lpue for the smaller individuals in the catch, suggest that recruitment to this fishery is quite variable. However, the fishery appears to have been sustainable with harvest rates below $\mathrm{F}_{0.1}$. In this instance, therefore, the use of $\mathrm{F}_{0.1}$ as a proxy for $\mathrm{F}_{\text {MSY }}$ (for the combined sexes) is considered appropriate as it will should deliver high long term yield with a low probability of recruitment over-fishing.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate values are considered preliminary and may be modified following further data exploration and analysis.

## Outlook for 2012

Basis: F2011 =F2008-10 $=7.4 \%$, Bias corrected survey index $(2010)=469$ million, Mean weight in landings (2006-08) $=28.9 \mathrm{~g}$, and retention factors ( $72.1 \%$ ) based on 2006-2008 sampling.

| Basis | Harvest rate <br> $(\%)$ | Landings 2012 <br> (tonnes) |
| :--- | :---: | :---: |
| Closure | $0 \%$ | 0 |
| $\mathrm{~F}_{\mathrm{sq}}$ | $7.4 \%$ | 700 |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | $13 \%$ | 1270 |
| MSY framework | $9.8 \%$ | 960 |
| $\mathrm{~F}_{\max }$ | $16.4 \%$ | 1600 |

## MSY approach

Following the ICES MSY framework implies the harvest ratio to be no more than $9.8 \%$, resulting in landings of 960 t in 2012.

## Additional considerations

The Nephrops trawl fishery takes by-catches of other species, especially plaice, but also, whiting and cod. Selectivity of this fishery needs to be improved to reduce bycatches of cod, whiting and undersized plaice

The fishery peaks in summer. Some UK vessels temporarily relocate, targeting the Farn Deeps Nephrops fishery on the east coast of England for the winter months.

## The effects of regulations

The cod recovery measures introduced in 2000 includes effort limitations. The cod long-term plan was introduced in 2009 (EC 1342/2008). Annual effort in Nephrops trawl fisheries (Effort group TR2 OTB 70-99 mm) in Division VIIa as a whole has been reduced by $25 \%$ in 2009 and a further $25 \%$ in 2010. However, Nephrops effort is free to move between FUs and therefore the effect of this regulation may not be restrictive on a FU basis.

## Changes in fishing technology and fishing patterns

In contrast to the overall effort reductions in Division VIIa, effort in FU 14 has remained relatively stable since 2001. Fuel prices have affected the choice of gears. Despite reasonable catch rates some skippers are less inclined to go to sea unless they can guarantee to cover their costs. This might bias the lpues as a measure of stock abundance.

## Uncertainties in assessment and forecast

General comments are made at the start of section 5.4.34.
The short time series of more reliable commercial data and UWTV surveys means that biological reference points for this stock are imprecise.

Uncertainties in the survey, mean weight in the landings and discard rates are not taken into account in the advice.

## Comparison with previous assessment and advice

In the 2010 advice for the fishery in 2011 the evaluation was based on trends in population indicators and catch options derived from short time series of UWTV surveys. The present assessment is based on revised survey data. The present advice for the fishery in 2012 is based on the MSY approach adopting $\mathrm{F}_{0.1}$ as an $\mathrm{F}_{\text {MSY }}$ proxy.

FU $15:$ International Landings

Figure 5.4.34.2.1 Nephrops in Irish Sea West (FU 15). Long-term trends in landings (tonnes), recent UWTV abundance (in millions; SSB proxy) (with scaled trawl survey cpue) and harvest rates (prior to 2007 the harvest rate is considered to be a minimum estimate due to possible under-reporting of landings. The horizontal lines represent MSY $B_{\text {trigger }}$ (upper panel) $\mathrm{F}_{\text {MSY }}$ (lower panel).

This stock has sustained landings at around 9000 t for many years. The stock increased until 2003, based on information from the NI-NEP-Trawl-Summer survey (Figure 5.4.34.2.4). Since then, the stock has decreased, but is still at high levels and above MSY $B_{\text {trigger }}$. Recent harvest rates have fluctuated around $\mathrm{F}_{\mathrm{MSY}}$.

## Management plans

No specific management objectives are known to ICES.

## Biology

Nephrops in the Western Irish Sea occur at very high density (average 1.1 burrow $/ \mathrm{m}^{2}$ ) and have a smaller average size and size at maturity than most other stocks. The high observed density implies intense competition for space and food on the sea bed. This is thought to make the stock resilient to high fishing pressure.

## Environmental influence on the stock

The environment in the Western Irish Sea is very suitable for Nephrops with a large mud patch and gyre which retains the larvae over the mud patch thus ensuring good recruitment. Nephrops are a major food species of cod in the Irish Sea.

## The fisheries

Gears used are a mixture of single and twin-rig otter trawls. A around $16 \%$ of Irish vessels are using separator trawls and Swedish grids to reduce bycatch.

$$
\text { Catch by fleet } \quad \text { Total catch (2010) } 10.7 \mathrm{kt} \text { where } 9.0 \mathrm{kt} \text { landings ( }>99 \% \text { otter trawls), } 1.5 \mathrm{kt} \text { discards. }
$$

## Effects of the fisheries on the ecosystem

The Nephrops trawl fisheries take bycatches of other species, especially juvenile whiting, haddock and cod.

## Quality considerations

The assessment is mainly based on an UWTV survey which is considered to be very precise but various uncertainties and assumptions do arise in the estimation by expert judgement of the bias correction factor. In the provision of catch options based on the survey estimates additional uncertainties related to mean weight in the landings and to the discard rates also arise. Harvest ratios since 2006 are considered reliable due to more accurate landings data reported under new legislation.

Scientific basis

| Assessment type | UWTV and trends, catch options based on UWTV and Fs from per-recruit analysis |
| :--- | :--- |
| Input data | One survey index (UWTV (FU 14 \&15) |
|  | One trawl survey index (NI-NEP-Trawl-Summer) |
| Discards and bycatch | Discards included in the assessment |
| Indicators | Size structure of catches, sex ratio and lpue |
| Other information | Latest benchmark was performed in 2009 |
| Working group report | WGCSE |

## ECOREGION Celtic Sea

STOCK
Nephrops in Irish Sea West (FU 15)

## Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY B $_{\text {trigger }}$ | 3 billion individuals | Minimum abundance observed based in a scaled trawl <br> survey |
|  | $\mathrm{F}_{\text {MSY }}$ | HR 17.1\% | Equivalent to $\mathrm{F}_{\max }$ for combined sexes in 2010. |
|  | Not defined |  |  |

(unchanged since 2010).
Yield and spawning biomass per Recruit F-reference points (2010):
Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | :---: | :---: | :---: |
| $\mathrm{F}_{\max }$ | $17.1 \%$ | $17.1 \%$ | $17.1 \%$ |
| $\mathrm{~F}_{0.1}$ | $11.0 \%$ | $10.2 \%$ | $10.6 \%$ |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | $14.1 \%$ | $12.7 \%$ | $13.4 \%$ |

Density of Nephrops in FU15 is considered very high (average density $1.1 / \mathrm{m}^{2}$ ),. Recent harvest rates have been high ( $>\mathrm{F}_{\text {max }}$ ) and the stock size has been stable at a high level. The stock has sustained landing around 9000 t for more than 35 years and knowledge of the biological parameters in the stock is good. The exploitation rate between the sexes is similar. A harvest ratio consistent with a combined sex $F_{\text {max }}$ of $17.1 \%$ is suggested as a proxy for $F_{\text {MSY }}$. A preliminary MSY $B_{\text {trigger }}$ has been estimated using the longer time series of survey trawl cpue.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate values are considered preliminary and may be modified following further data exploration and analysis.

## Outlook for 2012

Basis: $\mathrm{F}_{2011}=\mathrm{F}_{2010}=15 \%$, Bias corrected survey index (2010) $=5.0$ billion, Mean weights in landings $(2009-10,16.5 \mathrm{~g})$ and retention factors (70\%) based on 2009-2010 sampling.

|  |  |  |
| :--- | :---: | :---: |
| Basis | Harvest ratio | Landings 2012 (tonnes) |
| MSY framework | $17.1 \%$ | 9800 |
| $\mathrm{~F}_{2011}$ | $15.0 \%$ | 8600 |
| $\mathrm{~F}_{0.1}$ | $11.0 \%$ | 6300 |
| $\mathrm{~F}_{35 \%}$ | $13.4 \%$ | 7700 |

## MSY approach

Following the ICES MSY framework implies a harvest ratio to be less than $17.1 \%$, resulting in landings of 9800 t in 2012.

## Additional considerations

The Nephrops trawl fishery takes bycatches of other species, especially plaice, but also, whiting and cod. Selectivity of this fishery needs to be improved to reduce bycatches of cod, whiting and undersized plaice

The FU15 Nephrops fishery first developed in the late 1950s. Since then it has sustained landings of around 9000 t for more than 35 years. The environment in the Western Irish Sea is very suitable for Nephrops with a large mud patch and gyre which retains the larvae over the mud patch thus ensuring good recruitment. The ground can be characterised as
an area of very high densities of small Nephrops. All available information indicates that size structure of catches appears to have changed little since the fishery first began.

## Regulations and their effects

The cod long-term plan was introduced in 2009 (EC 1342/2008). Annual effort baselines in Nephrops trawl fisheries (Effort group TR2 OTB $70-99 \mathrm{~mm}$ ) in Division VIIa has been reduced by $25 \%$ in 2009 and a further $25 \%$ in 2010 . Irish effort in 2010 decreased by $23 \%$ relative to 2008 , UK-NI effort in 2010 is similar to 2008. Since 2009, four Irish vessels have been using "Swedish grids" in the fishery to reduced bycatches of cod, whiting and haddock.

The minimum landing size for Nephrops is 20 mm carapace length (CL), and less than $5 \%$ of the animals landed are under sized. Highgrading of Nephrops from FU15 since 2009 has increased.

Nephrops vessels are derogated to fish in designated parts of the cod closed area (early spring) in the western Irish Sea.

## Uncertainties in assessment and forecast

General comments are found at the start of section 5.4.34.
Uncertainties in the survey, in mean weight in the landings and in discard rates are not taken into account in the advice. Mean weights in the landings and discard rates are based on 2008-2010 sampling by Northern Ireland and Ireland.

The harvest ratio prior to 2006 maybe underestimated due to underreporting of landings.
The calculation of harvest ratio and reference points $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\max }$ are based on yield-per-recruit analyses and biological parameters estimated assuming the stock is in equilibrium. However, it is unlikely that the Nephrops in FU15 is equilibrium due to variable recruitment. In addition, important assumptions are made on growth, natural mortality and discard rates in the derivation of reference points.

## Comparison with previous assessment and advice

The assessment in 2011 is based on trends in population indicators and catch options derived from UWTV surveys as last year. The advice for 2012 is based on the MSY approach adopting $\mathrm{F}_{\max }$ as an appropriate $\mathrm{F}_{\text {MSY }}$ proxy as last year.

## ECOREGION STOCK

## Celtic Sea

Nephrops on Porcupine Bank (FU 16)

## Advice for 2012

ICES advises on the basis of precautionary considerations that catches in 2012 should not increase to allow the stock to rebuild.

To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

Figure 5.4.34.3.1 Nephrops, on the Porcupine Bank (FU16): Left, top; ICES landings over the years, bottom; standardised (scaled to mean by index) lpues by fleet (bottom). Right, top; Trends in an exploitation proxy for this stock (this is derived from the slope of the length-frequency for male Nephrops between carapace lengths of 41-56 mm which are considered fully selected in the fishery), middle; Trends over the years in biomass (in kg/haul) (top), bottom; abundance (individuals/haul) from the Sp-PGFS-WBITS-Q4 survey.

Effort, landings and size distribution indicate that exploitation rate has been high in the last 7 years. Survey information indicates that recruitment to the fishery has been very weak between 2004 and 2008 and the stock declined to a low level. The average recruitment observed in the 2009 survey has resulted in increased abundance and biomass in 2010. The fisheries lpue in 2010 is influenced by the seasonal closure introduced between May-July 2010.

## Management plans

No specific management objectives are known to ICES.

## Biology

Nephrops on the Porcupine Bank are fished in relatively deep waters occurring over a fairly widespread area at relatively low abundance. There is a wide variation in size structure of the catches spatially and temporally. Given the sedentary nature of Nephrops populations closed areas may be an appropriate management tool to recover the stock. The switch in sex ratio in landings and catches in 2007-2009 may be the result of over exploitation of the male component of the stock leading to sperm limitation in those years. The sex ratio in 2010 has switched back to a more usual situation where males account for the majority of the catches.

## Environmental influence on the stock

Productivity of deep water Nephrops stocks is generally lower than those on the shelf although individual Nephrops grow to relatively large sizes and attain high market prices. Other deep water Nephrops stocks off the Spanish and Portuguese coast have collapsed and have been subject to recovery measures for several years, e.g. FUs 25, 26, 27 and 31. Increased storminess related to the NAO has been linked to reduced recruitment and low lpues several years later on the Porcupine Bank (González Herraiz et al, 2009).

## The fisheries

The fishery takes place throughout the year with a peak between April and July. A seasonal closure was introduced between May-July 2010 that covers much of the stock distribution area. Most vessels are relatively large (between 20 and 35 m in total length) multi-purpose otter trawlers using single or twin rigs. Freezing of catches at sea has become increasingly prevalent since 2006.

Catch by fleet Total catch $(2010)>917 \mathrm{t}$ where 917 t landings $(100 \%$ otter $)$ and minimal discards.

## Effects of the fisheries on the ecosystem

Fishing effort directed at Nephrops will also have bycatches of hake, megrim, and anglerfish in mixed fisheries.

## Quality considerations

The survey series is short but gives consistent indications of recent changes in the stock. Landings length frequency data for all countries involved in the fishery have been very sparse in recent years. This influences the calculation of exploitation and recruitment proxies. There are concerns about the accuracy of the catch statistics and lpue information in some fleets. Growth rates cannot be well determined. Analytical assessments are not feasible at present.

## ECOREGION Celtic Sea <br> STOCK

## Reference points

No reference points are defined for this stock.

## Outlook for 2012

The assessment is based on several indicators, including survey cpue, commercial lpue, size and sex ratio. All of these indicate that the stock has decline to a very low abundance in 2008. The improved recruitment observed in the 2009 survey catches has resulted in a stock size increase for the first time in several years.

## Precautionary considerations

Effort, landings and size distribution data indicate that the stock is overfished. Biomass has increased in the last year. Therefore, catches should not increase to allow the stock to rebuild.

## Additional considerations

The Nephrops trawl fishery takes by-catches of other species, especially plaice, but also, whiting and cod. Selectivity of this fishery needs to be improved to reduce bycatches of cod, whiting and undersized plaice

The closure introduced between May and July 2010 was respected by the fleet. It has therefore afforded some protection to the majority of the stock area ( $\sim 75 \%$ ). For this part of the stock area fishing effort and mortality will have been reduced at a time of peak female emergence and typically high lpue and landings. The closure will also have inadvertently concentrated effort and fishing mortality $\sim 25 \%$ of the stock area not currently covered by the closure.

Nephrops on the Porcupine Bank are fished in relatively deep waters over a widespread area where they occur at low abundance. Given the sedentary nature of Nephrops populations the closure of the Porcupine bank for fisheries (1 May - 31 July) as introduced in 2010 (EC Reg. 53/2010) may be an appropriate management tool to substantially reduce catches and allow the stock to recover.

Productivity of deep water Nephrops stocks is generally lower than that in shelf waters, though individual Nephrops grow to relatively large sizes and attain high market prices. Other deep water Nephrops stocks off the Spanish and Portuguese coast have collapsed and have been subject to recovery measures for several years e.g. FUs 25, 26, 27 and 31. Recruitment in Nephrops populations in deep water may be more sporadic than for shelf stocks with strong larval retention mechanisms. This makes these stocks more vulnerable to over exploitation and potential recruitment failure as has been observed on the Porcupine Bank over the last decade.

Landings per unit effort (lpue) show a generally declining trend in most fleets over the time-series available. Mean size indicators in all commercial fleets and a survey indicate a large increase in mean size for both sexes in the past six years. There has been a large change in sex ratio in the survey catches and fishery landings with females Nephrops accounting for a larger proportion. Landings in $2009 \sim 825 \mathrm{t}$ are the lowest observed since the development for the fishery.

## Changes in fishing technology and fishing patterns

In the past the Nephrops fishery on the Porcupine Bank was both seasonal and opportunistic with increased targeting during periods of high Nephrops emergence and good weather. Freezing of catches at sea has become increasingly prevalent since 2006 and the fishery now operates throughout the year, mainly targeting larger Nephrops in lower volumes. Fishing effort has fluctuated considerably in the recent past in response to availability of Nephrops.

## Uncertainties in assessment and forecast

Large differences are seen in the length compositions from different countries, this could indicate different selection patterns or different high grading practices between fleets, but is more likely to be because of spatial differences in size structure. Nevertheless all data shows a similar trend to larger size over the last decade due to poor recruitment. International landed length distributions are used to calculate the exploitation and recruitment proxies. Several uncertainties are associated with this approach, particularly the poor levels of catch sampling.

The size distribution and catch rates in fishery-independent survey confirm the weak recent recruitment (except 2009) and decline in stock abundance up to 2008.

The increase in the length based proxy for exploitation rate coincides with an increase in effort and landings. There are concerns about the accuracy of the lpue information in some fleets due to change fishing practices. Growth rates cannot be well determined. Analytical assessments or catch forecasts are not feasible at present.

## Comparison with previous assessment and advice

The assessment and advice is based on similar indicators to last year. The 2010 data confirm a good recruitment for the first time in several years. The survey abundance indices show a stock increase to the highest levels observed in the last decade.

The advice last year was to reduce catches to the lowest possible level. The advice this year is less stringent because of the recent increase in stock size.

## ECOREGION Celtic Sea <br> STOCK Nephrops on Aran Grounds (FU 17)

## Advice for 2012

ICES advises on the basis of the MSY approach that landings in 2012 should be no more than 1100 t .
To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

FU 17: International Landings FU 17: TV abundance

Figure 5.4.34.4.1 Nephrops on Aran Grounds (FU 17). Long-term trends in landings (in tonnes), UWTV abundance (in millions; SSB proxy) and harvest rates ( $\mathrm{F}_{\text {MSY }}$ proxy shown as the broken green line).

The UWTV surveys conducted since 2002 give estimates of abundance that have fluctuated widely without a significant trend. The generally low harvest rate ( $9 \%$ average) appears to have little impact on observed stock fluctuations and is below $\mathrm{F}_{\text {MSY }}$.

## Management plans

No specific management objectives are known to ICES.

## Biology

The Aran grounds can be characterised as an area of relatively high density of small Nephrops. The sex ratio in the catches has a strong seasonal pattern.

## Environmental influence on the stock

The larval retention mechanisms on the Aran grounds are not well understood, but fluctuations in UWTV burrow abundance may reflect quite variable recruitment relative to other areas in Subarea VII.

## The fisheries

Landings and effort of twin rig vessels has increased to over $90 \%$ of the fishery. In the last few years the fishery has exploited more of the male component of the stock as a higher proportion of catches have been taken in the autumn.

Catch by fleet Total catch (2010) 1.2 kt where 1.0 kt landings ( $99 \%$ otter trawls, $1 \%$ other gear-types), 0.2 kt discards

## Effects of the fisheries on the ecosystem

Nephrops fisheries in this area also have catches of hake, megrim and monkfish.

## Quality considerations

Uncertainties in the survey, mean weight in the landings and discard rates are not taken into account in the advice.

## Scientific basis

| Assessment type | UWTV and trends of the size structure of catches |
| :--- | :--- |
| Input data | One survey index (UWTV-FU17), size structure of catches |
| Discards and bycatch | Discards are included in the assessment |
| Indicators | Sex ratio and lpue |
| Other information | Latest benchmark was performed in 2009 |
| Working group report | WGCSE |

ECOREGION Celtic Sea
STOCK Nephrops on Aran Grounds (FU 17)
Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY <br> Approach | MSY B $_{\text {trigger }}$ | Not defined |  |
|  | $\mathrm{F}_{\text {MSY }}$ | HR $10.5 \%$ | Equivalent to $\mathrm{F}_{35 \% \text { SPR }}$ for combined sex in 2010 |
| Precautionary <br> Approach |  |  | No reference points are defined |

(unchanged since: 2010)

Harvest ratio reference points (2010):

|  | Male | Female | Combined |
| :--- | :---: | :---: | ---: |
| $\mathrm{F}_{\max }$ | $9.8 \%$ | $13.0 \%$ | $11.1 \%$ |
| $\mathrm{~F}_{0.1}$ | $6.4 \%$ | $9.1 \%$ | $7.2 \%$ |
| $\mathrm{~F}_{35 \% \mathrm{SpR}}$ | $8.4 \%$ | $12.8 \%$ | $10.5 \%$ |

Density of Nephrops in FU17 is considered high (average density $0.9 / \mathrm{m}^{2}$ ), recent harvest rates have been low and the stock size has been fluctuating. For this FU, the exploitation rate on males is usually higher than on females. A harvest ratio consistent with a combined sex $\mathrm{F} 35 \% \mathrm{SpR}$ of $10.5 \%$ is suggested as a proxy for $\mathrm{F}_{\mathrm{MSY}}$.

All $\mathrm{F}_{\text {MSY }}$ proxy harvest rate values are considered preliminary and may be modified following further data exploration and analysis.

## Outlook for 2012

Basis: F2011 = F2010 = 8.3\%; Bias corrected survey index (2010) $=827$ million, Mean weights in landings (2008$2010,24.5 \mathrm{~g}$ ) and retention factors based ( $70 \%$ ) on 2008-10 sampling.

| Basis | Harvest ratio | Landings <br> 2012 <br> (tonnes) |
| :---: | :---: | :---: |
| MSY framework | $10.5 \%$ | 1100 |
| $\mathrm{~F}_{0.1 \text { Combined }}$ | $7.2 \%$ | 800 |
| $\mathrm{~F}_{2011}$ | $8.3 \%$ | 900 |
| $\mathrm{~F}_{35 \% \text { Combined }}$ | $10.5 \%$ | 1100 |
| $\mathrm{~F}_{\max \text { Combined }}$ | $11.1 \%$ | 1200 |

## MSY approach

No MSY $\mathrm{B}_{\text {trigger }}$ has been identified for this FU. Hence the ICES MSY framework has been applied only in relation to

## Additional considerations

The Nephrops trawl fishery takes bycatches of other species, especially plaice, but also, whiting and cod. Selectivity of this fishery needs to be improved to reduce bycatches of cod, whiting and undersized plaice

## Changes in fishing technology and fishing patterns

In recent years several newer vessels specialising in Nephrops fishing have participated in this fishery. These vessels target Nephrops on several other grounds within the TAC area and move around to optimise catch rates. Since the introduction of effort management associated with the cod long term plan (EC 1342/2008) there have been concerns that effort could be displaced towards the Aran and other Nephrops grounds where effort control has not been put in
place. Effort decreased in 2009 due to decommissioning of several vessels that actively participated in the fishery but effort in 2010 increased again.

## Uncertainties in assessment

Some general uncertainties are discussed in section 5.4.34.

New UWTV survey information should be available after June 2011 which will provide a more up to date prognosis of stock status. The use of the most up to date survey information will be evaluated by ICES, and if appropriate this advice might be revised during this year.

There are several uncertainties in the survey, mean weight in the landings and discard rates which are not taken into account in the advice. The Separable Cohort Analysis (SCA) and yield per recruit analysis was based on 2008 and 2009 sampling, the fit to the SCA model was problematic so $\mathrm{F}_{\mathrm{MSY}}$ proxies are likely to be uncertain.

## Comparison with previous assessment and advice

The assessment and advice basis is consistent with last year.

## ECOREGION Celtic Sea <br> STOCK <br> Nephrops off the south-eastern and south-western coasts of Ireland (FU 19)

## Advice for 2012

ICES advises on the basis of the precautionary considerations that catches in 2012 should be reduced.
To protect the stock in this functional unit, management should be implemented at the functional unit level.

## Stock status

| F (Fishing Mortality) |  |  |
| :---: | :---: | :---: |
|  |  | 2008-2010 |
| MSY ( $\mathbf{F}_{\text {MSY }}$ ) | ? | Unknown |
| Precautionary approach ( $\mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\text {lim }}$ ) | $?$ | Unknown |
| SSB (Spawning Stock Biomass) |  |  |
|  |  | 2008-2010 |
| MSY ( $\mathbf{B}_{\text {trigger }}$ ) | ? | Unknown |
| Precautionary approach ( $\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}$ ) | (?) | Unknown |
| Qualitative evaluation | $\Leftrightarrow$ | Stable |

Landings per unit effort (Ipue)

Figure 5.4.34.5.1 Nephrops off the south-eastern and south-western coasts of Ireland (FU 19): Long-term trends in landings (tonnes) top left. Fishing effort by all Irish Nephrops targeting vessels (solid line) and vessels $>18 \mathrm{~m}$ total length (dashed line) top right. Landings per unit effort (lpue, $\mathrm{kg} / \mathrm{hr}$ ) for all Nephrops targeting vessels (solid line) and those $>18 \mathrm{~m}$ total length (dashed line) bottom right.

The available information is insufficient to evaluate the exploitation status. Commercial landing per unit effort (lpue) has fluctuated without trend since 1995. Therefore, the state of the stock is considered stable.

## Management plans

No specific management objectives are known to ICES.

## Biology

This area has numerous small and spatially distinct mud patches. Survey information indicates consistent differences in mean length in catches between mud patches, suggesting variable population densities and growth. Sampling of commercial landings shows large variations in size because of this.

## The fisheries

This is mainly an otter trawl fishery using single and twin-rigs and cod end mesh size of $80-99 \mathrm{~mm}$.
Catch by fleet Total catch (2010) 700 t where 700 t landings $(98 \%$ otter trawls, $2 \%$ other gear-types), and unknown discards.

## Effects of the fisheries on the ecosystem

Nephrops fisheries in this area have bycatches of megrim, hake and monkfish.

## Quality considerations

Lpue data are the only available indicator of stock trend. The accuracy of this is uncertain because of changes in fleet composition, targeting behaviour, fishing patterns and the patchy distribution of Nephrops within this area.

## Scientific basis

| Assessment type | Survey trends |
| :--- | :--- |
| Input data | Landings, effort and lpue |
| Discards and bycatch | Unknown |
| Indicators | Mean size in landings. Historical survey indicators (UK-WCGFS) discontinued since 2006 |
| Other information | None |
| Working group report | WGCSE |

## ECOREGION Celtic Sea <br> STOCK <br> Nephrops off the south-eastern and south-western coasts of Ireland (FU 19)

## Reference points

No reference points are defined for this stock.

## Outlook for 2012

No assessment can be presented for this stock.

## Precautionary considerations

The exploitation status is unknown and stock trends indicators have been stable. Therefore, ICES considers that catches should be reduced.

## Additional considerations

Nephrops fisheries in this area are fairly mixed also landing megrim, anglerfish, haddock and other demersal species. The main discarded species are haddock, whiting and dogfish."

Comparison with previous assessment and advice
The perception of the stock has not changed. The advice in 2010 was based on the transition to the MSY approach and precautionary considerations. This year the advice is based on precautionary considerations.

## ECOREGION Celtic Sea <br> STOCK <br> Nephrops in the Celtic Sea (FU 20-22)

## Advice for 2012

ICES advises on the basis of the MSY approach that landings from FU22 in 2012 should be no more than 2300 t. For the remaining areas FU20-21 ICES advise on the basis of precautionary considerations that landings should be reduced.

To protect the stock in these functional units, management should be implemented at the functional unit level.

## Stock status

FU 20-21

| SSB (Spawning Stock Biomass) |  |  |
| :---: | :---: | :---: |
|  | 2008-2010 |  |
| MSY ( $\mathrm{B}_{\text {trigger }}$ ) | ? | Unknown |
| Precautionary <br> approach ( $\mathrm{B}_{\mathrm{pa}}, \mathrm{B}_{\text {lim }}$ ) | (?) | Unknown |
| Qualitative information | $\bigcirc$ | Stable |

FU 22

Figure 5.4.34.6.1 Nephrops in the Celtic Sea (FU 20-22). Long-term trends landings (t) for the whole area and from FU 22 since 1999 (grey bars) (top left). Nephrops directed fishing effort by country and total Nephrops directed effort (top right). Mean standardise lpue indices for Ireland FU 22 and FU 20-21 and France for FU 20-22 (mainly operating in FU20-21 during the last decade) (bottom right).

The status of the FU20-21 component of the stock is unknown. Landings are stable and the effort by the French and Irish fleets are showing opposite direction, respectively downward and upward. Overall, the effort is steadily decreasing since the early 90 's. The lpues of the French and Irish fleets in this area, although variable, are very similar over the last 5 years (when the figures may be compared since the French fleet has mainly operated in FU20-21 during that period). The lpues alternate period of increasing and decreasing trends, so that the overall perception is mainly stability.

Figure 5.4.34.6.2 Nephrops in the Celtic Sea (FU 22). Recent international landings in tonnes for FU22 (Smalls) (top left); UWTV survey abundance for FU 22 (top right, proxy for SSB), and harvest rate (green dashed line represents $\mathrm{F}_{\mathrm{MSY}}$ harvest ratio) (bottom right).
The FU 22 stock component is considered to be stable based on indicators (lpue, mean size) and recent UWTV survey data. There have been indications of strong recruitment in recent years (e.g. 2006) as underlined by the Irish UWTV survey in 2006 and by commercial lpue for Irish in 2007 and for French trawlers in 2008 and 2009 (Figure 5.4.34.6.1).

## Management plans

No specific management objectives are known to ICES.

## Biology

This area has several distinct mud patches. Survey information indicates consistent differences in mean size of catches between mud patches, suggesting variable population densities and growth. Sampling of commercial landings shows large variations in size between areas within FU20-22.

## The fisheries

The fishery is prosecuted by twin and single trawlers. Landings are almost exclusively (more than $90 \%$ ) provided by France and Republic of Ireland.

Catch by fleet Total catch (2010) 4.62 kt landings ( $100 \%$ trawling); total discards 1.23 kt

## Effects of the fisheries on the ecosystem

Nephrops fishery in Celtic Sea has bycatches of whiting, cod, and to a lesser extent haddock and hake.

## Quality considerations

Discards are thought to be extensive, but observations are insufficient to provide a reliable time-series.

## ECOREGION <br> STOCK

Celtic Sea
Nephrops in the Celtic Sea (FU 20-22)

## Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :---: | :--- |
| MSY <br> Approach | MSY B $_{\text {trigger }}$ | Not defined |  |
|  | $\mathrm{F}_{\text {MSY }}$ (whole FU20-22) <br> harvest rate | Not defined |  |
|  | $\mathrm{F}_{\text {MSY }}$ (FU22) harvest rate | $10.9 \%$ | MSY under SCA model |
| Precautionary <br> Approach |  | Not defined |  |

(updated in 2011)
For FU 22, the absolute density observed on the UWTV survey is medium ( $\sim 0.5 / \mathrm{m}^{2}$ ) suggesting the stock has moderate productivity. The fishery in this area has been in existence since the 1960's and has been relatively stable for many years. Recent harvest ratios in this FU have been variable but generally around the $\mathrm{F}_{35 \% \mathrm{SpR}} . \mathrm{F}_{35 \% \mathrm{SpR}}$ (combined between sexes) is expected to deliver high long term yield with a low probability of recruitment overfishing and therefore is chosen as the FU22 F ${ }_{\text {MSY }}$ proxy.

For FU 20 and 21 it is not possible to currently estimate an $\mathrm{F}_{\text {MSY }}$ proxy.
All $\mathrm{F}_{\text {MSY }}$ proxies remain preliminary and may be modified following further data exploration and analysis. The time series is too short to propose a MSY $\mathrm{B}_{\text {trigger }}$.

## Outlook for 2012

There is no analytical assessment or UWTV survey for FU 20-21 and it is therefore not possible to provide catch options for 2012.

Catch options can be proposed for the Smalls (FU 22) based on an UWTV survey and sampling for that component of the stock.

FU 22: Basis: $\mathrm{F}_{2011}=\mathrm{F}_{2010}=10.9 \%$; bias corrected survey index (2010) $=1.1$ billion; mean weights in landings (2009-10, 23.2 g ) and retention factors based ( $80 \%$ ) on 2009-2010 sampling.

| Basis | Harvest ratio | Landings 2012 <br> in the Smalls (FU 22) <br> (tonnes) |
| :---: | :---: | :---: |
| MSY framework | $10.9 \%$ | 2300 |
| $\mathrm{~F}_{2011}$ | $10.9 \%$ | 2320 |
| $\mathrm{~F}_{0.1}$ | $7.5 \%$ | 1580 |
| $\mathrm{~F}_{35 \%}$ | $10.9 \%$ | 2300 |
| $\mathrm{~F}_{\max }$ | $12.3 \%$ | 2600 |

## MSY approach

Following the ICES MSY framework implies the harvest ratio for the Smalls FU22 to be less than 10.9 \%, resulting in landings of less than 2300 t in 2012.

## Precautionary considerations

Considering the recent stable lpues and unknown exploitation status for FU20 and 21, catches should be reduced.

## Additional considerations

The Nephrops trawl fishery take bycatches of other species, especially whiting, much of which is discarded. Any measure to reduce discarding and to improve the fishing pattern would be beneficial to the whiting stock (see section 5.4.6).

In 2010, French official landings reached the lowest historical level mainly due to the strong reduction of the number of vessels because of European decommissioning schemes. Fishing effort in this fleet has declined more than $70 \%$ since early-1990. This fleet operates mainly in FU 20-21. The Irish effort has increased over time mainly in FU 22. Irish landings declined between 2008 and 2009 although they changed upwards in 2010. However, information on mean sizes in landings, discard rate, abundances provided by UWTV survey suggest no major change in the status of this stock.

French Nephrops trawlers usually switch to finfish (cod, whiting, and haddock) when Nephrops catch rates are low. This can occur within a trip (e.g. because of diurnal variations of catchability for Nephrops) making the analysis of catches of fish from so-called Nephrops trips difficult. An analysis of the catch composition on a haul by haul basis is needed to estimate the actual amount of by-catch and discards really caught in Nephrops-directed activity.

## The effects of regulations

The minimum EU landing size (MLS) for Nephrops in this area is 8.5 cm of total size ( 25 mm CL), whereas French Producers' Organizations adopted for a long time a specific regulation of 11.5 cm of total size ( 35 mm CL). This has led to discarding of Nephrops above the legal minimum landing size by the French fleet. The proportion of individuals landed as tails in French landings increased significantly over the recent period (up to $20 \%$ in the late 2000s). These are mainly individuals below 35 mm (CL) which would have been discarded previously. French fleet use mesh size 100 mm , and Irish fleet 80 mm .

## Uncertainties in assessment and forecast

The discards observations are insufficient to provide a full time-series of discards.
There are several key uncertainties and bias sources in the method base on UWTV survey used for projections in FU22. The survey estimates themselves are very precisely estimated (CVs 2-6\%) given the homogeneous distribution of burrow density and the modelling of spatial structuring. The cumulative bias estimates for FU22 are largely based on expert opinion. The precision of these bias corrections cannot yet be characterised, but is likely to be lower than that observed in the survey.

In the provision of catch options based on the absolute survey estimates additional uncertainties related to mean weight in the landings and the discard rates also arise. For FU22 deterministic estimates of the mean weight in the landings and discard rates for 2008-2010 are used although there is some variability in these over time. Particularly when large recruitments are observed in the stock as was the case in 2006 and 2007.

## Comparison with previous assessment and advice

This year the assessment was extended to make use of the FU22 UWTV survey to provide catch options for that component of the stock. The basis of the advice is precautionary considerations for FU20-21 and MSY approach for FU22.

## ECOREGION Celtic Sea and West of Scotland <br> STOCK <br> Sole in Divisions VIIh-k

## Advice for 2012

ICES advises on the basis of precautionary considerations that catches in 2012 should not increase.

Figure 5.4.35.1 Sole in Divisions VIIh-k. Official landings in tonnes.
The state of sole stock biomass in Divisions VIIh-k is unknown. However, exploratory estimates of mortality suggest that the current fishing mortality in VIIjk is close to current proxy for $\mathrm{F}_{\text {MSY }}$.

## Management plans

No specific management objectives are known to ICES.

## The fisheries

Sole in Divisions VIIh-k are mainly taken by otter trawlers and beam trawlers.

|  | $\mathrm{F}_{\mathrm{pa}}$ | Not defined |  |

(unchanged since 2010)

## Outlook for 2012

No reliable assessment can be presented for this stock. The main cause of this is that catch numbers-at-age are only available for Irish landings. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

The state of the stock biomass is unknown, but exploratory estimates of mortality suggest that recent fishing mortality for the major component of the catch is to close to $\mathrm{F}_{\text {max }}$ which is used as a proxy for $\mathrm{F}_{\text {MSY }}$ (Figure 5.4.10.3). Therefore, catches should not be allowed to increase in 2012.

## Additional considerations

A proxy for total mortality ( $Z$ ) was estimated from the Irish catch numbers at age in VIIjk (Figure 5.4.10.2). Exploratory estimates of mortality suggest that the current fishing mortality in the VIIjk part of the stock is around or below $\mathrm{F}_{\text {MSY }}$ estimated from a yield per recruit analysis.

Comparison with previous assessment and catch options
The assessment is based on a catch curve through landings-at- age data for sole in Divisions VIIjk which is the same as last year. Exploratory estimates of mortality and $\mathrm{F}_{\mathrm{msy}}$ are similar to last year. The basis for the advice is the same as last year.

## ECOREGION STOCK

## Celtic Seas

Demersal elasmobranchs in the Celtic Sea and West of Scotland

## Advice for 2012

The advice given in 2010 for these stocks is biennial and valid for 2011 and 2012 (see ICES, 2010). This year ICES adopts the transition to the MSY approach as the basis for advice, which corresponds to landings less than 9900 t for the main species of skates and rays, and no increase in catches for Scyliorhinus canicula (Lesser-spotted dogfish). Advice given for individual stocks is given below.

Advice for 2011 and 2012 by individual stocks

| Species | Area | Advice |
| :---: | :---: | :---: |
| Common skate complex ( $=D$. batis, which has recently been differentiated into $D$. flossasda and D. intermedia, see Additional Considerations) | VI | No targeted fishery |
|  | VII | No targeted fishery |
| R.. clavata (thornback ray) | VI | Status quo catch |
|  | VIIa,f,g | Status quo catch |
|  | VIIe | Status quo catch |
| R.. montagui (spotted ray). | VI | Status quo catch |
|  | VIIa,f,g | Status quo catch |
|  | VIIe | Status quo catch |
| L. naevus (cuckoo ray) | VI | Reduce from recent catch level |
|  | VII | Reduce from recent catch level |
| R. brachyura (blonde ray) | VIa | No advice |
|  | VIIa | No advice |
|  | VIIe | No advice |
|  | VIIf | No advice |
| R.. undulata (undulate ray) | VIIj | No targeted fishery |
|  | VIId, e | No targeted fishery |
| R. microocellata (small-eyed ray) | VIIf | Status quo catch |
| L. circularis (sandy ray) | VI | No advice |
|  | VIIbc, h-k | No advice |
| R. fullonica (shagreen ray) | VI | No advice |
|  | VIIbc,g-k | No advice |
| Dipturus oxyrinchus (long-nose skate) | VI-VII | No advice |
| Dipturus nidarosiensis (Norwegian skate) | VI | No advice |
| S. canicula (lesser spotted dogfish) | VI and VII | Status quo catch |
| S. stellaris (greater spotted dogfish) | VIIa,e,f | No advice |
| Mustelus spp. (smooth-hounds) | VII | Status quo catch |
| Squatina squatina (Angel shark) | VI,VII | Retain on prohibited species list |
| Rostroraja alba (White skate) | VII | Retain on prohibited species list |

## ECOREGION Celtic Sea and West of Scotland STOCK <br> Megrim (Lepidorhombus spp) in Divisions IVa and VIa

## Advice for 2012

ICES advises on the basis of precautionary considerations that there should be no increase in catch.

## Stock status

Landings

Figure 5.4.38.1 Megrim (Lepidorhombus spp) in Divsions IVa and VIa. Landings (' 000 t ) and trends in biomass from the combined fishery independent survey [upper panel]. Trends in exploitation rate and total biomass from exploratory state-space biomass dynamic model based on fishery independent survey data [lower panels]. Yaxis of survey cpue, exploitation rate, and total biomass are arbitrary scales and all start at 0 .

There is no analytical assessment for this stock. Survey indices show an increase in biomass over the time series (2005 to 2010). An exploratory state-space surplus production model indicates that the overall mortality rate has declined and stabilised at reduced levels in recent years and total biomass has increased.

## Management plans

No specific management objectives are known to ICES.

## Biology

There are two separate TAC areas for megrim, VI and IV, but there is little evidence to suggest that the megrim in Subarea IV and Division VIa are separate stocks. ICES (2011b) concluded that megrim in Divisions VIa and IVa should be treated as a single stock and megrim in Division VIb (Rockall) should be treated as a separate stock.

## The fisheries

Megrim are predominantly caught using otter trawls.

## Catch by fleet

 Total catch 2909 t discards range $1-23 \%$ by weight.
## Quality considerations

Imprecise and missing age data hampers the ability of ICES to carry out an age-based assessment for this stock. The extent of area misreporting between management or stock areas is unknown and for stocks like megrim and anglerfish on the northern shelf, there is a general need for improved spatio-temporal resolution of commercial catch and effort data through integration of VMS and logbook data from countries engaged in the fishery.

## ECOREGION Celtic Sea and West of Scotland STOCK <br> Megrim (Lepidorhombus spp) in Divisions IVa and VIa

## Reference points

No reference points have been defined for this stock.

## Outlook for 2012

The exploratory state-space model is only considered to evaluate stock trends. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

Survey information shows an increasing trend in biomass and exploratory analysis shows that the exploitation has decreased substantially in recent years. Therefore, catches should not be allowed to increase.

## Additional considerations

## Management considerations

There have been substantial reductions in effort associated with the Scottish and Irish fleets since 2002 and are considered to have contributed to the decline of landings in Subarea VI. Landings in Subarea VI are well below the TAC. Uptake by France, accounting for $44 \%$ of the TAC, is very low ( $\sim 11 \%$ ). Official landings in Subarea IV and Division IIa in recent years are close to the TAC.

Fishing effort in VIa and IVa has declined substantially since 2000.
Area misreporting has been prevalent as megrim catches were misreported from Subarea VI into Subarea IV, due to restrictive quotas for anglerfish (i.e. vessels targeting anglerfish misreported all landings including megrim from Subarea VI into Subarea IV). However, in the most recent years there is evidence to suggest that this has reversed as the subarea IV TAC has become more restrictive and increasing targeting of megrim in response to more restrictive fishing opportunities for other species, e.g. cod. The extent of this problem is unknown and should be quantified through integrated logbook and VMS analysis. Redistribution of landings between VIa and IVa has not be undertaken by ICES in recent years. Combining the stocks of VIa and IVa also has the advantage of negating the impact of area misreporting between the two areas.

ICES notes that the current TAC area is inconsistent with the ICES advice.

## The effects of regulations

In 2010, new mesh regulations introduced in Division VIa which have increased the mesh size from 100 to 120 mm (vessels $>15 \mathrm{~m}$ ) has resulted in an increase in the length of first capture. This measure, coupled with further effort restrictions associated with the long-term management plan for cod (Council Regulation (EC) No 1342/2008) is likely to result in further effort displacement away from the shelf fisheries in Division VIa. However, at this stage it is not possible to quantify this until an integrated analysis of VMS and logbook data is conducted.

No information is available on changes in the French and Spanish fleets operating in this area.

## Data and methods

The information basis for megrim is being developed, with improvements to both industry-related data and surveys.
Commercial lpue's from four fleets in VIa and two fleets in IVa may be considered indicative of stock trends, but these should be treated with caution as they may give an overly optimistic view of stock abundance as there is evidence of increased targeting in recent years. Exploratory analysis using a state space surplus production model that uses all available survey data in Division VIa and IVa, are informative as relative trends in biomass and exploitation rate.

## Comparison with previous assessment and advice

Last year's assessment was based on survey trends. A new exploratory assessment was used in 2011 as basis for an assessment, following recommendations from the benchmark assessment meeting (ICES, 2011a). WKFLAT(ICES, 2011a), based on survey data( SCO-IV-VI-AMISS-Q2), concluded that megrim in Division VIb is a separate stock. The advice given this year is applicable to megrim in Divisions IVa and VIa. Advice for Division VIb is available in section 5.4.39.

The advice is the same as last year for the combined stocks, but extended by ICES new form of advice for data poor stocks.

## Assessment and management area

Since 2009, ICES advice on megrim includes Subarea IV (North Sea). This is because the spatial distribution of landings data and survey catches provide good evidence to suggest that megrim population is contiguous between Divisions IVa and VIa and ICES now considers megrim in VIa and IVa as a single stock. This is inconsistent with the current management separation of VI and IV.

Figure 5.4.38.2 Megrim (Lepidorhombus spp) in Divisions IVa and VIa. Management area (red boxes) and assessment area (blue hatched area).

| ? | Unknown |
| increasing |  |

Figure 5.4.39.1 Megrim (Lepidorhombus spp) in Division VIb (Rockall). Landings (in '000 t) and survey cpue based on fishery independent survey data.

There is no analytical assessment for this stock. Survey indices for Division VIb show an increase in biomass over the time series from 2005 to 2010.

## Management plans

No specific management objectives are known to ICES.

## Biology

There are two separate TAC areas for megrim, VI and IV, but there is little evidence to suggest that the megrim in Subarea IV and VIa are separate stocks. WKFLAT(2011) concluded that megrim in ICES divisions VIa and IVa should be treated as a single stock and megrim in ICES division VIb (Rockall) should be treated as a separate stock. The 2011 advice is on this basis.

## The fisheries

Megrim is predominantly caught using otter trawls.

## Catch by fleet Total catch 139 t . Discard data not available.

## Quality considerations

The extent of area misreporting between management or stock areas is unknown. For stocks like megrim and anglerfish on the northern shelf, there is a general need for improved spatio-temporal resolution of commercial catch and effort data through integration of VMS and logbook data from countries engaged in the fishery.

Working group report

## ECOREGION Celtic Sea and West of Scotland STOCK Megrim (Lepidorhombus spp) in Division VIb (Rockall)

## Reference points

No reference points have been defined for this stock.

## Outlook for 2012 and 2013

No reliable assessment can be presented for this stock. The main cause of this is the lack of basic data. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

Trends in biomass in recent years have increased. However, because the exploitation rate is unknown, catches should not be allowed to increase.

## Additional considerations

## Management considerations

There have been substantial reductions in effort associated with the Scottish and Irish fleets since 2002 and this is considered to have contributed to the decline of landings in Subarea VI. Landings in VI are well below the TAC.

ICES notes that the current TAC area is inconsistent with the ICES advice.
The effects of regulations
Technical measures are in place and the minimum landing size is 20 cm .
No information is available on changes in the French and Spanish fleets operating in this area.

## Data and methods

The information basis for megrim is being developed, with improvements to both industry-related data and surveys.
There is currently six years of survey data, which is now considered sufficient to provide advice on stock trends.

## Comparison with previous assessment and advice

Last year's advice was based on survey trends in combined stocks (including Division Iva and VIa).
The advice is the same as last year for the combined stocks, but extended by ICES new form of advice for data poor stocks.

## Assessment and management area

ICES considers megrim in VIb as a single separate stock since 2011. This is inconsistent with the current management area.

Figure 5.4.39.2 Megrim (Lepidorhombus spp) management area (red boxes) and assessment area (blue hatched area).

## ECOREGION STOCK <br> Celtic Sea and West of Scotland Pollack in Subareas VI and VII (Celtic Sea and West of Scotland)

## Advice for 2012

This is the first time that ICES analyses data for pollack in the Celtic Sea and West of Scotland. Currently it is not clear whether there should be one or several management units. There is insufficient information to evaluate the status of pollack in this area. Therefore, based on precautionary consideration, ICES advises that catches should not be allowed to increase in 2012.

## Stock status

| $\qquad$ F (Fishing Mortality) |  |
| :---: | :---: |
| Qualitative evaluation | 2008-2010 |
|  | ? Insufficient information |

Figure 5.4.40.1 Pollack in Subareas VI and VII. Total official landings (tonnes) per country (2010 data is preliminary).
The available information is insufficient to evaluate the exploitation and the trends of pollack in the Celtic Sea ecoregion.

## Management plans

No specific management objectives are known to ICES.

## Biology

Pollack in the 0 -group are found in shallow coastal waters and may therefore be protected from fisheries in the early life stages. Pollack is benthopelagic, found mostly close to the shore over hard bottom. It usually occurs at $40-100 \mathrm{~m}$ depth, but is found down to 200 m . A maximum size of 130 cm , a maximum weight of 18.1 kg and a maximum age of 15 years are reported. Growth is thus fairly rapid, approaching 10 cm per year. There is a migration from the coast to deeper waters as it grows. Maturity occurs at approximately 3 years and spawning occurs mainly in the first half of the year, at about 100 m depth. The stock structure of pollack populations in this eco-region is not clear. ICES does not necessarily advocate that Subareas VI and VII constitutes a management unit for pollack.

## The fisheries

Most pollack in the Celtic Sea ecoregion is caught by trawls and gillnets, and other gears come to complement the landings, such as trolling line, seine nets or beam trawls (Figure 5.4.40.4). The overall gear contribution is unknown due to the lack of complete statistics. In 2010, $98 \%$ of the landings originated from the Subarea VII, and Ireland, UK and France together comprised $99 \%$ of the official landings.

Catch by fleet Total landings (2010) 4143t. Other removals unknown.

## Quality considerations

Pollock has a preference for wrecks and rocky bottom, making it difficult to catch with trawls and therefore poorly suited for monitoring by research surveys. Some length frequency data are available for recent years, but area specific data on life history parameters are missing. Data on growth and maturity, as well as more information from the fisheries are needed. Landings figures are clearly incomplete and erratic and further scrutiny is required.

The stock unit definition of pollack is not yet available due to lack of data.

## ECOREGION Celtic Sea and West of Scotland STOCK Pollack in Subareas VI and VII (Celtic Sea and West of Scotland)

## Reference points

No reference points have been defined for this stock.

## Outlook for 2012

No reliable assessment can be presented for this species in the Celtic Sea ecoregion. The main cause of this is lack of reliable data. Therefore, fishing possibilities cannot be projected.

## Precautionary considerations

This is the first time that ICES analyzes data for pollack in the Celtic Sea and West of Scotland. Currently it is not clear whether there should be one or several management units. There is insufficient information to evaluate the status of pollack in this area. Therefore, based on precautionary consideration, ICES advises that catches should not be allowed to increase in 2012.

## Additional considerations

This advice is not dedicated to a 'stock'. It relates to a species in a wider region where data are available. Further work is required of stock identity of all pollack stocks within ICES area.

The ICES official landings statistics displays erratic time series per country. For example in the period 1965-1972, Sweden is declaring substantial landings, whereas it is Spain during the period 1981-1988 (both included in 'Other' countries on Figure 5.4.40.1, see also Table 5.4.40.2). France, a major contributor to the landings, starts declaring in 1977 and has no declarations in 1999. From 1977 onwards, the picture shows a long term downward trend, due mainly to the French threefold reduction of landings over the time period. The erratic overall landings data are still more visible in the landings per areas (Figure 5.4.40.2). Nevertheless, it is possible to note that the Celtic Sea (i.e. Divisions VIIf-k) and the Western Channel (i.e. Division VIIe) compose the majority of the landings (Figure 5.4.40.2), and the Subarea VI as lost almost all of its past landings.

It must be noted that pollack is a target for recreational fisheries, especially angling from shore and from boat and spearfishing from shore and from boat. A survey conducted by France in 2006-2008 estimated annual recreational catches of pollack to be 3500t. +/-2500t. (ICES, 2010b).

## Data requirements

Further investigation on stock identity of pollack within the ICES areas is need, as well as more information on life history parameters, namely growth and maturity. Landings data figures are clearly incomplete and erratic and further scrutiny is required.
