Knowledge for better Cities

Contents

SHORT OUTLINES

PAPERS

AMSTERDAM How to build the city in a cooperative way?

ANTWERP How to rework the productive city?

BRUSSELS How to reconcile local expectations with strong international challenges when renewing a city?

DELFT/THE HAGUE How to create a sustainable knowledge region?

DEVENTER How to Implement a (National) Legal Framework through Local Integrated Planning?

DORTMUND How to leverage economic growth from spatial projects?

EINDHOVEN How to react when traditional industries move away?

GRONINGEN How to sustain energy resources?

MAASRICHT How to overcome national borders?

ROTTERDAM How to develop unprecedented port-city synergy?

SCHIPHOL How to connect in a globalized world?

WAGENINGEN How to feed the world's metropolises?

Workshop 1 Amsterdam

How to build the city in a cooperative way?

Chinis, Ioannis, Aristotle University of Thessaloniki, Thessaloniki, Greece

An anarchist approach on urban planning: the case study of Thessaloniki

The aim of this thesis is an anarchist glance on urban planning. Practically it examines the possibility of city planning for a society in a state of anarchy, through relevant literature and practical experiment, realized through the process of an alternative workshop, taking place of an occupied social space.

Chopra, Divya, New Delhi, India

Collective imaginations for everyday realities: city building through 'creative' cooperation

This paper articulates the need for collective engagement and conversations as a significant aspect of the 'creative' and cooperative city building framework while investigating the role of public art and co-design as necessary ingredients that could contribute towards a re-defined and inclusive way of building our cities for the future.

Davidovich, Ronit, DMR Planning & Development, Tel Aviv, Israel

An integrated and empowering service model for children and youth at risk – as a base for cooperative and activist management

Development of an integrated and empowering service model for children and youth at risk and the range of services that they need as infrastructures aimed to integrate and even leverage the quality of the public space for the community as a whole.

Featherstone, Jeffrey; Temple University, Ambler, Pennsylvania, United States

Addressing flooding issues in an environmental justice community: a complicated and multi-layered case study

This paper addresses flooding issues in an Environmental Justice community near Philadelphia, USA.

Gential, Oscar, Urbaplan, Lausanne, Switzerland

Creative workshops

Urbanism is a creative practice. Through comparisons of realized experiences (led by the office Urbaplan in Switzerland) and references, we aim to theorize an approach praising uncertainty and process, revealing a critical issue in any collaborative and creative approach: how to bring out the ideas of a group?

Giupponi, Noemi, Glasgow, United Kingdom

The development of a conceptual and physical model of a spatial data infrastructure for inclusive planning using critical GIS: a case study in the Gorbals, Glasgow

The design and implementation of planning support systems are key to the enhancement of learning in spatial decision making. By developing a socially inclusive conceptual model of space, a spatial data infrastructure including geographic information of people's life spaces is presented using critical GIS techniques for a neighbourhood in Glasgow.

Hanzl, Malgorzata, Lodz University of Technology, Lodz, Poland

Ksiezy Mlyn in Lodz, Poland - an example of a successful rehabilitation thanks to social engagement

The rehabilitation project of the 19th century industrial estate of Ksiezy Mlyn, Lodz Poland was carried out successfully thanks to the initial public acceptance generated by the impact of the social rehabilitation project. The strategy of the regeneration of the estate was created in collaboration with local citizens and NGOs.

Huguenin, João Paulo, Federal University of Goiás; Ghilardi, Flávio Henrique, Institute of Research and Urban and Regional Planning, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Housing cooperative movement as an alternative way of thinking, planning and designing residential neighborhoods

Analysing the genealogy of the cooperative housing production in Latin America and Brazil and accompanying a pilot experience – in which families make decisions collectively – we tried to show that solidarity and participation on management of the city are the way to the construction of fairer and democratic cities.

Kabali, Hema Priya, IDE Bangladesh, Dhaka, Bangladesh

Shared Amsterdam - affordable housing through cooperative urbanism

Affordable housing is fundamental to urban well-being and social sustainability. This paper analyses participatory planning and affordable housing practices across European housing sector drawing focus on Amsterdam and proposes strategic recommendations emphasized on public-private partnerships and mixed urban communities for greater social cohesion, inclusiveness and better quality urban environment.

Marozas, Martynas, MMAP, Vilnius, Lithuania; Jonauskis, Tadas; Muliulyte, Justina, Pupa - Strategine Urbanistika, Vilnius, Lithuania

New public participation practices for revitalizing Klaipeda's Old Market neighborhood

Public participation vacuum in Lithuanian planning system called for a new participatory planning standard in Klaipeda's Old Market development vision and plan. Public involvement and long hours of mediation resulted in a creation of the first "informal" planning document appreciated by local community and formally approved by the city council.

Monardo, Bruno, Sapienza University of Rome, Rome, Italy

Cooperation and mediation. The flexible geometry of public participation. Comparing US and France evolutionary approach.

The paper is focused on comparing the innovation of participation models in US and France through the concept of 'flexible geometry'. Reflexions and remarks consider the hybridization of original cultures into a cooperative approach to local redevelopment, based on the emerging styles and roles of community managers and facilitation professionals.

Mwang'a, Keziah Mwelu, Gran Sasso Science Institute, L'aquila, Italy

Building equitable cities through inclusive practices: case studies from the US partnership for sustainable communities initiative (SCI)

Changing city dynamics such as stagnant economic growth and the increased presence of diverse groups require that cities seek ways of fostering collaboration in the planning process. This paper demonstrates several practices that cities can adopt to bolster cooperation between communities, civil society and business towards equitable growth.

Okitasari, Mahesti, United Nations University IAS/Keio University, Tokyo, Japan

Governing the urban infrastructure in Indonesian cities: the role of institutional structure and policy instruments in collaborative policymaking and resource exchange

This paper discusses the governing of urban infrastructure through collaborative policymaking and resource exchange based on Indonesian experiences. It explores and compares cases of intergovernmental and cross-sectoral collaboration at the local level through analysis on the institutional architecture and policy instruments.

Pancewicz, Lukasz, Municipal Planning Office of Lodz, Gdansk, Poland

Sharing planning power as a way out of planning legitimacy crisis - why it matters for the CEE countries

Paper reviews the potential opportunities to reinvent planning system, brought about by devolution of planning via increased collaboration and participation in the context of Central European countries. First experiences in collective, participatory planning processes are reviewed as well as their political and societal context.

Zagow, Maged, Illinois Institute of Technology, Chicago, United States of America

Enhancing urban socio-economic needs, activities, and facilities, looking beyond conventional mixed-use development model

This study investigates how planners can implement successful mixed-use development, given Social justice as fundamentally approach, in terms of the distribution of wealth, opportunities, and privileges within a society, using multi-level data from location point to county level representing Chicago Metropolitan area with contrasting implementation methods of mixed-use development.

Workshop 1 Antwerp

How to rework the productive city?

Ahmadipour, Zahra, Tehran, Iran

Investigating the effects of industrial cluster development policy on the performance of urban and regional old industries (case study: leather products cluster)

The purpose of this paper is to discuss the effects of policies based on development of industrial clusters. The paper analyses and compares cases of conditions of small and medium manufacturers of leather that are located in Tehran before and after implementation of this policy.

Choo, Li Jie, JTC Corporation, Singapore, Singapore

Creating future-ready industrial estates: case studies from Singapore

This paper seeks to argue that industrial estates of the future should be planned as workplaces with strong connections to the rest of the city, rather than merely places for machinery; industrial estates should be guided by key principles of city-planning: 1) Compactness, 2) Mixed-uses, 3) Connectivity, 4) Managing Proximity.

Custers, Lieve; Dooghe, David, Buro Boris, Antwerp, Belgium

Urban circular economy

In the research project 'urban circular economy' will explore three models: business almost as usual, sustainability as pocket money and sustainability as life style. This exploration will give insight in the potential and positive or negative effects of an urban circular economy on the city and the future urban development.

Ferm, Jessica; Jones, Edward, University College London, London, United Kingdom

Reworking the productive city? Challenges of implementation

This paper provides a reality check to some of the optimistic, aspirational dialogues around the question of re-integrating production to support liveable and vibrant cities of the 21st century. Using London as an example of a successful, growing post-industrial city, it identifies concrete challenges, which need to be overcome.

Gheysen, Maarten Leiedal, Kortrijk, Belgium

Economic freckles in urban tissue, the case of South-West Flanders.

In a territory where available space is limited, it is crucial to evaluate and reuse as much as possible. Zoning for industry is no longer tenable. In order to evaluate and reuse, a shift in attitude, thinking and instruments is needed. Knowledge by design is a major input for this.

Neumayer, Vincent, TINA Vienna Urban Technologies & Strategies, Vienna, Austria

City logistics Vienna – transport challenges in urban areas within a disordered institutional framework

Production moved out of cities and goods distribution takes place on nearby green-fields. This paper examines in the context of the City of Vienna ways of both, bringing production and (green) logistics operations back into the city and defining opportunities for urban brownfields with regard to urban cargo distribution centres.

Pajevic, Filipa; Shearmur, Richard G., McGill University, Montréal, Canada

Intra-urban labour mobility: new perspectives for the use of big data in urban analysis

Labour mobility is linked in complex ways to ICT: it is both enabled by these new technologies and tracked by them. Labour mobility is a good example of a lens that, if looked through using big data, could produce a more informative portrait of the city and its daytime geography.

Prochnow, Simone, Uniritter Laureate International Universities, Porto Alegre, Brazil

Heterochrony in architecture

This study rethinks architectural project as an important tool for heritage preservation. Analysing cases done in some parts of the world, along with projects in the city of Porto Alegre, South Brazil, that now faces the question of the reuse of important old industrial areas as real state production sites.

Qiao, Jing; Geng, Hong, Huazhong University of Science and Technology, Wuhan, China

The plight of the 'Chinese-style peasant economy' in the transformation of the urban industry

Although, 'Chinese-style peasant economy' structure has the features of informal economy, it has made great contribution to the transformation of the urban industry in China. We explore how we can protect it to guarantee the farmer's interests in the development of rural industry which is the significant branch of service industry.

Quintana Malubay, Haydee Jacklyn, University Of The Philippines, Manila, Philippines

Reinventing a Philippine city through Vision 2020 plan

The planning story of reinventing Candelaria's desiccated coconut industry via Vision 2020, the five-year comprehensive land use planning process, mandated by Philippine law, sheds light on the many lessons planners can learn in upholding values towards sustainability for this and the coming generations.

Sergi, Giovanni; Rosasco, Paolo, Genoa University, Genoa, Italy

A feasibility study for a technological park undertaken in 2011 by the municipality of Falconara Marittima, province of Ancona-Italy.

The Municipality of Falconara Marittima decided in 2011 to undertake a feasibility study for a new Technological Park to promote the rehabilitation of a wide and complex brown area. This proposal puts together a project for new productive areas with new investments in the cultural sector and tourism.

Dhote, Meenakshi; Lata, Kusum; Singh, Gargi, School of Planning and Architecture, Delhi; India

Rejuvenation of the Productive Area in the City: E4 Subzone of Delhi

The paper elucidates the inherent problems of unplanned and unregulated industrial development and its social and environmental implications on the quality of life of a city in developing countries.

Sliwa, Marcin, Norwegian University of Science and Technology, Trondheim, Norway; Wiig, Henrik, Norwegian Institute for Urban and Regional Research, Oslo, Norway

Should I stay or should I go: The role of Colombian free urban housing projects in IDP return to the countryside

New apartments and houses given by the Colombian government for free to the displaced households 'cement' their choice to stay in urban areas. At the same time, they potentially contribute to the lack of success of the Land Restitution program, which fosters return of the victim population to the countryside.

Zaman, Jan, Brussels, Belgium

Industrious Flanders and Brussels – the northern area case

Two regional governments are taking the first steps in territorial cooperation through research and design proposals.

Workshop 3 BRUSSELS

How to match local expectations with strong international challenges?

Daneshmandian, Mahsa Chizfahm; Fattahi, Kaveh, Shiraz University, Shiraz, Iran

Shiraz small residential gardens

Shiraz is a city in Iran, famous for its Persian Gardens. We believe Shiraz as a city could save its region by renovate not in public Gardens/Parks but with its small Gardens within all residential houses. We propose evolving the old method of courtyards can regenerate the Shiraz city.

Ede, Precious; Owei, Opuenebo, Institute of Geosciences and Space Technology, Rivers State University of Science and Technology, Port Harcourt, Nigeria

Are cities in Nigeria keeping up with challenges for global competition?

Nigerian cities have been growing very rapidly resulting in a gradual decline in the quality of life. This study relies on published information on cities in Nigeria. The top ten cities where it is most conducive to do business were enumerated and the major factors militating competitiveness also highlighted.

Geambazu, Serin, University of Architecture and Urban Planning 'Ion Mincu', Bucharest, Romania

Dimensions of urban waterfront regeneration: Case study of Halic / The Golden Horn - an assessment of obstacles and opportunities for inclusiveness

The study reveals the dimensions of an urban waterfront regeneration project in which the rights of the future users of the space are lost behind a fight between the government and strong opposition parties gaining ground of governance landscape, motivated by their stake in the development.

Jin, Xin; Wang, Jianguo, Southeast University, Ministry of Education, Nanjing, China

Research on Landscape Promotion Strategy of the Grand Canal (Hangzhou Section) based on Landscape Visual Evaluation

This paper, using visualization as an operation method, constructed the dynamic tour system for the Grand Canal (Hangzhou section) based on the diversity of visual perception among different motion states and the concept of sustainable development.

Oikonomopoulou, Eirini, Lund, Sweden

New Mahalle – an urban green, inclusive neighbourhood

Strategies are presented to upgrade a poor-quality historic neighbourhood towards a qualitative, green, inclusive public life in a historic central district.

Papamichail, Theodora, ETH Zurich, Zurich, Switzerland

The test planning process and the case of Patras

In last decades the urban redevelopment of cities requires top-down policies complemented with bottom-up approach. A new informal procedure, called Test Planning, provides a collaboration basis among numerous stakeholders. It is examined in the complex task of railway redevelopment in Greece, specifically in the case of Patras.

Pisman, Ann, Ghent University, Gent, Belgium

A place based spatial policy in the multi-actor arena in Flanders

A place based environmental policy was already introduced in Flanders in the Flemish Mina-2 plan 1997-2001 and is more recently developed within the context of spatial planning. Different actors are experimenting with area development in Flanders. In this article two cases in Flanders are described and results are presented.

Rijpma, Jelle, Jelle Rijpma Advies, Heeze, Netherlands

Smart managing the city

Looking for new forms of cooperation within cities, in a continuous project called 'Open City'. Through pilot projects and practical examples, a conceptual framework for the Open City is developed. This framework reflects the changes and dynamics of the society. The conceptual framework consists of three leading cornerstones.

Shih, Wanyu, Ming-Chuan University, Taipei, Taiwan

Optimising green infrastructure to cool built environments: a case study of the Taipei basin

This research found that increasing greenspace size and vegetation density (trees) in a more compact and simple shape; and enhancing tree proportion on the adjacent areas of greenspaces will contribute better cooling effect of greenspaces to surrounding built environments.

Souza Cruz, Andrea, Unisuam, Rio de Janeiro, Brazil

Case study to urban regeneration on sustainable basis: Bonsucesso - Rio de Janeiro

The city of Rio de Janeiro - Brazil is the city with the largest population living in substandard clusters in the country, about 22% of the city population lives in slums. This research presents some recommendations to obtain socio economic growth on sustainable basis in this region.

Stupar, Aleksandra; Grujić, Aleksandar; Grujić, Biljana, University of Belgrade, Belgrade, Serbia

Toward the urban transition of Kragujevac: a new life of old urban generators

The focus of this paper is the city of Kragujevac (Serbia), which is facing numerous problems and challenges related to the shift of production and development priorities, changing urban identity, the recent production of urban space and a questionable or delayed reactivation of abandoned urban sites and ex-industrial facilities.

Taheri Moosavi, Somayeh, University of Manchester, Manchester, United Kingdom

A systematic approach to regenerate neighbourhoods with an activity-based approach

We should shift our focus from people-based and area-based regeneration to activity-based regeneration which encompasses the complex interaction between people and places. An activity-based approach shows how existing urban policies, service programmes and regeneration proposals work, and envisions what their future effects will be with considerably high level of certainty.

Tasyara, Fisqa, Directorate General of Spatial Planning and Development, Jakarta, Indonesia

Ecosystem service-based green space allocation planning: a new way to construct urban spaces

Green spaces are often developed based on land availability and without taking notice how the benefit can be delivered to the human population. Ecosystem service-based green space allocation planning answers this need to ensure that the location of an ecosystem service provider is most effective to provide the needed benefit.

Tillner, Silja, Architects Tillner & Willinger, Vienna, Austria

A new planning culture - cooperative planning processes; case studies in Vienna

Cooperative planning workshops have replaced planning studies and masterplans in Vienna, which has experienced a transformation of its planning culture from a closed to an open process. These recent changes in planning have had a positive impact on the public debate, yet the results vary and are some-times controversial.

Van Herck, Tine, PTArchitecten BVBA, Brussel, Belgium

Working within the human context

We are developing a method for a human based design process. This means a design method that enables to improve the social relevance of projects. It can be applied to projects of different scale : from interior architecture to landscape strategies. The research uses projects of our office PTArchitecten.

Vickery Hill, Adrian, BUUR, St Gilles, Belgium; Kaethler, Michael, KU Leuven, Leuven, Belgium; Kampelmann, Stephan, Université Libre de Bruxelles, Brussels, Belgium

Creative stakeholder engagement: the curatorial model

Planning and planners are increasingly accepting complexity as a fundamental challenge to bottom-up planning processes but struggle to identify tools and approaches accommodating it. Adopting the notion of the curatorial from art and design, we are exploring a new approach that celebrates complexity as intrinsic to its form of function.

Wang, Xi; Han, Feng, Tongji University, Shanghai, China

Historic urban landscape research of the canal heritage city Yangzhou

In 2014, Grand Canal (China) included on the World Cultural Heritage List. As the canal's cradle city, Yangzhou is now facing the challenge of conserve heritage value in rapid urbanization context. The research uses the approach of UNESCO Historic Urban Landscape Recommendation (2011) to interpret debates and propose solutions.

Yang, Jianqiang, Southeast University, Nanjing, China

Centre redevelopment of productive city based on system coupling and function optimization

City centre redevelopment is one of the important subjects at a time of global urbanization. This paper analyses the situation of China's city centre redevelopment and gives suggestions on how to improve it in the aspects of basic theories, technology and methods.

Yinan, Dong, Southeast University, Nanjing, China

An exploration of architectural inheritance and innovation methods in urban fringe belt based on typo-morphological research-- a case of expansion project of the second middle school in Xuancheng, China

Like Brussels, Xuancheng, a small historic city in South-East China has to combine the expectations of maintaining its traditional urban form and the necessity to develop its international dimension. We are lucky to get a chance to expand an old middle school in the urban fringe belt in Xuancheng.

Yuen, Belinda, Singapore University of Technology and Design, Singapore, Singapore

To be inclusive is to be age-ready: perspective from Singapore

This paper dives deep into the Asian city of Singapore to illustrate key examples of reinventing ageing-ready neighbourhoods in practice.

Workshop 4 Delft/The Hague

How to create a sustainable knowledge region?

Brouwer, Jan, ABF Cultuur, Delft, Netherlands

A new approach in planning of European cities

European cities are entering a new phase. In the past there was continuous growth. Planning was the management of growth. In the future there will be more emphasis on transformation and redevelopment. Every city has built up values. Steering based on these values is important to achieve the right choices.

Gong, Bin; Zhuang, Jie, Guangdong Urban & Rural Planning and Design Institute, Guangzhou, China

Landscape design promotes sustainable development of cities - case of 'Sino-Singapore Guangzhou knowledge city' urban design

Based on the research findings of 'Sino-Singapore Guangzhou Knowledge City', this paper introduces the practice of urban design which applies with the theory of Landscape Urbanism. This paper is focused on how to promote sustainable development of the city by shaping landscape.

Hulshof, Ineke, Hulshof Architects, Delft, Netherlands

DelftEDesign - bottom up approach towards a sustainable existing housing stock

DelftEDesign, is a cooperative of ten firms specialized in sustainable techniques, architecture and consultancy. DED is supported by Delft Technical University, Woonbron and the City of Delft. DED aims to realize a bottom-up movement to achieve large scale user powered energy saving and production in the existing housing stock.

Ma, Chao; Yun, YingXia, Tianjin University China, Tianjin, China

Research on the strategies of cultural heritage in villages and towns characterised by aboriginal participation

Two new methods (aboriginal participation and aboriginal autonomy) used to seek for the strategies of cultural heritage with planning formulation mode are proposed in this paper.

Reiss-Schmidt, Stephan, City of Munich, München, Germany

City planning between decline and emergence

After 50 years of CARP, it is time to reflect on the continuing decline of our profession. Nowadays, with globalization and digitalization, planning seems to become a “dying craft”. A cooperative transformation of the city gives the opportunity for a renaissance of planning.

Santamaria, Mar; Martinez-Diez, 300.000 Km/s, Barcelona, Spain

How urban fabric fosters knowledge transfer and innovation: the example of Barcelona

The innovation ecosystem of Barcelona, based on a diverse and compact urban fabric that enables positive transference of innovation and knowledge to different parts of the city, could become a reference for Delft which is actually transforming its university campus for a better integration between innovation tissue and the city.

Thadani, Dhiru, Thadani Architects + Urbanists, Washington DC, United States

Rediscovering the college town

Nothing matches the energy and pulse of a college town. These places continue to attract a diverse socio-economic population. The research documents 40 college towns in North America and identifies common spatial characteristics, land-uses proportions, and sustainable development opportunities.

Vaillant, Philippe, University of Lorraine, Charleville-Mézières, France

Let's reinvent convivial regions: in Bill Twittchet's memory

The world is limited. Our cities grow. In contrast nature is destroyed. Now we are faced with a balancing act between nature and city. A new organic approach to planning is developed on Bill Twittchet's notion of convivial regions. This approach shows how to create a sustainable knowledge region.

Zhu, Hua, Urban Planning Design and Research Institute of Southeast University, Nanjing, China

Opening and closure – two methods of how the college help to create a knowledge city

The paper illustrates the possibility and necessary of reinforcing the connection between college and city by a series of history traces and case studies. Following the typological research and deconstruction of modern colleges, a new conceptual urban design strategy (opening and closure) will be presented.

Workshop 5 Deventer

How to implement a (national) legal framework through local integrated planning?

Ayrancı Onay, Irem, London, United Kingdom; Gülersoy, Zeren, Istanbul Technical University, Istanbul, Turkey

Reinventing the planning process: monitoring and evaluation Istanbul case study

This paper will become a guide for cities that experience similar problems centred on the integration of different plans and coordination of different planning institutions; for creating an easier, better and faster decision making structure by using the provided Monitoring and Evaluation model in reinventing the planning process.

Beriatos, Elias, University of Thessaly, Volos, Greece

Interaction between national planning and local spatial plans in Greece

The paper tries to examine the interaction between local and national planning in order to make the appropriate suggestions for improving the efficiency of planning policy. Furthermore, there is an approach of the recent reform at local level in an attempt to measure compatibility between administrative and spatial structures.

Du, Shu; Zhou, Ruoqi, China Centre for Urban Development, Beijing, China

Pattern of multiple plans integration — study of Shunde planning system construction

This paper is an introduction to a study regarding how to solve planning excess and conflict by creating a coordinated planning system for the Shunde local government in China.

Goldie, Stephen, Abu Dhabi Department of Municipal Affairs, Al-Ain, United Arab Emirates

The impending revolution in urban planning practice: intelligent and automated, but will it be garbage in, garbage out?

New technologies promise plans for new cities in months and planning permits in an instant revolutionising the relationship between the national or provincial legal framework and more local integrated planning. Combined, they will create a revolution in urban planning, but at the cost of many existing safeguards.

Heyer, Antje, Stockholm University, Stockholm, Sweden

Discussing collaborative planning in Cape Town - a case study on in-situ informal settlement upgrading and the role of planners and the local government in bottom-up projects

My Master Thesis on Collaborative Planning presents the strengths and challenges of in-situ informal settlement upgrading in Cape Town. It discusses the project management of the bottom-up process and the role the municipality, informal dwellers and NGO based urban planners take, as well as their learning outcomes.

Owei, Opuenebo Binya; Ede, Precious, Rivers State University of Science and Technology, Port Harcourt, Nigeria

Re-inventing urban planning in Nigeria: the case of the land use policy of the new Port Harcourt city

The case study focuses on the land use policy prepared by a group of indigenous development professionals for the Greater Port Harcourt City Development Authority in 2013. The essence of the land use policy is to provide a framework that defines the key measures required to address land use planning.

Tang, Lei, Jiangsu Institute of Urban Planning and Design, Nanjing, China

People's livelihood-oriented multi-level cooperation: the urban renewal experience in Zhangjiagang, China

Zhangjiagang won 2014 Jiangsu Province Planning Award in China. Its people's livelihood-oriented multi-level cooperation included (1) Multi-sectoral Cooperation of Land Management, (2) Multidisciplinary Collaboration of Planning, (3) Multi-group Cooperation of Construction, (4) Multi-platform cooperation of Urban Management, (5) Multi-genre Cooperation of Urban Cultures, and (6) Multi-Capital Cooperation of City Operations.

Toto, Rudina; Shutina, Dritan, Co-PLAN, Institute for Habitat Development, Tirana, Albania

Planning as the technology of politics – to be used or misused; the case of Albania

Albanian spatial planning has dynamically evolved in the last 20 years, continuously conflicting with governance decentralization, development interests, territorial resources and political setting. Occurring in local social-economic contexts and confronted with EU knowledge, Albanian planning experience provides a unique example of key recommendations and avoidable mistakes for other reforming systems.

Visigah, Paul Nekabari, Oxford Brookes University, Oxford, United Kingdom; Kakulu, Iyenemi Ibimina, Rivers State University of Science and Technology, Port Harcourt, Nigeria

Integrated sustainable waste management - a tool for stimulating the waste economy in Port Harcourt, Nigeria

Delivering sustainable livelihoods via the waste economy is an inevitable route as African cities strive to manage the challenges of rising poverty and dwindling economies. This discourse evaluates the need to diversify the urban income base through ISWM Policy initiatives, and the potentials this holds for Port Harcourt, Nigeria.

Workshop 6 Dortmund

How to leverage economic growth from spatial projects?

Al Ani, Mohammed, Al Nahrain University- Collage of Engineering, Baghdad, Iraq; Alwehab, Abdelwehab, Baghdad University, Baghdad, Iraq

Urban optimization of transit – oriented development in Baghdad City

TOD is an urban planning tool to redevelop specific area in a city in order to transform it into a more liveable and resilient urban space. In light of TOD benefits and principles, a multi parameter evaluation of “Baghdad Comprehensive City Development Plan 2030” is undertaken, where shortcomings are outlined.

Baltrusaitis, Donatas, BUUR, Brussels, Belgium

Running up circular economy

On the relationship of resource cycles and how a shift in the treatment of these resources can have a positive business spin.

Bannaga, Sharaf Eldin Ibrahim, Bannaga Consult, Khartoum, Sudan

Understanding cities’ dynamics and the need for recurrent urban structure adjustment

Cities growing with conflicting forces of interests and landuses undergo urban transformation, and the larger the city or the urban entity the more complicated are these interests and their conflicts. Disparities exaggerate until the time comes when conflicts can only be resolved by urban interventions.

Camprubi, Alejandro, Pubang Design Institute, Guangzhou, China; Landeros, I.D., UNAM, Beijing, China

Engineering the public realm for thriving sustainable communities

The successful public realm has a positive impact on a multi-layer phenomenon that takes place in its surroundings. This paper explores place-making and creative communities to engineer the characteristics of physical surroundings and the correlation on the composition of the different elements that define a thriving sustainable urban community.

Huang, Wei, Jiangsu Institute of Urban Planning and Design, Nanjing, China

Exploration on transforming “new development area planning” to “built-up area planning” of the development zone in the new normal —with planning practice of national development zones in Suzhou as a case study

China is now undergoing an in-depth reform; its urban planning is transforming “new development area planning” to “built-in area planning”. Adopting the planning practice of national development zones in Suzhou as the research object, this paper explores the ideas, methods and implementation approaches of “built-up area planning”.

Jimoh, Usman Umar; Falola Olusegun Joseph, University of Ibadan, Ibadan, Nigeria

‘Reinvigorating the Nigerian industrial sector’

Industrial development has been a major catalyst in the employment of people in Nigerian labour market. Due to Poor regional development plan, the industrial sector have been neglected for the oil sector resulting into the relocation of industries, thereby creating unemployment and regional imbalance. This paper examines the possibilities of ‘reinvigorating the Nigerian industrial sector’.

Mohlmann, Joost, UN-Habitat, Kigali, Rwanda; Gibert, Montserrat, UN-Habitat, Barcelona, Spain

Leveraging economic growth through rapid urbanisation in Rwanda

Rwanda, the densest country on the African mainland, is promoting urbanisation to leverage economic growth. UN-Habitat supports the Rwandan government by developing local, regional and national spatial development strategies.

Niu, Yuan Sha, Nanjing, China

Region integration research based on the industrialization of cultural resources—taking Huai-salt industrial district in China as example

Huai-salt industrial district is the greatest salt production areas in China. Cities in it are confronted with the cultural, economic, ecological problems caused by the industry recession. Concerning this, Culture-Network Theory about the Huai-salt space characteristics – an innovative regional integration method based on the cultural resources industrialization is proposed.

Ogawa, Hiroki, Wakayama University, Wakayama, Japan

Problems of outer mega region in the mature period - case studies of Tokyo and Osaka region, Japan

This study clarified the problem of the difference in the inner and outer mega region in the mature period. Population decrease and the reduction of areas with increasing and decreasing populations do not happen equally throughout the whole region.

Skodra, Julita, IMIBE, Essen, Germany

Urban transformation of deprived neighbourhoods in metropolitan regions: the cases of greater Manchester and the Ruhr Metropolitan Region

Urban transformation is a complex process influenced by different challenges specifically in metropolitan regions facing structural change. Regeneration efforts, highly dependent on financial means, in the wake of economic slowdown present another challenging issue. This comparative study aims at exploring the mechanism that enabled successful urban transformation of deprived neighbourhoods.

Wang, Yi; Geng, Hong, Huazhong University of Science & Technology, Wuhan; Ouyang, Guohoi, Changsha University of Science & Technology, Changsha, China

“Imbalance” of regional industrial spatial development of small towns in the context of urban-rural integration--a study based on the case of Anshun City, Guizhou province, China

The author studies the strategies concerning and the layout of “imbalanced” regional industrial space in the urban-rural integration of China’s small towns

Workshop 7 Eindhoven

How to react when traditional industries move away?

Ahmad, Amira, Izhevsk State University, Izhevsk, Russian Federation

The history and rebirth of an industrial city: the case of Izhevsk, Russia

Studying Izhevsk as post-industrial city led to identifying a set of tools, which can contribute to reinventing other post-industrial cities. This model proves that industrial cities, which were developed and controlled by traditional centralized policies can be reinvented by the efforts and ideas of their active societies.

Grover, Paul, Arup, Liverpool, United Kingdom

Liverpool: a journey from a giant of world trade into a city where giants now walk the streets

The city of Liverpool has successfully managed to reinvent itself from a city that was once in decline resulting from shifts in World trade, into a World class Waterfront City that is now at the forefront of delivering culture and the arts to its citizens

Guo, Xiaodi, Nanjing, China

The exploration of industrial transformation in Chinese new economic normality—case of Yangcheng Lake Area planning in Suzhou

This paper chooses Yangcheng Lake Area located in the northeast of Suzhou for example to direct the industrial transformation. This includes the way of choosing economic category which suits for the environmental resources and economic conditions here, and the suitable path of industrial transformation.

Kamrowska-Zaluska, Dorota, Gdansk University of Technology, Gdansk, Poland

Social change from the solidarity to urban movements - design thinking approach in co-producing city of Gdansk

The paper presents bottom-up project of revitalization of interior urban quarter's in Gdansk using Design Thinking approach as a users' needs oriented method for co-producing of space. This pilot project could be a canvas to elaborate the model of intervention for other spaces in need of similar intervention.

Kelly, Erin, Detroit Future City, Detroit, United States

A little about lots: implementing land revitalization in Detroit

This case study will provide a measured description of Detroit's present inventory of vacant land and share the process behind developing a collaborative tool for parcel (or lot-level) interventions from A Field Guide to Working With Lots, the first community based, web-design tool for transforming vacant land in Detroit.

Lin, Yan; Wang, Jian-guo, Southeast University, Nanjing, China

Research on revival mode of China's traditional settlements based on "bottom-up" urban design method

The "bottom-up" urban design method can be supplement and improvement to the current general "top-down" method. Taking Cangshu, Mudu, Suzhou as an example, the article demonstrates and summarizes the "bottom-up" urban design method by operating the urban and architectural designing process on the ancient town.

Liu, Jie; Geng, Hong; Lu, Ningxing, Huazhong University of Science and Technology, Wuhan, China

Generation mechanism research on landscape of traditional settlement based on folk ritual

The paper integrates knowledge about architecture, folklore, sociology, history, geography and other related subjects, adopts basic methods of environmental aesthetics and settlement geography, and studies the correlation between Chinese folk custom ceremony and the generation mechanism of traditional settlement public environmental landscape.

Martinez-Diez, Pablo; Santamaria-Varas, Mar, 300.000 Km/s, Barcelona, Spain

AtNight project, designing the nocturnal landscape collectively

By means of "AtNight" project, we have explored the possibilities offered by digital technologies to propose new collaborative and efficient design scenarios. Given a model of nocturnal urban planning based on top-down management, we propose a new approach based on the perception of citizens.

Priyomarsono, Naniek Widayati, Tarumanagara University, Jakarta, Indonesia

Revitalization of batik business at the time of post-declaration of Laweyan's Batik Village Surakarta, Central-Java Indonesia

Laweyan is a pouch-formed settlement region of Pajang kingdom, having been developing since the sixteenth century. Laweyan holds typical societal characteristics namely societal groups of batik entrepreneurs. In the 1970s batik business started to decrease and even was assumed near-dead. The paper explores business revitalization as one way of prevention.

Van Strien, Anne; Boot, Isis, Eindhoven, Netherlands

Eindhoven in transition - reinventing the city from within

Eindhoven is a city in transition. Through a transition fieldwork study, collecting and connecting transition stories from a broad range of city makers. Our aim is to gain understanding and create new meaning of the city from within while reinventing our role as urban planning professionals.

Xu, Wei; Li, Juan; Chen, Chao; Su, Liangtao, Southeast University, Nanjing, China

Research and study on the town-rural planner system under the background of South-Jiangsu transformation in China

This research is based on several comparatively high industrialized countries in the south of Jiangsu Province and it looks into the "bottom-up" community planner system. By combining the "top-down" and the "bottom-up" mode, we believe that marketization helps to make up for the shortages of traditional South Jiangsu mode.

Workshop 8 Groningen

How to sustain energy resources?

Demerutis, Juan, University of Guadalajara, Guadalajara, Mexico

Planning for sustainable water and energy: a perspective from housing and urban development policy making in Mexican cities

The focus of the study is on housing through community building, under the premise of looking for compact, denser cities. A proposed planning tool comes in the form of a local government initiative to certify "Green Development" as a response to large water and energy consuming developments.

Momm-Schult, Sandra; Empinotti, Vanessa; Travassos; Luciana, UFABC, Sao Paulo, Brazil

The relation between the water resources management and territorial planning in São Paulo macro metropolis (Brazil)

How to ensure water access and supply to a 30 million people macro metropolis such as São Paulo? This article aims at the identification and analysis of the institutional arrangements and legal frameworks already in place and how capable they are in providing water security in the macro metropolis territory.

Mukoya, Kent Alwaka; Mwaura, Mbutu, Nairobi City Water and Sewerage Company, Nairobi, Kenya

Corporate social responsibility as a trajectory to actualization of corporate governance strategy - case study of Nairobi City Water and Sewerage Company

Responsible business practices can in many ways contribute to sustainable development.

Nabielek, Pia, TU Vienna, Vienna, Austria

Wind power deployment in urbanised regions: towards a comprehensive approach for renewable energy and spatial planning.

This research examines the implementation of onshore wind power by 'wind power-zoning plans' in European urbanised regions. It questions, whether these plans are comprehensive, that is if they promote both national wind power growth and regional-specific interests.

Papa, Enrica; Boelens, Luuk, Ghent University, Ghent, Belgium

Spatial, mobility and energy planning: a cross-sectorial and actor-relational approach

Energy's decarbonisation and a move towards a sustainable energy system is a massive challenge that can only be achieved by combining spatial, mobility and energy policies. Planning should address the integration with a collaborative and actor-relational approach.

Van Noordt, Anneloes, Spatial Development Department Flanders, Brussels, Belgium

Analysis of the impact of positive and negative criteria on the siting of wind turbines in Flanders

If Flanders wants to reach its target of 10,5% renewable energy by 2020 it has to step up the realisation of the siting of wind turbines. Based on a GIS analysis the impact of positive and negative criteria on siting of both current and future wind turbines will be performed.

Wang, Qianna, Sichuan University, Chengdu, China; M'ikiugu; Kinoshita, Isami, Chiba University, Matsudo City, Japan

Municipal renewable energy planning in support of post-earthquake revitalization: an application in a Japanese municipality

A GIS-based approach for municipal renewable energy planning and its experimental application in a Japanese municipality to support post-earthquake revitalization.

Yuan, Wen, Urban Planning and Design Institute of Nanjing University, Beijing, China

Planning in regional cooperative way to develop cities in ecological protection area: take Tongyu, China as an example

Cities in ecological area have long been confused both in green protection and local development, and planning in such area has long been difficult. In master plan of Tongyu, China, we are trying to deal with the circulation problem in a regional cooperative way.

Zhai, Baoxin; Zhu, Wei, Tongji University, Shanghai, China

Optimum population capacity forecast based on ecological footprint analysis: A case study of Xi'an

For the purposes of ecological balance and sustainable urban development, this paper used the Ecological Footprint Model to calculate the Optimum Population Capacity of Xi'an.

Workshop 9 Maastricht

How to overcome national borders?

Bacharyar, Abdul wasse, DeCoBa, La Wantzenau, France

The convivial regions in the world

Convivial regions or friendly areas consist in the union volunteer from several countries in the world based on historical, geographical, and socio-cultural approaches.

Boeger, Louise; Andrade, Hana, Universidade de Brasilia, Brasilia, Brazil

Brazil's federal district economic development integrated region (ride/df) and the regional mobility management

The paper presents the capital of Brazil and its Economic Development Integrated Region (RIDE), which comprehends twenty-two cities from two different states. We are going to understand the challenges involving public transportation in a metropolitan region by making an analysis of public policies implemented in the RIDE since 1998.

Caner, Gizem, Lodon, United Kingdom

From a barrier to a bridge: Nicosia and its national borders

Nicosia, the divided capital of divided Cyprus, offers unparalleled perspectives on the issue of transboundary cooperation and movement. This paper provides inputs on how a barrier can be transformed into a bridge, even when such a transformation is perceived as unthinkable.

Chen, Haining; Wang, Jianguo, Southeast University, Nanjing, China

Trans-boundary urban development cooperation as the new global growth engine: the research on mechanism of Sino-Singapore cooperative city building practices

The paper mainly elaborates the research on mechanism of Sino-Singapore cooperative city building practices through the discussion on trans-boundary urban development cooperation as the new global growth engine, with analysis models built from four Sino-Singapore cooperative cases.

Li, Lei, Beijing, China

Build a trans-boundary urban system from the top design to bottom practice

Urban design has changed with the development of science, technology and other factors. We need to break-through and build a trans-boundary urban system in a broad sense, beyond the achievement of all related, integrate and optimize them with adaptable methodology and systems from the top design to bottom practice.

Liu, Lixun, University College London, London, United Kingdom

The impact of rail transit systems on urban regeneration areas in a Chinese large city

The research topic is the impact of rail transit systems on urban regeneration areas, in aiming to understand how the impact on development and regeneration differs by locations and population groups. It also explores what associated policies and planning interventions should be introduced to achieve greater outputs.

Ningbo master plan: a world connected metropolitan achieving port-city symbiosis

In 2015, the China's State Council approved the new "Master Plan of Ningbo" once again stressed the city's function as: the important port city in the southeast coast of China. For the objective of enhancing the international port, the new master plan proposed.

Niemann, Beate, University Wismar, Wismar, Germany

Sustainable urban waterfront development in port-cities

What specific content included such strategies to develop the port and the city in sustainable strategies? To gain answers, global case studies and reference projects will be analysed and critically scrutinized. Of crucial importance is the derivation of recommendations for the future development of the port-city with international charisma.

Nyamai, Dorcas; Wall, Ronald, Institute of Housing and Urban Development, Rotterdam, Netherlands

Wealth and the City: The competitiveness of port cities and non-port cities

Shipping companies now have the power to choose where to locate no matter the magnitude of investment by ports; making ports just a part of the value chain system. Strategies are needed for ports cities to remain competitive in the face of globalisation and export-oriented market strategies.

Pagés Sánchez, José Manuel, Hafencity University, Frankfurt am Main, Germany

Port-city relation: integration - conflict - coexistence - analysis of good practices

The port-city relation has evolved from integration, to conflict and then to a current state of coexistence. What are the main reasons for this change? What strategies are being used? What outcome are they getting? Most importantly, is this the right path?

Tsatsou, Alexandra, Institute for Housing & Urban Development Studies, Rotterdam, Netherlands

Port cities in action for resilience

Port and city are developing into entirely separate entities, spatially and functionally. Building resilience through port-city collaboration on climate change response is a mandatory condition for reducing risk and establishing ground for economic growth. Collaboration on climate actions can be the backbone of port-city cooperation on economic level.

Van Den Berghe, Karel; Ghent University, Ghent, Belgium

The Economic Port City Interface of Ghent, Belgium

Based on research of the port city of Ghent, this paper explores the different interfaces of the port city. Using different actor-relational techniques, it shows how the different interfaces are diverse and dynamic. This way, this paper contributes to the recent post-structuralist attempts in the port city research field.

Velnidis, Anastasia; Goethals, Sebastien, Citilinks, Chengdu, China

Perspectives and challenges of port-city interfaces in Chinese coastal cities with the lessons of European old ports regeneration: the case of Qingdao.

In 2015, eight of ten largest seaports are located in China, mostly in coastal port-cities. Recently, European largest ports such as Rotterdam have built innovative approaches of port-city synergies. In its development context, the port area of Qingdao faces similar opportunities and challenges of integrated coastal management and post-industrial rehabilitation.

AMSTERDAM

How to build the city in a cooperative way?

An Anarchist Approach on Urban Planning: The case study of Thessaloniki

Ioannis CHINIS, Aristotle University of Thessaloniki, Greece

1. An introduction on anarchist planning

At the beginning of the 19th century, historical, political, economic and social fermentations resulted in the final transition from the era of the pre-industrial city to the urban center's one. The cities are exponentially larger, highlighting new needs. In more than two centuries, and already a canvas for a range of city planning approaches, the construction of the modern city continues to create and accumulate distortions.

Dystopian phenomena, such as spatial and functional fragmentation, uncontrolled suburbanization, urban sprawling, ghettoization, spatial exclusion of the economically weak and minorities, desertification and social alienation require the appropriate design solutions. However, from the age of E.Haussmann's operations in Paris, to the modernists of CIAM, to Keynesian government interventions and the General Urban Plan, up to the strategic planning and the post-modern approaches at the dawn of the 21st century, the town planners seem unable to give the required solutions. In this hierarchical politico-economic system the contemporary urban planner "acts as a mitigator against the ills of dehumanization, exploitation and societal divisions that capitalism brings, while simultaneously helping to facilitate the spreading and strengthening of that capitalist exploitation. This is a cause of much grief and cognitive dissonance for the planner, as they are trying to do several contradictory things at once, mitigate exploitation while allowing it to occur, and in this way they are participating in and perpetuating the exploitation and social inequalities themselves". (Tveter, 2009). The limited vision of the design process sets limits on design solutions that can be developed. The system of property ownership ensued by capitalism and, in more general terms, the power relations in our society convert spatial planning tools in policies which reproduce the aforementioned restrictions.

Design fails to extricate itself from property ownership and exchange, which create and nourish class differences, inequality, exploitation (of human and natural resources), division (social and regional) –conditions it is supposed to ease and eliminate. With limited ability to perform this role, design leads to distortions and sometimes gets bogged down over time. (Tveter, 2009) We, therefore, come to the conclusion that design must operate without norms imposed by capitalist interests, with the capacity to produce a wide range design of solutions for the well-being of society and the protection of natural environment. In order to serve these principles, a new socio-political context is necessary, without haves and have-nots, masters and servants, and of course without property, which is the backbone of all the previous conditions. A classless and anti-hierarchic framework. A stateless society, which will not be organized on personal power or governmental authority (Tveter, 2009) (Black, 2004).

Could we end up with a radical change in the political, economic and social system? If the society could cease the societal power relations, and, above all, the property relations, which are the foundation of the current system? Would it be possible to ensure the welfare of a society, through a model which does not follow the rules of a hierarchical, top-down" (top-down) design? Are we referring to a "bottom-up" (bottom-up) planning process (?). And what if we eliminate the term "up" from this sequence?

Since the 19th century, all these questions are being answered by theoreticians such

as Proudhon, Bakunin, Kropotkin and schools of thought, such as those of mutualism, federalism, anarcho-collectivism, anarcho-syndicalism, anarcho-communism. They envision a classless, stateless, anti-capitalist society, which is a result of spontaneous associations of free people into federalized social groups. They envision a society in an anarchist form. In addition they introduce a new way of organizing, without exclusions, exploitation, ownership, but with mutuality, solidarity, functionality and spontaneity. An organization planned from directly concerned people to serve themselves.

The gaps left in the structure of society in a state of anarchy would be prevented by free association among the society's members. When interaction between people is higher than the interpersonal relationship, "it takes some sort of institutional form; the community, the workplace, family and society as a whole, whatever it may be, should be subject to the direct control of the participants. This would mean works councils in manufacturing, people's republic in societies, interaction between them, teaming up in larger groups, up to the level of the organization of an international society" (Chomsky, 2004).

In an anarchist society, organization does not derive from the constitution and the institutions of a strong state mechanism. It isn't governed by the laws of the so-called free market, nor has the consistency of a national or a religious dogma. Its coherence comes from the solidarity relations developed between the people. People who neither accept the role of a private unit, nor operate as a homogenous whole. This diversity of associated members is the main "force" of society to avoid stagnation, not to run aground.

In accordance with theoretical analysis, we could identify the prerequisites for a truly unfettered, design process in a social situation of anarchy. It is normal, however, for questions to arise. Initially to investigate how the planning process in general, and how urban planning in particular, are being formed as the society is being organized in an anarchist way. The way and the instruments for the bureaucratic organization of modern states and the complex systems spatial planning, which have been institutionalized, are being replaced. And finally what is the role of the urban planner, within the whole planning process, considering the new anarchist organization?

1.1 Design process - Spatial organization

The urban planner and anarchist Colin Ward, identifies a series of principles entailing the entire organization of an anarchist society. Therefore, processes of urban planning in the context of this society are identified as well. An organization that stems from the bottom, framed with horizontal processes, does not establish and does not impose anything, in contrast with the type of organization in the modern capitalist system. It should be voluntary, functional, temporary and small-scale. (Ward, 1990)

As a result, we end up with a design system in which the residents of a small residential unit meet voluntarily, in order to arrange all territorial issues. Sharing common needs, this collective of people, through trial and error, improvisation and experimentation, and with experience (or information as defined by Bookchin, 1990) gained on design matters, is led to a state of "spontaneous order" according to P. Kropotkin on "Mutual-Aid". An order more direct and more closely related to the needs of people than any other kind of exterior and enforced hierarchical order (Ward & Bookchin, 1990).

1.2 The role of the urban planner in anarchist planning

The designer, now, is not supposed to set up, dictate, oversee, impose or exercise control during the process of planning and implementation. Instead, she offers her knowledge and experience as a consultant and work training, by injecting the designer's mentality to the collective and to each of the people who make up. At the same time she has to be aware that a very important aspect of the anarchist emancipation is the matching of everyday life with the element of playing a game, in which capitalism-derived separation of "working time" and "free time" ceases to exist. The planner may propose to the collective, this time by way of a

game, a range of ideas and projects, which are free from restrictions, could be bold, or even be considered surrealistic. And the collective, for its part, is able to discuss, develop their functionality, and evolve them. (Tveter, 2009) (Bonanno, 1998 (1977)).

1.3 Application examples of anarchist theoretical background

The framework anarchist thinkers propose for the organization of society has become the base for residential projects since the 19th century till today. An analysis of anarchist design will be presented highlighting examples of deliberately anarchy-based residential organization, such as the Israeli Kibbutz communities and the Freetown of Christiania in Copenhagen and examples with spontaneous elements of anarchist design as well.

Even though anarchy emerges as a political theory in the 19th century, its existence as an organizational situation can be traced back in much earlier times. In addition to academic literature, samples of anarchist organization can be found throughout the evolution of human society. Since the time of man as a gatherer, there is evidence of groups of people organized in anarchist fashion, albeit in a spontaneous mode.

Amid the social conditions prevailing in the 19th century, the first deliberately anarchy-influenced ventures emerge, with strong support by writings on anarchy published one century ago. In the context of these efforts, the anarchistic approach to social and residential organization is realized via expropriating means of production, housing and functional assignments, and the development of a new standard residential organization - the conscious community.

The phenomenon of occupying an abandoned or empty building or land, in order to cover basic housing needs, has been highly prevalent, if we consider that a population of approximately 863 million people in the world live in slums. (Cordaid, 2014). The practice of occupation, a common practice for societies throughout history, obtains an ideological basis for the first time by the works of anarchy scholars of the 18th and 19th century. Kropotkin, in his book "The conquest of bread", argues that expropriation of both means of production and housing, to meet the needs of society, is a non-negotiable condition for the transition to anarchistic society (Kropotkin P. 2007 (1892)). This gives rise to a new kind of occupying space, one with political and theoretical background.

Such occupations will appear in Europe after the 19th century and would not cease to proliferate as today, advocating a wide occupying movement in countries such as the Netherlands, Germany, England, Italy, Spain and Denmark. In the course of the 20th and 21st century, similar projects exceed the scale of a building or a block. These projects extend to the scale of settlements, operating as experiments, serving as a confirmation for the potential for anarchistic organizing of society. Bringing together all those elements (organizational and operational) they form an alternative basis for the replacement of a modern urban metropolis. Prominent examples include the Kibbutz communities (in particular in the first half of the 20th century B.C.) and the settlement of Freetown Christiania in Copenhagen.

The movement of Kibbutzim, particularly before 1948, manages to encapsulate the best version of the 19th century theoretical anarchists' vision of 19th century, in an alternative, directly democratic, pluralistic social infrastructure, a state level, on the basis of cooperative labor, and in the residential organization a federalist system federalized communes. (Horrox, 2009). As stated by one correspondent of the London-based anarchist journal Freedom in 1962, it is one of the best examples of democracy that there is and certainly the closest to anarchy implementation. Any anarchy-leaning theory ... (is) part of the daily survival pattern. Here in this microcosm, the authorities which may occur in a genuine free society are easy to identify" (Horrox, 2009).

Respectively in the example of Christiania, a system of organization of the settlement (operating as design instrument in real time, through the spontaneous actions of inhabitants) contains all the attributes of a free society. Elements, such as self-

management, solidarity, small scale, functional and temporary management of issues, enhancement of spontaneous action, as well as the anti-hierarchy, anti-capitalist and decentralized organization of life, make the Freetown of Christiania, a successful model of anarchistic social organization, within a modern metropolis, a highly capitalist environment. As a result of this theoretical approach, an experiment is attempted, emanating from academic texts and practical experience of similar projects. The goal is to examine first-hand the design process in an anarchistic environment and if a project similar to the ones of Kibbutz and Freetown Christiania could be realized within the limits of Thessaloniki, a familiar residential area.

2. The case study of Thessaloniki, Greece

2.1 Anarchism in Greece

With the roots of anarchist school of thought in Greece to have as a starting point the distant 1880, had to spend several decades to become witnesses of the first speck of both in the political life of the country, and the urban canvas. With important milestone in 1968 and with the particular social patterns that are formed before and during the dictatorship of the colonels' extends a trend that challenges the daily routine, that over the last years of dictatorship will meet with the political bases which have already been set by the first half of the 20th century the Stinas and Castoriadis, shaping the first groupings self-named anarchists/ antiauthoritarian. Under the influence of the policy concepts deriving from the Italian autonomy, the "Situationist International", the Cornelius Castoriadis and the American 'Movement', there is the gradual emergence of a/a 'space', together with the late appearance of the spirit of '68 and in Greece. Something which is reflected in soundbites of the events of 1973 (such as "the power", "April-May ' 68 ") (Σούζας, 2014).

Go to "transition from dictatorship to democracy is", we are dealing with a growing 'space', which self-excluded from the overall climate apparent cooperation and solidarity policies and social fabric, which brings the fledgling parliamentary democracy, moves in a multidimensional isolation. Whether this means the delegitimation of holders of the same and to criminalize large part of its activity, or the land of marginalization in the central areas, such as the plate and then of Exarchia.

The Exarchia with the particular characteristics which distinguish them (strong presence students, old quarter with similar urban background), have encouraged the establishment and flowering publishing projects. Between these and the first "family groups" who will comprise the a/a 'space', which makes the first steps of the kinematic setting post-war Greece initially to continue strike demonstrations in the second half of the 70s, culminating with the greek wave of those occupying the university buildings at the end of 1979 (Σούζας, 2014).

This time, amid the quirk repressive policy of the state, we are witnessing an historic phase of "space" and more generally of competing movements fiord in Greece, as well as for the first time occupied housing make their appearance in two large urban centers. These ventures as an expression of voltage prefiguration (Σούζας, 2014), which is emerging from the ranks of the a/a "Space", operate by applying and creating experimental, emerging from the '68 new political concepts, which place emphasis on the immediate "here and now" pursuit of desires, making blurring the boundaries between personal life/lifestyle and political motivation (Σούζας, 2014). Moreover, at European level, there is already the experience, with the squatting phenomenon is booming in after '68 period.

In the years ahead, occupied buildings will continue to emerge both in Athens, and in smaller cities the Greek territory (Real, 2013), including in Thessaloniki. The migrating sites mosaic, which is configured on the urban construction of Thessaloniki, enriched, supplemented and spreads, often in response to local and wider political and socio-economic developments (by the anti-globalization movement Genoa 2001, summit Thessaloniki 2003,

December of 2008, Capitalist crisis of 2008), by new housing assignments (Black Cat, Terra Incognita, Delta, orphanage, Libertatia, Fabrika Square YFANET), functional squatting ventures (Sporeio, Scholeio/School), as well as self-managed areas and spots that operate in leased facilities (Micropolis, Domino, Without Authorities, etc.).

2. 2 Option exercise-region study

From the extensive wine list to complement these efforts, causes a particular interest in the initiation of the investigation, gathering characteristics which are not found in other examples. Is the "free social ski school for the learning of freedom", which is housed in the 2010 grade II listed building on the corner of Bizaniou str. with Vasileos Georgiou str. (extension of Queen Olga str.), where the 12th elementary school Thessaloniki had been housed until 2004. This project seems to collect all those characteristics (in spatial, functional and ideological level), to operate as cradle of another-an alternative proposal for the setting up of urban space and the organization of life thereunder, as a source of aggregate rupture with this politico-economic system. As distinct from the political context of the assignment, special attention from the initiators of the project is given in point of space and the process of reclaiming from society, freed from the dystopic characteristics which have borne the chronic distortions of harmonized with the capitalist system design, and their use in accordance with the collective needs and desires of local society. Features referred to by the same: "liberalizing public spaces from the abandonment and the lack of power. Taking place in freedom and meant to individuals and groups to the total social emancipation from any repressive, extortionate institution and dominating control" (Convention E. X. School , 2010).

The assignment "school" regardless of the features that gives it the organization of everyday life and the kinematic measures of states, is in itself a statement. Sheltered in one of the few luxury buildings that have survived on the length of the former Exohon Boulevard, the current Vas. George Ave. in contribution with the Bizaniou str. The Administrative area to which the assignment belongs to E-municipal community of Thessaloniki municipality, becoming the first residential area that meets someone if moved from the edge of the historic center and the White Tower, to the south-east conurbation. An area with unique historic, urban and architectural interest, as well as part one of the first extensions of Thessaloniki at the end of the 19th century, outside the traditional limits (Γερόλυμπου., 1995 (1985).

Thus, the choice of the building of the first Croat squatters, in addition to the obvious practical reasons that the attached, such as the beneficial ownership (ownership of the church in this or the public in other cases) and the years of depopulation, has strongly semantic sleight nature. The so-called "towers" the avenue, were for decades average view of wealth and social symbol separating the bourgeoisie of Thessaloniki. With the occupancy and ownership of the building, from people-entities which are based on disengagement from the system that produces these class differences, there is a symbolic victory in the context of this particular "semiotical guerrilla warfare" (Umberto Eco,1989, from (Σούζας, 2014); the a/a space with the state, the bourgeoisie and the church (in which the building is owned by, and in accordance with complaints of local civil society, has attempted to change its use by school in commercial, anticipating a higher income) (Convention E. X. School , 2010) (Krümel, 2005). It is a practice which is prevalent in many other examples those occupying, creating a phenomenon of intrusion of the anti-culture and the squat movement in a symbolic and historic stronghold of urban culture (Σούζας, 2014). It could be said that the appearance of these migrating sites, their prevalence (in areas with specific characteristics) and networking to develop between them and the rest urban fabric, constitute a peculiar, the construction urban phenomenon, which brings in practice and with the most bold way the libertarian theoretical framework in urban areas.

In fact, therefore, a study on the implementation of an anarchist approach to design an urban center, such as the Thessaloniki, it is directed to the occupations, the spots and the social areas, but also the wider residential environment, as well as able to operate except areas of everyday life and kinematic action, as hob emergence of a new reality for

the current urban centers. A reality, which (as has been analyzed and the theoretical framework of research) starting from the level of the neighborhood - commune can be developed federalist as the level of confederation, covering existing hyperlocal spatial units and overhead levels of planning.

As an ideal setting in which to unfold such an experiment qualifies the e. X. "Schools", an area which brings together all the elements that could make it a representative example of squat movement, but also with special features that stand out from the other operations of Thessaloniki and contribute to highly developed relations with local civil society. In conjunction with the qualities of the area and the historic load, accompanying the urban background on which rests, emerges as a sole interest case to study.

3. 1 The workshop process

In November 2014 the general assembly of the School shall be informed of the issue and the content of the pilot project "DIY Urbanism Workshop // An anarchist approach on urban planning in Thessaloniki", and decide unanimously for the hospitality two six-hour meetings on the premises, on 5 and 12 December 2014. The next few days update (via the internet, posters, flyers) to a broad base, which includes members of the local society, people involved in the occupation, but also students of AUTH), that from the first moment showed a great interest on the project. A people for a whole week, and in particular for the 12 hours that would last the processes in the laboratory, we tried to simulate the processes of design collective, and to reach some initial proposals for the spatial organization of the region.

The first meeting of the workshop (5/12) begins with an initial approach in the theoretical background of an anarchist urban planning method, through presentation of bibliographical sources and a question-and-answer (Q&A) and free debate, with an eye to the best possible understanding of the framework by the participants. This is then followed by the presentation of the program, as well as the analysis of procedures and design tools, with the main to be the psychogeographic walk and the World Cafe, with the use of the design he now forms part at the end of two daily meetings (5 & 12/12) is in a position to put forward its proposals for the study area. This is the last intervention from the side of the researcher in the process and the manner in which the discussions of experimental collective.

So, through the design procedures proposed in he now forms part of the follow-up to the laboratory and following horizontal procedures, this is an attempt to analyze the area outside of the contractual procedures followed usually (for example in the study of a General Plan), while at the same time an attempt is made to identify trends, be deposited with new ideas, to challenge and to develop existing, to test the limits and the design features of our urban environment, and ultimately to establish a plan to regulate urban area study in accordance with the needs of stakeholders.

Το εργαστήριο πραγματοποιείται στα πλαίσια διπλωματικής εργασίας του Τμήματος Μηχανικών Χωροταξίας και Ανάπτυξης, Α.Π.Θ.. Για τη συμμετοχή **δεν** απαιτούνται ειδικές γνώσεις.

1.1 3.2 *Psychogeographic walk - Registration /analysis*

Returning to the case "DIY Urbanism workshop", the application of the first of the two major design tools analyzed above, the psychogeographic roam, is used as a first acquaintance with the area study, for those participants are not at the same time and its inhabitants or the review of the region under a different perspective, from those who are already familiar with this. The roam is converted in this way in a particularly useful procedure recording and analysis of the area, in which the territorial-urban, morphological, physical, architectural features, but even the demographic and economic trends in the study area are identified by means of direct observation by the participants. The transfer of the bulk of urban analysis, from the "Office" and processing numerical data, the "road" and the emotive recording, it introduces the boldest concept of human scale urban planning.

The psychogeographic roam is the second in series planned action, for the first day of the lab. After a brief presentation of the theoretical background and the discussion in the framework, the first step was the participants to purchase charts and aerial photographs of the region, so as to facilitate the movement and the recording of impressions, and then to form spontaneously brings together wandering groups, which choose from a color to distinguish it from the other (orange, red, green, blue). Each group before you start exploring the town, selects a scenario, a predefined methodology by which outlines the course of the urban fabric. Thus, the members of the resources released by the responsible for the selection of the route during the experience of psychogeographic wandering around, and is free to be released exclusively on the observation of the urban environment. With regard to the free movement of information participants provide spontaneously and the overall size of the study area. Something that intentionally has not been established from the outset, as well as the division of space with any subjective or of what it seems like an objective justification by the investigator is an arbitrary nature in general, and the nature of the project in particular. As formulated by the German sociologist and philosopher Georg Simmel, "The limit is not a spatial fact with sociological effects but sociological fact that formatted territorial" (Simmel, 2011).

The methodologies traffic within the study area, to be selected by each group at the start of the promenade psychogeographic game, similar to those listed in the manual of the US Office Unknown destinations, but they are composed by creating hybrids. In particular:

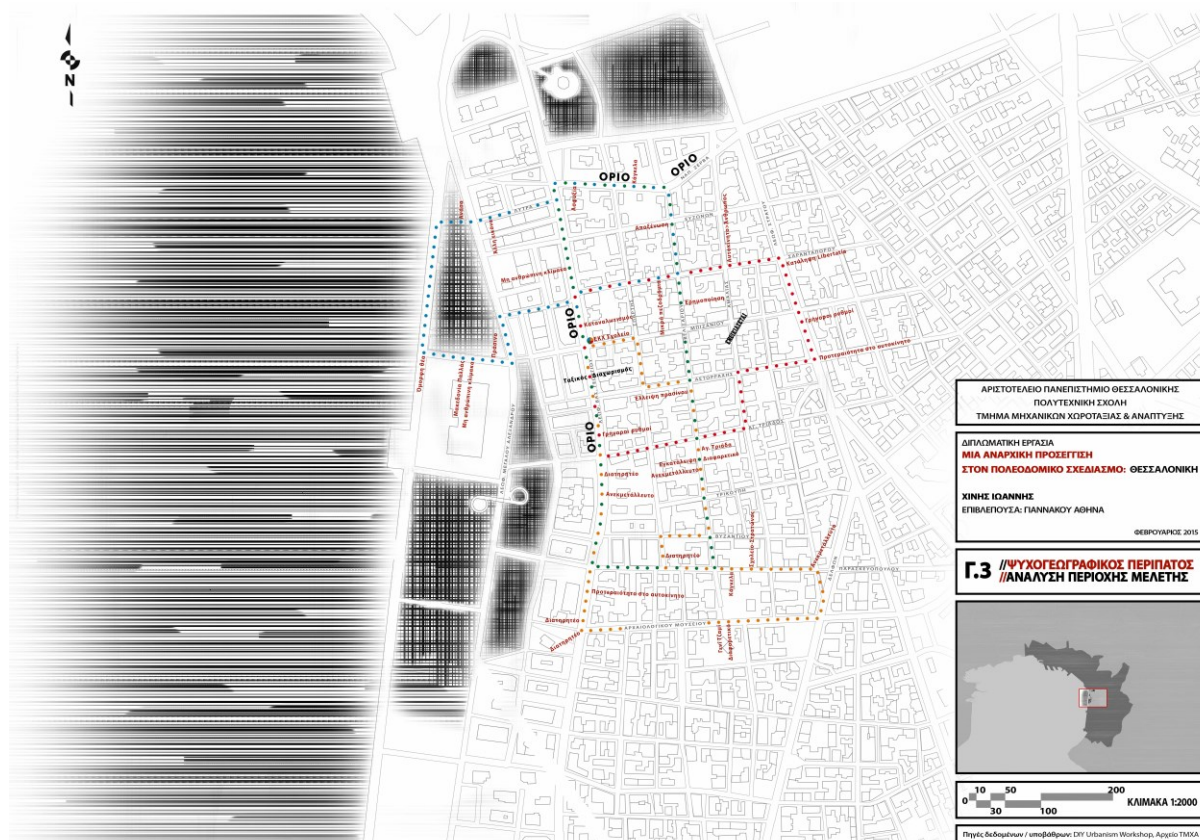

The "orange" team selects to follow an aesthetic roam. Making the aesthetic stimulus more concrete is chosen by the members of the group to follow the buildings with architectural interest. What ultimately drives more interest is the remaining villas (whatever remained to be reminded of the holiday Exohon Avenue), the neoclassical buildings with eclectic (middle-class dwellings are surrounding the villas at the beginning of the 20th century B.C.) and the architectural monuments (e.g "Mosque of Donme" or "Yeni Mosque" by Poselli Vitaliano property) that can be identified within the study area and are an integral and important part of the historical, architectural and urban background.

The "red" group following an aesthetic plan guided walks but, under an inverted, from aesthetic elements Mr. Linkohr's members of the negative. In other words, a route which is attracted to the "bad". An option that is very useful as it offers, as will be seen below in the analysis of space, a mapping of less attractive areas.

The "green" group moves in accordance with a simple scenario, which however enables it to cover a large area with plenty experience and the environment in the region. By selecting to move straight changing route and always turning left whenever a random stimulus leads to such a change.

And finally, the "blue" team combines two methodologies wandering around to complete the psychogeographic walk. While, initially, the members of the group agree on an algorithm and traffic route selection at each crossing, the form two right turns and three left, when they are the pair of roads Vas. George Ave. and Lytra str. and coming in visual contact with the New Beach, choose to follow an aesthetic criterion motion before returning to

area of assignment. So after moving algorithmic, left to the pacing are what will draw them in sensory stimuli of the beach front, creating the option of a hybrid algorithmic and aesthetic psychogeographic promenade.

The traffic routes of the groups during the psychogeographic walk are also ultimately spontaneously define the study area, which extends approximately from the street rpn. Zerva Napoleon str., near the Floral Park, up to the Archaeological Museum str. and the Yeni Mosque (the former archaeological museum, hence the name of the road), and from the Army Avenue down to the new Beach. This definition is the first decision to be taken by the design he now forms part, even if it is the momentum. The choice is a component of the natural movement of the members of which is affected by physical and morphological characteristics of the region, thereby implementing a concept, the theory of that moment of spontaneity and insecurity, and not as a result extrinsic factors (as is the case in the current urban and administrative division of the urban area).

After the return of all groups in society, starts the recording phase and analysis of impressions of psychogeographic wandering around. Each group after it identifies and plans the exact route on the chart of the region, is attempting to describe the other members of the collective, using photographic material, sketches, testimonies collected in notes, the experience gained from the walk and in particular elements which give a first idea for the area. Each group according to the scenario which has followed during the psychogeographic promenade, concentrates and in different territorial issues. Thus, during the debate on the analysis of the results of the psychogeographical process expressed both concerns shared by all groups, and in particular subjects dealt with only one of these in the course of wandering around. Through the concentration and the debate on the comments of the promenade, from which there are disagreements on details and construction subjects, identified and recorded through the filter of this collective process the

main points of the spatial resolution for the study area. Points which have been confirmed by the urban, environmental, demographic, economic, historical and morphological characteristics of the region.

The analysis of the region begins with a problem which all groups identify and record the impressions. Wandering on the main roads (Vas. Sofia Ave., Vas. George Ave., Army Ave., Delphon str., Alexander the Great Ave.), gives you the feeling of a non human-centered urban environment. Starting with the human mobility and senses, which are, according to Jan Gehl (2013), the key factor of all activities, communication and the peoples' behavior in general in the public space.

The mismatch of the urban environment in our region (but also in the wider region) with the characteristics of an average person, as analyzed above, is initially detected in the design of the road system. The parallel to the waterfront collector streets (Vas. Sofia Ave., Vas. George Ave., Army Ave., Delphon str., Alexander the Great Ave.) which divert the movement of vehicles to or from the center of Thessaloniki, include four traffic lanes each, which puts their width and the distance between the pavements on each side of the road at 15m, enabling the vehicles to develop speeds which are approaching the 50km/h. It is evident, therefore, the design's tendency to meet the needs of the vehicle, and not the human ones. A phenomenon that not only occurs on the main road axis but also on the residential area east of Vas. George Ave., where the mobility of pedestrians is limited to really narrow, incomplete -ramps and tactile paving does not account for the largest part of the network-and/or non-existent sidewalks, because in some parts are occupied by parked vehicles.

However, the sense of a non-human scale design is not just on the road, but also extends to the built environment of study. The main structural component of the urban environment and, more generally, the Greek urban center, the apartment building, contribute significantly to impression that members of collective. The vertical development at heights above 15m (most buildings feature 5 to 6 floors apartment), which is supplemented by the repeatability and the uniformity of the building structure, creates an environment in which, because of scale and morphology, fails to irritate the sensing of wandering, leading to it is irrelevant and boring.

The limited space, the barriers, the noise, the pollution, the risk of accidents and in general the hostile conditions, are the everyday life of the inhabitants of the region, such as those of most cities. If, indeed, we consider that the vertical build in small area and high travel speeds of vehicles allow you to maximize the exploitation of high rents showing an urban center, and the extension of these high rents in agreement with the pattern of urban diffusion length of the motorways. It will be necessary to note that this increase in speed does not have an impact on the lives of the people as well as the average time displaced in urban areas as well as in Thessaloniki remains stable in recent years despite the growth of urban centers. That means that residents do not save time due to the higher speed, simply travel further (Καυκαλάς, Λαμπριανίδης, & Παπαμύχος, 2008). It is confirmed, for example, and in this case the orientation of modern town planning initially in feeding the capitalist standards economic growth and secondly to meet the needs of people.

The green spaces which are recorded in the region is minimal, with the only exceptions of these Park Floral Park and the New Beach area, an area which has emerged from the post-war infill (decades ' 50- ' 70) on the beach front along the Exohon Avenue. A project originally with purely military nature (as cold-war defense project), which has been developed into a pleasant and lively and hyperlocal important public space, with the only discordant note the compact volume of Hotel Macedonia, which was raised on the beach in 1960 (Χαστάογλου, 2008) (Γερόλυμπου, 2008). Some green "touches" to the region are given by the gardens of the remaining eclectic buildings of the 19th and early 20th century, but the majority of them remain inaccessible for the local society, behind the bars of the fences. While a significant reserve landscaping is trapped in the unroofed building blocks. Something that comes as a result of the rapid, since the nineties 60, reconstruction and replacement of the original attribute beauty spots of wider area, with massive construction. (Γερόλυμπου, 2008)

The issue of enclosures seem to employ all groups after the psychogeographic stroll. As mentioned above, the handrail which erected around many buildings of area study (within these and the listed buildings) reinforce the image of the limited open-public sites in the region. Operating as a means separation and protection of property (either private or public), scattered in area fences isolate one important piece of potential open space available, creating effects fragmentation and discontinuity of public space, as well as a strong sense of exclusion to vagrants of the venture.

Features include examples, which referred to during the recording of experience psychogeographic promenade. The first is located on seven stored apartment buildings along the rpm. Zerva Napoleon, which both as building blocks as well as the fences which the projections are a visual and natural border of the region with the park of the floral park, where sometimes bloodline through his father the stream of field of the Champ de Mars. A further example is that of the schools on the Paraskevopoulou and Archaeological Museum str, which in addition to the separation caused by territorial, contribute to a second level in isolation of the educational process from the functions of the rest of civil society, giving level symbolisms the feeling of "army barracks". At this point it would be worth commented on that during the recording very few people who raised the existence fencing around the two occupied buildings in the area (e. X. School and Libertatia), whose presence is still a factor that indicates the historical and class background of buildings. This two-pronged approach which is recorded, after discussion between the members of the collective, is detected in predisposition which causes the open, of both territorial and functional nature of squatting projects and free access to them during the day.

However, the most intense limit identified in study area is drawn from the shaft of the VAS. George. Both the same avenue as a main road with similar traffic volumes and noise pollution, as well as the visual barrier that forms the "wall" buildings, which have been built in the villas of the last century and in the area of the New Beach, contribute so that in several cases a traveling circus on the Vas. George str. not to realize the existence of beach front and the largest open space in the region, the new Beach.

The spatial separation that causes the Vas. George, in this case it is considered that separates two situations, taking and class character. In accordance with the comments made by the homeless on the axle, the apparent differences in morphology, the components of the building and, more generally, the qualities of the space segment of the road extends to the Thermaikos Gulf, in relation to the "inside" part of the region, indicate a differentiation of social composition and the income profile of the inhabitants of the two parts. Something that is confirmed if study the differences in the prices of real estate across the avenue (and especially those who are facing the sea), and the demographic composition of the two compared regions (with the "internal" to hosts social groups of students and economic immigrants of decades 1990-2000, which indicates and cheaper rent houses and smaller percentage owner-occupied dwellings in relation to the "Beach" blocks) (Λαμπριανίδης & Χατζητροκοπίου, 2008).

The diversification of the region between the two highways (Vas. Sofia Ave., Vas. George Ave., Army Ave.), in relation to the "Beach" area, intensify the sense of abandonment which derive the members of the group wandering on the streets of first, mainly because of the lack public infrastructure (insufficient network pavements, damaged road network), the phenomena of disrespect in public space (vehicles are parked on pavements, overflow bins etc), and the diffuse visibly neglected buildings from the early 20th century. The unadorned areas, which until a few years ago-orientated retail outlets and workshops small nuisance (something which has declined as a result of the economic crisis of 2008) contribute and they significantly to deterioration of the residential section.

Under these conditions the linear development of business activity which is observed along major axes of Thessaloniki (to keep pace with the objectives set out in an approved General Plan), reinforced by prioritizing the boulevards of the test residential section, and in particular

the Vas. George, in key actors of commercial and social activity. Character which this road is not lost ever since the period of fire in 1917, when she hosted for the first time the evicted from the historic center commercial activity. When, therefore, the crisis is now, at the end of the previous decade, the great bargain stores for rent and the need for economic survival will lead even commercial level center neighborhood to gather as close as possible to the axis.

The territorial fingerprints of economic crisis is apparent, not only in the residential area between the highways, but also to the same shafts, and mainly in the Vas. George str., where the 1/5 of shops at ground floor of flats remains without a renter. A phenomenon that is not limited to the narrow area of study, as well as part of the widespread rapid economic activity of the city degrowth.

The conditions under which continues to shape the economic crisis and the spatial implications these in Thessaloniki, in conjunction with the attacks that has managed the modern way of life within the urban center (fast pace, solo lifestyle), the social ties of residents, build in parallel with the economic and social crisis. Cannot be compared with apparent alienation - alienation of the individual, and intrusion of the social fabric in other urban areas. However, the signs are obvious and recorded by most of the groups in the psychogeographic procedure. Information which is sufficient to raise a feeling of insecurity to vagrants in some parts of the route. Such characteristics indicate a participant: "I would not have felt comfortable to circulating evening in this area", by entering the debate and a 4th dimension exceeding the spatial resolution, this time, in which reinforced (or otherwise retract) some stimuli that gives us the urban environment.

Finally, in the course of wandering psychogeography have been detected by all the groups extremely samples of historical, architectural, cultural and social background of study area. Starting from the villas of high income strata Belle-époque along the highways, the remaining class educated backgrounds eclectic data homes, up to the ceremonial buildings (some in office, as the Christian church of St. Trinity, and other ineffective, as the Yeni Mosque), one can roam notional in all the historical phases of the test area. Moreover, indicative of the predominance of these buildings is the choice of one of the groups (orange) to navigate the site using the. And can the emergence of Thessaloniki in European Capital of Culture for 1997 has given rise to many of the monuments, which were rescued from the building frenzy of the past few decades, to sustain themselves and to maintain, but a large part of building this capacity (especially the "internal" residential area) in accordance with the recording remains unprotected in damage that brings the time and wasted.

To sum up, it may be useful to set out the cumulative list of problems, which were detected during the process of psychogeographic promenade and the debate - analysis followed by the area of the "school" and which are the starting points for the reasoning of the participants in the second phase of the simulation experiment, the phase World Cafe - proposal, as formulated by the design he now forms part:

- "Non-human scale."
- "Priority in vehicle against human (reduced mobility) ."
- "Homes boxes - uniformity - lack of different."
- "Lack green particularly over the Vas. George Ave.. The private parking is very public-open."
- "Handrail (separation - protection of property). Schools-barracks."
- "Diversification to limit the Vas. George Ave.. Spatial - class warfare division."
- "Sense of abandonment-desertification over the Vas. George Ave. (internal area) ."
- "Concentration functions to main routes."
- "Surveying the collapse of the "capitalist dream" into space."

- "Alienation - Insecurity."
- "Derelict / without a use historical-architectural monuments. The only different characteristics in study area."

3.3 World Cafe -Proposals

A week after the psychogeographic walk and the analysis of the collective area, the second part of the lab followed. Members of the collective, combined with new entries, gathered for the second time at the premises of the school, on Friday 12/12/2014. Immediately a general discussion on what happened last Friday started and, at the same time, the necessary information on what people are new to the process. For the next six hours we will participate in an experimental simulation of what a design collective would be like inside an anarchist society. The process of World Cafe is ready to start.

The members of the collective are divided into five tables, with each table hosting three and four people, with a different thematic debate on each one of them. The five themes relating to basic planning functions, which were found in the first chapter have been dealt with in theory of some of the most developed proactive anarchist thinkers. Thus, the participants are invited to discuss and to submit their proposals, in rounds of 20 minutes, for the issue of residence (the right to housing, the construction, the location of the site, and its relationship with other functions), for the ecology and the configuration of the urban environment of the region, the infrastructure networks and the way in which govern the other functions, for the adjustment of the production process, and finally to the new forms which will organize infrastructure system education, welfare and health.

The members of the collective will be witnesses and involving -expressing views, presenting ideas, evolving and revising the in many cases, arguing, questioning, finding mutually acceptable solutions, and ultimately bringing the theme up to the stage of the proposal; it is unprecedented for all. As long as the rounds of talks are interchangeable and the participants (together with their ideas and experience gained) move between the thematic tables, paper each thematic are filled with reviews and sketches, and the conference hall of the school with intense talks. The observer of this process can feel the tension between the discussers when there is disagreement, and pleased when the problems are exceeded and the common solution takes shape on the paper. Putting the image with allegorical figure available, it could be said that one can see that "signal" (according to Murray Bookchin) travels through the area, and as well as over each 20-minute is complicated, weave and the final proposal.

The World Café is coming to an end at the afternoon of the same day. All the design collective's members group together and the coordinator of each thematic table undertakes to present his table's proceedings in front of the entire collective. After each presentation, referred to some necessary clarifications, expressed the past disagreements, and once they solved, recorded the proposed objectives and actions per thematic; urban operation, the design collective is now ready to submit her approach on the design of the urban environment in a state of anarchy, to form proposals for the functional planning of housing, ecology and environment, infrastructure networks, the production and at the end of the education, health and welfare systems.

3.3.1 Housing

The residence, as the cornerstone of housing organization, garnered from the first informal discussions the interest of all members of the collective. Furthermore, considering that a dwelling is the first and most basic need - pursuit of a human, just after he ensures his food. It is no coincidence that the solution to the problem of housing over time is a key issue in the ranks of the planners.

Of course, the need for each person for a home involves much more than the simple desire for just a roof over his head. The residence except of providing protection of natural phenomena, is a key factor of determining and regulating social relations developed in a residential environment. Without any deterministic attitude, it could be stated that the housing model in each society may have a direct or indirect impact on the formation of social ties and, consequently, the social function. It is not difficult, therefore, for the members of the collective to argue that the basic housing model in the region must be undergone profound changes, so as to harmonize with the anarchist imperatives of social organization. Imperatives that this lab is trying to give a spatial substance to.

In accordance with the design team, in apparent isolation, social alienation and mask divisions, as highlighted by the spatial analysis of the region, can provide answers even through small-scale, directly feasible objectives, actions, and interventions on the planned area. And this by taking advantage of the opportunities given by the built environment to provide a fertile ground for the development of a social organization based on collegiality, anti-hierarchy, solidarity, mutual help, self-determination and the harmonious coexistence with the natural environment.

Flexibility

The initial concern arising from the discussions of the collective is the abandonment of strict a certain area of residence, which in our modern society has been configured as a direct reflection of ownership relations, as it is dependent on the socio-economic position of the occupants, and is (to a greater or lesser extent) a reflection of wealth and consumption patterns. Isolation, as a tendency of the contemporary metropolis, is resupplied through the converter of strictly defined apartment-concrete box. The apartment can be described as the microcosm of the modern human being.

In accordance to Greek planners, one of the most important causes of alienation in Greek urban centers, as well as in Thessaloniki, is the issue of residential building. However, an examination of the typology of dwelling which demonstrate that it may well be the basis for the development of flexible forms housing, able to supervise and to support a collective way of life. In a society based on solidarity and the coexistence of human beings in every aspect of their lives, the "common" maximized against the "staff". The capture of the above conclusion in spatial dimension would mean, in accordance with the he now forms part, a core facility to serve basic functions (health/focus), public areas which allow the widest possible interaction of inhabitants, and a range of flexible and adaptable, minimum areas for the hospitality of personal functions of every human being.

Consolidation

As the main problem, in addition to the isolation caused by the existing model occupation, and the fragmentation of urban areas, which sift-proof building volumes and the fences which are spread across the surface of the region, stopping the continuous of the urban landscape. The objective of the collective, as expressed through the proposals of its members, is the restoration of this continuity through the integration and efficiency of all unused and inaccessible places at the disposal of the local society.

In the first instance, the consolidated overdrawn and fenced areas of building blocks, they can be converted into hob coverage collective needs. On a case-by-case basis, can be used as meeting places, interaction and entertainment, as crossings, as urban gardens, or as the first nests-green lungs which will arise in an otherwise drab gray environment. The same may be applied, at the second level, and for the roofs of blocks of flats, which connected to each other and, through the facility each building, with the network of

integrated sites, can contribute to the creation of an escalator to urban environment, an extended collective residence. In this way the building blocks of flats do not adversely affect the urban streams and the qualities of the built environment, but also help to strengthen them.

In this way, the transition from the strictly defined limits dipole "public/private" area, in a model of territorial differences consistent. There shall be established a harmonious relationship between the "collective" and "staff", which is distinguished from the "collective" rather than with spatial terms privacy, introversion and need ownership of property, but in the sense of ensuring diversity.

Respect for the past

Important and separate part of the building stock of the region are the buildings of the last century. As was able to capture through the experience of psychogeographic promenade members of the collective, buildings and monuments (historical, architectural, religious) are scattered throughout the study area, adding different features in the image and becoming very important element of its historical landscape.

The preservation and maintenance of this beauty spots, which is a direct view of the past quarter of Exohon (and in general of Thessaloniki) in this, is one of the priorities of the design approach of the collective. The objective is the buildings do not remain, as simply a memory of the past, but to become practical. Moreover, the example of the same variety in which is housed the project of the school, is a guide for the way that these buildings can be used in the context of the new urban plan. In particular the reuse of symbols of a farprivacy, of wealth and of the class separation, giving space for the collective development activities \rightarrow -these could be for example meetings neighborhood; includes powerful symbolism.

Long-term objectives

With the above proposals the residential environment of the study area can be drastically changed, so as to keep pace with the needs generated by the new social situation, without having to make extensive changes to the existing building capacity. Of course, this does not mean that long-term the same model of organization of the built environment will continue to be sufficient to service the new forms occupation and organization of life. In accordance with the design team, the gradual change of the population model of the vertical typology of dwelling-unit, to a model closer to human scale, with a view to strengthening the conditions of collective lifestyles, perhaps should also be outlined.

3.3.2 Environment

With the, promoted by the he now forms part, extensive practical integration of structured and unbuilt area, as mentioned above, the figure of the urban environment changes dramatically. The design of the urban environment is oriented toward a more coherent model, which aims to take place all the functions of the settlement into a single spatial framework. It could be argued that the relationship and the degree of interaction between staff and open-public space, put on a new basis.

The role of environmental planning, the setting of this new status organization of settlement, it is catalytic. In this sense the design structure, seeks proposals that will enable them to develop environmental plan, freed by the external constraints imposed by the current political system, and capable of producing a viable human-built urban environment.

Zero ecological footprint

As the primary objective for the he now forms part, is the reduction of the ecological footprint of the agglomeration even at zero level. The development of an ecological conscience of the members of the commune, it is essential both for the attainment of the objective, or as a whole for the survival of the enterprise. The degrowth of each facet of the consumer behavior of individuals (which would have meant emphasis on quality and not the quantity of construction and choice of products), the reduction and elimination of

polluting activities, to avoid creating nuisance, and a shift to more sustainable transport solutions for themselves and cargo, are a series of basic individual changes that need to be achieved.

At settlement level this effort can be framed through practices recycling of inorganic materials, composting of organic waste and exploitation of rainwater and household (graywater) water. In this way obtained raw materials, which in turn can be re-used to make new products or, respectively, to serve the lubrication and the irrigation. Completed in planning, with moves toward the development of a policy for renewable energy sources (solar, wind, and wave) by exploiting the physical and climatic characteristics of the region, is in a position to offer the settlement energy self-sufficiency.

Ecocommunity

In the scenario that the design team is working on the study area, the distinction between the green areas and the remaining urban environment (with more features all the examples of the new Beach and Park the scope of Champ de Mars or Floral Park) ceases to exist. This contrasts with the natural environment is part of the urban environment, through the exploitation of the natural dynamics of the region (sea, streams), through the establishment of focal points cape throughout the area and with the assignment (as mentioned in the analysis of population model) surfaces of the structured space, having impact on run ecologically, productive and aesthetic level. Proposed, therefore, to strengthen the relationship of the region with the waterfront and the exploitation of the possibilities the Thermaikos provides, through non-intervention initiatives (e.g. floating platforms), and the return to work of the watercourse "Seytan Deresi" east of Field of Champ de Mars - something for which there should be agreement and cooperation with other directly affected communes at the federal level, which can assist in the water supply, to improve the urban microclimate and aesthetic upgrading of the region.

In making the above objective otherwise, it could be said that settlement which envisages the design he now forms part is configured to not only to integrate elements of the natural environment within the EU, but in a way that it fits seamlessly in the ecosystem and the wider bioregion in which it belongs. A human-built ecosystem, which is inherent in the natural -and not just co-exist with it; taking care to preserve and strengthen the environmental component.

3.3.3 Infrastructure Networks

The networks urban infrastructure and facilities are an integral part of the urban fabric and the functions, affecting key development. The management of waste, sewage and rainwater, water supply, energy and telecommunications, as well as the movement of persons and goods transport modes is examined and adjusted in the light of network infrastructure. With the introduction of new guidelines for the residential organization and environmental design, the everyday life of the inhabitants of the region, there is a need to review and configure network infrastructure, in order to accompany and support the decentralizing planning functions and the self-management effort of the daily life of the inhabitants of the settlement.

Waste Management

With regard to the management of waste in the region, he now forms part proposes a decentralized network, which will place an emphasis on recycling and the reusing, and will be organized around a system which will ensure a repeatable process sorting of waste. Something which will initially with the distinction between organic and inorganic at a building level, then through site selection and storage objects to reuse the neighborhood, and finally a level agglomeration with the collection and management of balance volume in local recycling plants. The organic waste can be treated in each building separately, through the composting procedure, and channeled to lubricate plants and vegetable gardens.

Water-stormwater-sewer

The first action on the water distribution networks, sewerage and rainwater, proposed by the he now forms part is the maintenance of piping so as to minimize any potential leaks and the risk of contamination of a network from the other. While gradually proposed the renewal of the whole network. There will be again based on the guidelines of the local management, with small-scale processing units, recovery and re-use waste water, as well as self-sufficiency, through a policy of reducing consumption, use of rainwater and graywater as well as the water resources of the watercourse of the scope of the Champ de Mars.

Energy - Telecommunications

The decentralization of energy production and the integration of neighborhood and building small-scale production units, will lead to the gradual minimizing the need for extensive distribution networks of energy.

So the community is directed at small-scale production networks and providing clean electricity. A changing energy policy in which contribute actively working groups in the neighborhood and settlement, which undertake with the help of local residents, the securing of energy self-sufficiency of all buildings in the region. Design, manufacture and install a range tailored to the specific needs of the environment and local needs, production units and power supply.

With regard to the telecommunications network within the settlement, he now forms part focuses on more comprehensive and modern artificial means handling information and communication, the internet. Furthermore, the structure and development of the internet, through a decentralized network throughout the world servers, similar to the organizational structures and network interdependencies a confederation anarchists communities. Special emphasis is given, therefore, to develop a wireless network (with technologies Wi-Fi / Li-Fi) covering the whole surface of the agglomeration, providing access to the internet in all the states of the Community.

Transport

The attention of the design collective directed to restore the human factor into the urban environment. So, strengthen the human scale travel and transport, with emphasis on encouraging pedestrian movement and use of bicycles. Promoted, for this reason, urban design space so as to allow for a more efficient movement of pedestrians in the greatest possible extent (something which will contribute and the multi-level integrations buildings and building blocks), an extensive network cycle paths (the morphology of the ground in the area can support such a move), but infrastructure that will enhance the mobility and accessibility within the agglomeration (ramps, rails wraps blind, lifts).

The main hyperlocal roads (Army Avenue, Vas. George and Alexander the Great str), hold the capacity of the corridor, but directed in service of traffic-calmed public transport (MMM). While throughout the rest of the region provided the design and technical specifications, in order to allow the approach of buildings by vehicles waste collection, handling (minimizing the absolutely necessary cases) and emergency (ambulance, fire-fighting vehicles).

The network traffic and transport is completed, in accordance with the he now forms part, with a flexible system UMM, serving the local movements of people (namely, covering the area of the village and adjacent areas). Is selfmanaged, and is based on the logic of carpooling, likening in a more sophisticated form of own-requirements' measures system Roter Punkt (movement of red comma) in Hanover in 1969, which the position of the card with the red dot to the vehicle, to inform the parties involved that can accept passenger, can get online applications (applications). While, the fleet of vehicles is to be kept and be available for collective use in the underground car park, which involve, in order not to prejudice the archaeological background and the aquifer in the region.

3.3.4 Production

With regard to the setting and the integration of the production, in the context of the total population, the design he now forms part is oriented toward a decentralized system small-scale and low noise levels, which is consistent with the human-built and natural environment of the region. Proposes, namely, the creation of production which both small-scale so as to be sufficient to cover the needs of the Community, but to be borne by the natural ecosystem.

Community laboratories

The proposal of the collective focuses on creating flexible sites, fully integrated into the residential environment and in the daily lives of residents, who provide and, at the same time build on their premises the productive means deemed necessary on each occasion for the production process. Potentially will collect production activities of all kinds, and when the operation will be open to all members of the Community who wish to participate voluntarily in horizontally structured work or have the intention to start a new production project.

Technology

These areas, or "laboratories" as Ward (1996 (1973)) calls them may create consortia for building larger-scale or to share means of production (tools, machines, transport vehicles) and manufactured products for the achievement of production objectives. A proposal which could be confused with the model urban industry in Northern Italy, where small, flexible laboratories cooperate in the production of compound products. If these practices combined with innovative technologies, such as 3D printing, it can easily be noticed the range of dynamic and yet unexploited opportunities for Community workshops, and through the solutions that they would offer for the whole community.

In the context of a Community laboratory's operation, means to provide energy may be constructed and maintained, making use of innovative technologies, as explained above, and easily accessible via the internet information; all this will contribute to the goal of energy self-sufficiency. At a second level, laboratories may contribute actively to upgrades and renewal of building projects.

Food

The same process should be followed in food production, so as to enable the Community to become food self-sufficient. There is, thus, a decentralized system of urban vegetable gardens, greenhouses, mixed crops (hydroponics and aquaculture) and plant production of animal products, sited in unstructured areas, consolidated open wheelers and roofs, but and in autonomous premises volumes, which extends throughout the settlement, in harmony with the other planning functions. This system can be integrated as proposed by members of the collective, with building structures exploiting the typology of vertical units to combine agricultural and livestock production.

While, in the long term the same system may be directed to produce only non-animal products, the possibility that a society geared to more sustainable solutions (diet composed exclusively of vegetable products) of the food problem, and with references to anti-speciesism, according to which the recognition of other animal species as less than human is considered to be arbitrary, and therefore their exploitation is unethical and against the principles of non-hierarchy society. Finally, the above production processes, governed by a collective policy in order to ensure access to food for all members of the Community, thereby creating an integrated approach to the objective of food self-sufficiency of the Community. For the implementation of this policy it is proposed that the central level, in part thereof, management and storage of surplus products manufactured, in specially equipped facilities (a proposal that was supported by members of the collective to be realized on the building which is now shelters Hotel Macedonia, on the New Beach).

3.3.5 Education - Health

The collective proposes that education -as a learning process- should not be limited to a specific space since it can potentially be combined with any other operation which takes place within the agglomeration. This is the basis of a set of learning procedures where freedom, solidarity and equality are daily experience through actions and life attitudes of participants.

In particular, children in school age, participate in self-teaching workshops, during which children learn from each other through a process of discussion, practice and game. Adults could also attend the workshops, helping whenever necessary. These specific courses can take place in various areas within the settlement, depending on the purpose, while participating actively in Community activities. For these children school entails the whole Community.

Through these practices the children are exposed to a learning process, which is so closely connected with their daily lives, with the result that the leaves or as adults. In the context of lifelong learning, any new knowledge and experience gained by members of the collective, either through collective actions or personal research and experimentation, are at the disposal of all and work to their advantage.

At this point, a decentralized production unit, as analyzed above, the laboratory should be considered. The laboratory hosting and combining the function of production and of education, similar to a Bakunin inspired "Academy". A model for how to set the educational function in this area, it is the assignment of schools in hosted the exercise of specific diplomatic work. Meanwhile the "DIY Urbanism" lab stands as a very good example of a creative process of self-teaching, which could be realized in the context of a Community laboratory / college.

Finally, with regard to health services, the collective now proposes decentralized action that imitates other planning functions. The care of patients is left to the rest of the Community, being a collective "obligation" and maximum proof of solidarity co-existence. At the second level, health structures which are responsible for serious incidents, are to be established in central and easily accessible spots from the local community points of settlement.

Conclusion

By bringing together the urban planning of anarchy leaning theory and studying the examples, we can say with some confidence that we are moving toward to solve problems, such as functional fragmentation, social alienation, exclusions, conflicts, environmental degradation etc. which are obvious in a modern urban center. Problems created and maintained, by the same politico-economic system, which an urban planner is called to ease. And it's quite clear from this experiment, that similar attempts may not be successful, if the planner (and society in general) does not develop relationships necessary for disengagement from the hierarchical, property-based, capitalist system.

Elements of this alternative vision, such as the autonomous groups, spontaneous order, the collegiality, the principle of federalism, aggregated in a coherent theory of social organization, alternative to the strict, hierarchical and institutional social philosophy of modern society. The person will be required, supported by Kropotkin, according to Ward (1990) "to find new forms of organization for the social functions which the state meets through bureaucracy", and insisting that "as long as this is not happening, nothing is going to happen". The literature and examples, to investigate this work, paving the way in which we can build a new design standard for the city, but it certainly does not give us answers for the form which will include this (or even if there will be a spatial entity) in a future anarchist society. This is not an obligation (or even possible) of town planning to answer, but it is left to free people to decide. Is the organization and their active participation, through the support structures, which will give an opportunity to seize their needs and goals.

Through the anarchist approach recommended in society an alternative realistic urban design, truly "open" (with the weight they attach to the term by post-modernists) and realistic, who will redefine the urban planner's role that would allow both to advise the design structures and to experiment with new approaches without posed external restrictions. Such as, the main actors in Freetown Christiania we, as planners and mainly as free people, to find out that these new forms of organization, turning opportunities into action.

This has been attempted through the processes of "DIY Urbanism Workshop // An anarchist approach to urban design of Thessaloniki", an attempt to give image and form in what in theory and research were examined in relation to the way we approach the city and the design in the light of anarchy. During these two days a group of people gathered and worked, through horizontal processes, trying to shape its own vision of the urban future of a central residential area of Thessaloniki. I have heard many opinions, there were even more disagreements, but what caused the greatest impression was the possibility of (for the needs of the laboratory) the collective to regulate itself and to overcome these discrepancies, finding mutually acceptable solutions.

The procedure is not completed in this laboratory meetings. It couldn't, due to the dynamic nature of the proposed design approach and does not allow any final completion. The consolidation - formalized procedures, in accordance with anarchistic teachings, can lead to a structure in a quagmire. The proposed planning process does not run the risk of ending up in a convoluted institutional system, but it manages to remain a flexible instrument for the setting of the urban environment by those directly concerned, following parole in simple rules, such as solidarity, equality, collegiality, mutual aid and harmony with the natural environment.

The design process, which is simulated in this lab, is the start of a long process, which goes hand in hand with the constantly changing human and natural environment, is affected by this, changing forms and finding new ways to become more efficient. This process opens a window, allowing the participants to look through this. It gives them the opportunity to understand what they can manage, keeping the contact with anarchy principles and their eyes on utopia.

New public participation practices for revitalizing Klaipėda old market neighborhood.

Martynas MAROZAS, MB Martyno Marozo architektūra ir planavimas (MMAP), Lithuania

1. Context and ambition

Klaipėda municipality is planning to create a long-term vision for the Klaipėda old market quarter for its sustainable transformation. Both municipality & old market company have a substantial amount of real estate in their possession suitable for redevelopment. A wise investment here, can be a complete game-changer not only for the market, but for an old town as a whole. Currently this area houses a significant number of parties whose interests must be moderated and integrated within the future plans meanwhile relationships between different parties have always been tense.

The main goal is to create a strong impulse for the old market neighbourhood and for revitalisation of the old town as a whole. In this case old market becomes a central axis of the entire transformation process, while stimulation, creation and facilitation of new cultural, economic & spatial dynamics is the core aim of this concept. It cannot be achieved without the participation of all current stakeholders and future users; therefore it calls for an open and interactive approach.

2. Process

Pre-investment concept-definition process is divided into three stages: First, scenario development with existing & potential users, CCI representatives, local community representatives, investors and city officials. Second, creating common ground for common vision & agreeing upon the intentions and path to be taken. Formulating a qualitative criteria, character & guidelines for spatial development. Last, strategic (action) plan for implementation, with concrete guidelines, responsibilities of different partners and financial assessment.

Figure 1: Process diagram

Usually, with such an amount of different interests, planning processes come into a halt because of poor communication, bad design solutions (that do not resonate with local

population) or just because people are against change. Therefore a rather untraditional (for Lithuania) approach was proposed for the first stage. First - mapping all the interests, ideas, ambitions & visions, which is executed through series of interviews & informal conversations with all parties. Second – a thorough analysis of current strengths of the city. And last – identifying the users of the area & inviting personally to the workshop.

A second stage involves not only local users & potential investors, but also real estate experts, legal consultants and social advisors. A common vision for the old market quarter is aiming at formulation of qualitative criteria for future development. The increase of social capital, new opportunities for entrepreneurs & transformation of the urban environment in a sustainable manner. Vision also prioritizes upon potential pilot projects and provides input for investment assessment and a strategic (action) plan.

A strategic (action) plan will define concrete steps towards implementation, investment priorities & investment demand at different stages. It will also cover the responsibilities of different development partners and partnership model that suits best.

3. Ideas for development

Ideas for development were formulated during the first & second projects stages through workshops, series of informal interviews & surveys. Most of the participants concur that market building has to retain its current function, on the other hand participants stressed that it has to become more efficient and attract new clients. Marketing professionals claim, that currently Klaipėdas' old market is loosing competition to two other markets in the city, namely "New market" & "Tilžės market", therefore it has to specialize more and invest more in branding, marketing, renovation and improving quality of its products. On a positive side they stress that because of its prime location, accessibility & the fact that Klaipėdas' commercial centres are located in the north and south, but not in the centre - it has a unique opportunity to transform into a largest trading spot in the city centre.

Quarter around the market and the surroundings are mainly designated for small-scale commerce, arts, crafts and cultural facilities, however there's also a need for a mid-sized cultural facility. Opinions vary on what specific function it has to house, concepts range from theatre, youth centre, dance studio to a cinema, museum or any other similar activity, but everyone agrees that it has to be incorporated into market hall or on a lot next to market square. Department of cultural heritage points out that it is an imperative to mind historical urban structures and its elements, therefore restoration of these elements is encouraged.

4. Impact on urban development

Vision and strategy aims at improving working conditions of existing market salesmen, old town entrepreneurs, CCI entrepreneurs and living condition of existing and future residents through provision of variety of new spaces and establishment of new synergies within the area. CCI incubator "Kultūros fabrikas" is located across the Tiltų Street which already gives a powerful stimulus to Klaipėdas' CCI scene for reconsidering old town as their possible office location while focus on small scale is vernacular to old town cityscape.

Currently there is a pack of issues that have to be tackled in order to ensure a more sustainable future for the neighbourhood. Old market does not live up to its full potential, public amenities are underdeveloped or insufficient, physical condition of buildings is poor and vast amounts of undeveloped vacant lots since the WWII fragment the image of the city. Klaipėda has a linear urban structure aligned to the Curonian lagoon and therefore all the public transportation connecting north and south is now concentrated on one axis (Tiltų street). On one hand it is good that the old town is a major transfer point and on the other, it is out of balance and has an enormous environmental pressure, therefore it call for a more sustainable alternative. Klaipėda is ideal for cycling, not only because of a mellow climate,

but also because of flat landscape, however local still prefer cars over bikes or busses leading to larger investments into roads rather than public space. Naturally, there is much more to be done to promote healthy lifestyles and ecological transportation modes, however these decisions are political and have to be solved on a city scale, while market and its surroundings can become a pilot.

Development scenarios, vision and strategy aims at proposing design solutions and concepts that can substantially improve economic competitiveness, urbanity and life in the neighbourhood. Improvement of public transportation nodes & promotion of multimodal access to the site is expected to increase number of customers for the market & for local business owners. Handicapped, pedestrian & cyclist-friendly public spaces promotes healthy lifestyles and improves accessibility, while diversification of spaces attracts different groups of people. In the long run it can stimulate creation of strong and cohesive social fabrics.

5. Potential users

The old market & surrounding quarter plays a major strategic role in revitalisation of Klaipėda old town, which means that it is a hot-topic for the majority of Klaipėda's population. There is a myriad of potential partners & clients, however the major parties involved are: Klaipėda municipality (Major land owner), UAB "Senasis turgus" (Old market company) (Major property owner & investor), CCI representatives & entrepreneurs, association of old town entrepreneurs (over a 100 different companies interested in revitalisation of old town), UAB Friedricho pasažas (major interest in development), local residents, kindergarten "Radastele", Klaipėda public transportation company (sees a part of the site as a transfer hub), Department of cultural heritage (KVAD), Architects union Klaipėda (LASKAO) and others.

6. Elaboration process

On 27th of September PUPA together with MMAP organized six one-hour workshops with local residents, entrepreneurs & city officials, where everyone could have their say. Main goal was to get as many ideas as possible & encourage participants to share them with each other. In addition – establishing new relationships between municipality, planners & users – can lead to a much smoother processes when it comes to decision making and implementation. Asking what people want before drawing enables designers to create plans that people are both engaged & believe in. All the input was summarized & presented to participants in a form of a newspaper, which can be downloaded here: http://www.mmap.lt/st/131008_Naujienlaskis.pdf

All the input gathered during the previous sessions serves as a basis for further elaboration of the vision. The main goal is to agree upon a concrete character for the old market neighbourhood & establish clear qualitative criteria for development. Therefore final product includes not only detailed urban analysis of the old market in multiple layers but also historical analysis (prepared together with department of cultural heritage & local historians), a real estate & development condition overview (general, detailed plans, archaeology, available, market conditions, competing projects and availability of municipal subsidies etc.) together with development trends & future uses for the old market building. The draft version of the vision will be discussed several times during the process and on 7th of December 2013 and it will be presented to the public during "Old market culture night". All the feedback and comments during this event will be summarised incorporated into the final version of that vision.

The third stage – strategic plan is done together with legal experts, municipality and development partners. Team of experts will present several public & private partnership options that suits best for the specific case of Klaipėda old market quarter, which will enable legal experts to prepare all the necessary documentation. Strategic plan draft will be

presented several times to the public & officials for evaluation. After integrating all the comments it is now possible to sign intention agreements & pursue towards the implementation.

7. Development scenarios

Several possible scenarios were presented during the workshops & people were able to react upon them by mixing and combining different ideas in a large scale model. Participants created six different scenarios where each represents one or other opinion on how the area should transform. All the ideas and results are covered in the publication downloadable from http://www.mmap.lt/st/131008_Naujienlaskis.pdf

Participants agreed on several key issues, one is that the market has a long history, therefore it has to stay, second is that it can be much better therefore it has change and upgrade, and lastly that neighbourhood is not for lucky few, but for everyone – it has to become a diverse high quality environment for living working or just spending free time.

The **first group** sees an opportunity to enlarge the old market making it the icon of the neighbourhood. They also pointed out that there is a need for high quality public space, more room for small scale entrepreneurs & more cultural activities.

Figure 2: Scenarios on an interactive model

Second group envisioned the neighbourhood as a place for crafts & small businesses. Discussed about the need for flexible public spaces with multiple uses, cultural activities, gourmet market, restaurants & cafes. They also see that market hall building has to transform and incorporate much more diverse programme.

Participants of the **third session** see the neighbourhood as a place for large scale commerce - some sort of “open air shopping mall”. Boutiques, cafes restaurants & known brands surround the market hall, this way attracting people to the old town rather than large shopping centres outside the city. Differently from other sessions – this group does not think that this neighbourhood is suitable for living, on the other hand they believe that it’s a perfect place for hotels accompanied with some tourist attractions.

Fourth session was dominated by the young, as a result the proposal was youth-oriented. The expressed a need for more places where young people could spend their free time & socialize. Their scenario incorporated a large youth centre, cinema, new market hall with roof terraces – all surrounded by a vibrant public space to meet & hang out.

Fifth group wants a large & modern fish market in Klaipėda’s old market neighbourhood, since there is a long on-going discussion that there isn’t one yet. They also made a point the market square must house more functions than just shopping stands.

The **last session** was visited by more than 50 people: entrepreneurs, cultural representatives, city officials, architects & local residents. Participants discussed a lot about the identity & history of place and how to extract & show-off cultural layers from the past by bringing them to the present. Most importantly, entrepreneurs do not think that there is a lack of space for their businesses, in contrary they pointed out that in order to revitalize the area – municipality should consider focusing their energy on provision of new high quality housing. This led to an interesting urban configuration where all the commercial programme is clustered around the market hall with the square while the neighbourhood itself has a rather residential character.

All six scenarios differ, therefore they represent different development models & financial investment demands. Large scale developments can be undertaken by big developers while smaller scale will retain an organic character. It would be inaccurate to speculate further on the cost of this project while strategic plan is not ready. On the other hand, when discussing about the concrete pilot projects that will need to start & will serve as a trigger for transformation - three absolute winners dominated the discussion: 1. Market hall transformation, 2. Quarter next to existing fish market building & 3. Market square. All the other vacant plots – can be developed separately or sold. To facilitate the first steps municipality is preparing a land-use plan, on the other hand research on archaeology & cultural heritage still needs to be carried out.

Figure 3: Moments from the workshop

8. Vision for development

Vision for development is based upon scenarios that were elaborated during the six workshops, where the main goal was to create one common vision that would integrate the interests of all different groups and users, define a qualitative criteria for the neighbourhood and propose a functional programme for the market company. Even though scenarios were different, each of them had something in common, everyone agrees that market has to stay but has to be more efficient, the market square on the other hand – must have more uses

and become not only space for selling groceries, but also a place for culture, entertainment and recreation. Market itself has to have a much cleared entrance and use its spaces much more efficiently. Another important starting point is to maintain current market salesmen and relationships that are already established within the complex. Lack of cultural facilities was regarded as a problem not only in the neighbourhood, but entire old town, therefore it was proposed to reserve space for that. Accessibility is a big issues which if not solved can hinder the success of the entire development. All in all one of the main proposed goals was to create more diverse functions within the area, combining commerce, market, offices and residential programme.

The main conclusion coming from workshops was that *old market defines the character of the area, therefore it must become a central axis for the regeneration of the neighbourhood.*

9. Design proposals

Klaipėda old market is within the borders of old-town heritage and is protected by the government, therefore all developments here are evaluated by heritage department of Lithuania. The main criteria for evaluation is if the plan is respecting the urban structure and allotment of XVIII-XIX century, which is considered the most efficient tool to preserve a tiny scale of Klaipėdas' old town. Currently old town lack a clear idea for circulation within the city, it means that there's no clear routing between different cultural or historical spots. Lastly, there's no major economic activity within the old town while most of the commercial programme is located in the north and south of the city.

The first ambition aims at using a market regeneration as a central axis for solving the aforementioned issues by establishing clear routing, filling the economic gap within the city and regenerating through restoration of historical urban structures.

Figure 4: Spatial concepts on city scale

9.1 History

In XVI century the quarter was called “leather quarter” which a century later became Friedrichstad. A market was designed in late XVII century and remained there until WWII. Market square was never built up, therefore it is an imperative that it remains open. Historical quarters on the northern side were destroyed during the war and shortly after market hall was built in 1956. Even though the market building is out of scale (according to heritage department) it still has some value. Design-wise, it is essential that market renovation contributes to restoration of historical urban fabrics, otherwise it will come into a halt because of heritage department evaluations, which in Klaipėdas' case is extremely orthodox.

9.2 Public space

Main focus in public space is on pedestrians and cyclists rather than cars. It does not mean that automobiles are not allowed, just that car traffic is discouraged. New public spaces encourages both locals and city dwellers to use them while a diversity attracts different types of people. An integral structure of squares and small parks provides easy access and vitality throughout the day and different seasons of the year.

Figure 5: Priority for pedestrians and diversity of public space

9.3 Access & traffic

Multimodal access is the core aim once talking about traffic and transportation. On one side, the site has to be accessible by all means of transportation and on the other, the area has to become an ideal transfer spot within the city.

Figure 6: Market as end destination and transfer point

9.4 Programmatic diversity

Next to a market programme there is space for work living and small scale commerce. Programmatic diversity ensures the vitality of quarter. Diversity of typologies is proposed in order to create a healthy social mix.

Figure 7: Typological diversity

9.5 Regeneration of the market

Market does not live up to its full potential, therefore there are several steps that need to be taken. First clear concept and target group definition, then renovation and development or realisation of vacant lots. Marketing consultants claim that this market has a unique opportunity to fill the commercial gap within the city centre, but it has to specialize more. Out of all concepts proposed during the workshops, it is clear that one way or the other it has to become an attractive place to buy meat, fish and groceries.

9.6 Pre-investment design concept

The plan incorporates all the design constraints and provides a good overview of synergies between different functions. It is the intention to double the amount of space within the market hall, renovate public space, create space for new residential and commercial programme and restore historical structures at the same time. New transfer at the northern

entrance of the market encourages sustainable mobility while easy access and pedestrian friendliness – increases customer flows for the market.

Figure 8: Masterplan

10. Public presentation of the vision

On 7th of December all the participants of previous workshops were invited to participate in the public presentation of the vision and discussion. Participants were encouraged to express their opinions and point out weaknesses of the plan. Some were doubting some parking solutions, but the overall atmosphere was positive. The model receive many positive comments that were integrated into the final vision sketch.

Figure 9: Moments from vision presentation even

11. Outline of necessary investments

Municipality of Klaipėda has an ambition to apply some of available financial engineering instruments in order to implement this particular project, which means that they want to limit their financial investments to a minimum. On the other hand they own a substantial amount of non-financial assets e.g. real estate, decision-making powers & a good will of course. There is a strong belief that these assets can become a good starting point to establish some sort of partnership with the private sector (a development agency, a development fund, a corporation etc. which will be outlined during the strategic plan phase).

An integral vision for the area is enough to state wither there is a need of **one big development partner** or in contrary - a **development agency** which would negotiate with multiple investors or perhaps a **development fund** with hundreds of small actors pursuing a common vision.

Current economic assessment of proposed programmatic column and mix is regarded as healthy with a investment return of 8 years. This assessment indicates value of a specific project based on current market conditions and forecasts, supply and demand of commercial, residential and office buildings. This assessment does not include archaeological research that must be undertaken. Since it can extend substantially project implementation and risk it is advised to carry it out before design phase starts.

12. Possibilities for financing the investments

Financing the necessary investments is determined by choices made in the vision & strategic plan, however today there are several possible sources. National programme “Atnaujik būstą” that finances the renovation of buildings in integral manner, however if focuses more on technical aspects of buildings. Municipal tax reliefs for building renovations. Several entrepreneurs in the area that declared an intention to buy property once they are presented with the chance to do so. Several developers expressed willingness to participate in the partnership if this model will be chosen. Market company that now owns a substantial amount of real estate and municipality are seen as the main contributors to renovation of public space. URBACT was discussed as a potential source for extra funds, a sustainable market regeneration is their main focus, however applications will follow once the vision is approved.

13. Municipal funding

Even though municipality wants to limit their financial investment – they show good intentions and will to facilitate the development through preparation of necessary legal documentation & planning documents. Municipality is also preparing a public space investment plan for next 20 years, where next to physical renovation of the public space (hard measures) there is a set of soft measures like promotion of entrepreneurship, increasing social cohesion and community involvement. Shortly it will be clear how much investment it is possible to expect for this particular neighbourhood.

14 . Development options for the market

Currently there five options on how to pursue towards the development. **First** option is that UAB “Senasis turgus” (market company) is the sole owner and developer of the area, however this model is criticized because market company and municipality doesn’t have capacity or are not allowed legally to undertake such projects. **Second** is when municipality is the main shareholder of UAB “Senasis turgus”, but private market operator is hired. **Third** option still sees municipality as a shareholder of UAB “Senasis turgus” together with private investors who hire a private market operator. **Fourth** option is to rent out UAB “Senasis turgus” with legal obligations to renovate it for 20-30 year, however case studies of Vilnius market hall shows that once investments are done, market operator loses its interest for further investments and focuses on maintenance only. The **last** option is to sell everything to the highest bidder, however this option is not accepted by city officials, since municipality wants to retain its influence and preserve markets function as such. All in all, it is most likely that development model will be chosen out of middle three where city still has some degree of control over the development of the area.

15. Time line

Strategic plan will be prepared shortly after the vision is approved. This will be enough to start the quest for development partners & draft the investment agenda for coming years. Once the development and partnership model is chosen by the municipality, it becomes possible to have a clearer overview about the timeline, however there are two possible outcomes. If it is chosen to establish a partnership with only few investors – the process can be fast & entire transformation can be ready for use in less than 8 years, on a down side - the risk of failure is much higher. If decision makers want to keep it safe & go for *slow dynamic*, then the process can take over 20 years but on a positive side – small changes will be visible almost instantaneously and will gain speed over the course of time.

Economic assessment is done for a rather modest, but safe 8 year investment return cycle, however it will only be clear once partnership model is set.

16. Expected output

The aim is to create more opportunities for local businesses, more space for cultural facilities & high quality living environments. No matter which path is taken there will be a substantial improvement for the city as a whole including local CCI scene. Creation of High quality public space & living environments will undoubtedly serve as powerful stimulus for the revitalisation of the old town & increase of social capital within the area.

Current residents will benefit most from investments in public space on one hand because of higher value of their property and on the other a more diverse environment for recreation and living. Market company and its current salesmen will still remain as main users, however renovation can generate more customers and more profit for company. CCI representatives are offered more space for working and ideas similar to market and old town entrepreneurs who benefit from increasing numbers of people in the city. And lastly – residents of Klaipėda, who get a system of diverse public spaces with more things to do in the city.

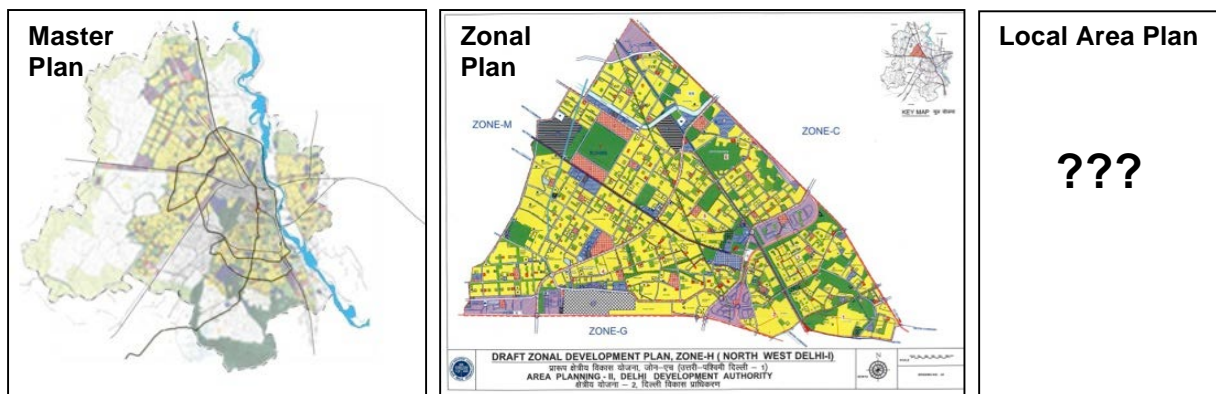

Collective imaginations for everyday realities: City building through 'creative' cooperation

Divya CHOPRA
INDIA

This paper articulates the need for collective engagement and conversations as a significant aspect of the 'creative' and cooperative city building framework while investigating the role of public art and co-design as necessary ingredients that could contribute towards a re-defined and inclusive way of building our cities for the future.

Often defined as complex microcosms of socio-spatial relationships, Indian cities are in constant negotiation with multiple polarities of existence. Intertwined within the spatial network is a complex interwoven social fabric representative of a wide spectrum of socio-economic groups in the city (from rural migrants to the global diaspora), which has further augmented a scenario of splintered urbanism. From being one of the most interesting cities in the world with their multiple historic layers embedded over one another, cities within the Indian subcontinent are continuously dealing with the complexities of their everyday realities.

With reference to Delhi, the conventional city planning process has by and large been a top-down approach focusing on expansion-based strategies, including concepts of functional zoning, neighborhood planning, pre-defined commercial centers, etc. *"Delhi's Master planning framework is based on a hierarchical system of developmental zones addressing different levels of population needs starting from the neighborhood, the community, the district and further to the zonal and city level. For each of the identified planning units, policies and decisions are to be correspondingly articulated through the overall Master Plan of Delhi (MPD) at the broadest level and then through Zonal Development Plans (ZDPs) to Local Area Plans (LAPs), and finally Layout Plans for detailed guidelines and regulations".¹* The city development plans that define the trajectory for future growth and expansion are primarily two-dimensional overviews that largely focus on resource allocation, use-distribution, movement systems and development norms for the city as a whole.

The Missing 'Link' (base map source: <http://dda.org.in/>)

Planning for Delhi so far has remained confined to the broader level imagination of the overall city and surrounding regions through successive Master Plans from 1962 onwards and is yet to get formulated at the necessary levels of local areas and neighborhood. As of now, beyond the Master Plan, the city has formalized only 11 zonal plans out of the 15 planning zones identified and local area plans along with layout plans as required, are yet to see the light of the day. Further, the physical boundaries of the zonal plans as defined by the

¹ Divya Chopra, 2008, "In-between" zones as resource. Case: Delhi, 44th ISOCARP Congress

MPD do not overlap with the ward boundaries that are based on population distribution and local unit of city governance.

Apart from the above disconnect with the local, the existing provision for participation as articulated within the planning process is negligible and inconsequential to the decision of city building. It happens only through inviting public suggestions and objections for modification once the draft Master Plan is already prepared and if the public has any suggestion or objection they can respond to the notice within a period of 45 days. This process however reaches a very small proportion of the existing population, which has access to the document, ignoring a large section of city dwellers,² resulting in a one-way partial engagement of citizens within this process of city planning. There seems, therefore, a lacuna with respect to visualizing the city in terms of its multiple discreet parts as well as a lack of dialogue between the plan/policy makers and citizens of the city.

This disjunction between planning norms at the broader scale and everyday needs could be best highlighted by the infamous 'sealing drive' in Delhi conducted by city authorities when thousands of commercial establishments and institutions were 'sealed' all across the city under the pretext of being 'unauthorized'. What is important is to note that this condition of 'unauthorized commercial establishments' arose from the strict zoning regulations of the Master Plan which stipulate mono-functional residential districts across the city confining commercial activities into pre-designated and hierarchically disposed 'commercial centers' as envisaged in the plan. These planned commercial centers were neither adequate nor appropriately located with respect to the everyday needs of the rapidly growing urban population in this city. The resultant gap between the imagined planned vision of a functionally segregated ordered city and the ground realities of increasing demand became the underlying reason for this contestation, leading to protests and violence across the capital and even after eight years there seems to be a lot of resentment among the citizens who were affected by this drive.

The 2021 MPD however mentions 'public participation' as one of the major highlights of the plan through decentralized local area planning by participatory approach, further defining this approach as involving the private sector in the assembly and development of land and public participation in policy and implementation. This suggests a perceptible shift towards privatization, which may lead to creation of exclusive domains in the city. The planned city is now being increasingly imagined as a city of glitzy malls, super-fast metro, high-end condominiums, and entertainment zones. The everyday city lost in this urban milieu continues to find minimal or no reference within this formal planning framework, resulting in creation of disjointed pockets of development, dominated by non-descript urban form catering to selected social groups and ignoring a large population of those in the margins. These kind of contestations and continued mismatch between planning objectives and ground realities that are visible in many cities in this part of the world following the 'master planning' approach have resulted in widening the ever-present gap of socio-economic disparities, highlighting the need for focused attention on the missing link that could develop critical synergy between planning visions and 'the everyday'. A change in perspective is vital

² For an estimated population of 18.2 million (as per the 2011 census), a meager response of about 7000 objections / suggestions were received for the Draft Master Plan (2021) which was notified for inviting public objections / suggestions through Gazette Notification dated 16.03.2005 and public notice in newspapers on 08.04.2005. These were considered by the Board of Enquiry which met on 17 occasions and also afforded personal hearing to about 611 persons / organizations. The Authority considered the revised draft MPD 2021 along with the report of the Board of Enquiry in three sittings held on 29.12.2006, 4.1.2007 and 19.1.2007 before it was sent to the Ministry of Urban Development for approval. The Ministry of Urban development considered the proposal in the light of the inputs received from DDA and from various quarters and finally approved the Master Plan for Delhi 2021 in the present form. (MPD 2021 - <http://dda.org.in/mpd2021rsms/layouts/openoffice/suggestion.aspx>)

in the present planning scenario, from a singular, top-down 'macro-development' model, towards addressing micro-realities of the everyday city. *"The intersection between an individual or defined group and the rest of the city are everyday spaces – the site of multiple social and economic transactions, where numerous experiences accumulate in a single location. These spaces where differences collide or interact are the most potent sites for everyday urbanism".*³

Everyday spaces in the city (source: author)

While the prevailing development process has detached itself from the changing dynamics of everyday life, interestingly it is this everyday city that has found (or is finding) ingenious ways to address its multiple polarities of negotiated existence, which often define and characterize the spaces they inhabit. The social dynamics of contestations and negotiations are constantly being enacted within public realms which lie beyond the formally planned mechanism and consist of small residential neighborhoods, retail spines, community spaces along with sidewalks, pavements, nooks and corners dominated by informal occupation. It is at this local scale that a strategy for mediation incorporating multiple local aspirations through a 'creative' urban development framework that represents the widest range of stakeholders, acknowledging diverse voices within a pluralistic society like ours, needs to be integrated within the planning process for a more meaningful and socially inclusive engagement within our cities. This strategy could be dovetailed with the existing planning framework at the local area plan levels, which could then become effective mechanisms of addressing issues of everyday. An interdisciplinary approach allowing inclusion of divergent viewpoints engaging not just policy makers, planners and urban designers, but also artists, environmentalists, sociologists, economists, geographers, historians, etc.... on a common platform along with

³ Margaret Crawford, (ed.) John Chase, John Kaliski, Margaret Crawford, 1999, *Everyday Urbanism*, The Monacelli Press, New York

the voices of citizens could contribute towards the formulation of a more comprehensive discourse to address contemporary social and environmental concerns while envisaging a new urban future.

*“Everyday urbanism demands a radical repositioning of the designer, a shifting of power from the professional expert to the ordinary person. Widespread expertise in everyday life acts as a leveling agent, eliminating the distance between professionals and users, between specialized knowledge and daily experience”.*⁴ Whilst redefining the role of the designer, this new approach includes artists as significant contributors within the city building discourse. So far the role of artists and their engagement with the city spaces through public art has been ignored and its potential to address social change unrecognized. One of the strategies for this mediation could be based on the idea of *“critical spatial practice”* which allows us to describe work that transgresses the limits of art and (architecture) city design and engages with, both the social and the aesthetic, the public and the private. This term draws attention not only to the importance of the critical, but also to the spatial, indicating the interest in exploring the specifically spatial aspects of interdisciplinary processes or practices that operate between art and (architecture) city design.⁵ Public art needs to be seen as a social process contributing meaningfully to city re-imaginings. Intervention through public art as a medium of communication and outreach could result in new forms of civic engagement for a collective dialogue between the city and its citizens.

A small experiment held in Delhi in December 2008 offered insights for such a possible collaboration, where urban designers, artists, art curators, anthropologists and various other professionals came together for the first public art festival, 48°c Public.Eco.Art, where for two weeks selected public spaces were transformed into open art galleries allowing the city users to engage with diverse art installations. Revolving around the notion of Delhi's changing urban environment, the festival aimed in bringing together a collection of art works in central urban spaces of the city to explore the possibility of a collective dialogue between city issues, urban spaces and citizens through the prism of public art. What is of significance is the immediate connect that the festival could establish with participants of these contested spaces in the city bringing forth into public domain, the dormant strands of various networks that constitute each of the selected urban pockets and allowed a new kind of dialogue between the city and the citizens that Delhi had not witnessed before. *The value of new genre public art is, (then,) in its ability to initiate a continuing process of social criticism and to engage defined public on issues...and in so doing create imaginative spaces in which to construct, or enable others to construct, diverse possible futures. New genre public art is process-based, frequently ephemeral, often related to local rather than global narratives, and politicized.*⁶

The following experiments within the stated public art festival highlight the connection between art and its intent on one hand and civic engagement on the other, for a wider urban discourse. The first set of experiments revolves around communication strategies towards deliberating on a significant concern/s related to the present day city and corresponding collective response. The second set of experiments offer public art as a proposition to resolve or address issues of generic or specific nature in relationship to their location within the city.

An uprooted tree loosely hanging over an abandoned colonial bungalow in the commercial hub of metropolitan Delhi was met with reactions of shock and awe by most street users, 'Crane+Tree', one of the artworks by artist Krishnaraj Chonat was a surreal take on the ever-

⁴ Margaret Crawford, (ed.) John Chase, John Kaliski, Margaret Crawford, 1999, *Everyday Urbanism*, The Monacelli Press, New York

⁵ Jane Rendell, 2006, *Art and Architecture: A Place Between*, IB Tauris, London

⁶ Malcom Miles, 1997, *Art, Space and the City: Public art and urban futures*, Routledge

present dichotomy between development and environment. This hanging tree signified the fate of numerous other trees that once allowed everyday life to perpetuate below them but were sacrificed for an underground metro line connecting the CBD to other parts of the city. Through this spectacle of drama, the fundamental dilemma on development needs against environmental loss was communicated en masse to the millions of commuters and users engaged with this space.

Another artwork on the same site by artist Navjot Altaf titled 'BARAKHAMBHA' was a video installation of previously recorded dialogues with various occupants of Barakhamba road and adjoining by-lanes, city authorities, planners and other experts highlighting various transformations that this space has experienced after the metro. Subsequently a live video stream projected parallel discussions among the audience about the changing nature of this space whilst raising pertinent issues of urban development decisions and everyday patterns of space usage.

Artwork 'BARAKHAMBHA' by Navjot Altaf

The above examples of public art showcase the creative potential of mass communication strategies in both the evocation and provocation of collective memory and experience of city users with respect to the developmental processes that affect their everydayness. The following artworks go beyond, establishing a necessary dialogue on urban concerns between city users and decision makers towards offering possible directions and ideas on resolving location specific, community problems and/or, demonstrating proto-typical design interventions addressing generic everyday needs.

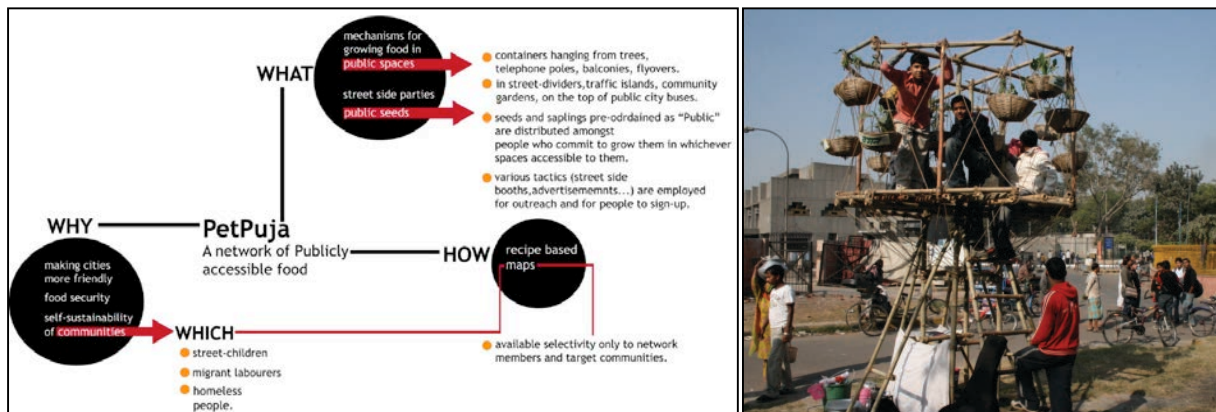

Roshnara's Net by artist Mary Miss located in a deserted garden from the Mughal era tried to reconnect a community with its lost city space. Once a thriving economic zone, this area is now a run-down quarter within the city as a result of a Supreme Court ruling of 1990s for a 'clean Delhi green Delhi' campaign that led to an overnight shutdown of factories employing thousands of people. A larger dream for a 'cleaner' Delhi was actualized at the cost of local livelihoods and primary sources of sustenance. Mary Miss's artwork was based on a strategy to give new hope to this community by drawing them back to their abandoned park, but with an added purpose and meaning to it through the incorporation of an Ayurveda / medicinal garden. *For her "this territory that we occupy, that we are involved in, is what's going to allow us to deal with these issues that are confronting us, imagining new ways to live and new ways to think".⁷*

Artwork: 'Roshnara's Net' by Mary Miss (source: author)

Located in the busy public street of Chandni Chowk in Old Delhi, artwork by artist Prayas Abhinav titled 'PetPuja' / 'Canopy' was a publicly installed bamboo structure that ingeniously accommodated a dual use of public space. It allowed a teashop to function at the street level along with a space for children to climb over it and grow vegetables and medicinal plants for themselves...whilst looking at expanding the nature and use of public and unused urban spaces. This art experiment resulted in the creation of an urban proto-type bringing the two realms of art and design together as a refreshing approach to address vexed problems of catering to the informal sector and its relation with everyday space.

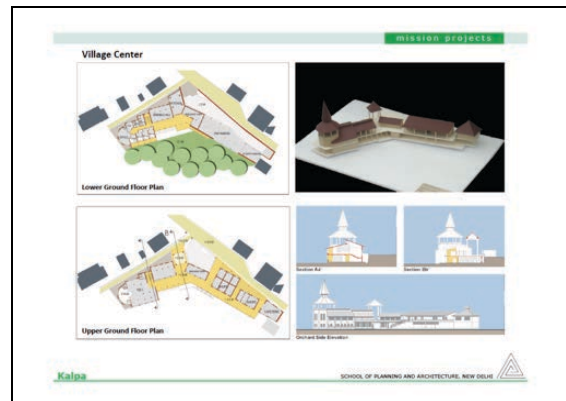

Artwork: 'PetPuja' / 'Canopy' by Prayas Abhinav (source: <http://prayas.in/projects:canopy>)

Both the above sets of experiments extend possibilities of revisiting existing tools and strategies of city building processes and highlights the need to harness such creative resource for a stronger and more inclusive way of engaging with our city spaces.

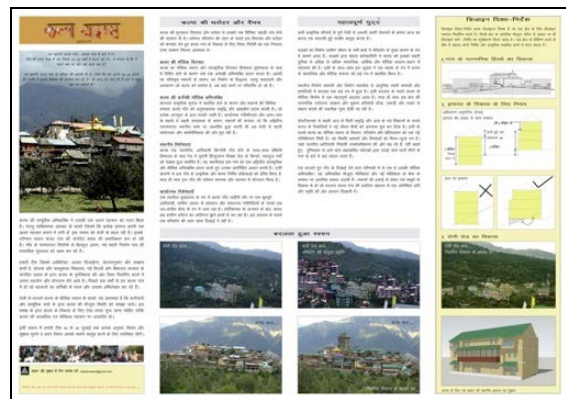

Beyond the role of public art as exemplified in this paper above, a wholesome strategy for a 'creative' urban development framework involves the need for design integration as a vital component to this process. Here, design caters to all scales of the urban environment especially the public domain ranging from the doorstep and the immediate street to neighborhoods, city districts and beyond. Design here, also incorporates creative ideas across disciplines like urban design, architecture, landscape architecture, product and graphic design etc. Finally design here, refers to the creative potential of both, technical / professional design service providers as well as community members and city users. The idea of co-design as a deliberate tool in accordance with differentiated needs and community aspirations thus forms an important aspect of the suggested development framework.

An ongoing experiment as an example of a co-design collaboration discusses a decade long association with an urbanizing rural Himalayan settlement undergoing rapid transformation. The core areas of this action research program lies in inquiring into the urbanization patterns of such settlements, which are trying to simulate the city and its contemporary urban forms primarily under the influence of heightened tourism activity in the region. One of the fundamental principles of this project has been the aspect of community participation towards defining future development paths and their connected physical manifestation. The project was envisioned with the idea of a place, where development happens through active participation, consensus and management by resident community. In this endeavor the technical team of designers, planners, architects and others was positioned between the local village community and the state government as a facilitating group. This way of association allowed for a mutual and collaborative partnership among the diverse sets of decision makers for this place. An extended period of community engagement of over more than ten years with continuous mediation through co-design by planning, design and social experts, government planning departments and the village community has nurtured a multi-layered process of co-operative building beyond the formal development framework.

2003-2006: Community Design and Interface (source: Dept. of Urban Design, SPA, New Delhi)

The initial field visits concentrated on documenting built transformations along with preparing design schemes for the community as well as individual stakeholders as a means of suggesting appropriate building types in response to the sporadic mushrooming of alien built inserts within the vast natural landscape. Socio-cultural trends were recorded through a structured questionnaire and through parallel discussions with the community and the government authorities allowing for mediation between top-down decision-making and bottom-up articulation of ideas and possibilities. The process involved organizing community meetings in the presence of state officials towards collective design thoughts using various tools for communication and outreach such as presentations, exhibitions, posters, and newsletters in local language (Hindi) for a wider outreach amongst the range of stakeholders.

2010 – 2012: Forms of outreach - presentation, exhibition and newsletter in Hindi (source: Dept. of Urban Design, SPA, New Delhi)

The project continues to track and document physical and socio-cultural transformations; suggest design ideas for public as well as private projects; interact with the community and political representatives as a means of strengthening this long-term association. Multiple discussions with village residents, women groups, along with the Panchayat over the course of time and during the recent 2015 field visit, has resulted in formulation of a village development committee comprised of local residents that would oversee the physical development in the village. Also, the local MLA has sanctioned a proposal for a 'village development center', which would seek to provide skill-based training for building and construction activity to the youth of the village.

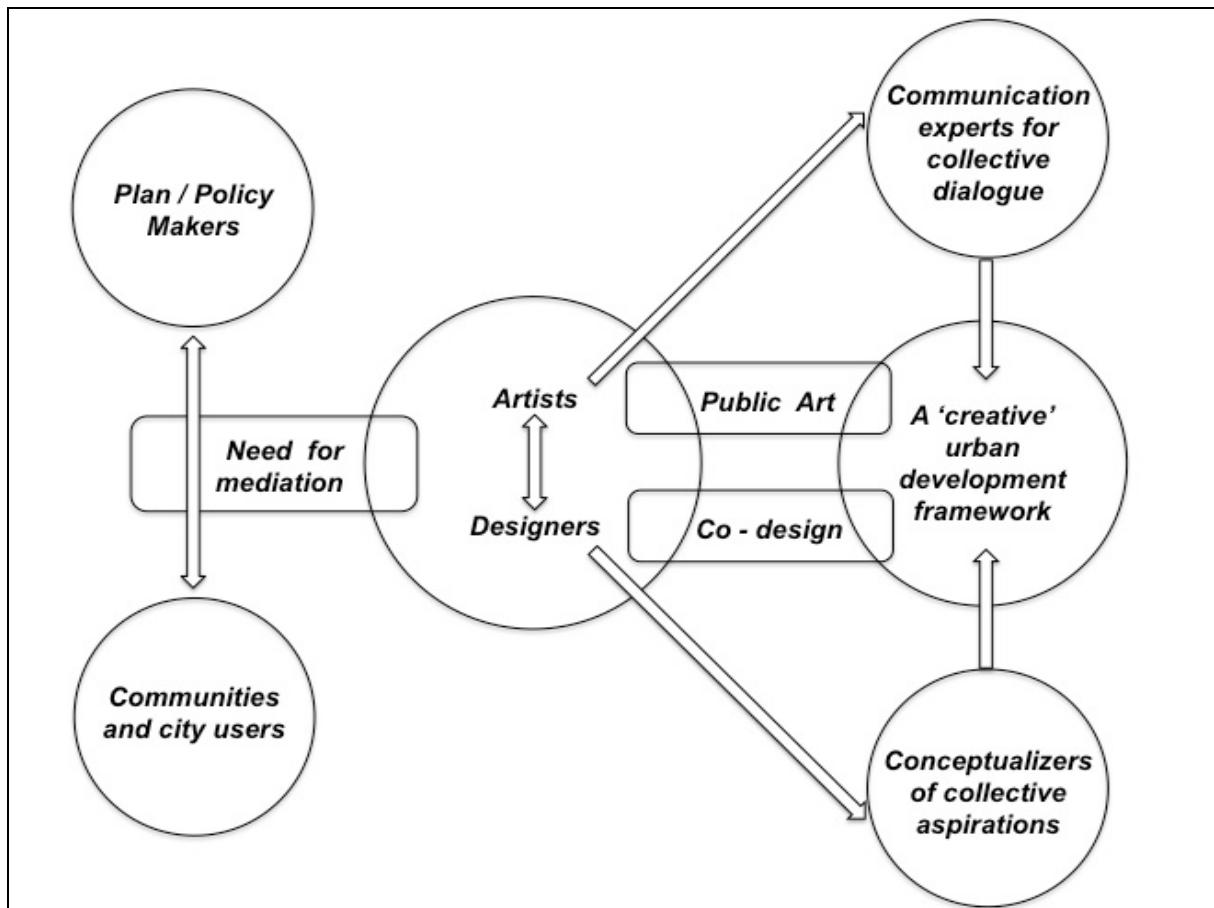

2015: Meeting with the MLA and the community (source: Dept. of Urban Design, SPA, New Delhi)

The project focuses towards initiating non-planned conditions (settlements outside the formal planning process) into an organized, cooperative way of decision-making for future directions where the ideas are being collectively nurtured at all scales from the regional to the settlement levels and finally to building or unit level. This involves multiple stages of engagement using a cyclic approach wherein study, analysis and propositions are carried on simultaneously rather than in a sequential linear path. A long association with the place has helped the designer to become concurrent with the community as a learner, an educator, a facilitator and an equal partner in devising a future course of action. For the members of the technical group associated with this endeavor, sustained engagement with the place and the community, initially as student volunteers to project associates has resulted in a new perspective towards the city building discourse. The project allowed exploration of new dimensions, skills and techniques using a multi-stakeholder approach towards a cooperative way of architectural production in transforming contextual settings such as these.

In conclusion, the distance between planning ideas, concepts, norms and urban ground realities in our cities could be bridged through a deliberate strategy of mediation using the creative disciplines of art and design. City visions at one-end and ground level, micro-development initiatives at the other, may have opened the need for a strategic interface between the prevailing planning system and local communities.

A new integrative strategy for cooperative city building engaging the community as collective creative resource incorporates public art as a communicative tool for dialogue along with co-design collaboration for local place-making. These two significant components can be viewed as an extension of the prevailing planning process to realize developmental objectives and community aspirations at the everyday level, where artists and urban designers have a significant role to play apart from, and in association with, planners and policy makers. This paper puts forward a 'creative' urban development framework as a productive intermediary to define and strengthen the cooperative city building process as a vital step for a new and an inclusive way of shaping our present and future urban environments.

A 'creative' urban development framework (source: author)

An effective development framework that connects between visionary ideas with ground realities cannot operate without the disciplinary convergence between planning, design and art. Till date this dimension of multidisciplinary creative inputs into the planning process has been negligible or at best accidental. The roles of the designer and the artist, especially in contributing to the shaping of the built environment and its final realization, cannot be overlooked further. For future cities to be sustainable and meaningful, the idea of citizens as active agents of critical assessment as well as creative imagination of their own habitations needs to find centrality in the discourse on urban development. Socially responsive planning needs to embrace this paradigm towards a more relevant and democratic future path of urban decision-making. *"Dwellers are also experts on their city and if so, their expertise begins in their awareness of the spaces around the bodies and the lattices of memory and appropriation they assemble as a personal reading of the city. From this it follows that the role of the planner becomes that of enabler, assisting members of communities in acquiring the vocabulary and information, added to the empowerment of community identity, to affect planning outcomes"*.⁸ To reinvent planning, it is time now to look beyond small corrective measures within the prevailing top-down, singular framework and embark on a new trajectory of a participative co-design and development alternative that mediates larger city visions with multiple aspirations and everyday realities.

An Integrative and Empowering Model of Services for At-Risk Children and Youth:
A Paradigm for Cooperative and Activist Management

Dr. Ronit Davidovici-Marton
Michal Rubin and Michelle Oren

Introduction

Public land-use allocation specifically and public space plans as a whole are high impact tools that enhance planning processes' influence over the quality of life of the local community.

Public land-use allocation constitutes one of the leading physical planning tools that enable us to address social and communal characteristics, foster encounters, and promote opportunities for self-actualization, recreation, leisure, and culture – all in a manner that is timely, accessible, suited to actual needs, and substantively valuable.

Children and youth are a major constituent element of the community. They symbolize growth, the future, the next generation, and new opportunities in years to follow. Land use allocation plans for children and youth are most often limited to educational facilities and institutional spaces of activity. In practice, however, children and youth are spending an increasing amount of time in front of the screen: smart phones, computers, television, and movie theaters. If they do leave the home, school, or facilities for institutional services of whatever sort, they tend to spend time with groups of friends in a "format" and of a profile that resemble their own: friends from their own neighborhood, from school, or from extracurricular activities, family members, and the like. Youth are perceived as an "avant garde," creative, and "anti-establishment" age group. Indeed, it is hard to draw them towards institutional services; they tend to demonstrate behavior patterns that express independence, rebellion, and an attitude of resistance. Yet in practical terms, they are still dependent on school, on finishing their high-school studies and passing their matriculation exams, and on adults for accessibility and movement within the surrounding space, among other factors. This age group aspires to increase its spheres of life: to make new acquaintances, to expand the physical space of life, to display and demonstrate maturity, while at the same time they are still bound to the educational establishment, the family, and their parents.

The Public Space: A Platform for Inclusive and Collective Urban Pluralism

Urban planning uses a variety of tools to create public spaces that include roads, public buildings, open spaces, and spaces for transit or rest that are suitable for diverse target audiences. The projects presented here underscore the importance of transitioning from serving the needs of the "average resident" to addressing the needs of the city's diverse communities, using models that enable everyone's needs to be met, offering everyone opportunities and a sense of relevance, while simultaneously creating a whole that combines all of these into an integrated public space that is of high quality, intriguing, and inviting, both individually and collectively. This is the challenge at the basis of integrated

management, urban-communal cooperation, and the pluralism that fosters self-actualization alongside integrated urban belonging.

Youth – An Unrecognized Key to Renewal and Growth

Youth are a population group that requires special attention. First and foremost, there are almost no guiding standards that address and take into account their lifestyles, characteristics, and experiences, while reflecting their most current and changing reality. Mid-twentieth century standards that address youth clubs, libraries, and the like, are no longer relevant to contemporary youth lifestyles. Evidently, today's youth do not spend time in youth clubs, community centers, or organized extracurricular activities, but rather in spaces dedicated to sports, physical activity, and consumer activity (malls and so on), as well as, primarily, in front of screens. Moreover, the youth are a population group whose very nature embodies rebellion, adolescence, expansion of the spheres of life, new acquaintances, and the like. Accordingly, any effort by the establishment to attract youth to participate in activities constitutes a special challenge.

When it comes to youth, there is a lack of contemporary tools, standards, norms, and models that reflect the needs stemming from today's reality. We do find that over the years unique youth centers have been opened, providing a range of interesting programs that combine technology, sports, social gatherings, youth involvement, alternative learning, volunteer initiatives, and more.

The recognition of youth as a key population group that greatly influences the quality of public space as a whole, individual security, patterns of use of public space and time, quality of educational life and social experience – thereby creating a social foundation that provides opportunities for urban renewal, the re-imagining of urban spaces, and residents' aspirations of belonging to the neighborhood and surrounding space and being part of it – all these form a basis for generating comprehensive urban growth.

Image 1: A neighborhood shopping center as a social and diverse cooperative space, in Kiryat Hayovel

The youth (ages 12-17), who constitute more than 23% of Israel's population, are one of the keys to successful urban planning and development. This is particularly true for the youth termed "at-risk" because they do not always operate within recognized frameworks, they embody an element of violence and intimidation, they make use of public space in unconventional ways, and they often foment public disturbances. A perspective that recognizes this youth group as an inseparable part of the whole community and integrates it

into efforts aimed at taking responsibility for its surroundings , for its sphere of life, and for the quality of the community in which it lives – such a perspective might "make the difference."

This insight requires initiating different, contemporary, and specialized planning processes with youth and the overall community. It requires a land-allocation approach that is socially sensitive and simultaneously fosters encounters and connections, and creates opportunities. This is a combination that makes it possible to meet the needs of every individual separately and of the whole community in an integrated manner – producing a steadily improving quality of urbanism.

This paper will present two projects we have initiated: first, a strategic plan for children and youth in a Jerusalem neighborhood undergoing rehabilitation; and second, the planning of processes that foster cooperation between boarding schools and youth villages, on the one hand, and local authorities, on the other, in order to generate quality services and growth for the entire space and all communities. This process was led by the Public Forum for Boarding Schools and Youth Villages within the National Forum of Boarding Schools and Youth Villages, a forum designed to enable the consolidation of efforts, cooperation, and lessons learned from colleagues and stakeholder groups comprising diverse participants (boarding school principals, relevant government ministries, donors and philanthropic foundations, professionals, academics, and more).

The Strategic Plan for At-Risk Children and Youth – Kiryat Hayovel, Jerusalem

This program aims to examine the needs of at-risk children and youth, as an integrative part of the community and, in particular, of communal efforts towards renewal, growth, and transition from a state of rehabilitation to the dynamics of growth. This combination – of a social analysis of children and youth on the threshold, defined and recognized as children and youth who are at risk, and the needs of the neighborhood and requirements for growth – has resulted in unique modes of cooperation, and in particular a new, contemporary perspective yielding a program that provides services and opportunities, with a view towards growth for the entire neighborhood, the children and youth who are defined as at risk, and all the neighborhood's children and youth, across the range of services and components of public space. The perspective underpinning this process views it as an opportunity to generate growth, with advantages for the entire community, alongside space for contemporary preventive and treatment measures that aim to change the approach towards services for at-risk children and youth within the overall public space. The process was preceded by meetings among various service providers, by thinking "outside the box," and by the most current ideas, including primarily the importance of involving children, youth, and their families in the thought process, planning, brainstorming, lessons learned from the process, and the like.

The planning process was based on a number of discussion group meetings with a variety of neighborhood service providers and municipal officials in a range of areas (physical, social, economic, and the like). All these, in advance of meeting with the residents, required a

Image 2: Renewal in Kiryat Hayovel

cooperative confidence-building process, as the neighborhood had undergone several renewal efforts during recent decades. The planning process was based on a mapping and characterization of the entire public urban space of Jerusalem, and on a characterization, mapping, and study of the various aspects of the network of services for children and youth generally, and at-risk children and youth specifically. An analysis was undertaken to examine the neighborhood's renewal plan, the construction, evacuation, and renovation of public space, and the development of mass transit systems, public centers, space for transportation, and the like, while also taking into account current trends regarding treatment, preventive measures, and integration for at-risk children and youth in the urban community and public space, through an integrative perspective. On the basis of all the above, a joint, multi-disciplinary workshop was held with the aim of examining where, how, and in what manner it might be possible to use existing neighborhood infrastructures as leverage, and how it might be possible to lead the neighborhood's children and youth, particularly those defined as at risk, to develop the means of leverage that will improve public space for the entire community and all its children and youth. Thought was also given to the question of how to generate public space that makes optimal use of public buildings, open spaces, spaces for traffic and public transportation, and the like, thereby improving their safety, quality, and potential for fostering encounters, opportunities, creativity, and a sense of initiative for the various local communities and the community as a whole.

The above process led to the conclusion that a number of key focal points in the neighborhood "make the difference" for the entire community. These are main focal points perceived as qualitatively significant, and they serve as anchors for growth. The program's recommendations were to use them as the foundation for treatment, prevention, and especially opportunities for encounters that foster creativity, currently relevant advantages, social and communal life, individual security, and shared responsibility and management – namely, urban cooperation that reflects a multi-faceted and inter-communal synergy.

Towards this end, a number of focal points of excellence within the neighborhood were identified, to serve as anchor points for the program. For example:

The Prestigious Experimental School – The initial process began at a unique neighborhood school, a branch of the prestigious municipal experimental school. A plan emerged to move the daycare center, which is intended for children on welfare, from the outer yard into the school, thereby intermingling the children who benefit from it and creating a social-educational space of prestige and quality that is also inviting. Simultaneously, a unique plan was adopted for renovating the school using models that engage the entire community, generate points of interface, prevent segregation, and create opportunities for encounters.

Image 3: The Argentina School in Kiryat Hayovel

The Shopping Center – This is the other focal point that serves as an anchor for neighborhood growth along all dimensions for the entire community. The program initiated a cooperative process involving business owners, shoppers, and "random" visitors. This led to a recommendation for a socially sensitive cooperative process that combines occupational training for at-risk youth, who will take responsibility for and leadership of the renovation and maintenance efforts, the creation of local social activity spaces, the promotion of local neighborhoods enterprises, neighborhood craft fairs, and the like.

Boarding Schools and Youth Villages – Cooperation with Local Authorities

Boarding schools and youth villages bring together children and youth who are identified as on the threshold – that is, children who are face a high risk, necessitating their removal from their original community, family, and friends. In Israel a forum was established to bring together the administrators and principals of boarding schools and youth villages, as well as representatives of relevant government ministries, philanthropies that support this population group, and others. Youth villages and boarding schools are remotely distributed, thus creating a "black hole" of sorts that is not recognized by the local community or local authorities.

One of the main insights of the forum was its emphasis on the importance of cooperation: among boarding schools and youth villages, various relevant government ministries, actors on the ground, and in particular, the local authorities in areas where these institutions are located throughout Israel.

Currently, it should be noted, youth villages and boarding schools, as well as local authorities, do not recognize the importance of the connectedness among them. On the contrary, their perspective embodies suspicion, lack of willingness to mix communities, and concerns that any form of cooperation might generate reciprocal requests for resources or spark conflict, for example.

The process we initiated was intended to highlight the

significance of connectedness, relationships, and cooperation between local authorities and the boarding schools and youth villages, and in particular it aimed to create opportunities for mutual growth. Cooperation at the social, communal, and administrative levels, cooperative use of infrastructures, the creation of new acquaintances and opportunities for meetings, the development of new "traditions" of meetings – annually or biannually, for example – all these provide opportunities to improve the provision of services by local authorities and at boarding schools and youth villages. Moreover, this process embodies a social message that recognizes the importance of making acquaintances and having encounters within a diverse community – as a source of leverage for social, economic, and environmental growth.

The process comprised meetings with forum representatives, discussion and debate among the various actors who are involved, and the production of a briefing book aimed at presenting the guiding principles and examples of multi-disciplinary cooperation, and in particular at encouraging the integration of successful examples from the field.

The discourse that emerged from the proposed process is intended to create opportunities for work with specific boarding schools, which will undertake physical renovation in the context of social, economic, administrative, and environmental cooperation with the local authority. This type of cooperation will create the type of unique interface that is so lacking among diverse population groups and the administrators in charge of growth in the public space.

– Available in Hebrew [Youth Villages](#)

Conclusions

The projects presented in this paper reflect a perspective that emphasizes the importance of shifting focus from the challenge of "attracting a strong population" towards a specific place, street, neighborhood, or city, to the more contemporary challenge that underscores the importance of "strengthening the diverse population groups of the place".

Image 5: : Planning with children

This is a modern, principled approach that views diversity as leverage for empowerment and the creation of opportunities that will yield new and up-to-date advantages. Here space is not used to segregate communities into neighborhoods and suburbs or to create areas divided by use and purpose; nor is the power of the community split into separate and exclusionary spaces. This is a perspective that recognizes the importance of interaction, relationships, openness, reciprocal relations, and synergy. This is the key to a style of management that produces shared responsibility, urban cooperation, and a contemporary communal and public quality of life.

Addressing Flooding Issues in an Environmental Justice Community: A Complicated and Multi-Layered Case Study

Mahbubur MEENAR, Ph.D., Temple University, USA

Jeffrey FEATHERSTONE, Ph.D., Temple University, USA

Jamie MAGAZINER, MS, Temple University, USA

1. Introduction

How to address recurrent and severe flooding issues in a community subjected to significant environmental justice (EJ) concerns? What should be the role of the surrounding communities? This paper presents a unique and complicated case study while addressing these broad questions. It focuses on a metropolitan watershed around a historic town (incorporated in 1888), located close to the City of Philadelphia, USA. It describes the process of developing a flood and stormwater management plan for the whole watershed, with a specific emphasis on the EJ community.

The term “environmental justice” was created in response to the increased prevalence of toxic pollution and its disproportionate impacts on poor, minority communities (Holifield 2012). EJ is defined as the fair distribution of environmental risks and hazards among all groups based on race, class, ethnicity and economic status. Environmental injustice is commonly described as certain disadvantaged groups of a population bearing a disproportionate burden of environmental hazards. The scope and range of EJ literature has evolved greatly since the origin of the term in the early 1980s. An EJ movement was born when a PCB landfill was set to be built adjacent to the homes of mostly low income African American residents in Warren County, North Carolina (Bullard 1993; Schlosberg 2007).

Over time, the scope of the literature has not only broadened to include various social groups, but also the various issues that can be associated with environmental hazards, including flooding (Holifield et al. 2009; Walker 2009; Walker and Burningham 2011). More recent natural disasters, such as Hurricane Katrina, lead the literature to look more closely at natural hazards as well as technological ones, which dominated the field for a long time (Colten 2007; Morse 2008; Stivers 2007; Sze 2006). Flooding is a significant component of this small but quickly growing body of work. Within this work flood risk is being framed as a potential component of environmental inequality and injustice (Walker & Burningham 2011). While a small group of literature exists on flood risk and its associated environmental justice issues, further research is needed as flooding issues grow worldwide.

The literature has also expanded to look at environmental justice as a multi-dimensional concept (Martin et al. 2014). Researchers look at EJ as having three main dimensions. These dimensions are: distribution, recognition, and participation (sometimes referred to as procedure). Early in the literature, distribution was commonly discussed and dominated the field (Walker 2012). Distributive justice refers to the “distribution of goods and bads” between different individuals and groups and has dominated environmental justice debates to date (Walker 2012). The field expanded to eventually include the dimensions of recognition and participation (Walker & Burningham 2011; Holifield 2012). The dimension of participation, commonly referred to as procedural justice, deals with the level of inclusion of individuals and groups within the decision-making process as well as who guides the process itself (Martin et al. 2014). Procedural justice is commonly defined as “the fair and equitable institutional process of a State” (Urkidi et al. 2011). Recognition acknowledges personal dignity of all individuals (Fraser 1995), collective identities and their needs or concerns (Staeheli 2008) or the overcoming of institutional harm to social status (Tschakert 2009). This dimension examines the role of history and process and evaluates the causes and consequences of environmental inequity (Pellow 2000; Sze 2007).

2. Context

The densely-developed West Ambler neighborhood, located in Whitpain Township, Pennsylvania and characterized by a low-income and minority population, has vacant and flood-damaged properties. The neighborhood faces environmental justice issues that include air pollution, surface water pollution and groundwater contamination. As seen in Figure 1, sections of Ambler Borough and the West Ambler section of Whitpain Township are located at the downstream end of the tributary watersheds and are subject to the accumulated effects of increased runoff from upstream areas. In addition, these areas are impacted by flooding from the main stem of the Wissahickon Creek. In addition, the West Ambler neighborhood includes the BoRit Superfund Site, which includes a six acre private tract with asbestos piles, a 15-acre reservoir, and an 11-acre park that has been closed due to asbestos contamination. Another site, the Ambler Asbestos Piles, is also located in close proximity to the EJ community.

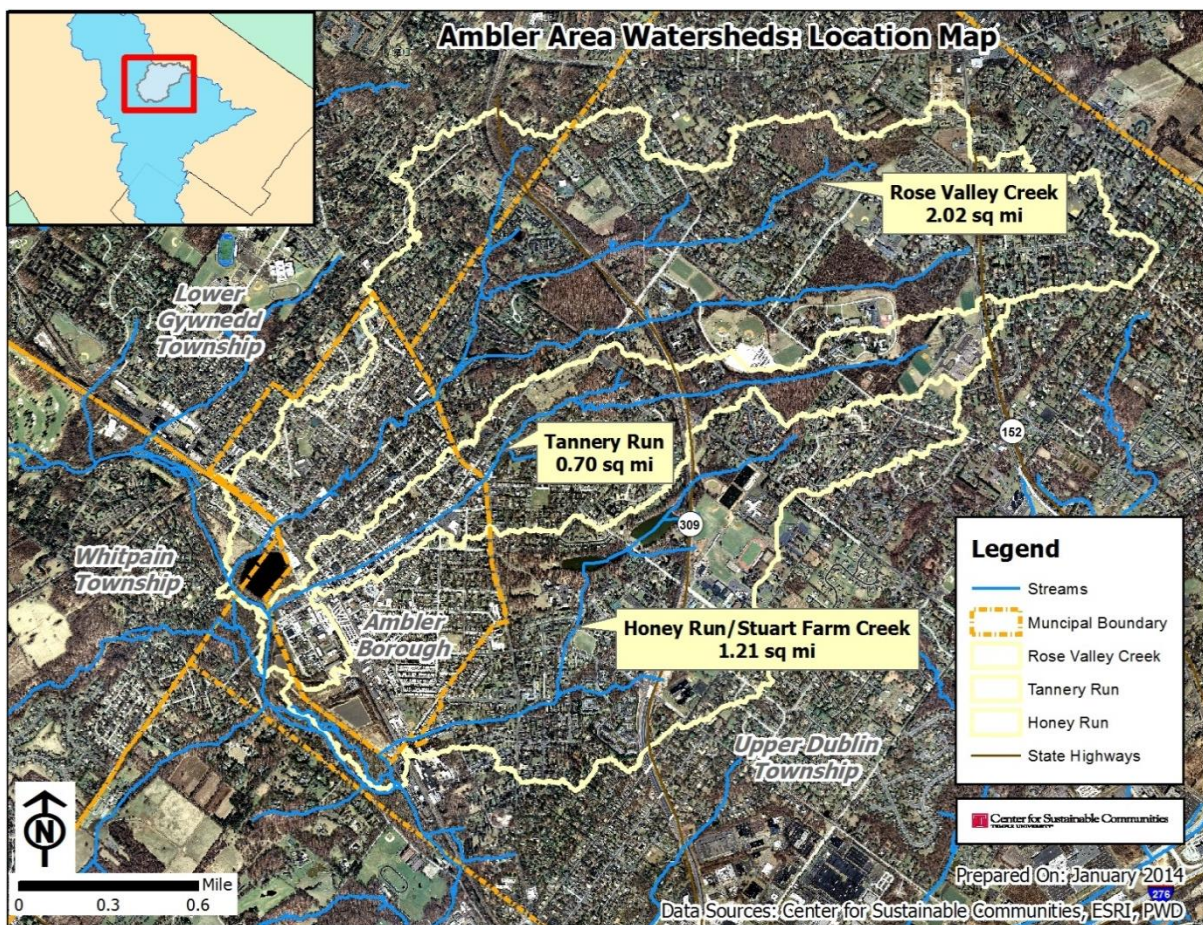

Figure 1: Study area

Ambler Borough has had a long and unique history of asbestos production and contamination that stretched from 1897 to the 1980s (CEET, Ambler n.d.). The superfund site has had a legacy of producing and serving as a dumping ground for asbestos products. It was selected for the Environmental Protection Agency's (EPA's) National Priorities SUPERFUND List in 2008 (CEET, Ambler n.d.). It is a high priority due to its proximity to several water bodies (Tannery Run, Rose Valley Creek, and the Wissahickon Creek) in addition to residences. Residents of the community have voiced their concerns about the site for several decades.

Communities in the Wissahickon Watershed have faced devastating effects from major flood events (Floyd 1999, Allison 2001, Ivan 2004, Irene 2011 and Lee 2011), and

have faced millions of dollars' worth of damage as well as loss of life. For the main stem of the Wissahickon Creek in Montgomery County, each of these events produced peak flows larger than the 100-Yr flood used for the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps (FIRMs). While flooding is a natural process and occurs in both developed and undeveloped watersheds, land conversion to less-permeable surfaces in the absence of stormwater controls leads to higher flood peaks, flood volumes, and frequency of flooding. This is of particular significance in the West Ambler neighborhood, where more severe impacts have been observed.

Environmental justice issues helped launch the Ambler flooding study. In 2011, Whitpain Township had received \$250,000 in streetscape funding from the Pennsylvania Department of Community and Economic Development to replace sidewalks in West Ambler. After the two storms and local devastation, West Ambler residents successfully argued that the flooding issues should be addressed before replacing the sidewalks. As a result, in 2012, the township engaged the Center for Sustainable Communities (CSC) to perform the flooding study for the Ambler area and the firm of Simone-Collins to prepare a revitalization plan for the neighborhood. The CSC created a Project Team of university researchers to perform the study.

The Project Team's discussions with community groups indicated that the disadvantaged West Ambler neighborhood faces severe flooding and poor water quality due to contamination from the asbestos site, posing a serious environmental justice problem in this watershed. Through this work, the interests of both the residents of the West Ambler neighborhood, who are disproportionately impacted by flooding, health risks, and floodplain map revision, and the surrounding communities of the Ambler Borough and Upper Dublin Township, must be balanced accordingly.

3. The Project

3.1. Initial Community Outreach

At the very early stage of this project, the team met with officials of the three municipalities, and representatives of environmental groups and community organizations. Ambler Borough officials indicated that mitigating recurrent flooding, managing stormwater and improving water quality are critical challenges to achieve a better quality of life for its residents. Whitpain Township officials said that emergency response, flooding mitigation and community revitalization are community priorities. Stormwater management and flood mitigation are longstanding priorities of Upper Dublin Township, which is implementing several stormwater improvements identified in a previous CSC project. The project team's discussions with local environmental councils and organizations indicated that the disadvantaged West Ambler neighborhood faces severe flooding and poor water quality due to contamination from the asbestos site, posing a serious environmental justice problem in this watershed.

The Project Team used outreach activities and stakeholder meetings throughout the two-year project period. A 24-member Watershed Plan Advisory Committee was formed in September 2012 consisting of representatives from government officials, municipal authorities, professionals, environment advisory councils, civic associations, environmental associations, business community and local residents. A project website (<http://amblerwatersheds.wordpress.com>) was launched in mid-September of 2012. The web site included project-related basic information, community priorities and challenges, and an online form for public input.

A "municipal problem area" survey was conducted in 2012. Municipalities within the watershed identified 163 locations where flooding, erosion, and sedimentation were occurring. Information on drainage problems and proposed solutions was solicited from each municipality by providing forms for each Advisory Committee member. The project Team studied local plans, projects, and initiatives addressing stormwater management and flooding issues throughout the study area. Examples included *Ambler 100 Rain Gardens*, *Rose Valley Creek Riparian Buffer Restoration*, and *West Ambler Revitalization and Action*

Plan, which focused on the BoRit Superfund Site and proposed channelization or day-lighting of the Rose Valley Creek.

A public stakeholder meeting was organized by the Project Team with the help of the Advisory Committee. Following intense advertising and outreach efforts, approximately 115 stakeholders attended the meeting, held in a venue located within walking distance of the EJ community. After an hour-long open discussion, the stakeholders of three municipalities (Ambler Borough, Upper Dublin Township, and Whitpain Township) staffed three separate stations in the venue to share their experiences with recent flooding events. They responded to a number of questions included in a survey. This session was facilitated by 15 volunteers from local municipalities and Temple University.

All attendees agreed on the importance of addressing the flooding and stormwater issues this area has been facing for decades. Nearly all of the respondents (90%) reported that their properties have been flooded at least twice in the past 10 years, with 52% of respondents reporting their properties have flooded five or more times in the past 10 years. Some respondents even reported that their properties flooded twice a year. Slightly more than 40% of respondents reported having flood insurance. More than two-thirds of respondents described flooding of their basements, incurring the loss of various appliances and personal effects. Many respondents also detailed structural damage to their finished basements, including damage to drywall and carpeting. Damage to exterior features, including landscaping, sidewalks, or driveways was also described. For some, flooding was so severe that vehicles parked on the street and in driveways were totaled.

Just over half of the respondents reported either taking action themselves to mitigate future flooding or knew that their municipality was taking action. Most reported that they had taken action themselves on-site: some of these actions included the installation or upgrading of sump pumps, different types of drains and drain pipes, berms, and reinforced or glass-block basement windows. Actions taken by municipalities that respondents described included commissioning studies, widening riparian buffers and replacing culverts. Many ideas and suggestions were offered as to what could be done to mitigate flooding in the future, ranging from the general to specific. Many respondents supported, in general, the restoration of riparian buffers and wetlands in the area, as well as improving existing detention basins. Some suggestions directly related to the pipes running under regional rail tracks, indicating that they should be replaced or redone. The installation of storm sewers and detention or retention basins on specific locations were also recommended.

3.2. Understanding the Watershed

Stormwater management planning must take numerous surface features into account, including topography, soils, land use, and impervious cover, as well as existing stormwater collection and discharge. Since the Ambler area watersheds are located at the center of Wissahickon Creek Watershed, a broader understanding of the Wissahickon Watershed was needed, especially for continuous data sets such as precipitation. Primary data were created by the Project Team and its sub-contractors. Secondary data were collected from various sources. After field verification of secondary data, which was complete by January 2013, the Project Team decided that some data needed enhancement and new ortho photography and elevation data were created and used in the analysis.

The Project Team conducted GIS analyses regarding watershed characteristics and runoff, including flash flood potential, land use, and precipitation. Analyses were also conducted in order to further understand stormwater and flooding issues in the area. The results of this assessment follow.

The Wissahickon Watershed is vulnerable to heavy rainfall from tropical weather events. Damaging tropical storms in recent years have included Floyd (1999), Allison (2001), Ivan (2004), Irene (2011) and Lee (2011). For the 30-year period from 1981 to 2010, precipitation at the National Weather Service (NWS) rain gage at nearby Springhouse averaged 47.4 inchesⁱ. This annual total, however, is not uniformly distributed over time and space, and extreme events can produce eight inches of rain or more in some areas in a single day. Although extreme storm events trigger the most damaging flooding in the

Wissahickon Watershed, most storms produce less than one inch of rainfall. These smaller storms produce a significant portion of annual runoff. For this reason, stormwater management measures designed for infiltration or extended detention of these smaller runoff events are effective in reducing non-point pollution loadings and stream erosion.

The elevations over the watershed range from 155 feet to 397 feet. The EJ community has the lowest elevation values. Runoff characteristics of various land uses vary with the underlying hydrologic soil group designation, and information on the location of hydrologic soils groups was used in the hydrologic modeling for this study. Hydrologic soils in the most part of Ambler area watersheds have medium to high runoff potential with low infiltration rates. Almost half of the study area has single-family detached residential land use, and about 7% is multi-family residential. The National Weather Services' Mount Holly Weather Forecast Office has conducted a GIS-based analysis of flash flood potential, based on digital data available for soils, slope, forest density, and land use. According to this data, the EJ community and surrounding areas have highest flash flood potential.

Based on field observations, digital ortho-photos, land use data, and outfall and drainage data provided by the Philadelphia Water Department (PWD), it was estimated that stormwater collection systems of various capacities have been installed in most of the study area, although many places have poor drainage. Based on field visits, the Project Team concluded that many existing detention basins within the watershed were not properly designed to address small storms, and runoff from these storms passes directly through the facilities. These structures represent opportunities for retrofitting to provide additional storage, infiltration, and extended detention.

Stormwater problems are created because of increased impervious cover, destruction of riparian buffers, extensive floodplain development, more frequent extreme precipitation events, extensive channelization and piping, higher peak flows, higher runoff volumes, loss of upstream storage, erosion, and obstructions to flow. Water quality problems are due to both point-source and nonpoint-source pollutions. All three creeks in the study area are designated as "impaired" in Pennsylvania's regulatory 303(d) list due to siltation, caused by urban runoff/storm sewers and habitat modification. Surface water quality is impaired from a lack of stormwater runoff management and nonpoint source pollution control. The Ambler area was almost completely developed prior to the Pennsylvania Stormwater Management Act of 1978 and lacks suitable runoff controls (PWD, 2007). Analyzing data created by the Heritage Conservancy, the Project Team concluded that increasing urbanization in the watershed has led to the destruction of riparian buffers, which has increased erosion and sediment loadings, leading to the widespread loss of habitat for both aquatic and terrestrial species, as well as propagation of invasive plant species. In terms of point source pollution, the Superfund Site was discussed in a prior section. Another source of pollution is contamination from wastewater treatment plant discharges and infiltration and inflow from sewer lines during storm events.

The study area has experienced severe flooding in many recent storm events, including Hurricane Irene and Tropical Storm Lee in 2011. Both storms produced peak flows larger than the 100-Yr flood used by FEMA as the basis for the current FIRMs. According to existing FEMA FIRMs, 101 building structures have been identified within 100-Yr floodplains and 163 structures within 500-Yr floodplains. There are many locations in this study area where existing FIRMs have become outdated. Figure 2 shows such as area (in a red dotted circle) that has faced severe flooding in recent large storm events, but is not inside FIRM flood-zones. Based on individual flood insurance claims data provided by FEMA, the highest density of claims has been in the lower reaches of the three tributaries within Ambler Borough (including the EJ community), with very few occurring in the headwater areas. According to FEMA statistics as of December 31, 2013, a total of 179 flood insurance claims had been filed in Ambler Borough alone with 157 of these claims paid, for a total payment of \$4.02 million since the start of the flood insurance program in 1978.

3.3. Engineering Models and Outputs

The Project Team used ArcGIS, HEC-HMS, and HEC-RAS software to conduct hydrologic and hydraulic modeling for portions of the Wissahickon Creek and three tributaries (Rose Valley Creek, Tannery Run, and Honey Run/Stuart Farm Creek) within the study area. The CSC is a FEMA cooperating technical partner (CTP) for floodplain mapping and has approved floodplain maps created by the CSC in recent years for other watersheds in the region (i.e., Pennypack and Sandy Run). New 100-Yr and 500-Yr floodplains for this area are preliminary pending final approval by FEMA.

Model results for the design storms were generated after calibration of the hydrologic model. The model outputs included peak flows, flow hydrographs, and runoff volumes for subbasins, junctions, and stream reaches. Two versions of the model were used in the study. Model outputs for current conditions were used to generate peak flows for determining flood elevations and flood maps. A second version was developed to represent future conditions assuming that upstream stormwater improvements proposed in this study would be put in place.

Figure 2 shows a comparison of FEMA and preliminary CSC 100-Yr floodplains for the study area. A significant portion of floodplains for the Rose Valley Creek in the West Ambler neighborhood (inside EJ community) was not previously mapped and is not included in FEMA's existing flood insurance rate map. This high hazard flood area is now included in the new preliminary maps and flood prone structures will become eligible for federal buyouts. In addition, most of the upstream portions of the tributaries were not included in FEMA 100-Yr floodplains, but are now within the new mapped areas. According to this new delineation, 136 structures are within 100-Yr floodplains (previous number 101) and 212 structures are within 500-Yr floodplains (previous number 163).

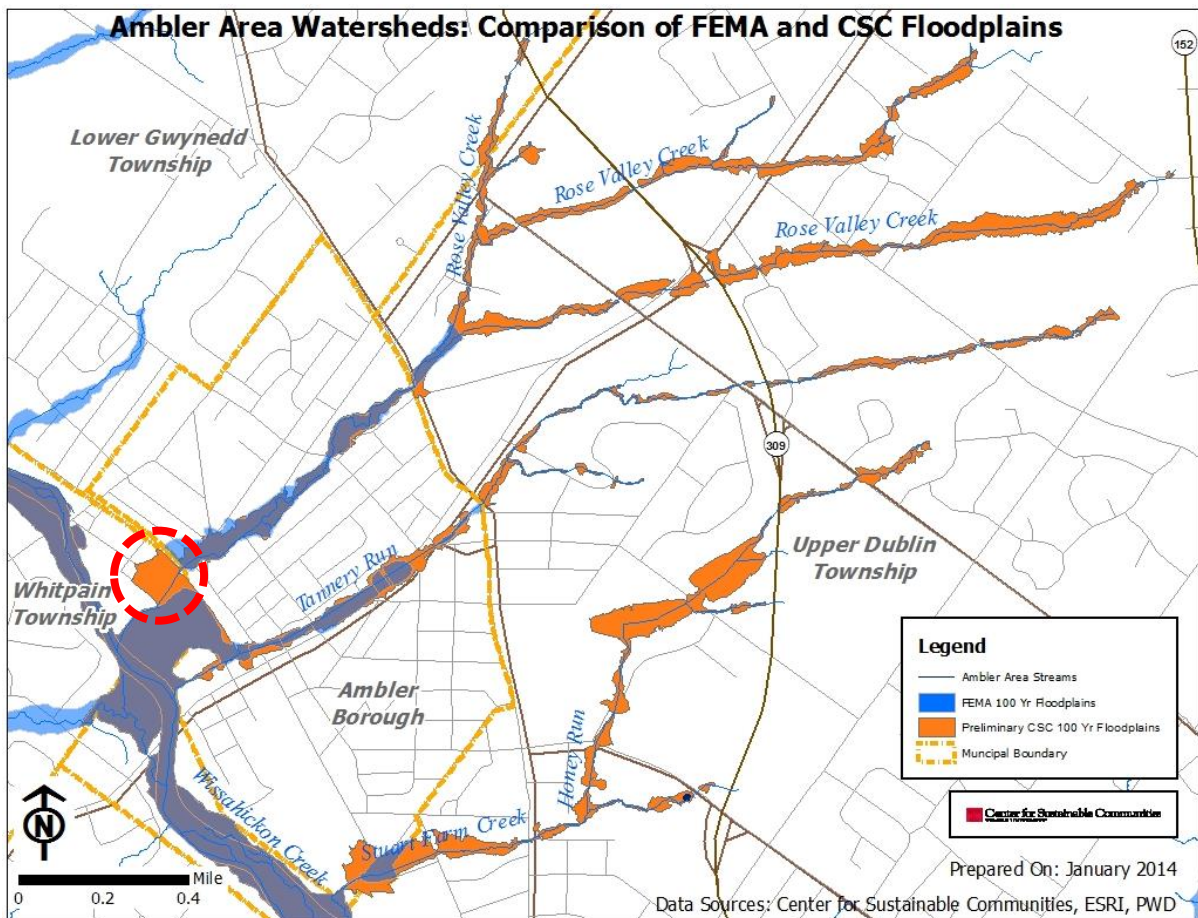

Fig 2: FEMA and preliminary CSC floodplain comparison

3.4. Stormwater Management Recommendations

Based on input from municipalities, community residents, and environmental groups as well as the field surveys, watershed assessments, and hydrologic and hydraulic modeling performed for the study, the Project Team recommended location-specific stormwater infrastructure (SI) facilities throughout the study area. In order to reduce runoff peaks and volumes, and address the widespread water quality impairments caused by stormwater runoff in the study area, various types of opportunities for improvements were evaluated, including but not limited to retrofitted detention basins, infiltration galleries and trenches, constructed wetlands, rain gardens, pervious paving, day-lighting streams, and riparian buffer. These recommendations are consistent with community needs, and community projects, initiatives, and plans.

As this watershed is essentially “built-out,” the Project Team concentrated much of its research on identifying opportunities for retrofitting existing stormwater facilities and finding locations for new SIs in areas not currently served by them. Additional flood control or mitigation options for the West Ambler neighborhood (EJ community) were evaluated. Because structural measures such as channel expansion and culvert enlargement can reduce floodplain storage and increase flows downstream, it is important that these measures be completed in combination with other stormwater control measures (i.e., stormwater best management practices – BMPs) that increase upstream storage. This approach would help prevent adverse downstream impacts.

After identifying potential SI projects and their possible locations, the Project Team assessed the hydrologic and water quality impacts of the proposed improvements. The proposed SI improvements were incorporated into a “Future Conditions” HEC-HMS model run, following same modeling approach described in previous section. In some locations downstream from potential improvements, the reduction in peak flow rates is sufficient to reduce water surface elevations for smaller storms. The combined potential additional storage provided by the three categories of improvements was estimated at 98.6 acre-feet, or approximately 33 million gallons. This volume of storage is equivalent to 0.47 inches of runoff from the 4 square mile watershed. The reductions in peak flow and volume would help reduce scour and erosion potential along stream reaches, and would be helpful where stream restoration is planned or has been completed. In addition, the recommended projects would provide for settling and storage of sediment in runoff and reduce sediment loading in the watershed. To provide a means of prioritizing further investigation of the proposed improvements, each site was rated based on three factors: (a) Effective use of additional storage during small storms – 50 percent weight of the total score; (b) Cost per acre-foot of storage provided by the site – 25 percent; and (c) Location in the watershed, with the upstream portion of the watershed receiving the highest score – 25 percent.

Recommendations include some structural measures within existing downstream floodplains. While such measures substantially lower flood risk, flooding would still occur if storms exceeded the design of the control measure. For the lower Rose Valley Creek analysis, the 500-Yr storm was used to determine the size of the enlarged channel, which would significantly reduce flooding in the West Ambler neighborhood. The Project Team recommended the site-specific projects only if the water released would be compensated with upstream storage or infiltration. All these recommendations were consistent with community input as well as the *West Ambler Revitalization and Action Plan*. Some of the site specific recommendations would impact many building owners. However, through daylighting the stream, the area subject to flooding could be greatly reduced, particularly in the West Ambler EJ community. While some properties would be impacted by this process, the damage inflicted overall by flooding would be cut back significantly.

The implementation of low-impact SIs will not likely impact flood control to a significant extent, due to their limited size, but have been proven to significantly improve water quality on a local scale. The placement of 5,940 rain barrels would absorb on average 1 acre-foot of rainwater and 100 rain gardens of 200 cubic feet each would absorb 0.46 acre-foot. Such projects may reduce stormwater marginally, but improve water quality by catching rainwater before it is polluted (rain barrels), by filtering pollutants out, or a

combination of both. In the case of rain barrels, the water can be reused for several household purposes.

3.5. Implementation Plan

After presenting the findings to municipal officials and Advisory Committee members, the following implementation strategies were proposed to the municipalities: the adoption and enforcement of new Flood Insurance Rate Maps (FIRMs), implementation of the stormwater improvements and flood control projects, adoption of municipal stormwater ordinances, institution of a flood warning system, and participation in FEMA's Community Rating System (CRS).

The municipalities were encouraged to independently or jointly submit the proposed new FIRMs to FEMA in the form of a letter of map revision (LOMR) and to adopt them as "best available information" for floodplain management purposes until the new maps are formally approved by FEMA and subsequently by the municipalities. The federal flood insurance program provides funding for voluntary buyouts of flood-prone properties. This plan identified several candidate properties. Typically, the federal government through FEMA provides 75% of the funding for property acquisition with the remainder of the funds coming from state and local government. The designation of properties as residing in a flood hazard zone through adoption of FIRMs is a critical step in the buyout process.

The municipalities were also encouraged to construct the stormwater improvements identified in this plan by increasing each municipality's capital improvement program funding. The various improvements were assigned a priority according to their location, cost – effectiveness, and capture potential, and municipalities could use this ranking as a basis for funding projects over a long-term period. Various state-level and local funding sources were listed. Flood control projects are eligible for federal funding. The three municipalities were encouraged to participate in the National Flood Insurance Program's (NFIP) Community Rating System (CRS) to get discounted flood insurance premium rates. A flood warning system for small watersheds requires forecasting, rainfall and water level monitoring, and response when flood rainfall rates or levels are triggered. The plan included initial recommended steps for the municipalities.

3.6. Post-Study Community Outreach

In March 2014, an early draft version of the final report was submitted to three municipalities (Ambler, Upper Dublin, and Whitpain) and Advisory Committee members for review. Based on feedback, corrections were made and a final draft version was prepared and eventually shared publicly in October 2014. An interactive online GIS map (<http://goo.gl/6yZBNG>) was published showcasing the comparison of existing FEMA floodplains and the new floodplains. Six weeks were allocated for public reviews and comments on the draft plan. Comments were received via emails, phone calls, and even personal visits. In late November the Project Team presented the study results in front of about 100 community residents, business owners, and other stakeholders (including federal, state, and local agencies) in a location within walking distance of the EJ community. Majority of the comments were received during and right after that presentation.

The presentation event transitioned into an interactive open conversation between the residents and the Project Team, the municipalities, and federal government agencies. Among the many Ambler Borough residents who have been subject to the accumulated effects of increased runoff, the concern of property damages caused by flooding being comprehensive and significant was greatly expressed. Indisposed with anticipation to address such concerns, the microphone wove through the audience as residents shared specific questions, suggestions, and comments. The Project Team received two general types of comments: informational and concerns or suggestions.

The informational comments were both general and study-specific. The general comments included questions regarding terminology (i.e., daylighting, floodplains), funding/ implementation/ timing, stormwater ordinances, and proposed developments in the area. The study-specific comments mentioned were questions about details of the SI projects and

explanations of the floodplain changes. At the public meeting, a resident questioned why most of the properties being removed from the floodplains after the stormwater measures were commercial and not residential. Several residents posed questions about plans for the development of a four-house subdivision in the Rose Valley Creek watershed and whether the study considered these plans.

The concerns and suggestions received can be broken into three primary categories: a) floodplains, b) stormwater management projects, and c) miscellaneous. Comments about the newly delineated floodplain maps were major concerns and/or opposition about individual properties being included in the preliminary floodplains. Concerns were related to expensive flood insurance, loss of property values, and restrictions on home improvement within flood zones.

Residents were informed that the Project Team used latest technology and data available for floodplain mapping and that they followed all the established standards and protocols set by FEMA. They were also informed that these preliminary floodplain maps would be scrutinized by FEMA and the Army Corps of Engineers (ACE), then revised by the Project Team if needed. On the other hand, many residents were delighted by seeing their houses or properties in the new floodplain maps. They acknowledged that this is the correct information. Some people commented that if they live in a high-risk flood area and are now required to get insurance, they will actually be able to purchase the flood insurance (because, according to the respondent, they are having problems getting the insurance), so “this is a win-win situation”.

There were concerns and suggestions in regards to the specific stormwater management projects proposed in the study. Residents questioned why certain areas and projects were or were not included and offered ideas for other projects to be considered. Some raised concerns about property acquisition. Based on public input, three additional site-specific SI facilities were included in the final report. There were only minor comments on the proposed detention basins, infiltration areas, and riparian buffer areas.

The remaining concerns and suggestions were on miscellaneous topics, such as problems related to FEMA flood insurance program, removal of the asbestos dumps that could free up over 70 acre feet of much needed lands for flood waters, and consideration of proposed developments in the engineering models. The Project Team forwarded the comments related to flood insurance program and superfund sites to FEMA and EPA respectively. Proposed developments were not considered in engineering models. The watershed is almost completely built out, so models were run considering the fact that land use would be mostly unchanged.

4. Conclusion

The Project Team used various community engagement tools throughout the Ambler study, including stakeholder meetings, surveys, websites, and direct interaction. While these tools were not specifically designed for addressing environmental justice questions, they were very useful for this purpose because the West Ambler community was specifically targeted by the project team and municipal officials for input and engagement. The Team’s experience with this study strongly suggests that direct contact with residents is preferable to the other tools as it enabled us achieve an initial level of trust with local citizens.

The municipalities also engaged the West Ambler community, which enhanced our study efforts. Whitpain Township created a West Ambler Revitalization Committee that includes local residents as well as officials. The committee meets quarterly at the municipal building. The township also holds quarterly public meetings in the evening with local citizens in West Ambler. At both venues, Project Team members briefed municipal officials and local residents on the status of the flooding study. These meetings provided an opportunity to directly engage local residents and receive more exposure and input for our study. Ambler, Upper Dublin, and Whitpain also participate on the BoRit Citizens Advisory Group created to advise EPA of actions taken at the Superfund site adjacent to the West Ambler neighborhood. The group, which meets monthly, includes over twenty members including the West Ambler Civic Association.

Sometimes community engagement raises difficult issues that might not have surfaced without it. Engagement does not always lead to public support. The flooding study led to the identification of many flood hazard areas that were not delineated on FEMA floodplain maps. While helping flood-prone homeowners better understand their flood risks, this information and designation as flood prone also was disconcerting to many Upper Dublin residents as their properties undoubtedly would be perceived as less valuable. At the stakeholder meetings several homeowners expressed this concern and sought to challenge the entire study. In contrast, community engagement was clearly positive for West Ambler as the routinely flooded sections of the neighborhood had not been officially mapped as flood prone and homes were not eligible for technical assistance and buyouts. The study and maps provide the means to make this happen.

The Ambler flooding study was conducted as a partnership between Temple University and the three municipalities. While funding was derived from multiple sources, the individual contributions of the municipalities and their willingness to hire the university were critical factors in securing financial and political support for the study. The university began forming these watershed partnerships back in the 2003 when it enlisted eleven municipalities to help finance a flooding study for the Pennypack Creek Watershed, also in suburban Philadelphia. The university raised \$100,000 from them, which it used to secure over \$1 million in funding from other sources, including a foundation and several federal and state agencies. Subsequently the university forged several other multi-municipal studies, including the Ambler Flooding study. Why has this been successful? This is most likely due to the Team's neutral/ independent status, student involvement, and comparatively lower cost may be contributing factors.

Acknowledgement

The authors would like to thank the members of the Project Team led by the Center for Sustainable Communities at Temple University. This work was supported by the US Army Corps of Engineers under Grant W912BU; UD Department of Housing and Urban Development under Grant B-1 0-20-402; and US Environmental Protection Agency under Grant UW-963153-01. Support also came from local municipalities, including Ambler Borough, Upper Dublin Township, and Whitpain Township. The authors are jointly responsible for the content of this paper.

Co, the possibility of a relational urbanism

Oscar GENTIAL, up - urbaplan, Switzerland

Prologue

Urbanism is a creative practice.

The constantly increasing number of parties and the shortened timeframes jeopardize the time of creativity and in return the time needed for creativity involves to extend the project process and to restrict the number of people sitting around the table. Therefore it is important to reconsider our methods.

The traditional practice in many design situations in Switzerland and in Europe in general consists of the implementation of processes such as competitions, competitive dialogues, etc.

Driven by panels of experts typically composed of professionals of urbanism and architecture as well as representatives of the project holders, these processes have the obvious interest to bring out a series of contrasting, creative and ambitious visions of a situation by submitting the same question to several teams. They develop their proposals along processes that normally last - from their initiation to their final conclusion - between nine or twelve months.

However, these kind of methods raise two critical issues related firstly to the control of the content – in that extent that the projects selection is delegated to a panel of experts, and secondly to the control of time. Moreover, because of formalism of its panel, we lose the opportunity of a truly dynamic and real-time confrontation of everyone's ideas.

Finally, the calendar of a competition or similar process engages the project leaders to “wait” for the results and their validation before continuing their reflections which will then be integrated into formal procedures, legal plans, regulations, etc. However, it is difficult to “freeze” the current projects for such a long period.

Alternatively, the project leaders could be attributed to a single private office the mission to develop a coordinated vision on the same site of intervention. This office would be responsible for defining the constraints and the opportunities of the site, and then would prepare several alternative development schemes that would come out with an overall strategy.

If it has the merit of simplicity and rapidity, this alternative is questionable because it would deprive the projects developers of the benefit of a creative ideas confrontation, which is undoubtedly essential to the emergence of an ambitious vision.

A third way is possible. It aims to combine the efficiency of a direct commission and the benefit of the confrontation of ideas in a competition.

The creative workshop allows both to open the debate on the challenges of the site in question, to focus the discussion on a significantly shorter period of time while preserving the decision control by direct association of projects leaders in the whole process. In this manner, it combines vision and pragmatism.

The creative workshop is based on the search for ideas immediately debated to bounce and make evolve them quickly. It includes several groups of players involved to varying degrees along the process (design group, critical group, moderator). They are gathered in a co-production working mode on a short and intense period.

Beyond the strict method of creative workshops, the approach seeks to develop a new vision of urbanism.

Through comparisons of realized experiences and references in urban planning and other creative disciplines (sciences, arts, etc.), we aim to theorize an approach praising uncertainty and process, revealing a critical issue in any collaborative and creative approach: how to bring out the ideas of a group?

1. Vision

A neighborhood, a city, or even a territory are living organisms shaped by the different players that constitutes it. Users, leaders, community groups, developers or experts (engineers, economists, architects, sociologists, etc.) are among those involved in both the development and the mutation of these organisms. The context in which an urban project is inscribed is made of a multitude of players with various opinions and skills. This diversity, which is *a priori* wealthy, could show signs of weakness when its management is inappropriate. Ideas coordination and confrontation play a key role in the project's quality and outcomes. It is therefore necessary for any project promoter to take into account the different perspectives and to build an ambitious and shared vision.

The creative workshop is a tool that comes to offer - for a short and defined period – a cell for intense exchange and brainstorming for different players, that aims to find a shared consensus, that eases potential issues, starts or revitalizes a project. Qs q result, the workshop enhances the project by confronting the skills and opinions of the multiple experts in real time on one hand, and on the other one brings out a common vision in a relatively short time.

The workshop directly questions our practices, our expertise, our interactions. It clearly reveals a critical need for sharing of knowledge. The evidence of a collective approach is not always implemented in practical developments of strategies or projects. Since forever, we find ourselves to share a meal, to play cards; why should we isolate ourselves to work?

2. Learning from crisis

The first creative workshops designed by urbaplan are linked to moments of crisis. We had to go beyond the traditional methods of urban planning to create transversal approaches between multiples players and to bring out new and shared proposals.

Figure 1: From crisis to praxis

The creative workshop, developed at first for this urgent start, has become a widespread practice that can be adapted to many situations and time frame. It imposes to better define the workshop as a process and to understand its possibilities and its conditions.

3. Atelier

Figure 2: French etymology of "atelier"

The multiple meanings of the word "atelier" - which designates both a manufacturing site, a place for design or a group of people - reveals the evolution of what it means, changing every time the society changes its own concept of working - production and manufacturing - over the economic, social and political transformations (Encyclopedia Universalis, MONDZAIN-BAUDINET).

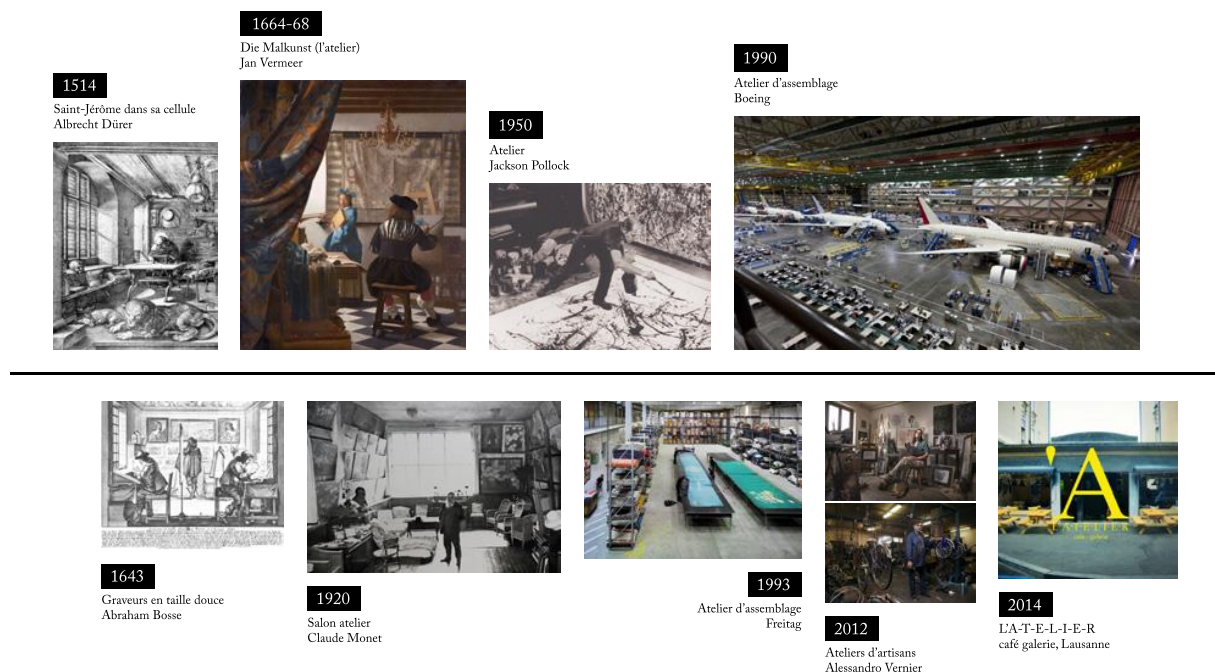

Figure 3: Chronology of the atelier

4. Tribute to process

How to bring out the ideas of a group? From art to science, creative processes can take various forms depending on the disciplines they're applied. Some similarities or differences can be found that may be vital supports for reflections and improvements of our own methods.

In a creative sense, the process requires to tell it as a story, to use it as a project. The storytelling becomes an evident communication tool and influences directly both the construction of the process itself and the strategic directions of the project.

"The creative process is a cocktail of instinct, skill, culture and a highly creative feverishness. It is not like a drug; it is a particular state when everything happens very quickly, a mixture of consciousness and unconsciousness, of fear and pleasure; it's a little like making love, the physical act of love."

Francis Bacon

"A process cannot be understood by stopping it. Understanding must move with the flow of the process, must join it and flow with it."

Dune, 1965
Frank Patrick Herbert

Figure 4: Quotes about process

5. Stimulation

Stimulation is part of any creative process. In the case of creative workshops, it emerges from the interlacing of intrinsic and extrinsic factors.

Regardless of a particular project context, curiosity is a creative engine for urban planners and more generally for all the players of urban fabric. This curiosity seems motivated by the understanding and analysis of complex mechanisms to raise up intervention strategies.

The circumstances of a workshop, its integration into a process and a context, its temporality, etc. create essential extrinsic stimuli that make each situation unique. The need to act in a crisis time – core of a dramatic action – results in a dynamic full of tension and intensity. Nevertheless, the uncertainties brought by every single situation constitute the principal stimulation. The dizziness that inevitably arises from dive into the unknown propels us into the creative craziness.

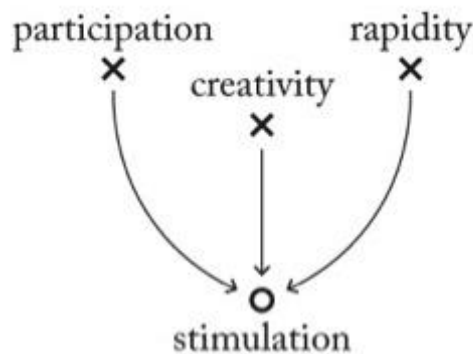

Figure 5: Stimulation

Three combined dynamics are the sources of stimulation of the creative workshop. Participation, or the ability to work together, to multiply forces. Creativity, or the invention beyond common sense, intuition or restrictions. Rapidity, or the intense compression of a working process period.

6. Simultaneity

“The effectiveness of urbanism depends on its ability to combine the imagination and the operational : to ensure the consistency between vision and action, willpower and realization, project and execution. These two registers have a singular propensity to discord: visions giving up the reality to prefer endless reveries; actions forgetting their purpose to be materialized on a case by case basis. That is why we must periodically retune them.” (QUINCEROT, 2013 – about the workshop *Nyon, cœur de ville* led by urbaplan)

The “*charrette*” is a widespread practice among designers – architects, planners, etc. Mostly suffered, couldn’t we use it in another way? Originally defined in the sense of an extensive work in anticipation of a possible delay in the execution of a project, its actual plural use reveals its drift. Indeed, the “*charrette*” means in North America a public meeting or a workshop devoted to a concerted effort in order to solve a problem by designing appropriate solutions.

The whole challenge of the creative workshop is to gather dynamics that traditionally can be dissociated during a process. The understanding of the challenges – framing, the buildings of arguments – storytelling, and the elaboration of solutions – design, are developed simultaneously.

The creative workshop defines a space-time where these actions take place “at the same time”, but also “with” multiple parties. These two notions – group and simultaneity – fit perfectly together in the prefix “co”. It becomes the essence of the vision of urbanism driven by creative workshops.

Figure 6: Simultaneity

7. Potentials

The workshop can take place during different phases of a process to achieve various objectives.

Firstly, it can be required in the case of a “crisis”. The concept of crisis can be shortly defined as the need for a decision for the proper development of an ongoing project. The workshop becomes a tool to deal with a looming uncertainty.

Figure 7: Crisis time

The need for the establishment of a workshop may be relevant when starting a project. It helps to define the mission, its specifications or a common vision to the different parties.

Figure 8: Start-up time

The workshop can then be seen as an opportunity to review a project under development. It is used as a downtime and allows to redefine the projects guidelines.

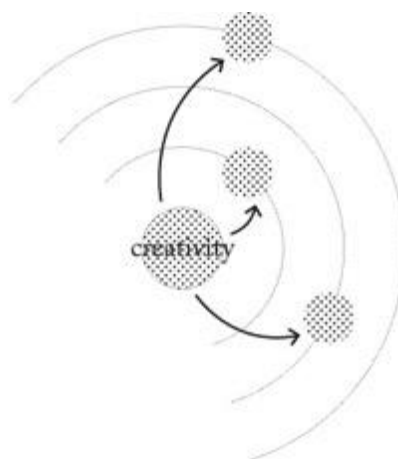

Figure 9: Downtime

8. Comparisons

There is no specific scale of intervention for the creative workshop. It may prove appropriate to plan the development of an entire region, a city, a neighborhood or a simple plot.

Numerous experiences allow us to validate this hypothesis which makes the creative workshop a-territorial: the Advisory Panels of the Urban Land Institute (ULI), the Charrette System of the National Charrette Institute, the Ateliers de Cergy or the Ateliers Nationaux are just a few examples.

Each situation and each method are unique. However, by developing a common base – type of parties, key moments in the process, etc. – we can try to compare them.

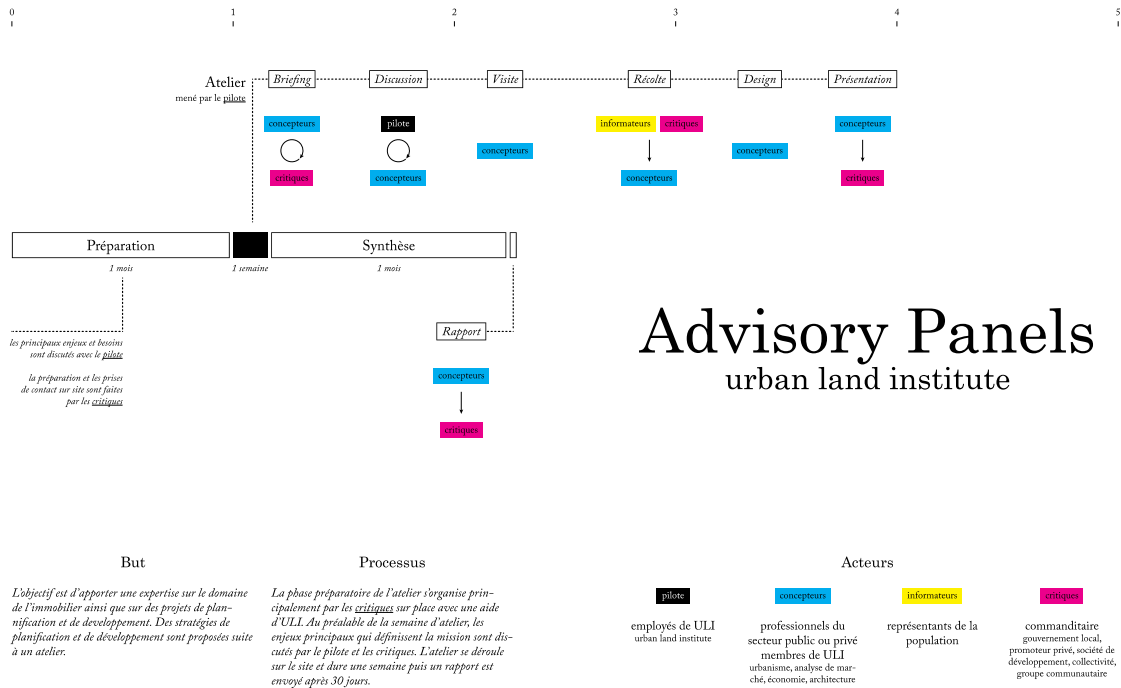

Figure 10: Example of comparative panel – Advisory Panels process - ULI

9. Tribute to uncertainty

Beyond the strict method of the creative workshop, the approach seeks to develop a new vision of urbanism.

The iconic image of the hand of Le Corbusier over the model of its *Plan Voisin* - a tabula rasa of the *Marais* district in Paris – demonstrates the omnipotence and the determinism of the planner. The creative workshop reveals a new vision – collaborative and flexible – based on a constant uncertainty in both the aimed objectives and the proposed results. Uncertainty is the new keyword of this open and collaborative urbanism.

Determinism	Uncertainty
Rigidity	Flexibility
Omnipotence	Collaboration
Closed process	Open process

Figure 11: New vision of urbanism

10. Leader and experiences

The experiences of creative workshops conducted by urbaplan are numerous and their objectives originally defined have upgrading. The creative workshop is now applied both in times of crisis, at the beginning of a process or during the development of a project. Nevertheless, it can not be used *a priori*, it always meets a specific need and can in no way be inevitable in every situation.

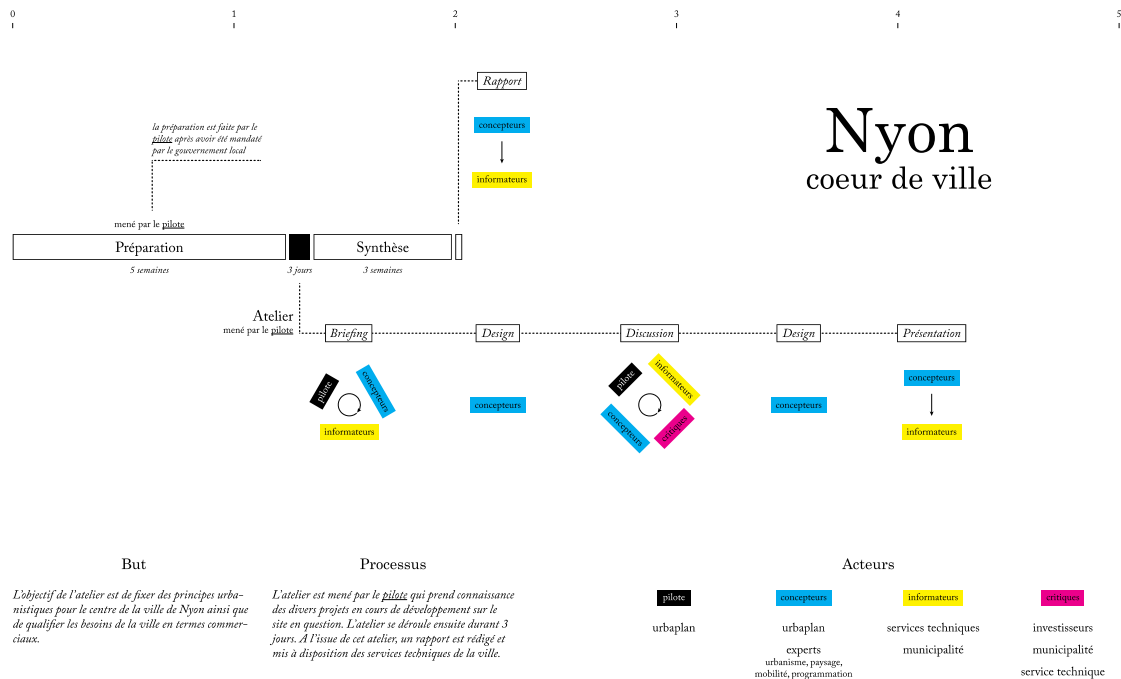

Figure 12: Example of comparative panel – Nyon cœur de ville, urbaplan

The keys of the creative workshop remained the same: to prevent a sideslip - rapidity, to ensure the projet quality – creativity – and to integrate external criteria – participation.

Participants of the creative workshop are diverse and numerous. They represent multiply interests depending on the situation and provide specific skills.

Figure 13: Participants à l'atelier créatif

The role of the “leader” has largely been clarified and strengthened since the first experience to the latest. The leader is more than just a moderator. Indeed, the moderator has a mission of neutrality, detachment regarding the particular situation and synthesis; while the leader is involved in the project, so he has the responsibility that obliges him to make choices. To describe the ideas shared with the participants is not enough; he needs to take responsibility for the choices made and the proposals designed by the whole group.

11. Postulates and conditions

To ensure its success, the creative workshop is based on different postulates. We need firstly to recognize the value of reflection and creative work in order to release a potential of exploration that is also guaranteed by the respect of the informal values of the workshop – work-in-progress, unfinished. Then this exploration helps to build the overall coherence of the project by incorporating the multiple factors and actors.

Finally, the workshop is based on a progressive enlargement governance, consultation or decision “circles”. The exploration is presented and debated from the bottom to the top – step by step – to ensure its legitimacy and its unifying role.

Conditions must also be met to ensure the smooth running of the creative workshop. The concern either the chosen location or the equipment provided that the number of participants, their attitudes and their relationships with each other.

12. Conclusion

The uncertainty is both a success factor – by the excitation it represents – and a difficulty factor – as the solution is not obvious. The stimulation is intrinsically linked to the success of a creative workshop. This philosophy helps to develop an approach that results in a technique that was built naturally, over the situations and projects, almost in spite of us.

The creative workshop reveals and carries a new vision of an urbanism that has no predefined form but chooses the uncertainty as a stimulant. Its ultimate aim is to generate relations. They define what's next.

“The opposition of intelligence and intuition tends to ignore the fundamental part of an immanent intelligence which is explained in the operating practices in which it engaged and that is transmitted through collective participation (savoir-faire transmissions).” (DEBAISE, 2004)

Note:

All the comparative panels of creative workshops conducted by urbaplan or other parties realized for this research are not displayed in this document. The full research, led by up – reflexive agent within urbaplan – will be published in September 2015 and will be presented at the 51st Congress ISOCARP 2015.

Submap: a conceptual and physical model of a spatial database for collaborative planning

N. Giupponi, C. Thomson

1 Introduction

This paper presents the second stage of a three stages PhD research investigating the potential of Geographic Information Technologies in promoting learning during collaborative decision making processes in planning. The first stage of research (Giupponi, 2015 under review) explored the limitations of specific applications such as Scottish National Statistics and Area Profiles in representing the lived space of communities during decision making. This was done by looking at the content of the spatial database used in Area Profiles and by identifying theoretical shortcomings within its conceptualization. The lack of spatial data semantically related to the subjective dimension of space is explained both pragmatically and theoretically: on one side, it is not practical to integrate subjective representations of space including multiple scales and temporal dimensions to formal data structures developed in existing geographic information systems while, on the other side, limited understandings of human cognition have ignored the eventuality that scientific evidence witnessed by planners “might not always be relevant to their plans” as other factors influence important cognitive processes of decision making.

This research responds to the need of adopting information technologies for creating imaginaries of cities capable of symbolizing relational and subjective spaces while influencing decisional processes. The online governmental technology of ‘area profiling’ is scrutinized for its ability to represent relational space and “enhance, rather than replace, dialogue” (Hoch, 2015); Giupponi (2015, under review) finds that the conceptual design of area profiling ignore the relational dimension of space and an innovative technique is presented in this paper that address the pragmatic and theoretical challenges of doing so. Cartographic design principles are applied for creating ‘Submap’: a map –and the techniques needed to create it- in which the spatio temporal dimension of subjective space is represented and symbolized. Examples are then provided of different applications of this technique using a pilot study in the Gorbals, Glasgow. Eventually, a conceptual model for a relational spatial database relating the data content of Submaps to the data content of traditional area profiling is proposed to explore the possibility of crossing between the quantitative and qualitative chasm (DeLyser, 2012) and access holistic representations of cities which could trigger sense making during decision making. Before moving on with the physical modeling of such database, in the next stage of research, a series of Submaps will be validated for their ability to promote sense making activities in different Communities of practice in planning (local communities, planners, architects, housing associations etc.) by comparing the breadth of the dialogues promoted by traditional area profiles to the breath of the dialogues promoted by traditional area profiles and Submaps.

2 Background

2.1 Urban regeneration and social displacement

“We are not building cities for people to live in; we are building cities for people to invest in” (Harvey, 2015)

In the last three years, Inner London boroughs have moved 50000 families to outer London neighbourhoods as a result of soaring rents (Douglas, 2015). This process is not new to urban planning history: in 1946, Sir Patrick Abercrombie’s Clyde Valley Report stated the need to disperse between 250,000 to 300,000 people from central Glasgow (Maver, 2014) in order to address urban decay. After 70 years, Glasgow remains ‘root-shocked’ from such mass displacement making it the perfect example for scholars writing about the idea of planning as intrinsically dealing with “problems from the past”. In the last thirty years, UK growth strategy for post-industrial cities like Glasgow has been the one to literally ‘make

space' in well connected city centres for Financial Districts and affluent communities. In 2011, Glasgow was in the European top fifteen Global Financial Centres which measured 75 financial centres across the world (Z/Yen Group and Qatar Financial Centre Authority, 2014). One year later, In 2012, Greater Glasgow scored the highest level of self-reported poor health measures among 33 other European cities (Grey et al, 2012) calling for a critical analysis of the relationship between growth and prosperity.

Spatial decision making processes (SDMP) and the Communities of Practice (CoP) involved in them, are often the focus of studies in urban research willing to understand the phenomenon of social displacement in relation to urban regeneration which undergo the umbrella term of 'gentrification studies' (Atkinson, 2000; 2008). Political economy approaches can illustrate the role of markets and governments in implementing values and rules which do not only influence SDMP (Smith, 1979;1987) but also affect the implementation of information technologies within them (Georgiadou et al. 2010). Diversely, this research takes a socio-ecological approach to the phenomenon of gentrification treating cognition and the environment in which SDMP occurs as important variables for creating broader discourses onto the paradoxical positive relationship between urban regeneration and social inequality. In fact, however enlightening results from political economic studies could be, their ability to improve SDMP is limited by the ability of SDMP of improving themselves. It is then suggested that there is a need to better understand learning in SDMP acknowledging both the role of organisational inertia (Hannan et al, 1984; Kelly et al. 1991) as well as the potential of 'reflexive social learning' and 'evaluation' in achieving effective SDMP (Sanderson, 2002) . Informal interviews to senior planners revealed that assumptions exist about the ability of the planning system to systematically 'pick up' lessons from the past to avoid "reinventing the wheel again". This kind of thinking is based on the hypothesis of information being automatically processed during cognition which contrasts with the idea that no boundaries exist between the 'processor' and the 'information' setting the grounds for a critical engagement with the topic of learning in planning. It is not the aim of this paper to study learning in SDMP on a theoretical level, but instead, to show examples and techniques of how information technologies in existing planning practices can be designed to address a key activity of reflexive social learning : sense-making.

2.2 Learning from the past: the idea of collaboration

Planning authorities willing to learn lessons from past regeneration experiences have engaged in promoting more socially inclusive and collaborative approaches involving stakeholder engagement to ensure that local communities have a voice in planning. However, moving from manipulative and consultative stages of participation to the empowerment of communities (Arnstein, 1997) has demonstrated quite challenging (Lawson L. et al. 2010) calling for an exploration of better strategies considering the paradoxes of control and collaboration in governance (Sunduramurthy et al. 2003, Whitehead M. 2003). In the same way, the non-transformative nature of collaborative processes legitimating traditional power structures of SDMP and reinforcing existing inequities (Plummer et al. 2007, Swyngedouw 2005, Van Bortel 2009) call for deeper and more detailed analysis of the existing codes and forms 'making' collaborative planning in order to allow for a 'purposeful' manipulation of these codes in the view of improving collaboration strategies. In the attempt of doing so, this research isolates the spatial information –grouped into different spatial datasets- which is currently used for area profiling in Scotland Neighbourhood Statistics (Scottish Government 2015). Their ability to provide adequate spatial representations helping their 'users' to better understand the societal needs of a particular area and promote collaboration is put under scrutiny theoretically and practically. A conceptual model is eventually suggested that could enable the integration of subjective spatial data to traditional database used for area profiling.

2.3 Urban governance through spatial technologies: metrics and new metrics

“Any account of a potential technology needs to avoid reading governmentality into outcomes (Cherney, 2004) and assuming that a particular technology will deliver a particular rationality. Instead, it needs to pay attention to the actual engagement of actors with such technologies and to the contingency of particular cases, rather than assuming that the implication of adopting a particular policy tool is effective ‘conduct of conduct.’” (Rydin, 2014)

After having set the need of improving learning in decision making processes in urban planning based on the emerging problem of social displacement and its related phenomena of polarization, marginalization and segregation (Kohn, 2013), the spatial unit of the neighborhood is isolated to carry out a theoretical and practical investigation into how the social dimension of lived space can be represented during area profiling. Three limitations of current representations of the spatial unit of ‘neighborhood’ are found in the literature: subjectivity, multiple scales and temporality (de Ham et al. 2013). These dimensions of space find some theoretical ground in Lewin’s ecological psychology (Burnes et al. 2013) which emphasize the univocal relation between the individual and his/her environment explaining how one shapes, rather than dominates, the other. Following this, objective representations of spatial realities are criticized for their inability of representing the relational dimension of space opening up new avenues to find different techniques leading to the production of spatial representations inclusive of relational subjective spaces. Considering that “what human beings are and will become is decided in the shape of our tools no less than in the action of statesmen and political movements” (Feenberg, 1992), the role of the tools adopted during spatial decision making in shaping our cities should not be underestimated. In the same way a magnifier allowed us to better understand the functioning of human organs moving beyond the limits of a cognitive system with poor sensorimotor skills, remote sensing technologies such as aerial photography, transportation monitoring, environmental sensors and cameras, allowed us to access information about cities we would not be able to access as limited by the constraint, for example, of being unable to be in two different places at the same time. However, there is a subtle difference between these two technologies: while a magnifier put the object and the observer in a direct relationship by improving the quality of the lenses through which we look at the world, remote sensing is, by definition, ‘remote’, and remove the physical contact between the object and the subject. Spatial representations of cities produced using remote sensing technologies have then the peculiarity of removing the physical relationship between the observer and the phenomenon and, whenever a physical connection is broken, something like a representation is required (Chemero, 2011).

From this perspective, planners, unless planning their own lived spaces, deal most of the time with representations of spatial realities which is what the critical work of Lefebvre on the three parts of the dialectic of space (lived, abstract and conceived) discusses (Lefebvre, 1991). It is then argued that representing both abstract and lived spaces during decision making can accelerate a holistic understanding of cities and eventually improve decision making. Before proceeding with such endeavour, it is important to identify the mechanisms, structures and rules of spatial representations in planning as well as the methods and elements used to produce them. This is done in Giupponi (2015, under review) by dissecting the content of the spatial datasets used for area profiling by the Scottish Government (2015) and showing the gap within the existing database structure of spatial information which can be semantically related to the societal need of ‘relatedness’ (de Haan et al. 2014). Moreover, direct observations¹ of contemporary efforts in providing ‘alternative’ representations of cities, revealed that existing representations of relational space, because of their informal data structure, cannot be integrated to existing formal spatial database which exist in planning

¹ The researcher has followed the initiative of community mapping organized in Glasgow as part of the bigger Future city agenda worth £24m (Future City, 2013) and got actively involved as a volunteer in a Community Mapping project for a Charity for people with learning and physical disabilities.

support systems like Geographic Information Systems, remaining therefore marginal tools to decision making in planning.

It is then iterated that reviewing the design of Spatial Information Technologies (SIT) and spatial data infrastructure (SDI) could be “an important experiment in governance that may be transformational not only to our identities as planners, politicians, or communities but also to the relationships that are shaped between us” (Miller, 2005). These tools are adopted to facilitate and mediate abstraction processes of future spaces (Feenberg, 1992) leading to the generation of “alternative ways of knowing to open up new possibilities at the level of interpretation and represent a vehicle to change, learning and transition” (Legendijk et al. 2014). Legendijk et al (2014), uses the word ‘metrics’ to describe abstractions used in planning for the representations of spatial realities; metrics can therefore be interpreted as the spatial datasets of variables relating to employment, access to services, education, pollution in a specific spatial unit (e.g. the datazone in the UK, or the Census Tract in the US) like n. of people using the local library, n. of people holding a degree, distance to contaminated site etc. In this paper new metrics are presented which can be used to collect, store and retrieve spatial information on ‘lived space’ by adopting the codes and forms of Information Systems implemented in current practices.

3 Background

3.1 Previous work in representing subjective spaces

The definition of ‘lived space’ as “directly lived through its associated images and symbols” (Lefebvre,1991:39) suggests that lived spaces are essentially subjective and collection methods of subjective data belong to qualitative science. The field dealing with representations of qualitative data in GIS is known as “Qualitative Geographic Information Systems” (QGIS) and spans between the fields of machine learning, artificial intelligence, feminist and public health research. The introduction of qualitative data in GIS enabled, for example, the exploration of natural language variations associated with different spatial variables (Shariff et al. 1998, Xu 2007, Eisenstein, 2014) as well as the identification of gender, age and cultural differences in spatial activities patterns and experiences of place (Kwan 2000, Mennis et al., 2013, McLafferty, 2005). These studies demonstrate an emerging approach in research for integrating qualitative data and qualitative analysis to traditional GIS defined by Jung et al (2010) as Computer Aided Qualitative GIS (CAQ-GIS) which “enable researchers to take advantage of the geo-visualization and spatial analysis capabilities of GIS as well as the qualitative analysis tools available in CAQDAS”.

Methods adopted in Qualitative GIS are essentially mixed as they can merge ethnographic methods and narrative analysis to spatial statistics (Pavloskaya 2002, Matthews et al. 2005, Bagheri, 2013, 2014, Curtis et al. 2014). Research in Qualitative GIS has been on the rise since 2002 and date back to the early work of Hagerstrand (1970) on time geography as a discipline in which the geography of everyday life is understood in terms of “the interaction between space and time and their joint effect on the structure of human activity patterns in particular localities” (Kwan, 2002). Time geography analyses human activity patterns and movements in space-time requiring detailed individual data and representations of space including the dimension of location, timing, duration, sequencing and type of activity; these are often used to explore migration, residential mobility, shopping travel and commuting behaviour useful for neighborhood planning.

A Qualitative GIS mixed method approach fits the purpose of this research, enabling the ‘lived space’ of neighborhoods to be represented in tandem with existing quantitative approaches which mainly draw on the ‘space-time of human activities’ originally developed with the purpose of exploring patterns in household activities and travel behaviour (Kwan 2000, 2006, 2014; Weber et al 2002, 2003).

3.2 Representing phenomenological 'lived space': from limitations to opportunities

The concept of phenomenological 'lived space' is approached via the notion of neighborhood. The vision of a neighborhood as self-sufficient container was introduced by urban ecological theories of the early 20th century like the garden city (Howard's, 1902) and Burgess's concentric model, and has persisted as a sociological orthodoxy until recently (Chaskin,1997); two main problems have emerged in the literature as a result of adopting representations of neighborhoods as bounded, static and a-temporal phenomena summarized in Kwan (2012): the first is known as the uncertain geographic context problem (UGCP) and it arises because of 'the spatial uncertainty in the actual areas that exert relevant contextual influences on each individuals under study'; the second is known as the modifiable area unit problem (MAUP) in which 'analytical results are biased by the zoning scheme'. Meanings and definitions of neighborhoods have clearly evolved as limitations of different interpretations were being unveiled. Van Ham et al (2013) makes a synthesis of the necessary shifts for carrying out studies on neighborhoods considering both UGCP and MAUP providing a theoretical framework for this work in which (selecting only a few of his recommendations) :

- Studies need to focus on the relationship between the built environment and the subjects of the neighborhood
- Subjective data should be considered
- The temporal variable should be considered (people's and places' histories)
- The spatial variable should be considered to broaden the neighborhood's horizon and include other spatial context which matter in addition to the residential neighborhood

Following this, it is understood why Qualitative GIS methods mapping subjective spaces of neighborhoods should directly engage with communities to spatially represent subjective and experiential spaces. In the context of information technologies for planning, these methods undergo the umbrella term of Participatory Geographic Information Systems (PGIS). PGIS methods aim to engage non experts to identify the spatial dimensions of social and cultural landscapes (Brown et al, 2014) via the implementation of different methods developed in virtual environments and digital game with the overall aim to improve participants' immersion by focusing on "the depth and breadth of user experience" (Gordon et al. 2011), therefore enhancing participation. PPGIS is described by Tulloch (2008) as "the field within geographic information science that focuses on ways that the public uses different forms of SIT (Spatial Information Technologies) to participate in public processes such as mapping and decision making. Private GIS-based businesses and public GIS-based services are growing in cities adhering to the smart city agenda and often provide tailored packages (phone applications) of map-based software tools. Users of these toolkits are citizens and there is a need to ensure that such information can be used to inform decision making processes at a city planning level. However, the formal structure of traditional Planning Support Systems such as Scottish Neighborhood Statistics discourages the utilization of unstructured spatial data ,such as subjective mappings, during traditional decision making processes. In order to address this barrier to collaboration, the following section shows how subjective spatial data could be formalized via the creation of 'Submap': a map of subjective spaces moving beyond a positivist approach to human geography. Examples of Submaps are provided in this paper and they will be validated for their ability to trigger sense-making in different Communities of Practice (CoP) in the next stage of research. The paper concludes with presenting a sketch of how a relational database including both subjective spatial data and official Scottish Neighborhood Statistics would look like opening up the possibility of integrating quantitative and qualitative for area profiling.

4 Extended Mapping and Submap

4.1 Extended mapping: maps as processes rather than knowledge

Cartographic design principles are used to guide the creation of new spatial representations and the first step in cartographic design is to consider the real world distribution of the phenomenon which is being represented (Slocum et al, 2014:240). Based on a literature review on space time geography and neighborhood research, it is understood that this is not possible when representing relational space since there is no such thing as a ‘one real-world distribution’ in subjective space but multiple ‘real worlds’ are accepted. From this perspective, spatial representations themselves are not interpreted as final products but as *processes* for investigating individual meanings of relational space and the possible existence of a collective relational space by representing cumulatively different individual spaces and identify patterns: this agrees with Montello (2002) who suggests that maps do not necessarily communicate knowledge but rather, stimulate and suggest knowledge through the transmission of information (Slocum et al. 2014). In order to distinguish this kind of mapping from the mappings in which spatial realities are defined and evaluated we define these mappings ‘Extended mappings’ for their ability to contribute to a process of sense making rather than merely communicating spatial knowledge.

In the second step of the design process, Slocum et al (2014) , the purpose of the map should be determined. As stated above, the purpose of this work is to add on representations of subjective spaces to decision making processes while considering the spatio-temporal dimensions of lived space. Neighborhood studies associate social networks, spatial occupation patterns, activities, residential history, perceived safety, perceived neighborhood, perceived landmarks etc. to the concept of lived space .By taking a pragmatic approach, nine face to face 60 minutes interviews to planners from four different Local Authorities in the West of Scotland were carried out to discuss the relevance of different socio-spatial concepts to decision making in planning in order to test their validity in a practice based context. These interviews resulted in the selection of fifteen elements to generalize subjective space (Table 1).

Before showing how the spatio-temporal dimensions of these elements can be represented using cartographic devices, it is important to take another crucial step of cartographic design which could strongly influence the breadth of sense-making during decision making processes: identifying the intended audience.

ELEMENTS OF A SUBJECTIVE MAP (SUBMAP)	
<i>Submap spatial</i>	
	My home
	My people
	My perceived neighbourhood
	My spatial movements in a typical week
	My perceived changes (positive, negative, indifferent)
	Place/s I think require change
	Place/s I want to stay the same
	Place/s I go often to in my free time
	My problematic areas (where I experienced problems in the past)
	My food shop/shops
<i>Submap spatio-temporal</i>	
	Residential history since date of birth
	Future prospect of moving out the area? Reason? Where to?
	How many hours per day outside your home
	How many hours per day outside your neighbourhood
	How many times away from home for more than one week in one year

Table 1: Selected elements representing spatio temporal patterns of subjective relational space

4.2 Sense Making and Gestalt psychology

“Because we do not believe there is any single correct ‘solution’ to such challenges –of contemporary urban theory-, our questions are intentionally open-ended. The goal, we repeat, is to open up horizons for thought and action, and through collective dialogue, investigation and debate, to begin to explore these horizons.” (Brenner, 2010)

The identification of the audience of a map is another important prerequisite to map design; different user groups will in fact have different previous experiences with map reading as well as with the phenomenon being represented. It is possible to imagine how a map of the geology of Scotland could differ if it was for a 10 years old or a 25 years old Geology graduate student. In a context of collaborative planning, representations of subjective lived space are intended to address different communities of practices (CoPs) involved in collaborative decision making such as community groups, architects or researchers. The common denominator between these groups is their interest in the socio-spatial processes of a specific area and their will to engage in some kind of sense-making activities. The purpose of subjective spatial representations is to create representations of relational space to different communities of practice involved in decision making processes of regeneration at different stages and trigger different sense making activities that can be used “ through collective dialogue, investigation and debate to begin to explore horizons for thought and action” (Brenner, 2011). In order to achieve this, it is important to get some basic understanding of how our cognitive vision system organizes spatial information and, both consciously and unconsciously, influence our generation of meaning. According to Gestalt psychology (Wagemans et al. 2012), Bertin’s (1983) principles of spatial organization such as closure, proximity, similarity are important criteria of relevance of spatial information for all users and choices on color, contrast, spatial hierarchies, size and other visual variables can be manipulated to make sure that confusion and clutter do not interfere with users’ spatial organization processes. Just to illustrate the relevance to users of carefully selecting different visual variables in the spatial representations of lived space some examples are provided.

In Figure 1 the Gestalt principle of ‘proximity’ is used to identify certain patterns of utilization of place during the free time of three different subjects. In Figure 2, different areal size shows the diversity of perception of neighborhood while in Figure 3, different linear size, color and spacing show different mobility levels at different scales for three different users. In Figure 4, the qualitative phenomena of ‘perceived changes’ (good or bad) is represented using the visual variable of color hues and, through the Gestalt principles of ‘similarity’ one understands that there is more positive rather than negative elements in the map. After demonstrating how different visual variables can influence sense making, the following paragraph illustrates how the challenges of representing multiple scales and temporality have been addressed.

4.3 Submap: a techniques for including multiple scales and the temporal dimensions in the spatial representation of lived space

No research has previously attempted to provide spatial representations of lived space which collect and represent data both at multiple scales (from local to global) and consider the temporal dimension within GIS. Creativity was essential to address these challenges and develop a mapping technique called ‘Submap’ for collecting and representing spatial data at multiple scales and including temporality.

Figure 5 is a simplified version of an A2 Submap which is used to collect data for surveying the fifteen different elements of lived spaces illustrated in Table 1. Four scales (local, city, national and global) are included in four different quadrants (Fig. 6) of a 2D Cartesian plane in which one unit is 16 pixel. A grid of 16X16 pixel is then overlaid on the Cartesian plane; through this simple manipulation, it becomes possible to collect, digitize and represent in one single database spatial datasets existing at different scales by using a coordinate system in which one unit (one side of one cellgrid) is 16 pixel. Open street data is used for the

background maps at different scales in order to avoid copyright issues. Figure 6 gives a better idea of the layout of the different scales in the four different quadrants of the Submap. Each 16x16 gridcell can be then defined by two integers using the Cartesian Coordinate system. The 16 pixel unit was carefully selected in reference to the size of the Submap in order to ensure that one cell could locate states in the global map and identify buildings in the local map. The choice of the paper size was influenced by the need of moving beyond the constraint provided by the size of common desktop screens limiting sense making activities to the common practice of zooming in and zooming out different scales denying the possibility of relating different scales. On the left and on the right sides of the simplified version of the Submap in Fig 6, two boxes are used to collect spatio-temporal (e.g. residential history since birth, willingness to move and time spent out of neighborhood and out of city). Fig. 7 is an example of an 'extended mapping' developed for the representation of space-time fields for different subjects.

These illustrations represent the first trial of the method and their aim is to refine existing map design and test surveying strategies. Although only three people were surveyed in a Park in the Gorbals in the Glasgow it is possible to observe similarities and differences in spatial perception and utilization patterns. By collecting core demographic data pooled from the main National Surveys such as the Household Survey, it is possible to explore whether patterns vary between different spatial and/or demographic variables. For example, if we consider the three space-time fields in Fig 5 it is possible to speculate areal size of perceived neighborhood to the different space time fields in Fig. 7. A bigger sample is required to test the procedure and collect representative data: a total of twenty community groups operating in the area have been identified by accessing the local library and will be contacted for collecting a sample which can be used to see whether further exploration of this technique could unveil unknown socio spatial correlations.

Digital mapping and door to door surveying are not seen as feasible methods for lack of resources and time but their advantages in collecting a more representative sample and improve the efficacy of the digitization process is recognized. After a larger sample is collected, Gorbals's Submap series, including a selection of visual displays similar to the ones presented in this paper, will be showed to different communities of practices in order to determine whether users find these maps useful and informative which is the final step of cartographic design process (Slocum et al. 2014).

5 Conclusions and future research: A relational database for inclusive area profiling

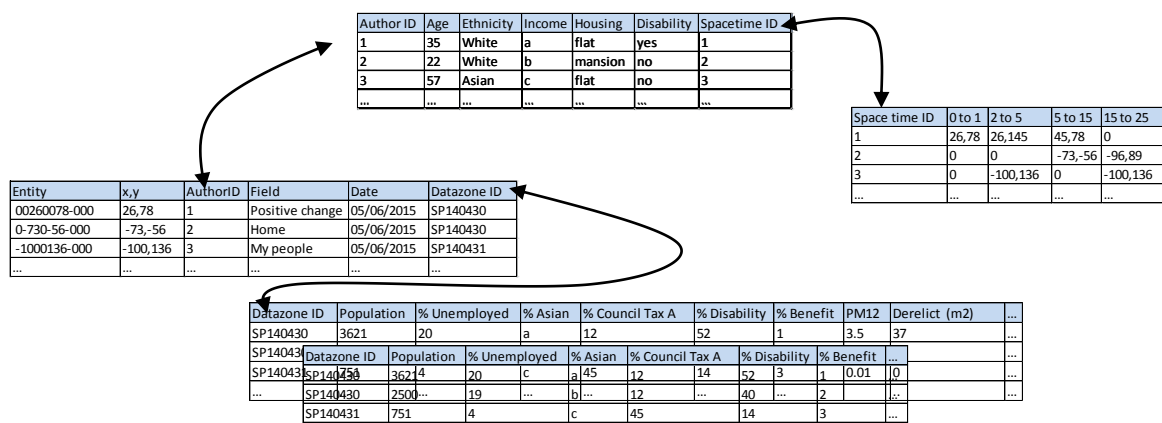

Figure 8: An hypothetical relational database for collaborative planning including subjective lived space

In Figure 8 an hypothetical relational database for GIS able to retrieve and represent both relational and non-relational spatial data is presented. This conceptual modeling is based on the idea of relating subjective mappings to demographic profiles and datazones. An important requirement of this relational database is the one of 'interoperability' between quantitative and qualitative spatial data. Submaps have been designed with this in mind by overlaying a grid system to a two dimensional Cartesian plane. Every cell in the grid system is given unique coordinates while being associated to a datazone and every spatial entity mapped by any author is instead associated to a cell in the grid system. In order to avoid replication of data, every spatial entity mapped by every subject is uniquely identified by a 12 digits code in which the first six digits are used for including the coordinates of specific spatial entities and the last three digits for numbering each entity uniquely. By relating these two datasets, Geographic Information Systems can store and retrieve quantitative and qualitative spatial data opening up new avenues for area profiling and monitoring which have not been explored before. More importantly, the symbolic inclusion of subjects in subject-free database is seen as a step towards the consideration of the paradox of 'control and collaboration' in planning.

Księży Młyn in Lodz, Poland - an example of a successful rehabilitation thanks to the social engagement

Małgorzata Hanzl

1. Introduction

The project of the social rehabilitation of Księży Młyn in Lodz, Poland conducted by the Association for the Heritage Protection of Lodz from July 2010 to July 2011 was focused on community empowerment of the small neighbourhood of 19th century workers' residential estate. The project was financed by the Stefan Batory Foundation as a part of the program Democracy in Action – Participation. The housing unit historically belonged to an industrial complex of Scheibler's textile factories, which once occupied a portion of over 70 ha of the downtown of Lodz. The estate, along with the huge cotton mill, are located in the very core of the complex and pertain to its most representative part. The layout of workers' houses, which are lined along the composition axe perpendicular to the edifice of the spinning mill, is considered the most characteristic part of the whole area.

During the transformation period the workers' houses, belonging formerly to the factory, became the municipal property. The initial renovation of the first house started in 1999 did not bring the expected results and a desired income of new inhabitants did not take place. In 2007 the workers houses were planned to be redeveloped to a gated residential estate, and inhabitants were promised new flats in the blocks of flats in the outskirts of the city. However the crisis made these plans impossible and the inhabitants were left behind without any decision about their future. The buildings, not renovated since their construction in the end of 19th century became deteriorated and the problem was more and more persistent.

The initial frustration of citizens living in Księży Młyn estate in the period when the social rehabilitation project occurred the main problem to be solved. During the year between July 2010 and July 2011 the project team conducted numerous activities with the objective to provide support and advice in order to let the inhabitants to become an active stakeholder in the further decision process with regard to the estate's future. The initial aim to create a common strategy of redevelopment of the estate was very difficult to undertake and the consultations and the actual work on this project could only start in the last phase of the project. However difficult did this occur, the Strategy of redevelopment was finally elaborated with the participation of the local citizens. Yet the most important results were the social capital and the start of the rehabilitation project by the Municipality of Lodz. Directly after the end of the social project, thanks to the popularisation of the topic as a result of its promotion and local citizens initiatives, the local government decided to assign a budget and to establish an administrative unit in order to start the renovation works. The project continues successfully until now.

The current paper presents details of the social rehabilitation scenario, evaluates the outcomes and provides conclusions with regard to other projects conducted for similar neighbourhoods.

2. Initial diagnosis

The project was conducted for the part of the workers' estate of the former Karol Scheibler and Ludwik Grohman's United Factories in Księży Młyn Street in Lodz. The delimitation of the site results from the presence of a concise unit of urban fabric perceived as a factory housing estate of clearly idiosyncratic character and specific spatial features. Moreover the site selection was a consequence of the former attempts to convert the area into a gated residential estate deprived of the current social housing component. The voice of the

previous inhabitants of factory houses was missing in the debate on the future of this site, challenging also from the heritage conservation perspective. There had been no attempts to solve the problems of the estate with the participation and empowerment of its inhabitants until the beginning of the project discussed in the current paper.

2.1 Historical background

Started in 1853 by Karol Wilhelm Scheibler, the textile enterprise developed in several phases to finally evolve in 1921 into a concise industrial complex of Karol Scheibler and Ludwik Grohman's United Factories, which covered the area of 500 ha and took 1/7 of the total surface of the town in its borders from 1914 (Ginsbert 1962). The enterprise considered the largest in the world at the time (Małagowski 1998), the total cubic footage of all its grand industrial plants exceeded 1 000 000 m³ and it was served by its own spur line (Ginsbert 1962). The name Księży Młyn (Priest's Mill) was derived from the former use of the site owned since the 15th century by the Lodz parish and where a water mill was located (Koboжек 1998). The first part of the workers complex erected between 1873 and 1875 along with the remaining edifices of the mills factory was further extended in the period 1884-1885 to Fabryczna street. Moreover at the turn of the Eighties and Nineties subsequent houses were built in Tylna, Widzewska and Kątna Streets. In ca 1888 in the total number of 46 buildings belonging to the factory there were 900 flats inhabited by 4785 people (2912 adults and 1873 children). Next buildings were added in 1891 to reach the total quantity of 65 (Pytlas 1979). The merger of two family enterprises in 1921 gave beginning to the United Factories, which continued until the World War II. After the war the enterprise restarted as a state-owned company, which since 1962 was known as Uniontex. The complicated history of the property changes: communalisation and afterwards privatisation during the period of transformation led to the final shutdown of the enterprise in 2006. While several of its properties have been since renovated and reused for various purposes, including housing and the whole range of services and industrial production, many premises still remain abandoned and ruined.

2.2 Composition and cultural values

The current elaboration refers to the initial phase of the development of Scheibler's factory houses constructed between 1873 and 1885 (Fig. 1). The first part of the estate comprised 18 two storey workers houses distributed in three parallel rows of six buildings. Centrally located alley planted with lime trees reveals along the axis of symmetry of the largest spinning mill of the factory and leads to its characteristic main entry topped with a clock. Another row of buildings faces Przędzalniana Street. The first extension comprised a set of seven further workers houses of which five were larger than the former ones. All unplaster brick buildings were accompanied by a characteristic c-shaped one-floor back-structures initially hosting outhouses and storage. The residential complex comprised also an industrial school attended by the workers' children, a canteen, a grocery shop, a hospital, a fire depot and a play hall. The estate was surrounded with a decorative iron fence, and there were guards posts next to the gates. The backyards contained gardens, initially planted by teachers of the local school and factory foremen.

The characteristic rhythms remaining until now the main idiosyncrasy of the estate are probably the reason for often repeating comparisons to the military barracks. The rhythms of buildings, windows and doors openings and panels on identical rude brick walls, along with the rhythmical planting of trees in the main alley and in the smaller lime alley in Koci Szlak, all these features offer the local unique atmosphere. The rhythmicity of enclosures and clear distinction between public and semi-private spaces provide the notion of order and stability.

The recent alteration of the sociometric layout of the estate in the form of spontaneous extensions of the backyards structures convey to the picturesque image of the estate. As a result the former uniformity of the site has been replaced by a range of smaller enclosures. The notion of idiosyncrasy of the estate is further enhanced thanks to the foliage of trees planted along Magazyńska street.

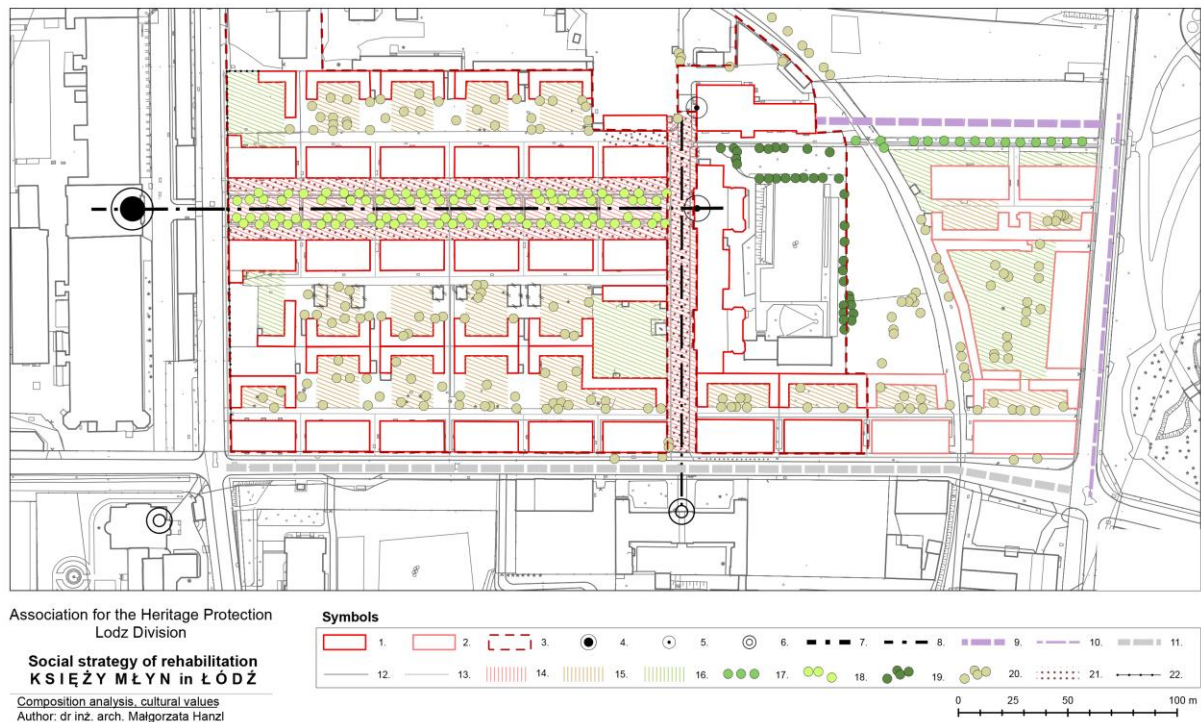

Figure 1: Composition analysis and cultural values. Symbols: 1. individual buildings in the Heritage Register, 2. entry A/44 to the Heritage Register, 3. areas listed in the Heritage Register. Composition values: 4. distant landmark, 5. landmarks – closing a composition axe, 6. local landmarks, 7. main composition axis, 8. perpendicular axis, 9,10,11. edges, 12. main paths, 13. remaining paths. Enclosures: 14. public, 15. semi-private, 16. private. Vegetation: 17. row of lime trees along Koci Szlak, 18. Lime alley – Księży Młyn Street, 19. old trees next to the school, 20. remaining trees. Other symbols: 21. preserved pavements, 22. iron-work fence.

The composition analysis of outside links next to the aforementioned relations with the edifices of New Spinning Mill and of the play hall in Przędzalniana Street, as well as the connections with the villa formerly belonging to the Herbst family, brings around the role of clear edges of the site: Fabryczna Street with Źródlińska Park on its opposite site, Przędzalniana Street which nowadays carries heavy traffic, and border with Textorial Park business centre.

2.3 Social situation

While circa 75 percent of the current population of Księży Młyn moved from other regions of Lodz, 12 percent have been living there since their birth. The remaining group are successors of the former employees of the Enterprise, who inherited rights to communal dwellings. During the project period the 25 workers' houses comprising 421 flats (including 4 social units) and 6 commercial premises, were inhabited by 932 people (in 2007 after Hanzl 2011). The popular opinion points at the deprivation and low social status of this small community, which require verification in order to avoid stigmatisation.

Considering all the four factors required for the delimitation of the area of rehabilitation: unemployment, poverty and living conditions, crime and education, in the case of Księży Młyn these conditions are fulfilled except for the level of crime which is not high, mainly because of the location distant from major urban nodes. The social criteria listed above are accompanied by degradation of urban structure, such as technical degradation of buildings, lacks of infrastructure, etc. Further characteristics includes: considerable share of elderly people, living on their limited pensions, which affects the general financial condition of the

neighbourhood. Next factor is the high level of unemployment, which generates negative social attitudes.

Poverty is considered the most common cause of the social degradation. At the same time the lack of sufficient funds for basic needs influences also other aspects of functioning of the family and community, including absence of proper education of children. Księży Młyn is considered one of those regions in Lodz where the poverty is inherited. Next common phenomena is failure to act and demanding attitudes as an effect of long-term unemployment and lack of interest in starting a permanent job. This by turn may lead to further pathology, such as crime and transfer of passivity to children. The phenomena, very popular among people of law education, gets stronger in the situation of structural unemployment, e.g., like in Księży Młyn, as a result of liquidation of the workplace. Here however the perceived level of safety is higher because of the presence of multiple interpersonal relations, this observation is confirmed by the location of multiple spots where children play. In addition the presence of strong neighbourhood relations makes the estate a lively place, where inhabitants meet, hung around together, socialise with each other, discuss perched on benches, etc – different than in most of the estates coming from later periods or constructed recently.

Moreover the positive image of the neighbourhood is influenced by several institutions of culture located in the proximity, the most significant among them: Book Art Museum in 24 Tymienieckiego Street, Lodz Art Centre in 3 Tymienieckiego Street. There are also periodic events, such as Księży Młyn Summer Resort in Grohman's Villa in Tylina Street. In the estate there are few institutions and firms: Post Office, Daily Stay House for Elderly People, Venaverte – Advertising Agency, Księży Młyn Publishing House, Posting Bookshop, Association of Children Friends (by Łódka Association), Information Point Księży Młyn, Career Development Office, Bajkad grocery shop, Ikona Art Gallery and Rapacholin Consortium – an art workshop. The school which continued the traditions of vocational school funded yet by Karol Scheibler, has been closed and the buildings are being renovated for the Academy of Fine Arts. In the beginning phase of the project there were two associations in the area: Citizens Association Adamus gathering mainly the owners of dwellings, which reactivated thanks to the project, and Women Club of Księży Młyn which was then officially registered.

2.4 Events preceding the project

The major redevelopment projects of the estate previous to the current ones:

1. a pilot renovation of the building in Księży Młyn 2 by the Municipality of Lodz (1999),
2. plans to move the inhabitants out to newly built blocks of flats in Widzew (Olechów), followed with buildings' renovations and conversion of the estate into the apartment complex by a private developer,
3. plans to recast Księży Młyn as a creative industries district within a framework of application for Lodz European City of Culture 2016.

During the renovation finalised in 1999, the pilot building was equipped with all the housing installations, including central heating. The dwellings were to be sold within a public bid, however due to the lack of interested buyers the building was in large part converted into social housing unit. The failure of the marketing of the pilot renovation led to the abandoning of the former plans of conversion of the estate into a bohemian neighbourhood. In the period of this project the plans to include Księży Młyn to the List of UNESCO cultural heritage were started. The survey conducted for this project showed that circa 40% of inhabitants want to remain in their flats, similarly to 15% of elderly people who also were to stay. The temporary moves out were to be scheduled for the renovation duration only.

In 2007 the Municipality of Lodz (the Resolution of the City Council of Lodz No. XXII/464/07) started preparations to a large-scale project of giving over of 25 buildings in the heritage

estate to a private developer firm in exchange for their renovation and providing new dwellings for the former inhabitants. The heritage site were to be converted into gated apartment complex. These plans were severely protested by the Association of Księży Młyn Residents Adamus, which gathered the 53 flats' owners. Eventually the project failed on the one hand because of the world's financial crisis and on the other because of the negative publicity. The legal situation introduced with the aforementioned Resolution constrained individual renovation activities or transactions. .

As a result of the preceding events, at the moment the current project started the inhabitants' confidence in the local government activities in the neighbourhood was virtually null. Former occurrences had conveyed to the demanding attitudes among local citizens, accompanied with utter lack of self-confidence when it referred to influence on the situation or improvements of their own living conditions. One of most important reasons for their helplessness and vulnerability was the inability to execute the proper maintenance of the buildings and their surroundings. The failure of the functioning of the managing unit led to progressing deterioration of the technical state of houses' substance and thus to the worsening of living conditions of the dwellers. As the citizens reported even the basic repairs of gutters, downspouts or deck flashings had required submitting repeating claims regardless the fact that lack of the proper and prompt intervention resulted in a more substantial damage afterwards, such as dampness of the walls or fungal coverage. Also the state of pavements was continually raised as an element which is left behind without proper maintenance. The aforementioned project of the conversion of heritage housing estate into the higher standard apartment blocks led to the emergence of two different approaches: people who wanted to improve their living conditions through displacement to another location and people who, in most cases having formerly acquired their flats, felt attached to the place and expected improvements of the situation.

3. Methodology of public participation in the project

The project initially aimed at *“the implementation of a concise program of the redevelopment of the area, which would be based on a comprehensive analysis of the initial state and potential development scenarios, as well as a large scale social debate on the topic, and which would be socially acceptable, both by the local citizens as well as the economic, cultural and all the remaining stakeholders from Księży Młyn and more generally from the city of Lodz”* (excerpt from Democracy in Action – Participation, Project initial proposal).

The initial attitudes of citizens in the estate, a direct consequence of the former unrealised plans described above, made crucial the tasks related with enhancement of mutual relations and interpersonal contacts within the estate. In order to start working efficiently the priority for the coordination unit had to be gaining trust and empower local citizens.

Thus in the early stage of the project the event for the “Andrzejki” celebrations was organised with the objective to enhance the integration of the inhabitants. A huge advantage to the program was a location of the consultation point in a local gallery Ikona. The direct proximity facilitated its availability for citizens and enabled direct consultations and individual discussions, this way providing a handy tool for explaining and clarifying all doubts, and gaining trust. Besides, other local institutions such as the Book Art Museum and Lodz Art Centre, actively participated in the preparation to meetings and exhibitions, providing location and cooperating in the organisation of events and projects. Moreover, in order to complement the participation process the website <http://naszksiezymlyn.pl> was started, which contained the current information on the project as well as gathered knowledge, photographs, etc. All exhibits were also available online.

In the project's framework, the following forms of direct participation were implemented: (1) plenary discussions, (2) individual consultations, (3) picnic targeted at all the citizens of Lodz, (4) neighbourhood picnic, (5) Future Game workshop, (6) mental map – a survey targeted at local school pupils, (7) workshop inspired with the Future Search Conference. A comprehensive scenario of all the events in the project is presented in the Figure 2.

3.1 Events and exhibitions

One of the crucial parts of the project became the exhibitions and events prepared by local citizens themselves and supported by the project organisers. This practice started from the initial celebration of “Andrzejki” (Andrzej’s name day) which gave the opportunity for the Club of Women of Księży Młyn to form. As part of the project Księży Młyn – Kaufhaus Interactions, the citizens from both neighbourhoods: Księży Młyn and Kaufhaus in Ruda Śląska in Silesia prepared two expositions answering the topic “Creative neighbourhood or deprived housing estate”. The Kaufhaus exhibition was presented in Lodz, in Art Books Museum and Księży Młyn exhibit was displayed in Silesia (Morozowska 2011). Both presentations were warmly received both by local citizens as well as the representatives of the local government. The events became also occasions to meet and discuss similarities and differences of both rehabilitation sites.

The project team participated in and co-organised several events addressed to the general public of Lodz. Beginning with the Picnic in Księży Młyn in September 2010, which served the promotion of the concept of Lodz City of Culture 2016, the Neighbourhood Picnic in 2011 was co-organised by the Project group. Such events serve the promotion of the site, they aid establishing the group of visitors enhancing their links with a site, they also provide the opportunity for all the citizens of Lodz to recognise the neighbourhood’s values and eliminate potential doubts referring to the choice of place for living or working.

3.2 Workshops and other methods of direct consultations

During the course of the project there were many workshops and direct meetings in order to put together an arrangement which could be possible to implement and satisfactory for all the stakeholders. Apart of regular plenaries and individual or group meetings, which were hold following the needs, the last phase of the project included several workshop sessions.

The concluding workshop consisted of three meetings. In the beginning of the first one, inspired with the methodology of the Future Search Conference (Wates 2014), participants together with a moderator knowledgeable in the site’s history revisited all the major events from the past of the estate, recalling their personal memories from those times. During the next phase they analysed strengths and weaknesses of the area, which was followed with a discussion and brainstorming on the vision of the best future. The last phase referred to the action plan for the formerly elaborated vision. The second meeting addressed the future of the site using the scenario building method. The two proposed alternatives of the redevelopment of the site were constructed, which was followed by a choice of the best path. The last meeting served the definition of priorities of development and its potential constraints (Boryczka 2011).

Also in the last phase of the project a workshop was conducted with 25 pupils of 4th grade of a local school. Children participating in this event were asked to draw their personal maps of the estate which afterwards served the discussion on positives and negatives of the site and on their dreams and wishes. As a kind of a complimentary activity yet in the beginning phase of the project, students of BArch course Architecture Engineering from International Faculty of Engineering, Technical University of Lodz directed by local citizens made photographs illustrating the deficiencies of the technical state of buildings in the estate and of their direct surroundings. Photographs, which answered the most common complaints of the citizens, were presented in the projects website and in the form of a catalogue.

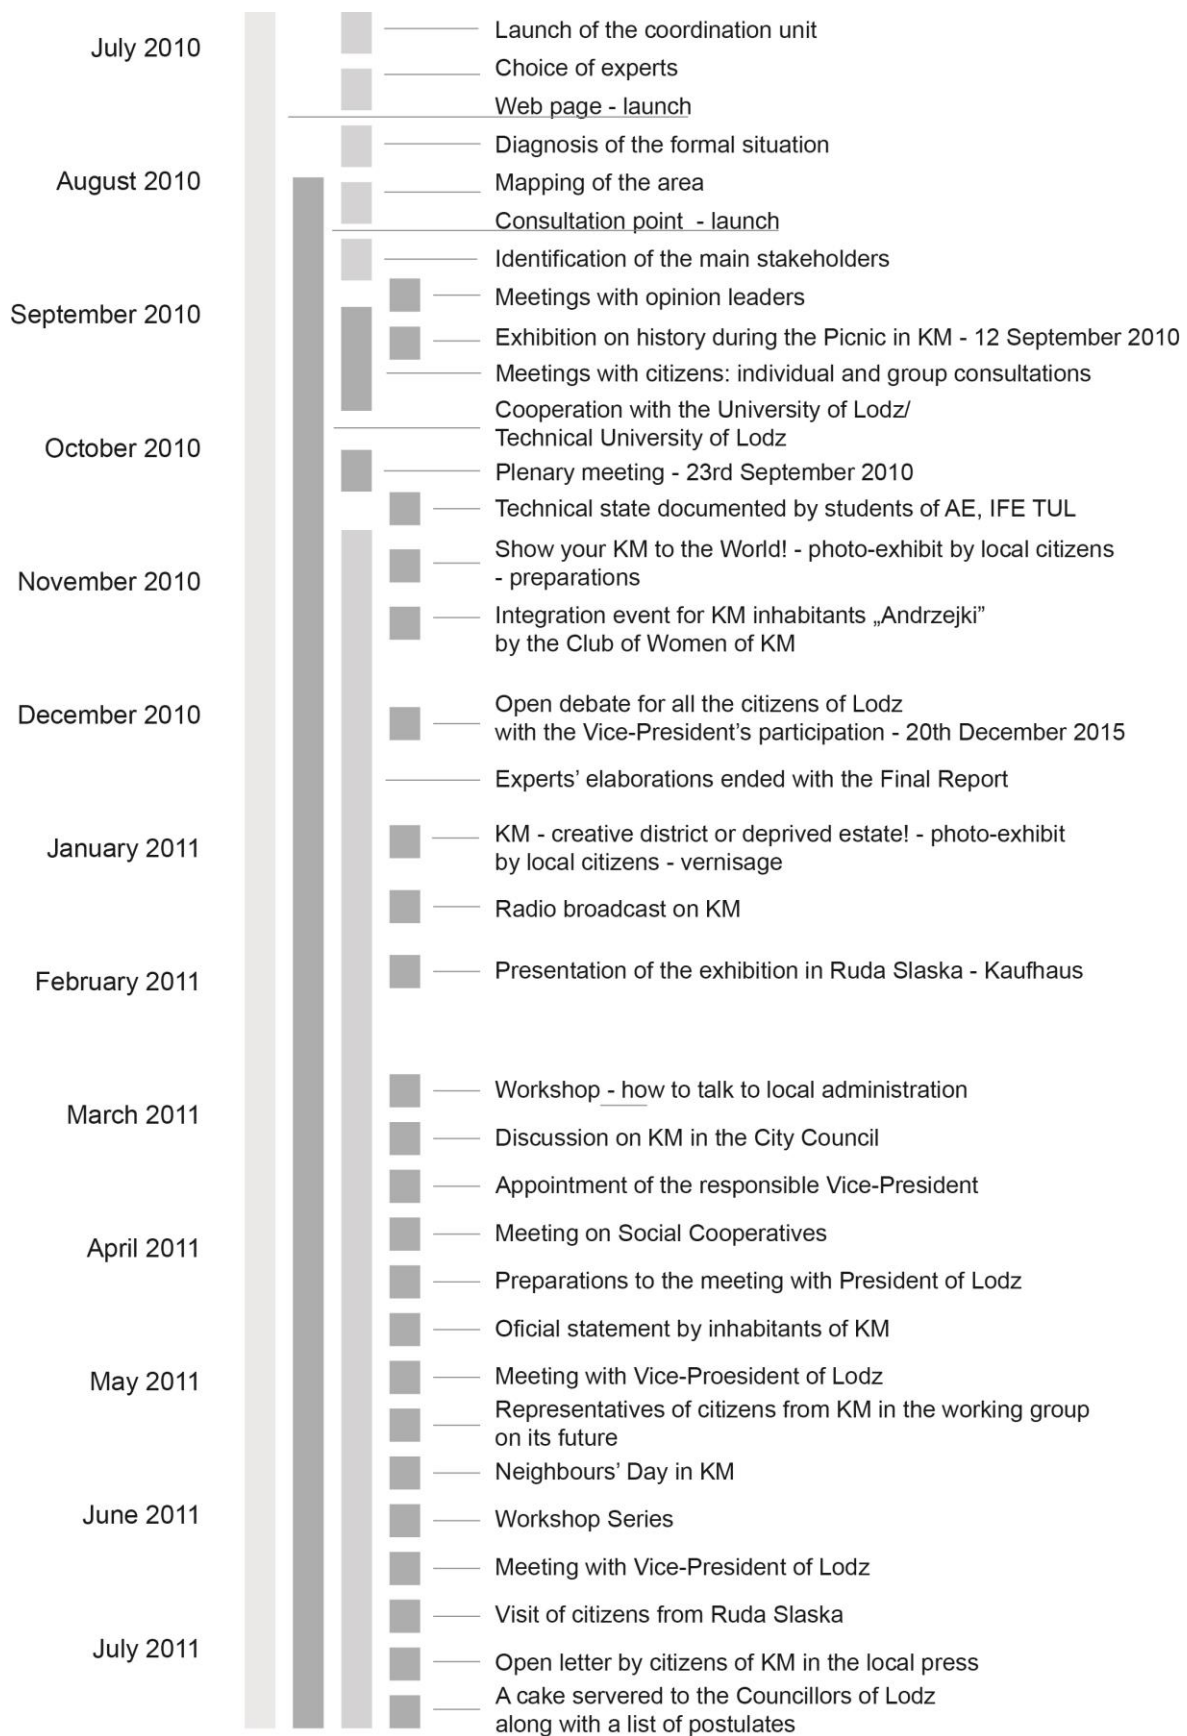

Figure 2: Graphic presentation of the scenario of social participation in the KM project

3.3 Other methods of empowerment

In order to enhance the citizens' skills with regard to communication with the local authorities, legal regulations and writing successful formal documents, as well as organisation, there were a few meetings and consultations with specialists organised. The results of these meetings were afterwards visible in the changed conduct and increased self-confidence of the local community.

4. Outcomes - evaluation

Among multiple activities performed in the framework of the project major efforts were put into the empowering of local citizens and encouraging them to undertake initiatives on their own. The efforts brought about positive effects in terms of increased self-confidence of the local citizens, which exhibited itself in the idea of inviting representatives of the local government to the debate on problems of inhabitants of Księży Młyn. The members of the Club of Women of Księży Młyn baked several cakes on this occasion and brought them to the town hall. Another spectacular outcome was the enhancement of the social capital, which manifested itself in the reactivation of associations formerly present in the area: Association of Citizens of Księży Młyn Adamus, and formation of new ones: Club of Women of Księży Młyn.

As a result of the current project the former strong and clearly opposite attitudes of readiness to leave and hopelessness of those who owned their flats, weakened and for a large group the initial desire to move out was replaced with the attachment to the site and declared willingness to become proprietors of the dwellings they lived in.

In the beginning of the project substantial difficulties resulted from the aforementioned distrust of the citizens, bordering with hostility. A barrier was a consequence of several instances of negligence. First the former pledges given by the local administration with the support of the private investor, to exchange old dwellings for new ones, were not fulfilled. Second the deficiencies of the proper maintenance of buildings, along with the constraints to inhabitants' initiatives and the feeling of hopelessness which followed, led to the negative approach to all forms of institutional support. These attitudes put off the actual start of work on the common strategy, the first few months being spent on building the social capital and mutual trust. The efforts and care to ensure proper collaboration finally turned the project into success, which as Sanoff (2000) emphasises is the value of consensus.

The survey performed directly after the last phase of the final workshop enabled citizens to submit proposals of immediate measures and long-term solutions for Księży Młyn. In the first group the most urgent tasks are the renovations of buildings and pavements and installation of central heating in all the dwellings. A substantial part of the proposals referred to the organisation of renovations. In the respondents opinion selling out the flats and creation of housing cooperatives may enable their owners participation in the modernisation costs. On the other hand those inhabitants who want to move out should be given such an opportunity. The inhabitants complained on the presence of social housing in the estate and on the negative influence of their locators' behaviour. Another remark referred to planting new trees and rehabilitation of existing green spaces. Moreover creation of art galleries, services, and gastronomy could attract tourists and other potential users to the estate. Furthermore local citizens were also asked about their ideas on more distant future of the estate. In their opinion the neighbourhood should become a creative district, which would integrate arts and crafts, based on the values of the local heritage, inviting Lodz designers and using uninhabited flats. The program should be complemented with cyclical cultural events, art exhibits, etc. Other proposals conveyed ideas on opening of a design school, development of tourist services and infrastructure: souvenirs shops, gastronomy, etc, as well as development of more comprehensive cultural programs based on the current environmental and historical assets of this part of the city. Some elements of similar concepts repeated also during the

workshop with local children. All the inhabitants' answers emphasised the need for immediate actions, which should comprise investments in renovations of heritage substance but also organisation of the efficient cooperation between all stakeholders and efficient promotion addressed to citizens of Lodz and potential visitors.

The final strategy prepared as the main part of the project outcomes by the experts involved in the project used the results of the survey. At the same time the last phase of the project, thanks to its publicity attracted media and public interest. The started cooperation between local groups of citizens and the Municipality of Lodz continued after the project end. The Decree No. 983/VI/11 of the Mayor of the City of Lodz of 22nd July 2011 set up the Team for the Rehabilitation of Księży Młyn. In the team, headed by the Vice-President of the town Agnieszka Nowak, there were also three representatives of the local community, as the result of the current project. A separate administrative unit was created for the estate, which since has been successfully managing its renovation. The unit's head Arkadiusz Bogusławski was engaged because of his former experience of the work for Zgierz Municipality on a similar topic. The Resolution of the City Council of Lodz No. XLV/843/12 on Integrated Program of Rehabilitation of Księży Młyn was approved on 4th July 2012. Since that time the renovation of three houses has started. There were two public bids open to the local artists for the spaces in the estate, which attracted several newcomers. Besides the works on modernisation of pavements and planting new vegetation began, along with the installation of new urban furniture following a comprehensive project.

Along with the renovations of the urban structures Księży Młyn became a place of multiple and various cultural and artistic events. The tradition of the organisation of Neighbourhood Picnics in Księży Młyn has been continued since the project times. There are several fairs of handcraft and artistic works organised each year for various occasions, which attract more and more visitors. Other events comprise meetings with interesting people, discussions with representatives of local government, urban games, workshops on various topics, concerts, historical walks and photo-walks, etc. Along with feeling of the places for artists the profile of events shifts towards more sophisticated artistic events, like plain-air painting or audio-walks with mp3 files presenting historical stories of the site. Apart of the official webpage of the estate http://uml.lodz.pl/miasto/rewitalizacja_i_zabytki_/ksiezy_mlyn/ there are now also several others referring to the variety of activities which take place there.

5. Conclusions and recommendations

The case study project turned out successful. As it is proved above the undertakings by the local government continued the once established course of actions. The artists and craftsmen accepted the invitation and look for new opportunities creating a special cultural atmosphere. The social capital which resulted as the effect of the project has been continued and developed through a network of direct personal relations. The atmosphere of trust facilitates collaboration in the redevelopment process. The role of the experts, who were involved in the project was mostly advisory. The direct and very tight collaboration with local citizens turned out successful. After the project termination its impact helped establish an efficient platform of collaboration with the local municipality, which owned or managed all the houses in the estate, and financially contributed to their maintenance and renovation along with applying for EU funds.

Citizens treated as partners of the local administration have willingly accepted the on-going changes. Multiple redevelopment concepts, which were elaborated for the housing estate of Księży Młyn in the former projects as well as within the currently discussed one, and both by the project experts and in the discussion with local citizens, involved similar solutions. In all of them the major task, which had to be performed immediately, was renovation of historical structures, including both residential buildings and their direct surroundings. The profound analysis and multiple discussions on the site renovation led to the situation that local citizens were able to articulate both immediate measures and long-term visions. Actually the current redevelopment process conducted in the neighbourhood since the end of the project may be

perceived as its direct continuation. Nearly all the ideas defined in the project strategy have been implemented. The management unit which was created after the project termination continued the project's course of action and used the social capital achieved as its result.

The bottom up character of the project was one of its main features, which strongly influenced the course of actions. The projects objectives were the same as the general goals of the Association for the Heritage Protection (TONZ) that had been confirmed in its former activities focused on the popularisation of the local tradition and heritage and their protection. As it has been mentioned the initial hostility and lack of trust was replaced with the cooperation and mutual respect. The reorganisation of the local administration structures and establishment of the unit located in situ helped to continue the direct contacts.

In conclusion this case study clearly demonstrates the role of cooperative attitudes in relations between various stakeholders of the rehabilitation process. The importance of the social capital and mutual trust cannot be overestimated. When local citizens are given opportunity to stand for themselves they are able to define solutions which are both short and long-term, taking into account even the most complex preconditions. In consequence the changes of physical development are accepted and the neighbourhood quality may improve unhindered.

6. Acknowledgements

The current paper resumes the outcomes of the Final Report of the Social Strategy of Rehabilitation of Księży Młyn prepared by a team of experts engaged by the Association of Heritage Protection, Lodz Division in which the author actively participated. The team work was coordinated by Jarosław Ogrodowski. The project was financed by the Stefan Batory Foundation, Democracy in Action – Participation program.

Housing Cooperative Movement as an Alternative Way of Thinking, Planning and Designing Residential Neighborhoods

HUGUENIN, João Paulo – Architect, Federal University of Goiás – UFG, Brazil
GHILARDI, Flávio Henrique – Sociologist, Institute of Research and Urban and Regional Planning, Federal University of Rio de Janeiro – IPPUR/UFRJ, Brazil

1. Introduction

The Uruguayan Cooperative model for housing arose from new paths that constituted Uruguayan civil society during the decade of 1960. Such model widespread through Latin America and eventually reached Brazil during the Decade of 1980, within the new Brazilian democratic context. The end of dictatorship period and the opening of Brazilian politics brought on new key actors, who, in leading urban social movements struggle for housing, tried to reset their repertoires of action, adding to the requirements postures a set of designing propositions for production of urban environment with effective participation of civil society. Movements for decent housing began to support self-management and mutual aid with a focus on housing designing projects, where direct participation of community members involved the giving up individual choices in order to build up an alternative formulated for and by the collective.

From the early 1980s, experiences that took places in different cities in Brazil showed some of these Right to the City ideas and principles. The municipality of São Paulo, in 1989, was the first to design housing cooperatives public policies addressed to low-income population. Eventually, in 2004, the Brazilian Government created the Crédito Solidário - Credit Supportive Program - that was the first national program addressed to the financing of decent housing to social movements active in Brazil. In 2009 came up at national level the program Minha Casa, Minha Vida - Entidades – My Home, My Life - Entities - expanding the volume of financial resources to low-income population housing cooperatives.

This program is carried out by a Non-profit Organizations that organizes low-income families to manage the entire production process of housing and “neighborhooding”, which means: from the conception of physical-space designing, through the production work to the social and urban management of the new neighborhood. A national housing program in a wide country as Brazil leads to multiplied and varied procedures according to local cultures. However, recent researches on social habitat production in Brazil – in which we were researchers – demonstrated that some practices had been extremely successful in designing cooperative neighborhoods. One example is the pilot project Parauapebas, managed by Fundação Bento Rubião - Bento Rubião Foundation - in the State of Pará in the northern region of Brazil. The project involves 500 families that currently are actively participating in social and urban architectural project designing. Parauapebas is a city of almost 200 thousand inhabitants located in the Carajas region, which houses the largest iron mine in the world. The city has a very specific demographic, economic and social dynamics. In a context of political apathy, in which families are not used to decision-making processes, the organizer and its technical assistance have sought to build a series of mechanisms to effect such participation.

Through community meetings and workshops, families involved have their voice heard and are enabled to compare their housing reality and what would be the ideal place to live. They are also enabled to make choices according to social, economic and cultural constraints of

their living context. In addition, eventually they reach the best design for the urban environment, planning of the public areas, collective spaces and even their own houses.

In this paper, we searched to analyze the genealogy of the cooperative housing production in Latin America and Brazil. Accompanying a pilot experience – in which families involved can recognize each other and make decisions collectively – we tried to show that solidarity and participation on management of the city are the way to the construction of fairer and democratic cities.

2. The source of the Brazilian model of social production of housing: the Uruguayan case

The beginning of housing cooperative production in Uruguay has begun since three pilot projects implemented in three country towns in the year of 1966. On the enterprise of Centro Cooperativista Uruguayo – CCU (Uruguayan Cooperative Center), a non-profit organization founded in 1961, the three projects proposed the house construction by organized families in cooperatives, with their own labor (called “ayuda mutua”, mutual aid) and with technical orientation (architects, social workers, accountants, lawyers).

The CCU proposal has received support from Uruguayan National Government, Inter-American Development Bank – IDB and from MISEREOR, a German Catholic Bishops’ organization for development cooperation. National Institute of Affordable Housing (National Government) provided the funds from an IDB’s financial loan and MISEREOR promoted the land access to the projects.

At the end of 1968, the Uruguayan Congress approved the National Housing Act, developed by a government initiative to answer the economic crisis of real state that involved the country in the late 1960s. In chapter ten, the Act regulated the system to financing the housing cooperatives.

In December 1969 was regulated the chapter about cooperatives in the National Housing Act and in May 1970 was concluded the first CCU’s pilot project, in Isla Mala. At that moment was founded the Federación Uruguaya de Cooperativas por Ayuda Mutua – FUCVAM (Uruguayan Federation of Cooperatives for Mutual Aid) that begins to represent the housing cooperatives constructed with own labor cooperatives.

In chapter ten, the National Housing Act establishes different housing construction modalities by cooperatives, so organizing the Uruguayan housing cooperative system that will be famous around the world. There is a first distinction between the “property cooperatives”, in which the house after construction will be property of cooperative family, and the “user cooperatives”, in which the house will be property of cooperative and the family will have a quota as a housing unit.

The construction system may be done by two ways: mutual aid, in which the nuclear family offers its labor to housing construction (21 hours weekly), corresponding to ten percent of the housing financing; and previous saving, in which the nuclear family contributes financially, before building, with fifteen percent of housing financing, doing just the project management¹. In 1969 is founded the “Federación Nacional de Cooperativas de Vivienda” – FENACOV (National Federation of Housing Cooperatives) representing the previous saving cooperatives, and in 1970 is created the Federación Uruguaya de Cooperativas por Ayuda Mutua – FUCVAM (Uruguayan Federation of Cooperatives for Mutual Aid).

From 1970, the Uruguayan Government starts to finance systematically the housing cooperatives. They should have the legal personality granted and the housing projects

approved by Government, besides contract the technical assistance, with the “Institutos de Asistencia Técnica – IAT” (Technical Assistance Institutes), to elaborate the project documents and provide building orientation.

The Uruguayan experience shows how possible is, through built environment, express desires of a different life. We believe that the good architectonic quality materialized in the pilot projects had helped to disseminate the image of a successful housing public police.

On June 27, 1973, there was a military coup in Uruguay. The first contracts between cooperatives and National Government were signed and the houses construction were beginning. In the initial years of military regime, the housing cooperatives were not considered as an “enemy” to militaries and the Government did not repress them. Thus, the housing cooperatives became “democratic islands”, where the militants wanted by dictatorship could take refuge.

In the early 1980s, FUCVAM adopts a political stance to struggle against Uruguayan dictatorship. As an answer to the Government’s legislative proposal to extinguish the collective ownership in user’s cooperatives, FUCVAM presented a counter-offer to promote a popular referendum to approve that legislative proposal (as foreseen in the Uruguayan Constitution). This strategy (with massive signature’s gathering to referendum initiative) gave a new political status to FUCVAM inside Uruguayan civil society after dictatorship’s end in 1984.

With the democratic opening after 1984 and the neoliberal context, FUCVAM again reinvents its political action. The entity operates in four lines action in the 1990s: struggle for urbanized land, organizing low-income workers, central area rehabilitation for housing and expanding the housing cooperative system to other countries in South America. In 2005, there is the election of the party “Frente Amplio” (Broad Front) to Uruguayan National Government. The Frente Amplio is a party organization of the left forces in Uruguayan politic. Then, the cooperative house system begins to get priority in the public police of the last two governments from Frente Amplio, with Tabaré Vázquez (2005-2009) and Pepe Mujica (2010-2014). During Mujica’s presidency, the cooperative system represented 37.5% of all the investment in housing policy, contracting to construction 9,913 housing units.

The large housing cooperative developments in Uruguay during the 1960s and 1970s demonstrates how the urban experience can be successful. With the gathering of several cooperatives and with public regulation, there are several cases of housing developments with excellent leisure, cultural and commercial areas, and good health and educational equipments (as example “Mesa 1”, figure 1).

After almost half century of history, the housing cooperative system became a great political force in contemporary Uruguay, influencing several countries in Latin America and in the world.

3. The contribution of Uruguayan cooperatives in the Brazilian context

The late 1970s and early 1980s mark out the re-democratization process in Brazil, when the military dictatorship begins a soft and gradual process to politic opening. Thus, the urban social movements start to strength and to structure in a national articulation, resulting in creation of the National Movement for Urban Reform.

The Catholic Church and the Base Ecclesial Communities, linked to Theology of Liberation (Christian theological current born in Latin America, which considers that the Gospel requires preferential option for the poor), had wide importance in social movements conformation. This importance is because other political articulation spaces, like politic parties, autonomous trade unions and civil associations, have had their operation blocked or hindered by military dictatorship.

In the 1980s, just the city of São Paulo had more than 1,300 neighborhood associations (SACHS, 1999). Those associations begin to claim a new political way to access the urban services, putting themselves as interlocutors to public authorities. With this claim and the moment of national economic crisis, the state started to develop housing programs that intended to encourage the employ of own population labor.

The project “Vila Nova Cachoeirinha”, initiated in 1981 in the city of São Paulo, represented a new paradigm to the social production of habitat in Brazil. The project tried to embody the Uruguayan system of housing cooperatives that was being publicized by some technicians with a video made by the engineer Guilherme Coelho in his visit to Uruguay (Baravelli, 2006).

The development of the program “FUNAPS Comunitário” (a kind of municipal public fund) in the city of São Paulo since 1989 represents a turning point in the housing public policy directed to urban social movements. For the first time a Brazilian public administration organizes a housing program to promote self-management, stablishing the roles of the state as project financing, of the social movement as leading actor throughout the process, and of the technical assistance as the offerer of technical conditions needed to project development.

However, the economic, cultural and legal specificities of Brazil reduced the action possibility of the housing movements. The main specificity to restrain the action of housing movements is the legal impossibility to constitute housing cooperatives. Unlike Uruguay, Brazil does not have a legal framework to create a housing cooperative with users' property, because the General Act of Cooperatives (Act number 5,764 from 1971) does not foresee that kind of cooperative.

Beyond the city of São Paulo, some municipalities in Brazil developed specific experiences in social production of habitat. In Rio de Janeiro, during the early 1990s, the non-profit organization called “Bento Rubião Foundation” began some pilot projects of social production of habitat. The organization became the entryway to social production of habitat in the city and region, despite the several difficulties experienced with no support from local public administration.

Nevertheless, after the second half of the 1990s the volume of the experiences in social production of habitat decays. Only with the election of Workers Party to National Government in 2003 and the creation of Ministry of Cities in the same year, the housing movements gets to influence more forcefully the government to create a public program to support self-management in housing construction.

Since then the housing movements in Brazil have proposed – and have accomplished – important advancements and some steps backward in the self-management housing policy. In a succession of public programs, in 2004 was created the Program Credit Supportive and in 2008 the Program Social Production of Habitat, with resources from National Fund of Social Housing. In the year of 2009 was created the Program My House My Life with the funding line called “Entities”, directed to projects proposed by social movements.

One of the basic differences between the social production of habitat in Brazil and Uruguay is the question of property. While in Uruguay the property is collective, in Brazil, after the end of construction the property of each housing unity is privatized. This property condition induces to the retreat of families’ solidarity ties after the building conclusion.

4. The Pilot Project Parauapebas

The Pilot Project Parauapebas is inserted in the context of social production of habitat, through self-management process. Planned as a proper pilot project of construction of ways to live in the city, the housing production through self-management arises as an alternative practice towards the capitalist structuration of the city.

Another important context to understand this project is the complementation of resources offered by Vale Foundation² for housing projects developed through public policies in accord to the criterions of the Urban Seal Quality. When complied with a series of quality standards of built environment foreseen in the seal, the project can benefit of a substantial financial contribution.

The Bento Rubião Foundation is the project’s organizer, being responsible both by organizing 500 beneficiary families in partnership with local social movement called “Pastorais Sociais” and by administrating the resources from Program My House My Life – Entities. The Municipality of Parauapebas is another partner in the project, which ceded the urban land where the project will be built.

In the Brazilian context, the production of dwellings with social interest had a significant increase in the last presidential terms since 2003. Nonetheless, that sort of production have serious problems with remote location from urban centers, lack of services, equipments and public spaces, monotony of standard housing developments, and low architectonic and constructive qualities.

In order to prove the possibilities to increase the quality of built environment, the Bento Rubião Foundation has attempted to promote a participatory project as a way to leverage the public resources from Program My House My Life – Entities for construction of cities more just, inclusive and fair.

4.1. The urban and social context

In the late 1960s, researchers founded the largest mineral reserves in the world in Carajás, at that time in the city of Marabá, state of Pará. Years later, the Federal Government granted to “Companhia Vale do Rio Doce”, a state-owned company (nowadays it is privatized), the rights to mine iron ore, gold and manganese in Carajás, an area secularly occupied by Xikrins, a group of indigenous people from Cateté.

In 1981 has begun the implantation of the Project “Iron Carajás”, when, in Parauapebas River Valley, also begins the construction of the Parauapebas Village. The news about the village construction induced an intense population movement to the area. Soon, the village grew up wildly, without planning. From that village was formed the present city of Parauapebas.

According to Brazilian Institute of Geography and Statistics, the city of Parauapebas has a total area of 6,886 km², a population do 176,582 inhabitants and a population density of 22.35 inhabitants per km². The IBGE data points that the population more than doubled between 2000 and 2011, with a rate growing of 123.88% in the period. The Parauapebas population is urban (90.11%).

The housing deficit in Parauapebas indicates a crucial question to be faced by the municipality. A study based on the data of Census 2010 shows that fourth of Parauapebas dwellings is considered as housing deficit, needing to be replaced by new housing. By absolute numbers, the housing deficit is more than 10,000 dwellings. The most aggravating is that the housing deficit more than tripled in the last decade.

The 500 families that will be benefit by the project are that with higher priority in social and economic terms. They must already reside in Parauapebas and have a monthly income up to R\$ 1,600 (EUR 400), as required by the rules of the Program My House My Life. In addition, the families cannot have a previous public housing benefit and residential property own or housing finance. Within the partnership between promoter institutions of the project, three institutions organize the families’ selection: Vale, municipality and Pastorais Sociais (local social movement).

The social profile of the families is composed by different family arrangements: single mothers with few and with many children, cohabitation with uncles and cousins as an economic strategy, and some singles. There are many recent migrants, mainly from state of Maranhão, and from Pará, Tocantins, Goiás and Northeastern states. Also, appear many unemployed with unstable income. There are also autonomous and outsourced employees and Vale service providers. Predominates horizontal house experience with open spaces for recreation and cultivation of plants.

4.2. The project team

The Pilot Project Parauapebas has the particularity of being a social project with repercussions on the physical plane. Thus, the project team has this double entry, focusing on interdisciplinary process with social workers, architects and urban planners.

The social team was coordinated by Bento Rubião Foundation, which had the sociologist Flavio Ghilardi, social architect Sandra Kokudai, the social worker Valerio da Silva and the social agents Maria Vanda Lopes and Wanderlei Nascimento.

The urban project has Arche Consulting, Planning and Projects as responsible technical, with the architects and urban planners João Paulo Huguenin, Elsa Burguière and Patrick Gomes. The housing typologies has authored by Arche Consulting, Planning and Projects, together with the architect Nanda Eskes, from Atelier 77.

4.3. A participatory methodology

The housing self-management means the capacity of a group to manage all the processes needed to build the own house, from the land access until the construction of house units, through the design of architecture and urbanism plans.

The option by the participatory project is a possible response to political and social problems involving architecture and urbanism. Even with limitations, the differential in this methodology is to capacity the families to organize collectively the build of a better housing and living in the city. The house, as a product of this collective organization, would be only the first step in the political transformation and development of citizenship.

To reach this, several activities are taking place with the families since June 2014, through meetings and workshops explaining how will be the project development and collecting information about the families imaginary of the “ideal house”, with drawing for example.

Encouraging the self-management

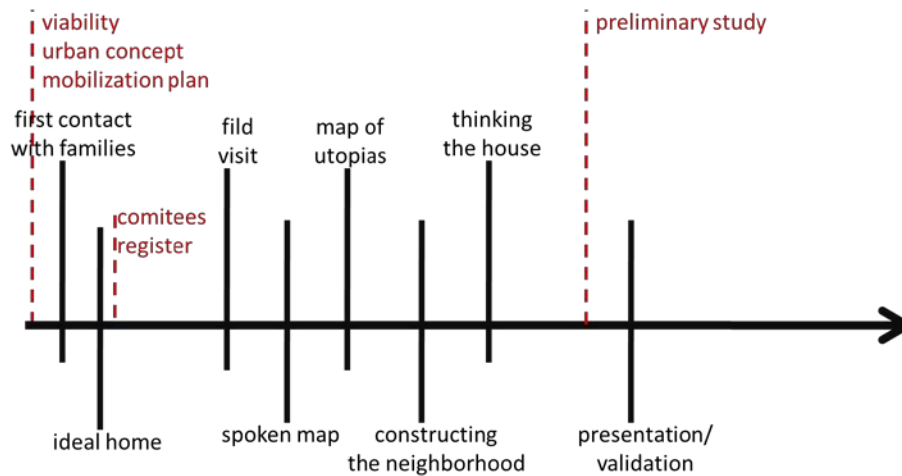

Figure 5 – Stages of the Pilot Project Parauapebas.
Source: Arche Consulting, Planning and Project.

In August 2014 has begun the initial activities of architectural and urban design. The big challenge was to carry out participatory activities with a large number of families (500). Therefore, the team formed nine groups with 55 families each, coordinated by three technical doubles (one architect and one social technical) and promoted two days of workshops in three shifts (morning, afternoon and evening). Each pair followed the idea of collecting information and subsidies to the development of three different housing typologies. Then, two typologies were developed by Arche Consulting, Planning and Projects and the other one by Atelier 77.

The first activity carried out in the workshops was the "spoken map", which aimed to visualize where each person does their daily activities in the current place of residence and, from that, reflect on the changes that the project will bring to their daily lives. Then the "map of utopias" identified activities, services and facilities demanded by the group according to their need. Going beyond the project land boundaries and covering issues beyond the physical structures of the neighborhood, participants put their views on the city they think is ideal.

Figure 6 – "Spoken Map" activity.
Source: Bento Rubião Foundation / Arche Consulting, Planning and Project.

Figure 7 – "Map of Utopias" activity.
Source: Bento Rubião Foundation / Arche Consulting, Planning and Project.

The third activity - "building the neighborhood" - worked the scale of the housing in a model in which participants by manipulating wooden blocks representative of housing units were able to view some spatial implications of the proposed development, such as density, clusters, verticalization, free and community spaces. Finally, the activity "thinking the house" made families reflect on the possibilities of indoor configuration and spatial organization of future housing.

Figure 8 – “Building the Neighborhood” activity.
Source: Bento Rubião Foundation / Arche Consulting, Planning and Project.

Figure 9 – “Thinking the House” activity.
Source: Bento Rubião Foundation / Arche Consulting, Planning and Project.

The validation of the first housing and neighborhood design occurred in November 2014 when were presented the first architectonics drawings. Also were realized an organization of social mobilization of the families to the future management of collective and condominium spaces. The families were organized in “cells” (about nine families per cell) for communication and decision-making processes.

Figure 12 – Master Plan

Source: Arche Consulting, Planning and Project.

Figure 13 – View of a neighborhood unit

Source: Arche Consulting, Planning and Project.

The next architectural design activities are: assembly to approve the neighborhood and housing design; approval of the projects at City Hall; detailed design of the neighborhood and the house for building and complementary projects (structure, installations) and planning the build. For social organization, the following activities are planned: analysis of the social profile of families; preparation of social work project; guidance on life in condominium; decision about the form of building self-management; validation of committees; and assembly to approve the social work project.

The main challenges facing the project are: traditional way of housing and conflict with new proposals (vertical and condominium); defining moments of decision on the project (regulatory and projective limits); organization, mobilization and decision in large groups; definition of the collective spaces, condominium, socio-productive and public spaces; and articulation of social organization activities with the architecture and urban planning discussions.

5. Concluding words

The cooperative way for housing, as emerged in Uruguay, shows several qualities and benefits, and may be a large different way of housing production compared to market production. In addition, it allows creating ties of friendship and solidarity among the people involved in the self-management process. In Brazil, the way the model was adapted to the legal and cultural realities reduces the possibility of strengthening these ties, mainly because the question of individual land ownership and the little concern about how the built environment can interfere in the social relationships.

Even though the public policy for housing self-management in Brazil restricts some innovations in the ways of living, some projects have achieved advances forward the production of social housing as a whole. In this sense, Pilot Project Parauapebas brings important contributions to take into account that all housing cooperative is realized through an architectural object, which influences on urban space. Thus, the active participation of families proves that the proposition of quality environments, stimulants, with public and private setting is part of the challenge for setting up a housing cooperative.

The differential of this pilot project is to enable the beneficiary families to organize collectively a better way for housing and living in the city. Therefore, the house, as a product of this collective organization, should be only the first step in the political transformation and development of citizenship of these families.

Endnotes

¹ Each cooperative must create its internal regulations governing all process of construction and ownership. The law also defines the form of cooperatives organization for building construction, by creating boards and special committees. The law also stipulates the existence of "central" and "branches" cooperatives. The first develops the role of "incubate" and support the emergence of the branches cooperatives.

² Vale is one of the Brazil's largest private sector companies. Besides being the leader in the country's mining sector, the company also has major operations in the areas of logistics, energy and steelmaking. Vale Foundation is a corporate foundation that promotes economic, environmental, and social projects in the regions where Vale operates.

Affordable Housing Through Cooperative Urbanism

Shared Amsterdam | Affordable Housing through Cooperative Urbanism

Hema Priya KABALI, iDE (International Development Enterprises), Bangladesh

Abstract:

Dutch housing organizations ensure that more than 2.4 million households have access to adequate and affordable housing aimed at improving the quality of life for the low and middle-income communities. While the proportion of affordable housing has continued to remain a national priority in the Netherlands and is the highest in Europe, the owner occupancy rate is still below the set European standards due to the absence of middle-income dwellings for rent, home-ownership or cooperative housing, unoccupied surplus accumulation by housing associations and unaffordability of social dwellings. Given the current trends in urbanization, McKinsey Global Institute (2014) contends that the affordable housing gap would increase from 330 million urban households to 440 million affecting 1.6 billion people who cannot secure a minimum acceptable housing unit for 30 percent of their annual income leading to an increase in affordability gap (the difference in amount between the income affordable for a housing unit by the low income groups and the actual development cost of the housing unit) and substandard living conditions. Due to growing shortage based on migration and income trends, McKinsey and Company (2014) contends that by 2025 households will either be 'financially stretched by housing costs' or be living in 'crowded, inadequate and unsafe housing.'

This paper has two principal objectives. Firstly, it explores the key regional trends in housing policies affecting affordability with a particular emphasis on housing type, tenure, target groups, providers and financing structures embedded in four social housing contexts- Austria, France, Germany and The Netherlands. In doing so, it analyzes affordability challenges and access to improved social housing across the countries to position the proposed urban concept of '*Cooperative Urbanism*'. After that, the four cost reduction levers as proposed by McKinsey and Company (2014) to the global affordable housing challenge are applied to connect policy level implications to strategic urban planning initiatives.

Secondly, this paper explores cooperative urbanism whereby through the lens of critical urban theory (Brenner, N. 2009) it proposes shared participation deploying collaborative city gaming and design thinking as innovative methods to generate strategic urban planning and design instruments that tackle the provision of affordable housing challenge in Amsterdam. To that end, the strategies formulated enhance and support differentiated housing supply and demand driven programming to leverage mainstream participation that is empowering to all, particularly to the lower income groups incentivizing citizens as collaborators, facilitators and managers to negotiate and empower others as agents of change. The paper further recommends to explore and test cooperative urbanism as future research to underpin and analyze local participation deploying new spatial paradigms to contribute in rethinking planning and policy initiatives in achieving affordable housing solutions under rapid urban, social and economic transformations.

Key words: Affordable Housing, Cooperative Urbanism, Participation, Collaboration, Social Housing

1. Introduction

Affordable housing is a global challenge for cities in both in developing and developed economies alike. With relatively well-established land and financing arrangements, evidence suggests that social rented housing is most prevalent in north-western Europe that is delivered through a variety of landlord models providing 'wider affordability' role than 'safety

net' role (Stephens *et al.* 2002; cited by Gibb, K *et al.* 2013). According to the Europe 2020 strategy (EU Commission 2011; cited by Pittini, A. and E. Laino 2011, p.1), 'the cost and quality of housing are a key determinant of living standards and well-being, especially for the most vulnerable people'. Further, in the particular example of the Netherlands, housing demand and supply vary between cities due to spill over effects with changing urbanization and metropolitan restructuring in the Randstad Region causing unavailability of affordable housing, unstable housing markets and lack of diversity in housing stock.

With over 35 percent of social rental housing in the entire stock, the Dutch housing associations are independent, non-profit organizations with public responsibility (AEDES 2013). Dutch housing organizations ensure that more than 2.4 million households have access to adequate and affordable housing aimed at improving the quality of life for the low and middle-income communities (Ouweland, A. and G. V. Daalen 2002). While the proportion of affordable housing has continued to remain a national priority in the Netherlands and is the highest in Europe, the owner occupancy rate is still below the set European standards due to the absence of middle-income dwellings for rent, home-ownership or cooperative housing, unoccupied surplus accumulation by housing associations and unaffordability of social dwellings.

This paper has two principal objectives. Firstly, it explores the key regional trends in housing policies affecting affordability with a particular emphasis on housing type, tenure, target groups, providers and financing structures embedded in four social housing contexts - Austria, France, Germany and The Netherlands. In doing so, it analyzes affordability challenges and access to improved social housing across the countries to position the proposed urban concept of '*Cooperative Urbanism*'. After that, the four cost reduction levers as indicated by McKinsey and Company (2014) to the global affordable housing challenge are applied to connect policy level implications to strategic urban planning initiatives adopting market-based measures applicable to any local context across all income groups, particularly aimed at reducing cost to increase the provision of affordable housing.

Secondly, this paper explores cooperative urbanism in the specific case of Amsterdam whereby through the lens of critical urban theory (Brenner, N. 2009) it proposes shared participation deploying collaborative city gaming and design thinking as innovative methods to generate strategic urban planning and design instruments that tackle the provision of affordable housing challenge in Amsterdam. To that end, the strategies formulated enhance and support differentiated housing supply and demand driven programming to leverage mainstream participation that is empowering to all, particularly to the lower income groups incentivizing citizens as collaborators, facilitators and managers to negotiate and empower others as agents of change. The paper further recommends to explore and test cooperative urbanism as future research to underpin and analyze local participation deploying new spatial paradigms to contribute in rethinking planning and policy initiatives in achieving affordable housing solutions under rapid urban, social and economic transformations.

Accordingly, the paper seeks to answer the main research question – How to build the city in a cooperative way to specifically tackle the challenge of affordable housing in a complex urban environment?

1.1 Definition of Housing Affordability

The definition of 'Affordable housing' changes depending on the context but broadly constitutes a financial component with low income communities as the principal target group incorporating household sizes, tenure options and income levels as eligibility criteria for housing assistance. UN-Habitat (2011) defines housing affordability as affected by many factors and is multi-dimensional involving more than often-used simplified conception of the ratio of house purchase price to household income. Housing affordability depends on two main variables – Capital variables and Occupation variables. The capital variables are predicated on the households ability to purchase a house as influenced by the purchase cost

including the sum cost of land, infrastructure, building materials, labor and profit while the occupation costs is the ability to finance the purchase including subsidies, payment requirements and balance of household savings (UN-Habitat 2011). Alternatively, the McKinsey Global Institute (2014) defines affordable housing on the basis a financial threshold module based on the share of the income devoted to housing, a standard module for what constitutes socially acceptable housing servicing selected income groups and income threshold module targeted at households that need housing assistance.

1.2 Measuring Housing Affordability

To address the increasing unaffordable and inadequate land and housing that affects a vast proportion of the vulnerable who often lack access to services, safety nets and political representation (UN-Habitat 2011) creating wider differences between social groups – low income, single parent or women-led households, UN-Habitat (2011) encapsulates on what constitutes an agreed measure for ‘affordable housing’. The first is house price to income ratio in which the ratio is divided by median house price by median household income indicating the annual median salaries that takes to buy a median priced house. The second is the house rent to income ratio in which the ratio is the median annual rent by the median annual renter household income. The third is the residual income assessment indicated as the percentage of household income spent on housing related expenses with the household’s ability to finance services without negotiating on non-housing related expenditure (Yang, Z. and Y. Shen. (2008); cited by UN-habitat 2011). Generally, housing is seen as affordable when the household spends less than 30 percent of the annual income on housing expenses including mortgage repayments for owner-occupied dwellings, rent payments for tenant-occupied dwellings and other direct expenditures related to taxes, insurances, services and maintenance payments. However, these parameters are deemed contextual and vary between countries depending on planning, quality and finance that support the provision of affordable housing and housing policies.

1.2 Affordable Housing Models – An Overview

Affordable housing plays a key role in the development of the city. The type of affordable housing models however significantly differ in terms of tenure patterns but on the basis of production and consumption of units can be broadly classified into two major models – Social or non-profit housing and Intermediate affordable housing for private-rental or private-owner occupied (EUROCITIES 2009; UN-Habitat 2011). Social or Non-Profit housing are rented units owned by local authorities and managed by housing associations, social landlords, NGOs or cooperatives while intermediate affordable housing provides housing at rates lower than market rates for private rental or ownership (EUROCITIES 2009) for single and multi-household dwellings for the vulnerable communities depending on the demand due to urban and economic restructuring in cities. To that end, without having to oversimplify the tenure forms adopted across European member states, it is critical to note that tenure choices can impact long-term housing, market stability and access to adequate and affordable housing. Although financially attractive on the long term, UN-Habitat (2011) report on affordable land and housing in Europe indicates a polarized tenure structure with high share of owner occupancy rates and fewer alternatives pushing newer households into rental housing that are financially stretched. Additionally, substandard housing conditions in terms of dampness, inadequate space, darkness and lack of access to basic services can affect the low-income vulnerable groups with poor quality, unsafe and unhealthy living environment.

2. Methodology

In the recent decades, affordable housing has been a widely debated political agenda at the national and local governments across Austria, France, Germany and the Netherlands. The methodology is divided in two parts in line with the two main objectives – First, outlining an

overview of major trends in affordable housing practices across Austria, France, Germany and the Netherlands and second, exploring the proposed definition and urban concept of *Cooperative Urbanism* with a particular emphasis on Amsterdam affordable housing supply.

Deriving evidence from secondary resources including statistical policy reports, pertinent literature and case studies, this paper analyses existing affordable housing practices at the policy level in Austria, France, Germany and The Netherlands to study the major trends and implications of top down planning, as indispensable to the creation of bottom-up strategic urban planning initiatives (Pittini, A. and E. Laino 2011; UN-Habitat 2011; EUROCITIES 2009; Whitehead, C. and K. Scanlon 2007). Although the affordable housing models significantly differ between the surveyed countries, the six housing indicators in terms of housing type, tenure, target groups, providers, financing and resultant trends will effectively present an overview of current practices in place. However, an urban dimension is critical to improving or renovating the existing housing stock that meets the aspirations of lower income and vulnerable households and build new stock with purchased land or renewal projects. To achieve that, the four cost reduction levers as proposed by McKinsey and Company (2014) to the global affordable housing challenge are applied to connect policy level implications to strategic urban planning initiatives adopting market-based measures applicable to any local context across all income groups, particularly aimed at reducing cost to increase the provision of affordable housing.

Following which through the lens of critical urban theory (Brenner, N. 2009), the historical growth of Amsterdam as 'A Connected City'¹ is captured to reflect the shift in the urban structure of the city – from a politico-economic, socio-cultural and urban-morphological standpoints (DIA 2012) impacting affordable housing provision. Further, to explore more on Cooperative Urbanism, key trends underlying the residential market in Amsterdam (CBRE 2014) are outlined to understand the implications of 'Shared Amsterdam' to mainstream participatory urban planning through a combination of 'Human-Centered' processes including collaborating city gaming (Tan, E 2014) and design thinking methods (Brown, T. and J. Wyatt 2010). Thereof, the subsequent sections package and link cooperative urbanism to appropriate strategic instruments towards devising housing affordability with respect to scaling density, mix programming and adaptive reuse as recommended high impact solutions to addressing housing affordability in the context of complex urban environments.

2.1 Defining Cooperative Urbanism

The paper proposes '*Cooperative Urbanism*' as a combination of strategic human-centered planning and design processes applying generative city gaming (Tan, 2014) and design thinking (Brown, T. and J. Wyatt 2010) techniques to tackle urban challenges. Taking an incremental and collaborative approach to developing urban solutions, *Cooperative Urbanism* is both a platform and a mindset aimed at achieving socio-spatial inclusiveness with a particular emphasis on developmental agenda, critical urban theory and social innovation. Embedded in the context of changing socio-cultural, politico-economic and geo-technical relations in complex, modern urban environments and expanding further on conventional participatory planning approaches, *Cooperative Urbanism* is an interaction of deep values and identities set in a particular context. Aimed at resolving the problem of affordability and spatial segregation in city spaces, *Cooperative Urbanism* focuses on mainstreaming local participation through enhancing and supporting developmental opportunities – like creating self-sustaining neighborhood's, establishing incentive structures, generating jobs and income diversification, facilitating empowerment, promoting good practices and innovative funding programs etc. Underpinned by systemic approach to problem solving and capacity building of citizens and stakeholders in complex urban environment, *Cooperative Urbanism* mitigates piecemeal development through strategic urban development negotiating power relations, priorities and preferences.

While the paper takes an epistemological and developmental standpoint to analysis, the concepts and processes described are limited to secondary knowledge in terms of affordable

housing and promotes *Cooperative Urbanism* as a strategic underlying urban principle to tackle lack of integration at the nexus of top-down and bottom-up approaches. However, it studies major regional trends aligned with that of existing urban practices as applicable to Europe and the Netherlands. In doing so, the proposed definition of *Cooperative Urbanism* seeks to justify and contribute to the current policy and planning level debates on affordable housing provision (demand and supply-side interventions) to effectively adapt and contextualize urban solutions as firmly anchored in both individual and collective identities and empower citizens to empower others as agents of change; and recommends further research as part of a wider extended discussion. As will be shown in section 4, in the case of Amsterdam, *Cooperative Urbanism* will critically explore and suggest strategic instruments to housing affordability.

3. European Housing Affordability – Key Regional Trends

In the recent years, there has been much debate around the future of affordable housing in Europe with particular emphasis on adequate housing stock availability, management and provision for all in achieving mixed communities and avoiding social segregation. Whether it means cost-based social rental housing in Austria (Hills, J. 2007; cited by Whitehead, C. and K. Scanlon 2007, p.4) or France's ambitious targets for new social house-buildingⁱⁱ; or Germany's approach of establishing a 'socially integrative city'ⁱⁱⁱ; or seeking potential alternative uses to housing surpluses accumulated in the Netherlands^{iv}; the aim is mainly to present a comparative insight of the key regional trends and a broad overview of the tenure patterns in Austria, France, Germany and The Netherlands. To retain the focus of this paper the study was limited to the above four member states in the Western European union with a high share of social or non-profit housing that builds on the existing body of knowledge and addresses gaps in the underlying social housing system, where necessary.

CECODHAS (2012) report defines eligibility to the allocation of a social dwelling in Europe through the use of income ceilings, wherein the maximum income is set to the highest to allow for income mixing in countries including Austria, France and Germany (Pittini, A. and E. Laino 2011). However, the eligibility criteria varies depending on the local needs and demands in the housing markets – to attract certain types of migrants, to provide housing for students, young people and single family households or to revitalize areas with ageing population etc. Further, the general trend is towards declining municipal involvement and increasing diversity in the range of actors notably through public-private partnership. Consequently, with the increased involvement of the private sector, the government subsidies and funding allocation are increasingly targeted and limited (Whitehead, C. and K. Scanlon 2007).

The following sub sections outline the major trends in Austria, France, Germany and the Netherlands according to individual country profiles on Housing Europe Review (Pittini, A. and E. Laino 2011; cited by CECODHA 2012) and *Social Housing in Europe* (Whitehead, C. and K. Scanlon 2007).

3.1 Austria

Type of Social Housing – In Austria, the social housing stock currently represents 23 percent of the total housing stock in which municipalities and public companies own 60 percent. Municipal housing or public housing is rental housing provided by municipalities. Limited profit housing is rental and owner-occupied provided on non-profit basis by investors with access to public subsidies. Housing promotion schemes define the type of housing and providers with rent limits and income limits for new residents.

Tenure Form – 56% owner occupied; 17% private rental; 23% social rental and 4% others with a balanced tenure structure offering a ladder of opportunities ranging from social to private renting to homeownership (2008).

Target Groups– Municipal housing focuses on working class and disadvantage people (working immigrants who arrived in 1960s and 1970s) while for-profit and public funded private sector focuses on middle class people. Newer municipal housing is inhabited by younger middle-class elderly occupy the older estates. In summary, the municipal stock is polarized with an old stock housing the elderly, very poor and disadvantaged and the new stock similar to that of housing associations.

Providers – As a limited-profit sector, social housing is provided mostly by cooperatives and limited companies with a small component subsidized by for-profit companies.

Financing – Austria combines long term public loans and grants at the level of federal provinces with commercial loans raised via HCC Bonds and developer/tenant equity. A typical social housing project comprised of - 20–60% conditional subsidies (grants, low cost loans) with limits to keep construction and financing costs down; 5–15% equity of developer; 0–15% equity of future tenants (right to buy in some circumstances) and 50–70% commercial loans, financed by commercial bonds and Housing Banks.

Key Trends – Much of the recent developments focus on a substantial reform plan in terms of public housing promotion with include the central state withdrawal from financing and federal provinces facing financial restrictions with the overall public grants decreased to 25% in 2010. Ongoing debate embedded in strong corporatist tradition also known as social partnership is undergoing economic and political restructuring impacting urban development with an increasing risk of socio-spatial segregation. Due to the high demand particularly with the level of immigration to Austria in urban centers, there is an expected shortfall in the supply of affordable housing with emerging concepts around ‘Public-private partnership’ and ‘new governance’ (Whitehead, C. and K. Scanlon 2007).

3.2 France

Type of Social Housing – Social housing is provided by HLM (*Habitation à Loyer Modéré*, organizations providing housing at moderated rents) organizations that are specific actors designated by the state. The social housing sector accounts for about 17% of the total housing stock in France overseen by legislative and regulatory bodies according to the Construction and Housing Code and broadly divided into 3 types – standard, upper and lower social housing for rental and home-ownership. Social housing is predominantly urban – 62% located in towns or cities with more than 100,000 inhabitants and 14% in towns and rural areas with less than 10,000 inhabitants. The spatial polarization in terms of affordable housing availability is particularly high in Paris, Lyon and Marseille and less acute in cities like Lille or Rennes (Whitehead, C. and K. Scanlon 2007).

Tenure Form – 57% owner occupied; 22% private rental; 17% social rental and 4% others including furnished units, sub-tenancy and free housing arrangements (2008).

Target Groups – Social housing allows for a certain degree of socio-economic mix and access to social housing is limited by income ceilings. Preference is given to bona fide applicants who are homeless, people at risk of eviction with no alternative housing, people with temporary accommodation, people residing in unhealthy or substandard accommodation, households with children in overcrowded units and disabled.

Providers – HLM organizations and to a lesser extent semi-public enterprises (*Société d'économie mixte*, SEM) and few non-profit organizations build and manage social housing in France. HLM organizations include both publicly and privately owned companies operating on non-profit basis under the control of the Ministry of Housing and Finance.

Financing – State and local authorities provide subsidies that lower the rents based on net construction cost and provide tax incentives. Housing benefits are made available to support the poorest groups paying the rent in line with the household's income proportionate to income ceiling. CDC (*Caisse des Dépôts et Consignations*) lends finance loans for new constructions and provides funds from ‘Livret A’ accounts, a savings fund with regulated

interest rate and subject to no tax. Other financing systems include employers grants and discounted loans from local authorities or the HLM guarantee fund. A typical financing scheme for a housing project (2009) comprise of – 76.5% from CDC loan (Livret A); 10% equity capital; 8% local authorities subsidies; 3% state subsidies and 2.5% employers grants.

Key Trends – The social housing sector has seen a steady increase in the proportion of poor households which is currently 35% of all HLM households having income become poverty line. According to the '*Grenelle de l'Environnement*', HLM organizations are engaged to renovate by 2020 targeting 800,000 social housing units to improve energy efficiency. With a long history of social housing, the market structure is unable to cope with the housing needs and the private rented sector devoted to affordable housing is reducing with very high cost of ownership and costly new incentives that may limit the capacity for further growth in the sector. Further, the social housing stock is expected to grow fragmented with increasing decentralization due to disconnect in responsible programming between local and national authorities to overcome socio-spatial segregation. In addition to that, l'Union sociale pour l'Habitat, a single body bringing together HLM federations is launching a new business model that takes into account the needs for affordable housing in France and the financial stress on public funds.

3.3 Germany

Type of Social Housing – In Germany, the social housing refers to publicly subsidized housing or housing promotion representing an overall 5% of the national housing stock and is market based. All housing companies are considered market actors with municipal housing companies acting in compliance with local policies and housing needs. There are three strands of social housing in Germany – The first strand is social rented housing with strict income limits and rent ceilings at €4/m² and increases as subsidies fall; the second strand is the elevated social housing developed through grants from new-build or rehabilitation and receive a subsidized mortgage with low interest rate with tax reductions; the third strand consists of the owner occupied social housing which households purchase. An increasing number of specialized units have been built in the recent years that include experimental live/work units, mixed generation housing and elderly homes.

Tenure Form – 42% owner occupied; 53% private rent and 5% social rent (2008).

Target Groups – Households who cannot secure adequate accommodation and need support are primary targets with particular emphasis on low income households with families, children, single parents, pregnant woman, elderly and the homeless.

Providers – The public intervention in housing policy is not linked to specific providers but entails public subsidies enforced by income ceiling and lower rents. Publicly subsidized housing include municipal housing companies and cooperatives from the traditional non-profit sector together with private landlords, commercial developers and investors.

Financing – No centralized funding systems because social housing programs have evolved over time with municipalities and provinces having a great deal of responsibility. Public subsidies are provided to builders including grants and tax relief systems covered gaps between perceived rent and cost rent. Dwellings can be let or sold at market prices at the end of amortization period which is typically 20-40 years for newly built dwellings and 12-20 years for renovated dwellings. All social dwellings in Germany is legally private where municipal housing companies act as private entities governed by commercial law.

Key Trends – New urban problems have emerged – regional economic disparities, demographic changes, urban polarization with over a million vacant homes make it necessary to address the need for appropriate forms of social housing in the reformed welfare state (Whitehead, C. and K. Scanlon 2007). The role of the public sector is towards reducing the cost gap between social and market housing. Emergency housing provision for homeless, refugees and other marginalized communities were never prioritized through

social housing finance programs but rather focused through social and health programs. Today, only a few towns and cities with the highest house prices and privatized markets focus on the production and maintenance of new social housing. The major urban initiative called the Socially Integrative City (*Soziale Stadt – Städte mit besonderem Erneuerungsbedarf*) began in 1999 to address the challenges posed in deprived areas including segregation but has been ineffective in providing affordable homes and improving local economic development through job creation markets. New interventions are being considered to support this initiative that are investment-oriented and socio-spatially sensitive to neighborhood growth to urban regeneration and creation of non-profit housing cooperatives (Whitehead, C. and K. Scanlon 2007).

3.4 The Netherlands

Type of Social Housing – With the largest share of social housing in European Union accounting to about 32% of the total housing stock and 75% of rental stock, The Netherlands dominates the affordable housing market with almost all owned by the housing associations. With the Housing Allocation Act of 1947, housing was allocated on needs-based system to cope with pressing housing shortages (UN-habitat 2011) until a choice-based letting system was introduced in the city of Delft in 1990s which is now a norm throughout the country.

Tenure Form – 58% owner occupied; 10% private rent and 32% social rent (2008). The Dutch government aims at creating better tenure mix in urban renewal projects offering opportunities for people to buy properties and attract new households. Of which 49.4% are single family dwellings; 15.4% multi family dwellings; 23.3% multi family dwelling with no lift and 12% others types (AEDES 2002).

Target Groups – The principal target groups in the lower income segments and the vulnerable communities including the elderly, the disabled, immigrants, permanent and temporary homeless, itinerant communities and asylum seekers. With a differentiated target group including the low income households and the intermediaries the social rented sector demonstrates economic and social benefits with an integrated approach.

Providers – Private non-profit organization known as *Woningcorporaties* are registered social housing organizations that operate on the basis of registration and supervision by the national government. At present there are about 425 of such registered organizations in the Netherlands. Although controlled by a legal framework, the Dutch housing organizations act independently setting their own objectives and bearing own financial responsibilities. As an integral part of the Dutch housing market, the housing organizations build, maintain, sell and rent social housing stock and provide services directly related to the use of dwellings and to the occupants.

Financing – Dutch housing organizations are financially independent from the central government since 'Brutering' or 'Balancing out' agreement in 1993 between the state and the national federations. On the basis of a 'Revolving Fund Model', the Dutch housing associations act independent in an environment of guaranteed capital market loans and rent-price regulation. With a three level security structure for funding (see figure 1) – the Central Fund of Social Housing (CFV), the Guarantee Fund for Social Housing (WSM) and the state and local authorities can intervene as last resort. The first security, CFV is a special independent public body that provides financial and project support to specific projects that operates based on the charges levied from social housing organizations. The second security instrument, WSM is a private organization that acts as solidarity fund creating incentive structures to benefit from interest rates to function in an open capital market. Thirdly, Dutch State and Municipalities act as a guarantor through the WSM, housing associations are able to borrow on the capital market at lower interest rates (Ouweland, A. and G. V. Daalen 2002).

Key Trends – Alongside changing market conditions, Dutch social housing organizations depend heavily on investments affected by tax-deductibility of mortgage interests, state

guarantees for buyers, high loans to value mortgage, strict rent regulation, restriction on special planning and state aid and solidarity instruments in social housing (AEDES, 2014). However with prudent management, low interest rates and steady rise in market values, the Dutch social housing model has been instrumental and responsible in the changing residential climate – at the level of dwelling, the residential complex and the neighborhood. The Dutch social housing sector is flexible, structured and organized and could act as a benchmark for social landlords in other contexts. However with increasing privatization of markets, lack of urban renewal projects, over priced dwellings in inner cities, unaffordable housing surpluses and noticeable shift towards owner occupied dwellings in outskirts and availability and affordability of housing stock for vulnerable groups seek for new initiatives.

3.5 Connecting Policy Implications to Strategic Urban Planning Initiatives

Although the affordable housing models significantly differ between the surveyed countries, it is clear that policy implications directly impact urban development. Accordingly, Ekim Tan (2014, p.31) in her research on 'Negotiation and Design for the Self-Organizing City' defines Bottom-up and Top-down as "Terms borrowed from systems science; In a top-down approach an overview of the system is formulated, specifying but not detailing any first-level subsystems. A bottom-up approach is the piecing together of systems to give rise to grander systems. Top-down urban processes are typically formulated in advance and are conducted by large urban stakeholders such as Cities, corporations. Bottom-up urban processes are aggregated by small scale enterprises or individual citizens, sometimes as collectives as well, formulating an urban order incrementally." According to UN-Habitat (2011), increased costs in social housing sector as explained above also have implications for access to adequate and affordable housing, particularly for the vulnerable groups. This is compounded by the irreversible trend of urbanization affecting housing affordability with significant pressure on available land and prices. Land acquisition and supply for new housing is necessary through market interventions and long-term urban planning strategies. Public-Private partnerships are becoming increasingly important to support additional funding in the form of private finance, public land and recycling existing assets (Ouweland, A. and G. V. Daalen 2002).

To mitigate the challenges posed at the nexus of top-down and bottom-up urban processes, the four cost reduction levers of McKinsey and Company (2014) are applied to address the shortage of affordable housing supply through coordinated planning in cooperation with civil society yet meeting the private and public interests through market-based measures applicable to any local context across diverse income groups. The four cost reduction levers proposed by McKinsey include unlocking land supply to open up opportunities for affordable housing; development to improve capital productivity and value engineering; operation and maintenance – improve energy efficiency and scalability to ensure quality and avoid dilapidation; and lastly, financing to reduce borrowing costs to buyers and renters and assist in developer financing (McKinsey and Company 2014). In doing so, a dedicated housing delivery platform is developed to facilitate and manage the interests of stakeholders and beneficiaries^v to offer appropriate housing solutions to local communities and create cross-subsidies with access to finance and governance structures to enhance local resilience in the delivery of units and streamline processes to monitor and evaluate performance.

4. Cooperative Urbanism – The case of Amsterdam, a call for action

4.1 Growth of the City

In Amsterdam, beyond inside and out (2005, p.1), Stephen Read describes the evolution of Amsterdam as 'A connected city', "First the welfare state with its state-sponsored housing, and then infrastructure and the explosion of mobility with the drift to the periphery, were the shapers of the further expansion of the city. In between, in the second half of the twentieth century, Amsterdam, despite its small size and population, and despite (or perhaps because

of) a paradoxical urban decline linked to global economics, played a central part in the emergence of a global urban culture.” What grew as a trading city in the 16th and 17th centuries, a bustling center of thriving activities – prosperous, expanding rapidly with an abrasive mix of merchants and shippers, shipbuilders and fishers, bankers and middlemen with a massive influx of economic migrants, itinerants and refugees (Read, S. A. 2005) has entered the network of ‘Global Cities’^{vi} (DIA 2012) with changes in modes of production shifting from a welfare state to free market. Consequentially, the municipality of Amsterdam instead of providing services to citizens provided services to corporations and investors. The switch to public private coalitions and partnerships although widely acknowledged is currently losing funds due to idle non-revenue generating derelict or uninhabited properties, unaffordable housing surplus etc. through locked investments.

4.2 Shift in Urban Structure

The development of Amsterdam that impacted the provision of affordable housing can be accounted to shift in structural planning from 3 different standpoints (DIA 2012) – first, from a politico-economic angle, with change in economic base from shipbuilding based economy to service based economy and further exacerbated by Amsterdam Schiphol International Airport, the historic inner city center, the new central business district of Zuidas that have influenced the emergence of a new polycentric city dependent on communications, connectivity and accessibilities. Secondly, from a socio-cultural angle, shifting from a social city to a multicultural city and from a creative city to a segregated city when the Dutch population moved to new towns during 60s and 70s and the relatively unskilled, non-western immigrants including ethnic groups from Surinam, Turkey and Morocco remained to be spatially segregated in outskirts or underdeveloped areas with affordable housing made available to very limited group of population. And thirdly, from an urban morphological and angle, shifting from social housing to free market housing wherein social housing is not owned by the local development but by independent (non-profit) housing associations who act as developers and provide 70% housing for sale to owner occupied units and 30% to affordable housing for low income groups. As a result, urban renewal and new housing developments have been both priorities offering a mix of tenure types and high quality neighborhoods.

4.3 Key Trends Impacting Residential Market

As stated above, the Netherlands has the largest share of social housing in Europe covering about 32% of the total housing stock, however, the Dutch residential market is evolving rapidly. As the 5th most important economic region in Europe, Amsterdam Metropolitan Area (MRA) is provides both attractive and ideal business climate. With over 2500 foreign companies (CBRE, 2014) includes 460 international headquarters, Amsterdam metropolitan area generates about 17% of Dutch GDP, a vast majority of which comes from business services, wholesale and financial services (2011). In addition to that, the strategic importance of Schiphol International Airport and Port of Amsterdam also contribute largely to the economic growth of the region. The city of Amsterdam actively contributes to about 40% of the total GDP of MRA. Market forecasts indicate a 12.5% growth in population by 2040 with 46% owned by social housing corporations, 32% owner occupied, 22% by private investors with 80% of all plots owned by the municipality and distributed on leasehold conditions (CBRE 2014) divided between regulated and non-regulated rental reforms with rents in Amsterdam as highest in the Netherlands €18.60 per sq m per year (Pararius, 2014; cited by CBRE 2014).

4.4 Cooperative Urbanism through Human-Centered Planning and Design

Recently, urban planning practices largely involve citizens more directly in shaping their communities through active engagement integrating local knowledge to mainstream participation from conception to decision making processes. Navigating complex urban processes not limited to changing demographics, people’s immediate urban needs and commercial interests requires collective vision, planning and production process aimed at

building trust, transparency and consensus that recognizes and speaks to the inherent values of the local communities. Human-centric planning and design to cities explores the 'City as a self-organizing system' through structured city-gaming techniques (Tan, E 2014) through a series of seven key urban processes in terms of:

1. Authorizing multiple agents (urban actors) including state representatives from local government, market actors and communities
2. Facilitating multi-dimensional platform that engages professional experts across interrelated planning disciplines – planning, finance, engineering, sociology and design.
3. Engaging in open dialogues collaboratively in an interactive environment.
4. Allowing for variations, interactions and iterations as part of an open, multi-agent and collaborative urban process over simple dynamic rules that influences the urban agents – land reforms, subsidies, priorities, tax incentives, spatial quality etc.
5. Simulating incremental urban development to embrace individual and collective actions of the various agents as a continuous urban process that evolves, innovates, mitigates conflicts and adapts with respect to changing urban conditions.
6. Ensuring constant learning that draws and supports collective intelligence through data management – generating, collecting, sorting, storing and sharing knowledge.
7. Operationalizing self-organizing urban processes applied to real world context.

Accordingly, city gaming method (Tan, E. 2014) offers a unique platform mainstreaming participation at the nexus of geo-political parameters – institutional plans, policies and reforms between individuals, state authorities, market authorities, individuals and collectives; and geo-physical parameters – topography, codes, regulations, infrastructure, density, land uses, prices, services and public utilities to inform policy, planning and design propositions that triggers collective intelligence of the players (see fig.1).

In doing so, cooperative urbanism proposes and develops inclusive 'micro-solutions' to 'macro-challenges' in this case with a particular emphasis on affordable housing, whereby planning decisions are highly localized and therefore, grounded in the needs and desires of local communities aimed at improving their ability to actively build consensus on the basis of shared priorities and shared values. Even more, promote self-build and self-management techniques to increase the capacities of local communities through strategic urban projects - oscillating between analysis and synthesis, between vision and action, between intuition and rationality, between the global scale of the city and the local scale of the neighborhood, and between the existing and desired spatial structure (Calabrese, L. M. 2011) – will be critical.

Taking that forward from project to people's lives is Human-centered design, it is a human-centered mindset from deep empathy and understanding of needs and motivations of people; it is collaborative benefiting from the views of multiple perspectives; it is optimistic built on the fundamental belief to create change and it is experimental based on rapid prototyping of ideas with multiple feedback loops for further iterations (Brown, T. and J. Wyatt 2010). Design thinking incorporates an in-depth understanding of consumer insights to create effective solutions addressing the needs of the people who will consume the product, service or infrastructure that enables it. Increasingly, businesses are embracing design thinking to innovate and differentiate their products and services in the market to design sustainable and scalable high-impact solutions which can effectively speak to social problems (Brown, T. and J. Wyatt 2010). As a system of three overlapping spaces, inspiration, ideation and implementation wherein inspiration is seen as the problem or opportunity that motivates the search for new solutions; ideation is the process of generating, developing and testing ideas; and implementation is realizing the program from project into people's lives^{vii}. Accordingly, design thinking taps into capacities of problem-solving practices focusing not only on the products but the process itself that is deeply human. With an ability to be intuitive, to recognize patterns and to construct ideas that powerfully associate emotional and functional

meanings of end users, design principles are generated and applied in context – be it a product, a space, a service or an entire system.

4.5 Shared Amsterdam - Strategic Instruments to Housing Affordability

As proposed, human-centered planning and design through collaborative city gaming and design thinking methods aims at understanding and investigating complex spatial processes and apply them to real time challenges. Different than conventional participatory tools, city gaming and design thinking allows for systemic analysis to changing urban structures with multiple stakeholders yet keeping the local communities at the core of design and decision making dimensions.

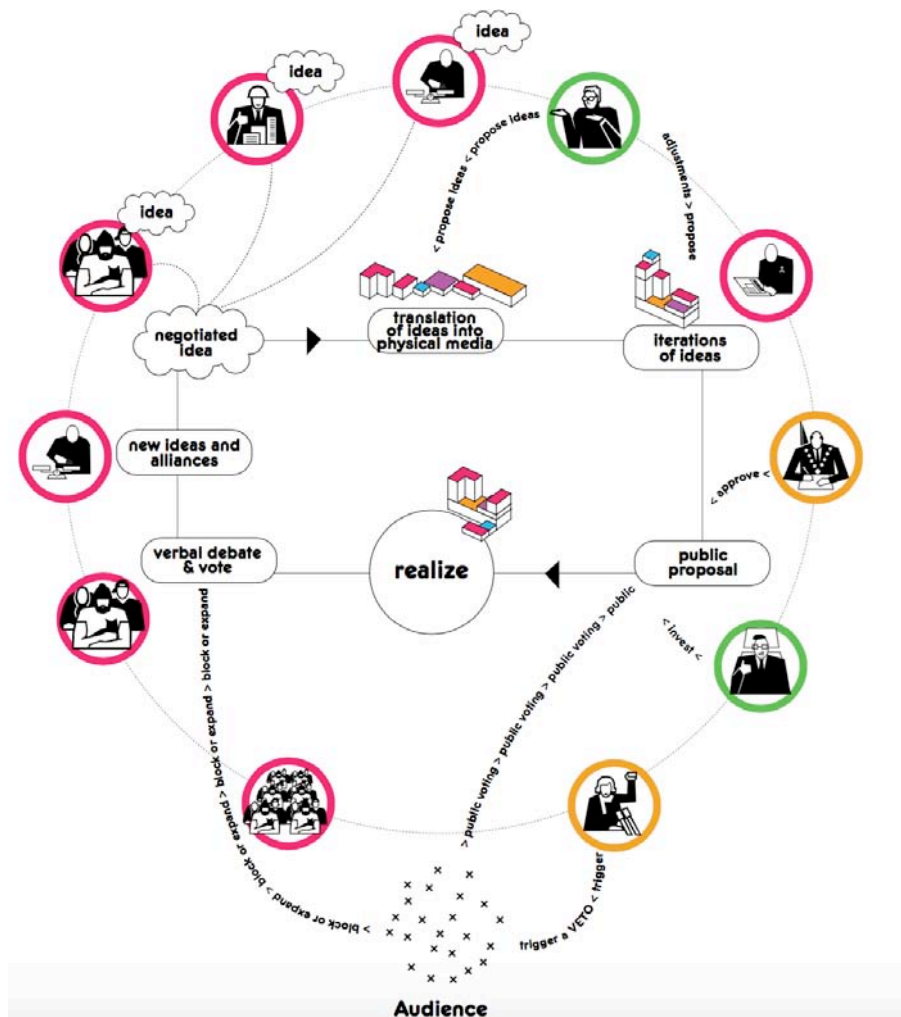

Figure 1: Generative City Game triggers the collective intelligence of players, source: Tan, E. 2014

While human-centered planning and design tools are applicable to an array of different urban problems – regeneration, renewal or restructuring of large, medium or small urban projects, this paper recommends three strategic instruments shaping the creation, development, adaptation and maintenance of a shared city in achieving affordable housing. These are applicable at both the local and policy levels and aimed at problem-solving, learning, strategizing, training and balancing power relations between politicians, developers, investors, builders and local communities. To enable and mainstream participation by means of differentiated housing supply and demand driven programming, cooperative urbanism aims at linking affordability to:

1. Scaling Density – Scaling up of high-impact urban solutions requires a three-pronged approach that factors the needs of the people, the housing and the market infrastructures with increasing returns and public good on investment. Achieving maximum scalability

through urban commonalities focused on value creation and delivery in terms of building typologies, functions, service, public utilities and particularly, density allowing compact development with increased and diversified number of dwelling units and building heights.

2. Mixed Programming – Mono-functionality to multi-functionality based on program scope and differentiation that focuses extensively on mixed-use planning integrating functions – a combination of residential, commercial, cultural, institutional, leisure, health or industrial uses and zoning – natural landscapes, street and pedestrian connectivity, public transportation to ensure and provide quality ‘individual and collective’ living standards known as ‘design for all’ towards making urban spaces livable (attractive and inclusive), accessible and sustainable for local economic development.
3. Adaptive Reuse – Urban transformation projects that effectively meet the demands of future needs with an in-depth morphological and typological understanding of local culture, politics and market structures integrated into participatory planning and decision-making dimensions.

5 Conclusions and Recommendations

Affordable housing is a global challenge for cities in both in developing and developed economies alike. However, urban processes are becoming increasingly complex and vary between countries impacting the provision of affordable housing supply and demand. While this arguably depends on the overall institutionalization and implementation of city’s wider strategic planning framework, engaging in different urban scales of the metropolis, city and neighborhood and incorporating innovative methods to planning – collaboration through city gaming and design thinking motivates and supports fair distribution of roles and responsibilities of shared urban resources. Nonetheless, with complexity emerge contradictions (Tan, E. 2014) when designing for diverse groups of stakeholders towards building of consensus and collectivities. Although evidence suggests reduction in affordable housing stock across Europe and particularly the Netherlands, mainstreaming housing affordability for the vulnerable through local participation leveraging the interests of public and private sectors has been a priority on the basis of income ceilings and households sizes. Still, the broad characteristics that make up affordable housing development often succumb to austerity measures (AEDES 2014) and policy reforms disconnecting local residents mainly the vulnerable from interrelated processes of evolution in design, planning, management, maintenance and decision-making, with limited or no choices.

This paper offers a modest attempt at clarifying the key trends that govern social housing in western European countries to highlight on the need for new spatial paradigms, as indicated above to achieve integrated and inclusive urban planning that mainstreams participation to effectively integrate top-down and bottom-up approaches. While most evidence is drawn from secondary readings, the urban concepts appropriate to the local needs and desires of the communities are deemed most fit. To that end, affordable housing practices require housing experts, planners and practitioners across Europe to adopt social innovation and strategic planning instruments stimulated by cooperation and partnerships across key urban sectors. It further recommends testing of cooperative urbanism towards deploying new spatial paradigms to contribute in rethinking urban planning and policy initiatives. Finally, it advocates for creative and collaborative Human-centered processes to systematically engage and strategize specialized approaches to affordable housing as future research. The existence and role of supply and access to quality affordable housing is both a challenge and an opportunity for economic growth for the Netherlands and Europe as a whole.

Cooperation and Mediation. The Flexible Geometry of Public Participation. Comparing US and France Evolutionary Approach

Bruno MONARDO, "Sapienza" University of Rome, Italy

Synopsis

The aim of these reflections is to argue and compare the emerging innovation of some participation models, tools and actors in 'Common Law' Countries (US in particular), and 'Civil Law' ones, as France, through the "flexible geometry" issue and the hybridization of original cultures of the cooperative approach for local development, based on the emerging styles and roles of expert community managers and mediation or facilitation professionals.

1. General framework and goals of reflexions

Within Urban Studies it is widely believed that municipal policy should reflect an equitable, virtuous democracy in terms of participation and deliberation. If we assume as a benchmark that politics, in its noblest sense, is rooted in relationships between institutions, communities and stakeholders - cutting across the demarcation between public and private life - then mature governance is reached when the community itself can contribute fairly to public decisions.

The profound changes focused by Zygmunt Bauman's 'liquid modernity' concept as well as the uncontrolled individualism which has been interpreted by Alain Touraine as the 'end of social reality', create an increasingly complex and fragmented landscape of stakeholders, and enhance the difficulty of inclusively managing participatory mechanisms. Moreover the participatory phenomenon in urban neighbourhood regeneration has recently fomented new interpretations, due to the enforced role of actors and tools for mediation. Originating from two major roots - 'Common law' countries (the US, UK, etc.) and 'Civil law' jurisdictions (France, Italy, etc.) - the evolving scope of mediator and facilitation professionals, in the context of divergent cultural contexts, is currently generating interesting new approaches to fostering shared community scenarios for local redevelopment.

The aim of these reflections is to compare the innovation inherent to participatory democracy models between the different juridical domains—considering the US and France respectively—through the concept of 'flexible geometry'. It will be argued on the hybridization of original cultures into a cooperative approach to local redevelopment, based on the emerging styles and roles of community managers and mediation and facilitation profiles.

In the first part, a general overview on the contemporary crisis of representativeness and the 'ancient dilemma' of the apparent dichotomy of historical democracy models is presented, through different consolidated and emerging cultural positions, trying to focus how they are affecting the innovation of styles, models and tools for exerting virtuous participatory democracy principles in urban redevelopment strategies.

In the second part reflections are focused on the emerging profiles of particular families of actors - mediators and facilitators in particular - who although their different "dna", share the mission of "third party neutral to help multy-party work groups accomplish the content of their work by providing process leadership and process expertise" (Fleischer J.M., Zumeta Z.D.

1999). These experts are more and more involved by the main actors in urban regeneration projects in order to rebuild or strengthen the weaker and weaker bridge of public participation among the privileged actors and the recessive stakeholders in local communities. Some significant tools and case-studies are shortly explored showing the diverse cultural interpretations of the so-called 'flexible geometry approach' and its implementation in US and France.

Final comments and reflections are devoted to the effective contribution that the emerging profiles mediation/facilitation-oriented can deliver to a general innovation perspective of the participatory and deliberative democracy scenarios in urban redevelopment policies.

2. The participation issue in urban policies. Short overview

Within European urban policies, in 'Civil law' Countries particularly (France, Italy), contradictory trends are strongly emerging: on the one hand, in the general atmosphere of a widespread disappointment about the implementation local governance principles, some radical theorists are fostering forms of participation and local empowerment closer to an ideal direct democracy model, tackling the primary role of privileged actors; on the other hand public administrations, professionals and scholars are forced to admit increasing difficulties in managing the participation process which is often affected by procedures still complex, exhausting, ineffectual, often disappointing for contents and outcomes, with the great temptation of coming back to a more centralised government scenario.

In the historical evolution of the doctrinal issues, several '*maitres à penser*' have shown that both the representative and the direct democracy models, together with recognised virtues, can assume drawbacks and critical consequences.

Jean Jacques Rousseau commenting ironically the democratic condition of the British, whose representatives were elected without a binding mandate, stated that "*the people of England regards itself as free; but it is grossly mistaken; it is free only during the election of members of Parliament. As soon as they are elected, slavery overtakes it, and it is nothing*" (Rousseau, 1762).

On the other hand, it's interesting to remind the model of direct democracy 'par excellence', the Athens of the fifth and fourth Century b. C. In his masterpiece, 'The Republic', Plato explains how Socrates deemed totally inappropriate that, in the deliberative assembly, ordinary citizens could express decisions on matters defined as important 'works of art' (like relevant buildings or ships), for which an 'expert knowledge' is requested. On the contrary, according to Socrates, when 'the Polis must deliberate on the State affairs', everyone can present his point of view - blacksmiths and shoemakers, merchants and sailors, rich and poor, noble and humble - and although they speak without any specific competence, nobody should have any objection.

Concerning the inclusivity issue and the stakeholder empowerment (Shiffman, 2007), one the leading contemporary schools of thought in Politics, within its theory on democracy has listed five criteria to guarantee everyone an equal right to be involved in decision-making (Dahl 1989). One of them is particularly cogent for these reflections, the so called 'effective participation'. Citizens and recessive subjects must have both the ability and the opportunity to ask questions, give suggestions, provide reasoning, and indicate preferences that can be included on the political agenda.

In modern times the inclusionary approach of inhabitants, beneficiaries and other members of urban communities in drawing up decisions on the transformation of the city, is a decisive issue in the idea of participatory democracy in answer to the emerging demands of contemporary society. It is not one of the possible alternatives, it is now an imperative, outlining a project of social cohesion which is founded not on '*a priori*' aseptic scenario but on

the difficult search for opportunities in order to extend consensus to the greatest possible number of diverse actors in the urban scene.

The evolution process of participatory democracy as a tool of decision-making necessarily entails developing active forms of involvement in drawing up the population's decisions as well as recognizing other stakeholders concerned with the transformation of the city. It is a continuous search for a delicate balance between the two extremes of a pendulum: the rhetoric of 'broadening participation' and the risk of the asymmetry between privileged actors and weaker subjects.

Within its evolutionary seasons, participation has been related to different interpretations (Lawrence, 2006) and the scientific literature could focus some typologies related to the diverse cultural contexts in which they could be reasonably embedded.

The first family is oriented in exploring the degree of stakeholder engagement. The "ladder of participation" (Arnstein 1969) is the seminal theoretical work on the subject of community participation. Arnstein's hierarchic vision was important for reflecting on passive or progressively active involvement of the weak stakeholders among citizens (Johnson et al., 2004). However, the limitations of such a schematic view are numerous: the levels of participations in the increasing density of the urban arena reflect a more complex continuum than a mere sequence of steps. Moreover, the conception of a ladder implies that more control is always better than less one, although an increased control may not always be fostered by the community in every condition and may lead to failure without the necessary support.

The "wheel of participation" (Davidson, 1998) has been suggested as an alternative to the ladder metaphor, emphasising the necessity to embrace a 'changing geometry' in the dialectic of subjects and the consequent legitimacy of different degrees of involvement which are likely to be appropriate in different contexts, depending on the objectives of the work and the capacity for stakeholders to influence outcomes (Richards et al., 2004; Tippett et al., 2007).

The second typology deals with the nature of involvement, identifying the direction of flows among the different actors. According to this view, differently from one-way flows of information and consultation, participation is virtuously conceptualised as two-way communication or a network, building an active dialogue among subjects (Rowe & Frewer 2000).

Other families are oriented in deepening the theories of normative or pragmatic nature of participation, the former focused on process, the latter on the quality of final outcomes. There have been interesting attempts to conceptualize the contrast between normative and pragmatic participation, as for instance in the 'communicative action' theory (Habermas 1987) in which participation should be "fair", representing the full range of relevant stakeholders and equalising power between participants.

Finally, the scientific literature underlines typologies on the basis of the objectives for which participation is used. In this domain some authors underline the difference between "research-driven" and "development-driven" participation (Okali et al., 1994), others distinguish the "planner-centred" participation that is focused on outcomes from the "people-centred" participation, which builds capacity and empowers stakeholders to define and meet their own needs (Michener 1998).

The short outline shows how scientific studies on participation went in depth on its 'ontological dimension' and on the dialectics and roles of traditional and emerging actors in the urban arena in front of new scenarios of urban redevelopment.

However, many schools of thought converge on the idea that it should be mostly argued and investigated about the difficulties in managing the frequent and paradoxically increasing gap between point of views negotiated by the privileged actors of urban scene - the so called

FIRE: Finance, Insurance, Real Estate - and visions, desires and demands as expression of the weak stakeholders, as single local citizens, inhabitant associations, representatives of small local business, and so on.

So, how is it possible to reduce the distance between ideal visions and concrete implementations in the participatory process within urban redevelopment programs and projects? What are the innovative tools and virtuous interpretations of participation in contemporary urban regeneration scenarios in the western economies?

In the last decades, despite of the bubbling rhetoric of the 'imperative of public participation', the increasing gap seems to be inexorable within the general framework of the decline of political representativeness and administrative capacity together with the growing phenomena of corruption and speculation. However, a glimpse of innovation in terms of cultural regeneration and operative exploration of new tools and potentials is represented by the increasing importance of the 'interface space' among policy makers, public officers, privileged economic actors and all the complex and fragmented world of the community stakeholders within the urban arena.

An 'interface space' more and more devoted and delivered to specific subjects supposed to be 'neutral' - private professionals or specialized nonprofit organizations - whose mission is increasingly oriented in involving stakeholders, facilitating the community participation, relating actors each other, mediating conflicts, supporting negotiations, encouraging the development of participatory and deliberative pathways, managing group dynamics, keeping under a reasonable control the process development and helping the decision makers and the other stakeholders to draft texts of agreements. Many school of thoughts (Gulliver, 1979; Amy, 1987; Forester, 1989; Ozawa, 1993; Bobbio, 2008) argued about the absence of a univocal term to define these emerging actors and underlined the deep diversities in roles and cultural interpretations. The widespread 'mediator' or 'facilitator' terms, as well as other more general definitions (participation experts, animators, negotiation consultants) are often used interchangeably, despite significant diversities.

From the point of view purely etymological, "facilitate" means "to make easier", so facilitators should make easier for people to accomplish specific goals in order to improve the life quality of their community. Helping people to think more in terms of interests than positions, the facilitation strategy should be oriented in providing process leadership and management expertise.

The 'time factor' within the 'process' road-map is probably the most significant diversity between mediation and facilitation. In not specialised literature facilitation and mediation are presented in a similar way, but going in depth they are considerably different.

Facilitation is primarily used in order to prevent the *conflict* or at least intervene in a *pre-crystallized* conflict phase. Facilitators, who could be deemed as sort of 'holistic physicians' (Fleischer, Zumeta 1999), can give their best contribution pushing people to work collaboratively toward their common goal, trying the different stakeholders to get rid of possible preconceived forms of prevention. That doesn't mean there isn't the *potential* for conflict, or that episodes of tough disagreement haven't already occurred. However in general the most important feature of facilitation is its preventative role for avoiding devastating conflicts.

Mediators, on the contrary, tend to be involved when huge conflicts are already in progress. There might be privileged powerful actors facing themselves from antithetic positions and almost forcing individual community stakeholders to choose different sides. When the lines between facilitation and mediation blur, experts define this condition and the derived strategy as a "multi-party mediation." Even if the entire group of actors is not directly involved in the dispute, the entire context is negatively affected. Sometimes scholars define such multi-party mediation a "facilitation" action, simply because it is more effective for the conflict deniers or the stakeholders who don't feel involved in the dispute.

In the following part it will be argued about some intriguing hints of innovation within two different countries, US and France representing originally opposite juridical cultures, the 'Common Law' world and the 'Civil law' domain. Referring to urban redevelopment policies and tools they nevertheless are implementing partnership approaches and related cooperation and mediation 'models' of particular interest (and potential) because of their capacity of flexibility and hybridization.

3. Emerging styles and actors for mediation and facilitation in US and France

Community Development Corporations (CDCs) are well known throughout the USA as NPO which aim at community social and economic development in low income and distressed neighborhoods. Some data may help understand the phenomenon of CDCs in USA. In 2006 there were an estimated 4,600 CDCs operating across all 50 States, some 1,000 more than in 1998 (NECCED, 2005) with an average annual production of 96,000 housing units, 7.4 million sq.ft. of commercial space, 75,000 jobs.

In order to understand the general reasons that back in the 1960s, starting with the federal programme "War on Poverty", led to the creation of these entities, their mission and focus, it is useful to refer to the consolidated literature which highlighted the use of CDCs as "*a strategy designed to solve many of the problems of discrimination, poverty, lack of citizen participation, and the failure of governmental institutions*" (Goodpaster, 1968).

This statement indirectly shows the areas of interventions and objectives typical of CDCs work which mainly relate to community empowerment, organizing, social and economic development, youth programs and job training activities (Schwartz, 2010). After the first experiences of the late 1960s when there was widespread federal funding and support for such initiatives, their focus switched from economic development towards affordable housing provision as a means through which community improvement could be delivered (Peirce & Steinbach, 1990; Vidal, 1992). Subsequently, federal funding was drastically reduced during the Regan's administration in the 1980s. In spite of this, the number of CDCs nearly doubled between 1981 and 1986 (Gittel & Wilder, 1999).

3.1 Participation, community empowerment and flexibility in US. The role of CDSs

The phenomenon of CDCs in US has been explored by a huge literature; despite some criticism about the 'supposed betraying' of the original social mission (Stoecker, 1997), the majority of authors (Hamilton, 1992; Bratt, 1989; Vidal, 1992) advocate CDCs as being able to responsively meet community needs and requirements and to represent community interests better than city-level administrations. Although from time to time some CDCs became more and more 'professional oriented', these entities should not be expected to have a 'high productivity' due to their original social 'dna'. Important comparative studies (Walker, 2002) demonstrated that there were positive results in the neighbourhoods of 23 surveyed cities where CDCs operated both in terms of results and of mitigating or preventing conflicts. Acknowledging the increasing size of the CDC industry, the number of affordable housing units delivered and the general quality of neighbourhoods reflected in the rising residential values.

However, the research on CDC phenomenon left on the background another emerging identity of these PPP tools in the urban redevelopment strategies: a real 'facilitator' of the dialogue among actors, often victims of prejudices and preconceived mistrust. In general CDCs are not an ordinary third-party facilitator, as residents often lead the Board of Directors, although including all other neighborhood stakeholder representatives in a democratically-elected, community accountable process. First of all, following the original mission of these NPOs, they are called to privilege the neighbourhood community interest.

Nevertheless, the increasing professional management skill they achieved in the last years can show their quality by playing different games for redevelopment projects, pursuing 'virtuous' agreements with a flexible panel of actors (first of all, investors and developers), treating advantageous scenarios for the community on a social, economic, financial and environmental point of view. The outstanding experience of Dudley Street Neighborhood Initiative (DSNI) in Roxbury neighbourhood of Boston (MA) is almost a unique case in this direction.

3.2 The experience of 'Dudley Street Neighborhood Initiative' (Boston, MA)

DSNI, one of the most renowned best practice of its kind in the United States, is a Non-Profit community-based Organization (NPO) created in 1984 through the passion and determination of Dudley residents, in the distressed area of Roxbury, Boston (MA), whose goal was (and still is) the revitalization of a neighborhood that in time had been ravaged by disinvestment, arson fires, criminality and dumping.

So, DSNI's mission is to empower the Dudley residents, workers and city users to organize, plan for, create and control a vibrant, diverse and high quality neighborhood in cooperation with community partners. Ever since, it has been operating in the neighbourhood, with a social and economic purpose.

In the late 1980's, through a comprehensive organizing and planning initiative, Dudley residents were able to establish community control over a critical mass of the 1,300 parcels of abandoned land that had come to characterize the neighborhood. As part of this effort, the City of Boston adopted the community's comprehensive development plan and granted the power of eminent domain over much of the privately-owned vacant land in the 62 acre area known as the "Dudley Triangle." Dudley Neighbors Incorporated (DNI) - a Community Land Trust - was an important tool for implementing the new local vision. It was created to develop Dudley's comprehensive master plan, take ownership of that land and realize a vision of redevelopment without gentrification.

Twenty five years later, more than 30 acres of formerly vacant, blighted land in the Dudley Triangle are now under neighborhood control through DNI. This land has been transformed into 225 new affordable homes, a 10,000 square foot community greenhouse, urban farm, a playground, gardens, and other amenities of a thriving urban village. Dudley Neighbors Inc. is recognized as one of the nation's most successful urban community land trusts and serves as a model for other communities organizing to promote development without displacement and long-term control of the land.

At the basis of the actions and initiatives undertaken by DSNI is a close partnership with different actors and subjects that range from NPOs to governmental agencies and other private actors.

The rationale behind the collaboration between the various partners is that DSNI does not follow the ordinary protocol of a Community Development Corporation, pursuing a changing geometry strategy for the conception, implementation and management of different projects. Due to policy lines, fundraising actions, cooperation patterns, stakeholder scenarios, DSNI looks for support creating agreements with different subjects. DSNI therefore creates appropriate partnerships with different actors, decided on the basis of the initiatives undertaken and promoted, and does not set up privileged cooperation. Therefore, it may be claimed that its role is mainly to propose, put forward and support new projects and initiatives, which are then carried out by other agencies.

Dudley Street Neighbourhood Initiative represents a unique case, from several different points of view. Although it is a community-based organization and even though it has all the characteristics common to a CDC, it is not a usual one. The great management flexibility allows DSNI to 'facilitate' the relationships between involved citizens and other stakeholders

and select the best partner on the basis of different criteria, different goals to be achieved, and different human resources to be engaged.

Evidently, it can be claimed that DSNi as a 'special community-based facilitator' plays a crucial role in urban planning and regeneration initiatives within the Roxbury area. Its special status as an *eminent domain authority organization* represents a unique case for which it is difficult to make a comparison to any other cases where a private (or public-private or non-profit) organization has been granted such a fundamental power for the planning activity. Its role within the community is proactive and its involvement in almost all of the planning and urban regeneration projects undertaken within the neighbourhood ensures that the community interest is always taken into consideration, revitalizing vibrant *urban atmosphere* and tackling any temptation of gentrification.

Through the Board structure, residents manage successfully the 'changing geometry' game of the implementation of different projects and increase the inclusionary level of all stakeholders in a democratically elected, community accountable process. Thanks to its role, DSNi was able to save and enhance the community identity, pursuing greater civic participation, economic opportunity, community connections, and opportunities for youth, beyond any diversity of language, age, race and ethnicity.

3.3 Public negotiation framework in France: the emerging role of new mediators

Since the ancient roots of the French Revolution and, mostly, the Napoleonic Code, France has been representing the most significant enduring example of the 'Civil law' culture, with a privileged, originally centralised role in the public action. From then on, the increasing prestige of the French juridical and administrative culture - with its logical arrangements in its internal structure and the 'architecture' of power distribution and management among the central and local administrations - have been influencing many European countries which chose to follow the French model and its evolution.

The general principles of the French negotiation are underlined in the *Charte de la concertation* (1996), conceived by the Territorial Planning and Environment Ministry. Mandatory for urban planning projects and for environmental policies since 2005, negotiating initiatives are adopted by the central government and the territorial communities in order to create direct relationships with affected populations. In French negotiation model many tools are available and in the last years, besides the leader role of the public administrations, private professional organisms are more and more involved and directly delivered as main responsible of the mediation and/or facilitation issues of the participatory inclusionary process.

The French negotiation consultants resume the typical coordination and mediation functions within the 'Civil law' cultural context. The public negotiation path should: product proposals, opinions and contributions replying to a specific question – 'ex ante' clearly defined – and improving the quality of decisions; enrich the project framework for the decision makers, adding new knowledge and hidden issues in order to optimize its implementation and appropriation thanks to the involved actors.

In France these professionals work sometimes in the public administration context or mostly in private firms; in the last years the French professional practice in public negotiation increased its importance right through the emerging contribution of such private consulting structures, specialized in building and animating inclusive processes with a collaborative driven approach. In about ten years these private bodies passed from the pioneering phase to the common acknowledgement by the public authorities and administrations. These consulting offices are negotiation providers, resulting from public tenders of a wide panel of public and partnership institutions. Public negotiation process is accompanied by other forms of participation: information, necessary to establish public dialogue, and consultation, which

allows querying stakeholders without constituting a direct dialogue among them (surveys, questionnaires, etc.).

The pursuit of governance network takes an even more prominent role in a legislative context composed by multiple instances leading to public participation. In France the theme of new tools and actors for coordinating the negotiation, both in public-public and in public-private relationships, permeates policy frameworks and regulatory domains of considerable importance and variety, such as, for instance, the '*Politique de la ville*' strategy and the '*Démocratie de proximité*' issue.

The first one was started by the State about thirty years ago with the mission of regenerating the blighted urban areas and reduce inequalities among territories. By the early 1970s, public authorities were aware of the difficulties of the "Grandes ensembles", huge social housing neighborhoods where the '*banlieu*' issue was exploding. After numerous cycles of alternating good and disappointing results, a new season of the '*Politique de la ville*' was recently opened by the national law 2014-173, '*Programmation pour la ville et la cohésion urbaine*' in which, the '*Contrats des villes*', city contracts between State and local collectivities for regenerating specific priority areas, are to be discussed and approved by a local Citizen board ('*Conseils citoyens*') after a diagnostic of participatory practices and initiatives. Inhabitant representatives and other local stakeholders, excluding policy makers, compose the Board that can be enhanced by external professional negotiators and mediators for setting up a virtuous inclusionary process.

The law 2014-173 is particularly cogent because it established the principle of cooperation in the construction of urban policy with the inhabitants: from then on, all regeneration tools ('*Contrats de Ville*' and any other project of urban revitalization) are to be designed and piloted by involving all citizens concerned. '*Conseils citoyens*' - created in the priority areas - have the mission to be places of exchange within the local community, to develop expertise (possibly with the support of external consultants), to ensure in every '*Contrat de ville*' the representation of the 'diverse souls' of the local human capital and create a space allowing initiatives coming from the needs of the community.

In the French context the 'proximity democracy' idea is explicitly related to the citizen's participation in local public services management and it has been deepened by the legislator introducing local democracy measures in municipalities with more than 3,500 inhabitants. The law '*Démocratie de Proximité*', introduced in 27 February 2002, suggested the creation of '*Conseils de quartier*' (neighborhood councils) in municipalities with at least 20,000 residents, making them mandatory over 80,000. Established by the City Council, they include municipal politicians, community representative personalities and residents' associations. They must play an advisory role to the mayor, mainly in the field of urban policy contributing with proposal and associated decisions in the way of public negotiation.

The '*Conseils de quartier*' let establish a genuine negotiation on issues about local public services. The periodical presence of concerned politicians and officials to listen to the request and the views of citizens is essential.

With these and other coordinated policies it is underlined the progressive change of the French negotiating framework that is moving from the original decision centralism of the public authority to the hybridization with models belonging to Common law countries where the local community, with the mediation of experts guiding the negotiation process, is taking on the 'turbine role' of the participatory process. The public administration, differently from the past, like a good referee, is mostly concerned to define the rules of the game and control the effectiveness of the process and the quality of final results. The case of the project 'Gratte-Ciel Centre Ville' in the city of Villeurbanne (Métropole de Lyon), despite choosing relatively traditional planning tools (ZAC), seems quite significant for the innovation of the participatory process and the privileged role of the mediator and facilitator actors.

3.4 The urban project 'Gratte-Ciel Centre Ville' (Villeurbanne, Lyon)

The present hyper centre of the city of Villeurbanne, belonging to the core of Lyon metropolitan area, was born 'ex nihilo' in the early 1930s. Due to the entangled efforts of a visionary mayor, Lazare Goujon, and an architect, unknown until then, Morice Leroux, the Gratte-Ciel centre is one of the most remarkable modern urban episodes of the XX Century in Europe and its skyscrapers are considered extraordinary masterpieces of the period in between the world wars, both on an urban and architectural point of view.

Today this 'historical' hyper centre is no longer suitable for the increased critical mass of Villeurbanne (145,000 inhabitants). After a long preliminary debate at the end of 1990s, some years ago (2008) an urban regeneration project was launched by the Lyon Metropolis (before 'Communauté Urbaine de Lyon' plus 'Conseil général du Rhône') together with the City of Villeurbanne for enhancing the identity of the hyper centre and giving a new dimension to the heart of the "agglomeration" by doubling its size (from 7 to 14 hectares) and delivering new residential and economic activities within a high quality public space and facility fabric. This urban revitalization initiative, in a neighbourhood marked by such peculiar heritage assets of the 1930s, is unique in France. As the original Gratte-Ciel project by Leroux in 1934 had donated a real identity and built the first new centre in Villeurbanne, it is possible to say that the planned extension in progress is one of the most ambitious flagship centralities for the new attractiveness of the entire 'Lyon Métropole'.

The framework of public, private and other partnership actors involved, mirrors the complexity of the project. The general control of the initiative is undoubtedly public, both at territorial and local level (Métropole de Lyon and Ville de Villeurbanne). The ZAC ('*Zone d'Aménagement Concerté*') project coordination and management has been assigned by the Grand Lyon institution to SERL (*Société d'Équipement du Rhône et de Lyon*), typical French public-private partnership organization (*Société d'Économie Mixte*). SERL operates in partnership with public and private actors to develop and implement urban regeneration projects in the region. Founded in 1957 on the initiative of local officials, SERL associates in its capital, the majority of local authorities and economic and financial partners.

In 2008 the first general master plan was entrusted to the famous planner Christian Devillers and its firm (ADA), whose blueprint construction has been the basic shared scheme for developing, in the second phase (from 2014 on), two detailed planning detailed scenarios, conceived by the planning and design firm ANMA.

Looking at the specific issue of the negotiation process, in the beginning of the first phase (2008-2011) the conduction entrusted to the public authorities followed the traditional "bottom up" approach with several opportunities of stakeholder involvement in the usual 'debat public' configuration. Despite the rhetoric of some official documents (mainly by the public actors), it is clear that the usual consultations (conferences, public meetings, confrontation with planning and design specialists, etc.) showed an evident asymmetry condition between privileged and 'weak' actors, a rarefied presence of widespread stakeholders (120 people in the 'ateliers', an average between 150 and 250 attendances at the main meetings) and a concrete contribution of only 26 organised remarks in the final report of public negotiation approved in the beginning of 2011 (period 2007-2010).

After almost three years of reflexion, the main pilot authorities realized that something different should be 'invented' for pursuing an authentic participatory democracy in the long way of the project implementation (2008-2027). The issue is not properly focused on the main planning and design axes that could be considered more or less sufficiently shared. The values and problems are extended to the symbolic identity of the new great centrality of Villeurbanne within the Lyon metropolis. And to the capacity of mediation relating to the very local interest of a huge number of single landowners involved by the urban regeneration plan.

The critical mass of the project area is the image of a strong ambition, expressed in the desire to 'build a great metropolis' and an attractive centrality 'that must be' an opportunity to

build a smart city, taking care of the environment and its inhabitants. Gratte-Ciel Centre-Ville will be a real laboratory for a sustainable city, a place to invent and implement the innovations of the future daily life.

Nevertheless this complexity at the very local scale involves the acquisition of a large number of plots and, presumably, a significant number of expropriations. This involves a significant risk of conflicts (of interest) with landowners for economic, social, practical or emotional reasons (the inhabitants are older than the average as indicated in the preliminary reports). These potential (or sometimes already emerging) conflicts could stop or viciously delay the implementation of the project to be realized in the next 12 years.

Therefore, in order to avoid such risks, in March 2015 the SERL has decided to appoint a private enterprise specialized in negotiation, mediation and facilitation to conceive, drive and implement the complex strategy of negotiation (*'strategie de concertation'*) for the 'Gratte-Ciel Centre Ville' regeneration project.

The strategy underlines that all involved stakeholders - privileged and recessive, public, private and non-profit - should be oriented in pursuing shared negotiation and participation values, following new themes as the 'urbanity of the public space', the 'liveability and greening' of the renewed skyscrapers - taking care in particular of general interest space (both common and private) - the transformation of in progress construction phases in opportunities (temporary space management for inhabitants initiatives, creative activities, artistic interventions, experiments, etc.).

4. Intriguing hybridization scenarios for community empowerment

Of course these reflections do not presume to indicate new absolute models of participation; however, hints of innovation within different cultural domains are clearly supported by the evolution of the roles of cooperation for the negotiation process through the contribution of mediation and facilitation expertise.

Best practices show that the community empowerment goal is possible, by place-based deliberation. A cooperative approach is needed to enable local development, by leveraging on the necessary mediation (when conflicts are already in progress), or facilitation (if it is possible to prevent them) between stakeholders and decision makers. And the traditional gap between privileged and recessive actors can be reduced through the professional action of mediation and facilitation experts.

Decentralized 'changing geometry' participatory models can be embraced, to get close to the authentic needs of local communities. Since the end of 90s, projects and experiences in US and Europe have been fostering these principles and enforcing good practices, in order to progress towards the real sustainability of an inclusive democracy.

Widespread in US as an effective tool for social and economic redevelopment in blighted neighbourhoods, CDCs identify an intriguing model of citizen empowerment, following the place-based approach within a 'changing geometry' philosophy. Nevertheless, there is an emerging dimension: the DSNI experience represents a cogent case-study in a virtuous mix of facilitation activity and civic empowerment mission.

The rationale which supports the CDCs action is embedded in the local scale, as neighbourhoods may be the effective economic development and employment generators thanks to the cohesion and mutual support which can be built in such communities. Thus, the CDCs social and economic redevelopment model strongly relies on bottom-up approach where residents' participation becomes central to the achievement of their mission and vision. As such, the benefits of CDCs, compared to the action of superimposed governmental

institutions, are linked to their ability of responding to, and take advantage of development opportunities in a faster and more flexible way than the public power.

In France, public participation, negotiation, mediation and facilitation are part of the public consultation process called '*concertation publique*'.

In this field, professionals of French consultancy firms (*bureaux d'étude*), are more and more involved in mediating area-based participatory processes for the territorial development with a multi-stakeholder approach, becoming increasingly effective and "mitigating" the original dominating role of the public power in the participatory democracy process.

Despite the enduring central role of the public administration in the participatory models, the general framework is changing in France: subsidiarity policies, new horizons for innovating the increasing pressure of communities and peculiar stakeholders in the public negotiation scene are related to the specific contribution of mediation and facilitation professionals, entrusted by the public authorities to manage the dialogue among the different actors, tackling or mitigating the occurrence of potential conflicts and pursuing inclusionary project scenarios.

It is interesting to stress how the original 'Civil Law' model, historically based on the incumbent, pilot role of the public administration (in France and in Italy too, for instance), has been progressively introducing flexible features, hybridizing somehow 'Common Law' styles within the stakeholders relationships and roles for fostering a consensus scenario. In this respect, Villeurbanne case-study represents a significant example, still in progress, of the increasing importance of the professional negotiation agencies in the public participation inclusionary process.

Moreover, in the involvement of the private and the public spheres, the case studies illustrate different economic implications.

In the *DSNI* the fragile balance between public and private sectors was managed by the 'leading' role of the Community based organization and its capacity of assuming at the same time different identities in the local scene: non-profit organization looking after the community interest, facilitator for the access to public resources, mediator with the developers, facilitator for preventing or mitigating local conflicts. The success of the redevelopment process was related to the 'flexible geometry' approach for the involvement of multiple and heterogeneous stakeholders, with the limited presence of public authorities. In such cases, when social problems are both the critical issues and the major driving force for the regeneration process, the possibility of adopting a flexible partnership model is strategic.

In both the CDC experience and in the French negotiation, run by the professional mediation firms, the hybridization of the 'civil law' with the 'common law' approach can occasionally allow the Public sector to be seen in a mutating role, changing from being a 'resource provider' to a 'resource broker', and a facilitator for the involvement of private investors and other fragmented stakeholders in the redevelopment process. In this sense, the Boston case as well as the Villeurbanne project cannot do without the direct and active involvement and cooperation of the entire local community in a flexible context of regeneration strategies.

The historic, original models are passing through an intriguing process of hybridization: in the US a new generation of NPOs, guided by the CDCs experience, appears to be more effective if the public government becomes a virtuous mix of the traditional 'referee' role and a sort of 'soft driver' when primary and urgent circumstances require a more active role and a direct public initiative; almost the opposite of what has been going in the 'Civil law' context where the centralised power is giving more and more space to the mediation and facilitation private expertise in order to bridge the gap between decision makers and local fragmented communities, starting from France experience as it was stressed before. Within this physiological trend it is crucial to join a 'flexible geometry' approach, interpreting the changing conditions of local culture, economy, society, time, and space.

Abstract

Changing city dynamics such as stagnant economic growth and the increased presence of diverse groups have led to increased polarization and exclusion in cities. Managing these dynamics requires that cities reinvent ways of fostering inclusiveness and collaboration in the planning and development process. Both local and federal government can play a significant role in fostering inclusion. This paper highlights several inclusive practices adopted by grantees (regional and local planning agencies) of the U.S Sustainable Communities Initiative (SCI) to bolster cooperation among governments, communities, civil society and businesses towards equitable growth.

1.0 Globalization and Changing City Dynamics

Over half of the World's population now lives in cities. Hence, cities embody the spaces where the fight for social inclusion, cultural diversity and economic growth will be won or lost (Kornberger 2012). Cities are engines of economic growth, social innovation as well as places to experience rich cultural diversity. Cities also host the highest concentrations of poverty, exclusion, ethnic polarization and segregation (Wacquant 1999, Atkinson 2000, Cassiers and Kesteloot 2012). Globalization and its associated processes, such as immigration and capital flows, continue to compound these challenges. For instance, the movement of capital from certain regions to others and the economic restructuring ongoing in many cities has rendered many city residents jobless, increasing poverty as well as social polarization (Wacquant 1999, Atkinson 2000, Defilippis 2004, Musterd and Ostendorf 2013). Increased social division and inequalities have heightened social exclusion for some, which in turn limits their ability to fully participate in the society (Musterd and Ostendorf 2013).

2.0 The Why, How and Costs of Social Exclusion

Groups are excluded or included on the basis of their identities that are defined by race, gender, ethnicity, religion, social status and disabilities (Beall 2002, WorldBank 2014). In all countries, whether developed or developing, various groups - such as immigrants, ethnic minorities and indigenous groups - face barriers that exclude them from participating in the social, political and economic processes of their countries (WorldBank 2014). Exclusion manifests through various forms like outright denial of basic services (housing, water, education, etc.) to limited opportunities in accessing social protection and economic opportunities. For instance, a study by Aalbers (2011) shows that lower income groups and racial minorities in the USA, Italy and Netherlands are more likely to be excluded from the mortgage markets through redlining or predatory lending in form of costly subprime loans (Aalbers 2011). According to the 2011 Uganda Demographic and Health Survey, people from the majority Baganda ethnicity were ten times more likely to have electricity as compared to the ethnic minority Lugbara and Ngakaramajong (WorldBank 2014)

Exclusion is costly both to the individuals being excluded and the governments of those Nations where such groups reside. A 2014 World Bank study found that Romania incurred about €887 million loss in productivity as a result of excluding the Roma people, an ethnic minority (WorldBank 2014). Similarly, the same report estimates that ethnic exclusion reduced agricultural productivity by up to 36 percent in Bolivia. Therefore, inclusion matters not only in itself but also as an economic imperative.

While the path towards inclusion may be uncertain and lengthy, there is evidence that inclusion can be planned and achieved (WorldBank 2014). Studies (Boonyabanha 2004, Brakarz and Aduan 2004, Cid and Paul 2004, Boonyabanha 2009) suggest that government actions and policies in markets, social services and spatial development can be powerful tools of fostering inclusion. For example, promoting access to services such as health and education may enhance human capital (Butala, VanRooyen et al. 2010). Improving transportation may boost mobility, hence connecting individuals to social and economic opportunities. Well-planned physical spaces that encourage integration can be useful in bridging social differences and attitudes (WorldBank 2014).

Through targeted interventions, the current exclusion in cities can be addressed. Nevertheless, effectively dealing with exclusion will require transformations in the ways planning decisions are made and how development takes place. For example, the recent economic recession has led to reduced city revenues, compromising the ability of governments to single handedly provide for their citizens (OLIFF, MAI et al. 2012, Pianin

2014). Consequently, addressing the current social inequalities and exclusion in cities will require concerted efforts among a wide range of actors including national and local governments, private actors as well as local communities.

The section below documents practices adopted by grantees of the USA partnership for Sustainable Communities Initiative (SCI) to include traditionally marginalized communities in metropolitan planning and decision-making processes. Information used for this paper is mainly drawn from a study carried out by PolicyLink on inclusive governance practices among several SCI grantees. PolicyLink is a national organization that deals with economic and social inclusion in the USA. The study was part of a capacity-building process that PolicyLink carried out for SCI. Additional information was obtained from agencies websites and project documents.

3.0 The Partnership for Sustainable Communities Initiative (SCI), USA: Working Together To Foster Regional Growth Through Inclusion

The Sustainable Communities Initiative (SCI) is a partnership of the U.S. Department of Housing and Urban Development (HUD), U.S. Department of Transportation (DOT), and the U.S. Environmental Protection Agency (EPA). The partnership established in 2009 and still ongoing seeks to coordinate federal investments in economic development and affordable housing with transportation and related infrastructure improvements. The program funds local and regional partnerships to plan and implement integrated projects that connect communities to opportunities by linking affordable housing, transit and job opportunities. The projects range from transit infrastructure, walking and cycling infrastructure, urban renewal programs and brownfields planning research. By 2012 the program had funded over 700 communities across the USA at a cost of over \$3.5 billion. Figure 1 below shows the distribution of SCI funded projects between 2009 and 2012.

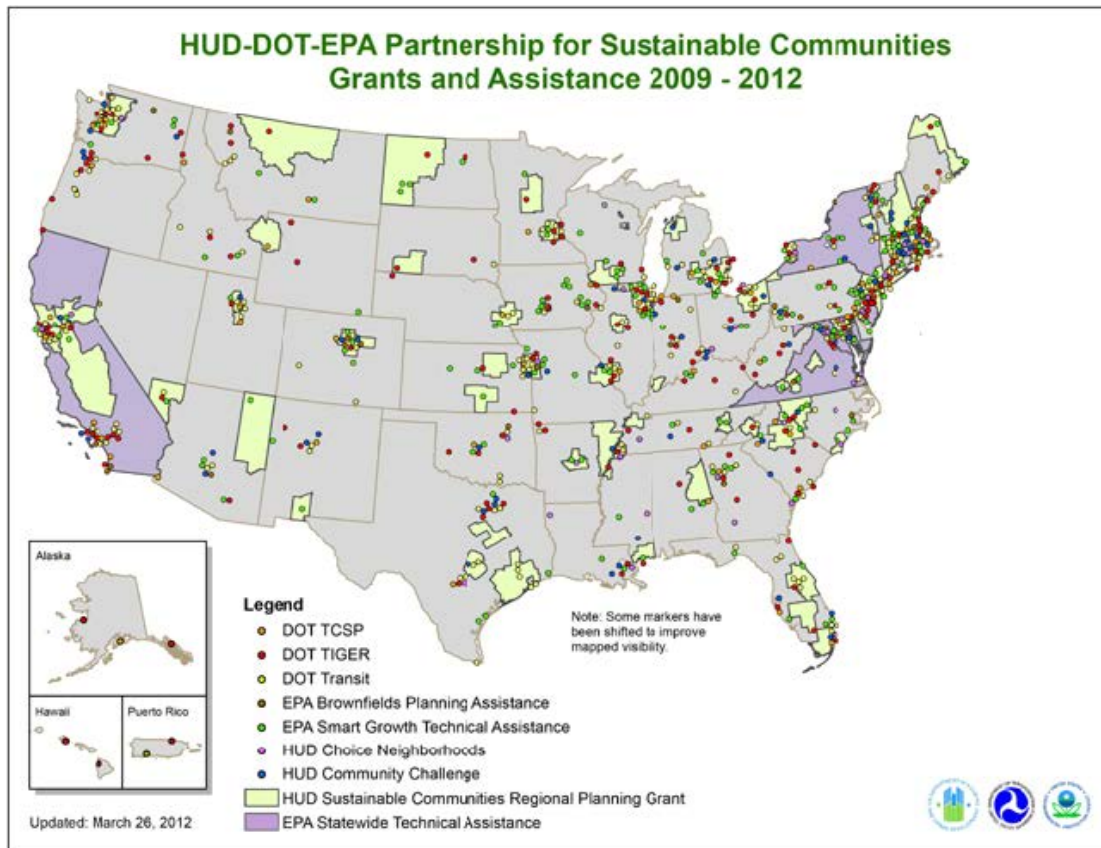

Figure 1: SCI funded Projects Between 2009-2012

Source: *Partnership for Sustainable Communities Accomplishments Report 2009-2013*

One of the SCI partnership's key objectives is to foster inclusive economic growth. Such growth should create a strong foundation for shared long-term prosperity and provide decent jobs to those that need them the most, particularly communities of color and low-income groups. To ensure inclusiveness in the regional planning and development processes, the SCI program requires regional grantees to partner with a wide array of stakeholders before they can qualify for grants. Particular emphasis is placed on working with equity leaders, communities of color and other leaders from communities that have traditionally been excluded from government planning processes.

This push by the federal government for local agencies to be responsive to inclusion has resulted in planning organizations applying various inclusive practices to eliminate barriers to community engagement as well as coalition formation with civil society and businesses. This paper documents practices adopted by Puget Sound Regional Council; the Metropolitan Council, Twin Cities, Minnesota; and the Boston Metropolitan Area Planning Council (MAPC) funded under the SCI model to create inclusive working partnerships in planning and development processes.

3.1 Puget Sound Regional Council: The Growing Transit Communities

The Puget Sound Regional Council (PSRC) is a planning organization for the Central Puget Sound region of Washington State. The region covers four counties (King, Pierce, Snohomish and Kitsap) with an estimated population of 3,898,720 as of 2015 (PSRC 2015). The council was funded in 2010 through the SCI to develop the Growing Transit Communities (GTC) Strategy- a transit network for the Puget Sound region. Built around the Transit Oriented Development (TOD) concept, the strategy seeks to create transit-served neighbourhoods by providing affordable housing, transportation options, employment investments and essential amenities around high capacity transit stations. The GTC strategy was completed and approved in 2013.

Several inclusive practices were observed in the Puget Sound region planning process. First, a broader stakeholder inclusion and robust community engagement regime demonstrated through the Growing Transit Communities Partnership. Second, an equity-oriented policy processes achieved through the establishment of a regional equity network. Lastly, a commitment to continued collaboration through the establishment of a Growing Transit Communities (GTC) compact as well as the institutionalization of equity measures in the Councils overall policy making process. The section below gives a detailed account of the above practices.

I) Establishment of the Growing Transit Communities Partnership (GTCP)

The Growing Transit Communities Partnership (GTCP) is a diverse coalition of partners established in 2010 prior to the application of the grant as was required of SCI grantees. The consortium consists of Puget Sound Regional Council (the lead agency), local governments, non-profits, businesses, developers and transit agencies. This partnership developed the Growing Transit Communities Strategy mentioned above, which coordinates investments in housing and jobs around high capacity transit. The consortium spurred several changes in the council's decision-making and planning processes such as the creation of the Regional Equity Network consisting of GTCP members and a robust community engagement process.

II) The Regional Equity Network (REN) and Community Engagement

Realizing the resourcefulness of non-profits and equity leaders in the region, the Council together with the GTCP established the Puget Sound Regional Equity Network (REN). The Puget Sound REN is a team of equity-oriented individuals and organizations working within the Puget Sound Region. The Network was initially tasked with assisting the commission to

weave equity into the GTC Strategy by providing 'expertise on equitable development principles and strategies'. The Equity Network liaised with communities to identify community-pressing needs to be included in the strategy. PSRC together with leaders of the Community Development Corporations (CDC's) provided funding to the Equity Network to facilitate its work with local communities regarding the plan.

The Equity Network was instrumental in ensuring that low-income communities and immigrants actively participated in shaping the plan outcomes. For example, with the help of REN, PSRC reached out to over 40 local groups representing immigrant communities and different religious and socio-economic groups to participate in the plan-making process. These community groups were provided with community grants to foster 'engagement, organizing and research'. Additionally, the Equity Network also carried out Opportunity Mapping to identify communities that needed investments the most. Lastly, the Equity Network also organized a joint regional Equity convening drawing over 400 participants from the public sector, private sector, non-profits and local communities to contribute to the GTC strategy formulation.

After the end of the grant period, the Equity Network continues to exist, fully supported by the council through the provision of administrative facilities such as meeting spaces and support staff. A member of the Network liaises with Council staff from time to time to ensure continued representation of community issues.

III) The Growing Transit Communities Regional (GTC) Compact

To facilitate the participation of partners post the grant period and in the plan implementation process, an agreement popularly referred to as the GTC compact was established. The compact is a commitment signed by partners that were part of the plan-making process to continue in the plan implementation. Though the compact is not legally binding, it provides opportunities for collaborative plan implementation as well as continued cooperation among partners. Members are allowed to pursue and implement strategies in line with local conditions and their organizational goals and budgets. As of March 2015, 40 organizations had signed the compact and committed resources in actualizing the GTC strategy. This buy-in by the partners and resource leverage was as a result of their inclusion in the design process.

Additionally the council formed a new regional TOD advisory committee that draws members from the compact and requires that one of the co-chairs of the committee represent non-profits or equity interests.

3.2 The Metropolitan Council, Twin Cities, Minnesota

The Metropolitan Council of Twin Cities in Minnesota covers a 7-county region with a population of about 3 million people. The council benefited from a \$5million HUD SCI grant in 2010 to engage in the planning and implementation of a regional transit initiative referred to as the “Corridors of Opportunity” (COO). COO’s main goal is to enhance access to opportunities near existing and planned transit ways in the region, especially for those with greatest need, through investing in transit enhancing strategies, affordable housing, and minority owned businesses near transit.

As required by SCI, the Metropolitan Council established a consortium structure consisting of a wide of range of stakeholders that included representatives from the state and local governments, the non-profit sector, philanthropists and the business community. The inclusion of diverse stakeholders in the planning process and especially the non-profit sector led to transformative steps within the Council decision-making structure as well the Council’s ability to leverage private equity. Below is a detailed account of the key steps taken by the council to enhance inclusion.

1) Establishment of a Community Engagement Team

Recognizing the importance of community engagement in the planning and implementation processes, the council together with the partners established the Community Engagement Team (CET). The CET drew members from three equity-focused community groups (Alliance for Metropolitan Stability, the Minnesota Center for Neighborhood Organizing and Nexus Community Partners) and worked to identify community assets and effective strategies of ensuring community inclusion in the COO planning and implementation processes (MetCouncil 2015).

To demonstrate the Council’s commitment to community engagement, a total of \$750,000 from the SCI grant was set aside to facilitate community engagement processes. CET was charged with overseeing the \$750,000 community re-granting process in addition to leading all other community engagement activities within the planning of Corridors of Opportunity. Through the re-granting, CET targeted community groups that work with underrepresented groups (communities of color, immigrants, low-income communities) to enhance their participation in decision-making and leadership activities related to COO planning and implementation processes. In addition to working to bring all relevant participants on the table, CET was instrumental in promoting systems change within the COO policy board. For instance, the initial policy board lacked equity leaders and people of color representation.

After CET raised the issue, the council was receptive and approved the expansion of the board to include equity leaders and community of color representatives with equal voting rights to all other members.

II) Staff Training on Equity and the Designation of a Full-time Equity Staff

The effectiveness of any public institution in delivering its mandate is highly dependent on the staff. Hence, during the grant period, all council staff were required to go through an equity training program to appropriately equip them to deal with the new dynamics and expectations to deliver on equity. This initiative was highly supported by the council and mayor. Additionally, the Met Council designated a full-time staff member to work specifically on equity issues by partnering with the Community Engagement Team on an ongoing basis even beyond the grant period.

III) Passing of Equity Resolution:

In 2013, the council passed an equity resolution to allow the establishment of a temporary equity workforce with the main task of assessing how the Council's internal and external policies and practices met or contributed to equity. Specifically the team was expected to make recommendations to the council on specific measures to bolster equity in its policy and decision making processes and particularly how to include communities of color and historically underrepresented communities in the council advisory committee. This commitment to equity culminated in the development of the ***“Choice, Place and Opportunity”*** report (MetCouncil 2015). This Met-Council report aimed to raise awareness on the interconnectedness of income, race, place and opportunity and to challenge actors in the region to ‘think regionally and act equitably’.

IV) Continuation of Corridors of Opportunity through Partnership for Regional Opportunity

Realizing the benefits of collaboration, the council vowed to maintain the COO beyond the grant period by establishing “The Partnership for Regional Opportunity (PRO)” (MetCouncil 2015). The Council sees PRO as a move from partnership within a single project to long-term commitment in the delivery of equity-oriented development. The partnership composed of former COO members is organized around 4 themes which include Regional Equity and Community Engagement, and Shared prosperity: Transit-Oriented Development and Transportation funding. It is important to note the maintenance of the Regional Equity and Community Engagement team. The new taskforce entirely focuses on promoting equity

through identifying and recommending policies and investments that reduce regional disparities and ensure continued engagement of historically underrepresented groups in the region's planning processes.

3.3 Boston Metropolitan Area Planning Council (MAPC)

MAPC is a regional planning agency within Boston that serves 101 cities and towns in the region. MAPC's commitment to inclusion materialized in 2008 when they launched the State of Equity Initiative to monitor key indicators of equity in the region (MAPC 2015). This commitment to equity and inclusion was bolstered by a 2010 grant from the SCI. The grant was awarded to implement Metro Future, which is MAPC's long-range development plan for the Metro Boston Region. The plan seeks to advance smart growth and partnerships in the region through 'investing in efficient transport systems; environmental preservation; equitable economic growth and enhancing access to education and health opportunities to residents' (MAPC 2015)

Following SCI's requirement of collaborative planning, MAPC established 'The Metro Boston Sustainable Communities Consortium'. The consortium consisted of a wide range of partners including: non-profits, trade associations, medical and educational institutions, and public and municipal representatives. Led by a 27-member steering committee, the partnership required that at least one member of the committee should come from an organization whose core mission include "reducing inequities among populations in the region, and building power in minority groups and low-income communities"(MAPC 2011). Key indicators of inclusion within the MAPC's decision-making systems include the following:

1) Establishment of Equity at MAPC Plan

Equity at MAPC is an initiative of the council established in 2010 and led by the Equity at MAPC team whose main task is to guide the agency in implementing equitable and inclusive practices and policies. The MAPC equity team, which consists of staff members drawn from diverse departments, works to:

- **Transform the organizational culture** towards equity by creating awareness among staff on equity and cultural diversity. Staff and project evaluation are mainly based on their contribution to equity;
- **Ensuring that the agencies policies, standards** and decision making processes reflect equity;

- **Transforming the administration and governance** within the agency by increasing diversity in staff hiring, committee representation and ensuring departmental collaboration towards equity;
- **Establishing equity standards** in the region's service delivery and;
- **Increasing access to information and transparency** within the organization by creating feedback channels and improved communication and relations with partners. This includes translating working documents to all languages spoken by the area residents.

II) Deep Community Engagement

Although community engagement was an important part of the MAPC MetroFuture planning process, it was during the SCI grant and implementation process that community engagement reached a critical high. As noted by one of the staff working at MAPC, "*... it was in the SCI that we reached the tipping point for people to understand that robust community engagement is an essential part of any planning process and that it is not enough to consult with the planning board or the council but that the community needs to be involved in a meaningful way...*" (Amy Cotter 2014). This realization was capped with a substantial amount of resources committed to community engagement during the plan implementation process and SCI grant period. For instance, part of the SCI grant was appropriated to enhance community participation, especially in the selection of projects to be implemented.

In addition several other provisions, such as providing childcare in meeting venues, translation and interpretation of documents in several languages, were made to enhance community engagement in the process. The MetroFuture plan was translated into 7 languages to allow easy dissemination to communities living in the region - especially immigrants. Furthermore, the 'Community Leaders Breakfast Series at MAPC' was established to create opportunities for diverse leaders in the region to exchange knowledge and ideas on an ongoing basis.

4.0 Conclusion

As a result of the world's population residing majorly in urban areas, how cities are managed will largely determine the success or failure of the quest for social inclusion. Cities that thrive will be those that seek to harness the wealth of resources presented by diverse populations and multiple actors. The cases from the Sustainable Communities Initiative projects demonstrate the great role that federal and local agencies can play to foster inclusion and collaboration in city building. Particularly the cases demonstrate the enabling

role that national or federal governments can assume to direct resources and drive local governments and agencies towards inclusion.

The requirement for the formation of inclusive partnership before grantees could qualify for SCI funding was instrumental in pushing local agencies to collaborate with a wide array of actors including traditionally marginalized communities. Inclusion proved not only to be beneficial for hitherto marginalized communities but also for cities and regions. For instance the move to collaborate with other actors was instrumental in leveraging private equity. The \$240 million in grants disbursed by HUD between 2010 and 2012 attracted \$253 million in private investment and commitments from local partners(EPA 2012).

The involvement of a wide range of actors in the Puget Sound Regional Council not only led to identifying the needs of local communities but also led to financial commitment by majority of the partners to implement the plan. Likewise, in Twin Cities, it wasn't until they had fully involved the equity leaders in the region that they realized how critical it was to also have appropriate racial composition in decision-making organs within the council. The inclusion of partners in Twin cities also translated to a continued pledge to work together and implement the plan through the Partnership for Regional Opportunity (PRO). In Boston, partnership with equity leaders and communities completely transformed how business is carried out through organizational culture change and embedding equity in all processes.

Overall, the cases clearly demonstrate that achieving social inclusion is an interplay between state and non-state actors. For example, though it is very clear that the federal government played a critical role in mobilizing planning agencies towards inclusion by tying funding to collaboration, it was the concerted efforts of all those involved that translated to inclusive practices. It is therefore critical that all actors involved in city building hold each other accountable, particularly in ensuring representation of local and underrepresented communities in decision-making processes.

Governing the Urban Infrastructure in Indonesian Cities: The Role of Institutional Structure and Policy Instruments in Collaborative Policymaking and Resource Exchange

Mahesti OKITASARI, UNU Institute for the Advanced Study of Sustainability, Japan

1. Introduction

Cities and metropolitan regions are the source of urban opportunities and challenges. In the developing economy such as Indonesia, the fast development growth put heavy pressures for city managers not only to provide basic urban services but also seamless ones. With the increasing urbanization rate, the demand for urban service mounts, particularly on infrastructure and energy, fresh water, sanitation, education and health service (UN DESA, 2013). Regardless the configuration of the governing system, the way urban infrastructure is governed continuously undergoes tremendous changes. Besides the opportunities and challenges presented by urbanisation, the alteration cities made in governing infrastructure are largely due to globalisation, which produces more tension on the local governing system. In particular, these challenges force cities to surpass local administrative and political boundaries as people expect seamless urban service.

This paper focuses on Indonesian collaborative metropolitan governance. It deals specifically with the governing of urban infrastructure in the border areas, in particular water and sanitation. This paper extracts findings focusing on the linkage between local institutional structures, policy instruments and collaborative activities. It aims to fill the gaps as research on collaborative governance in Indonesia has yet developed a real traction and the causal effect of local policies to the working of collaboration associated with policymaking and resource sharing remains under researched. Since the collaborative activity has become a consequential factor of city's infrastructure provision efforts as it relates to how cities manage their resources, research on the interlinkages between these issues help explaining the local governments' outlook on collaboration. Understanding the institutions and its linkage to the local policy outcomes and activities will also supply local governments with strategical information to advance their collaboration.

Applying to three metropolitan regions in Indonesia, namely Surabaya, Yogyakarta, and Denpasar, this paper explores the differing actor interaction and collaborative processes. Understanding the linkage between institutional structure and policy approaches allow us to explain the complexities of the governing of urban infrastructure in the city and between cities. It helps explain which policies would encourage or limit certain type of collaboration; intergovernmental or cross-sectoral, giving idea on practical issues needed to be addressed for governance reform. This paper argues that establishing a multistakeholder collaborative process of policymaking and resource sharing, regardless actors' motivation, varies according to the types of policy instruments and institutions adopted in the local jurisdiction.

1.1 Policy Approach on Collaborative Governance

Collaboration is strategic and embedded (Agranoff and McGuire, 2003b). The embeddedness and strategic nature of collaboration create interconnectedness between collaborative forms and actors involved and, in many cases, are driven from specific policy problems. In this sense, types of policy instruments characterising a collaborative activity directly influence the form and content of collaborative structure (McGuire, 2002). Thus, policy approach is undoubtedly difficult to be separated from any discussion considering collaboration and governance at large.

Policy streams, policy domain, actors, network and governance processes are one big interconnected system. In a similar hypothetical vein with the way collaboration formed, policy is the result of the interaction between actors in a certain situation which actors use perceptions to interpret their reality and to choose their strategies (Klijn and Teisman, 1997). The situation where the actors reside is conditioned by the rules and resource divisions of the network in which they take place. These rules and resource are part of the institutional setting of the governance system. Moreover, governing policy process in the network means managing the interactions in the situation and the setting of the said situation. Hence, managing governance also consists of managing policy process in governance network.

In the process of public policy making, for multitude of reasons, complex variables used as considerations complicated the process. There are various frameworks on policy process that is consistent and possess a fair amount of empirical testing. Among them, from the institutional perspective, are institutional rational choice (Ostrom, 1990), social construction (Ingram et al, 2007) and policy advocacy coalitions (Sabatier and Jenkins-Smith, 1988; 1993; Sabatier, 2007). Rational choice theory analyse within political institutions and society. It emphasises on examining policy change and its variety and measuring the stability through strategies taken by actors (John, 2003). Policy as an outcome are seen as the effects of the collective choices which makes it possible to examine the ways which collaboration emerge from analysing the policy process. On the other hand, policy advocacy coalition and social construction focus on understanding the shared value system and its influence toward actor relations (Ostrom, 2007). In particular, social construction sees that policy design shapes institutions and, thus, affects their broader society system (Ingram et al, 2007).

The core concept of policy instrument that refers to the political sociology conception (Linder and Peters, 1989; 1990) put efforts to bridge the gap between institutional structure and policy process. Their proponents see policy process as a part of instrumentation and can be examined in order to understand the motive leading to decision of selecting instruments and its implication (Kassim and Le Galès, 2010). In the similar manner, policy instruments and policy tools structure the interaction of actors within a governance network (Salamon, 2002).

There are many different typologies of policy tools and policy instruments that have been introduced. Salamon (2002) generally provided the most extensive overview of policy tool definitions and characteristics, particularly concerning regulatory and fiscal. Linder and Peters' synthetic policy design approach (Linder and Peters, 1990) presented a more general approach, a sample list that is more ensuring a representative field rather than imposing an artificial structure on people's perceptions compared to Hood's the tools of government (Hood, 1986). They also do not confine their list into a typological segregation like Hood's.

1.2 Governing Urban Infrastructure in Indonesian Cities

Governing urban infrastructure in Indonesia has been a constant struggle and even more so after the decentralization. While much attention has been on the administrative and fiscal decentralization of infrastructure provision to the local level, in practice, delivering urban infrastructure has been scaled up as a regional challenge, largely fuelled by lack of local infrastructure investment, disconnected infrastructure and regional disparities between cities. Pressures associated with resource scarcity and limited capacity often require that local governments act as catalysts for orchestrating other actors in the pursuit of providing urban infrastructure.

In order to accelerate the infrastructure development through the promotion of sectoral and intergovernmental collaboration, since mid of 2000s the central government has gradually enacted responsive policy instruments. The advocacy from the central government and the continuous remnant of decentralization have been inducing a repeat of institutional change at the local level. Against this background, local governments continue to struggle with the fragmented decision making and conflicting policies, largely in isolation between cities, sectors and different levels of governance.

1.3 Case studies: Surabaya, Yogyakarta, and Denpasar

As a vast archipelago country with large population consists of different ethnic, social, economy and cultural background, governance in Indonesia is built upon a fragmented system which varies according to cities and regions. Although the local governing system across the country follows the same framework given by the central government, the way local governments manage cities differs according to the underlying political and socio-cultural system embedded in the cities. The differences include how local governments behave with their neighbouring cities and with the higher levels of government. The political situation that often differs between jurisdiction and between actors managing the cities play an important role in shaping the local governing system. While during the centralised regime, these differences were abolished or largely ignored, decentralization nurtures them.

Decentralization brought changes on how local fiscal situation affects local decision making and relations. Under the fiscal decentralization law (Law 25/1999 amended 33/2004), the central government designates the equalization grants and sharing revenue to the local government which range between 50-80 percent of total local revenue (calculated from budget reports 1999-2013). In cities rich with natural resources, shares are usually higher. Yet for cities in the metropolitan regions the differences between cities are not high as most cities share similar characters; lack of natural resources and better capability to generate own revenue. Bigger cities, more often than not, receive smaller shares of fiscal transfer from the higher levels of government. As a result, cities with higher revenue but less central fiscal transfer have a higher command to govern their area which leads them towards a less control from the provincial and central governments. They also have more fiscal room to set local fiscal instruments than cities with higher shares of central fiscal transfer.

This paper examined 3 metropolitan regions distinct in economy, socio-cultural, and political characteristics to grasp a comprehensive overview of how collaborative metropolitan governance is managed in fragmented Indonesia. Economically, Surabaya region has the largest economic size according to its share of National GDP; 6.0 percent compared to Yogyakarta (0.7 percent) and Denpasar (0.8 percent). The regional disparity also differs among observed regions; Surabaya (0.987), Yogyakarta (0.401), and Denpasar (0.324) (Williamson Index on regional disparity, calculated using 2012 data). It is important to note that while Surabaya and Denpasar regions are predominantly urban, Yogyakarta has a higher percentage of rural area. Socio-culturally, the paternalistic culture is observed stronger in Yogyakarta compared to other regions due to the sultanate system of the region. This influences strongly the political situation of the region, which mostly homogenous over the years. Denpasar region also has a homogenous political environment with cities having a similar political majority and less political differences between the head of the cities and the local assembly. Surabaya region, on the other hand, is politically heterogeneous.

The observed regions vary on their historical establishment of collaborative metropolitan governance. The framework of collaborative metropolitan governance in Surabaya region was first set by the provincial government prior to the decentralization (commonly known as *Gerbangkertasusila*) while the collaborative arrangements in Yogyakarta and Denpasar were initiated by local governments after the decentralization, in 2001 and 2002 respectively. Collaborative governance was restructured to adjust to the change of governmental system and Surabaya observed the vacuuming of provincial power in managing its collaboration, while Yogyakarta managed to retain it. The collaboration in the Surabaya region is at present highly run in sectoral basis (e.g. infrastructure, transportation, planning) instead of comprehensive, unlike the collaboration observed in Yogyakarta and Denpasar. However, despite sharing similarity in the framework, collaborative governance in the latter cities differs from each other in term of partners. Yogyakarta is highly intergovernmental while Denpasar exercises both cross-sectoral and intergovernmental collaboration almost in an equal manner. With the decentralization giving the reign to local governments in planning, managing and financing their cities, assessing these regions in their institutional and policy approach is a step towards understanding Indonesian collaborative metropolitan governance.

2. Methodology, Data and Limitation

As this paper aimed to extract findings focusing on the linkage between local institutional structures, policy instruments and collaborative activities. The analyses were divided into 3 parts; to measure the institutional structure in collaborative activities, to assess the local policy instruments, and finally to examine the linkage between the first two analysis.

2.1 Measuring the Institutional Structure in Collaborative Activities

The measurement of local actors' interaction to assess the institutional structure of collaborative metropolitan governance is built on the basis of the operationalisation of regionalism. It assumes, horizontally, higher interaction between local governments and neighbouring cities and other local actors will result on higher probability of local governments becoming more proactive towards collaboration. The interaction can be sought through either formal or informal relations. Moreover, the measuring of institutional structure through local actors' interaction reflects the local capacity in handling certain functions on a multijurisdictional basis in developing collective platform, bargaining, and determining certain activities within their allowed capacities. In collaborative policymaking activities, the institutional structure is measured by identifying whether local governments include other local actors in the planning, goal development, and decision-making tasks of policy making. Similarly, collaborative resource exchange activities involve seeking and acquiring resources from multiple actors, as well as combining and leveraging resources among actors.

Unlike collaborative policymaking that is largely expected and practiced among policy makers, resource exchange is more challenging for local governments to pursue due to the complicated political and administrative nature it entails. Nonetheless, resource exchange is a necessary component to measure the institutional collaborative structure of a city. It frames the resource dependency across actors since it exhibits the interaction formed between actors that need the resources and how they work their willingness with actors that are accommodating to contribute resources. Local governments rationally will try and seek additional resources from their local partners in order to secure resources to achieve local objectives and pool them for the purpose of seeing their goals go through. Beside collaborative policymaking and resource exchange, this paper also measures the collaboration on project related activities.

This paper utilizes the measuring instruments originally developed by Agranoff and McGuire (2003) to analyse the institutional structure of collaborative governance. The parameters introduced by Agranoff and McGuire offer a thorough accounting of activity that parallels the bureaucratic management closely related in explaining the structure of institutions. For this paper, weight is added to the activities which are potential to promote collaboration in order to gauge the individual intention of local governments. Weight is given to collaborative policymaking activities as they are considered the initial activities leading to an established and comprehensive collaborative governance. Weighting method used in the analysis is done by multiplying the result of weighted activities twice.

Table 1: Measurement for the analysis on the institutional structure of collaborative activities.

Collaboration	Activity	Weighted
Joint policymaking	Consolidate policy effort	✓
	Engage/agree in formal partnerships	✓
	Engage in the joint policymaking	✓
	Engage in joint policy implementation	✓
Resources exchange	Financial resources sharing	
	Personnel sharing	
	Exchange information/share ideas	
Project based works	Partnership for project planning	
	Partnership for project implementation	
	Asset specificity and monitoring

2.2 Data Collection

A structured survey was conducted during two periods, from October to November 2012 and from May to June 2013. The survey targeted chief officers from local governments (municipality/regency level) working with the Local Development Planning Agency and City Planning/Public Works Agency/Collaboration bureau. These officers are responsible for the planning and implementation of collaborative activities in their respective cities. The respondents were interviewed about decision process underlying collaborative activities. They were asked to identify each activity their cities currently engage or have in the past collaboration with other local actors. Activities asked in the questionnaire are an elaborated version of the measurement presented in Table 1. Table 2 lists the organizations and agencies of potential collaborative institutions asked to the respondent.

Table 2: Lists of institutions/agencies at the local level.

Neighbouring local government institutions	Nongovernmental institutions at local jurisdiction
1. Local Development Planning Agency	1. State owned company
2. City Planning Agency/Department of Public Works	2. Chamber of commerce/Real estate consortia/Private sector association
3. District office	3. Private sector and developers
	4. University
	5. Non-Governmental Organization

Source: Author (2014).

This study describes the intergovernmental collaboration as a cooperative interaction among governmental actors between cities in the metropolitan region. Cross-sectoral collaboration in this study is identified as cooperative relations between local governments/local governmental agencies and nongovernmental sectors, including non-profit (civic) and private sector taking place in the local jurisdiction. Cross-sectoral collaboration often referred by the government as a public-private collaboration.

The primary variable in the institutional structure is the total number of interactions, measured as the sum of all linkages as reported by respondents. The maximum score is the total possible interaction between local governments and their counterparts on collaborative activities, e.g. intergovernmental interaction was calculated by multiplying 10 collaborative activities by 3 neighbouring governmental agencies. In total there are 8 possible agencies (governmental and nongovernmental) in local level as part of the selection, making the maximum interaction up to 80 interactions (10 activities, 8 actors). This study measured 3 types of interaction in the region; the overall interaction to represent collaborative governance, the intergovernmental interaction to represent the intergovernmental collaboration and the cross-sectoral interaction to represent the public-private collaboration.

2.3 Analysing the Local Policy Instruments

The analysis of the local policy instruments is based on the hypothesis that the local structure of collaborative governance shapes and is shaped by the policy selection of local government. The collaborative architecture is set through local and regional political process and influenced by social, and cultural characteristics. In return, institutions and policies create a local platform for local governments to conduct their activities. This assumption is built upon understanding that policy design –statutes, guidelines, programmes– directly and indirectly affect society while poses as a reflection of the culture and values of society itself (Schneider and Ingram, 1990).

The primary data used to analyse the local policy instruments in this paper is the variety of policy instruments adopted. This study used 20 policy instruments, identified after cataloguing policies issued by local governments in their websites, annual reports and development plans from 1999 to 2014. All of the policy instruments selected were enacted by local governments to encourage collaborative arrangements in their jurisdictions, directly and indirectly related to the collaborative activities at the local level.

This paper utilizes the sample of the instruments of public policy by Linder and Peters (1989; 1990) to classify the local policy instruments of observed cities. The instruments from Linder and Peters were chosen due to its wide variation in instrument appraisal that gives space to understand the role of institutional factors which is partial to to grasp clear perspective on collaborative metropolitan governance. Only six out of seven classes provided by Linder and Peters are adopted for this study by annexing subsidy and tax into one fiscal related class in which this study refers as fiscal/subsidy/tax (see Table 3). The underlying reason is that after looking at the list of collaborative-supportive policy in Indonesian cities, there was not enough fiscal instruments available.

Table 3: Instruments of collaboration-supportive policies in Indonesian cities.

Exhortation	Direct provision	Fiscal/Subsidy/Tax
1. Advocated in Master Plan	1. Shared local funding to state enterprise	1. Grants
2. Advocated in the midterm Development Plan	2. Shared local funding to third parties (private sector/ other local government)	2. Incentive
3. Advocated in the long-term Development Plan	3. Local budgeting authority	3. In-kind transfer
4. Advocated in the Program	4. Infrastructure transfer	
	5. Management of local asset	
Contract	Regulation (for Collaboration)	Authority
1. Consolidated contract issuance	1. Regulation covering all sectors	1. Procedural guideline in collaboration
2. Evaluation scheme	2. Regulating nongovernmental sector only	2. Sub-district and village collaboration guidelines
3. Conflict solving	3. Regulating local enterprise only	

Source: Author (2014).

3. The Institutional Structure of Indonesian Collaborative Governance

How common are collaborative activities among the observed cities? The vast majority of the cities report a high number of joint policymaking (Table 4) with Denpasar and Yogyakarta report almost 100 percent. This means every city at least conducted one collaborative policymaking in their jurisdiction. The report on resource exchange activities is slightly less, about 10 percent less than joint policymaking activities. More than 90 percent of the cities appear to consolidate their policy and collaborate in a policymaking and strategy making with their neighbours and/or with other local actors. Around the same number of cities has a formal partnership with at least one counterpart in the local level. However, while cities conduct a collaborative policymaking, it does not automatically mean that they decide to engage in a collaborative policy implementation scheme.

Table 4: The region-based percentage of respondents using collaborative activities.

Activity	Surabaya	Yogyakarta	Denpasar
Joint policymaking	78	96	100
Resources exchange	67	94	93
Project-based works	83	89	100

Source: Author (2014).

3.1 The Structure of Collaborative Governance

This paper expects that meaningful differences between regions of their collaboration level are present due to the fragmented nature of Indonesian system. These variations are necessary in observing the impact of the institutional structure towards the collaborative tendency at the local level as well as the propensity to collaborate with certain actors. For the analysis, three variables were designated according to the possible relations pursued in the questionnaire; overall, intergovernmental and cross-sectoral interaction.

Table 5: Mean of the institutional structure of collaborative metropolitan governance.

	Max Score	Surabaya	Yogyakarta	Denpasar
Overall interaction	80.00 (112.00)	22.90 (28.80)	24.67 (31.17)	31.60 (39.80)
Intergovernmental interaction	30.00 (42.00)	8.90 (11.40)	18.17 (23.50)	15.40 (20.40)
Cross-sectoral interaction	50.00 (70.00)	14.00 (17.40)	6.50 (7.67)	16.20 (19.40)

Note: Weighted score is bracketed.

Source: Author (2014).

The horizontal dimension produces the most complex results of all indices in both intergovernmental and cross-sectoral interaction, with Surabaya and Yogyakarta are located at the extreme ends of the spectrum. Among three regions observed, Denpasar displays the highest overall interaction level –both intergovernmental and cross-sectoral interaction–. On the intergovernmental interaction, Yogyakarta is twice higher than Surabaya, showing that the extent of interaction and collaboration between local governments is significantly higher in Yogyakarta. It means the local governments in the Yogyakarta region are more likely to interact, exchange information and collaborate with each other than cities in Surabaya.

The exact opposite result of intergovernmental interaction is observed in the cross-sectoral interaction. Cities in the Yogyakarta region are the least frequent users of the cross-sectoral interaction. This lead to assume that the Yogyakarta region employs a limited cross-sectoral collaboration and put more focus to develop their intergovernmental structural institutions. On the other hand, cities in Denpasar regions pursue about twice and half as many cross-sectoral interaction than cities in the Yogyakarta region.

When the extent of change from weighted to unweighted measures is compared, a closely similar value increase in the intergovernmental interaction shows that all three regions have a corresponding view on their priority in developing its intergovernmental collaborative environment. The change on the cross-sectoral interaction is more diverse with Surabaya puts the most changes, followed by Denpasar and Yogyakarta. Surabaya is less likely to have interest to collaborate with its neighbouring municipalities than with the public or private sector and Yogyakarta employs the exact opposite preferences. This result implies that local governments in Surabaya are more open in accommodating non-governmental sectors in their planning and infrastructure provision than its counterparts in Yogyakarta.

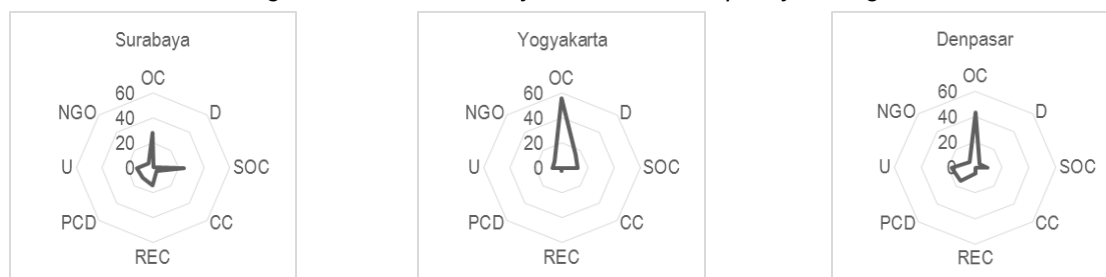

3.2 Actor Centrality

The analysis of activity centrality captures the relative importance of actors in a specific group of collaborative activities. While in a complex network analysis centrality is specified as being based on degree, closeness, betweenness, and information (Wasserman and Faust, 1994), in this paper it is measured by the extent of the involvement of an actor. In this paper, actor centrality explains the aggregate of preferred actors chosen by local governments in a particular activity. To determine actor centrality, the total number of linkages for each player is converted into a percentage to measure the aggregate relative involvement of each actor within a specific activity. Actor centrality is measured according to the following formula:

$$\text{Actor centrality} = \frac{\sum \text{number of linkages conducted with Actor A in Activity X}}{\sum \text{number of linkages in All Actors in Activity X}}$$

The nature of the actor interaction of each region for collaborative policymaking is predominantly similar to each other, while interaction for resource exchanges varied especially on their lead partners. Cities in all observed regions depend on their neighbouring cities in dealing with inter-jurisdictional policy issues, citing neighbouring local government agencies as their most important collaborative partner. In resource exchange activities, local governments in Surabaya are likely to be dependent to the private sector more than with their neighbours while cities in Yogyakarta with their government-led activities work with civic sector as their back-up plan. Cities in Denpasar, in contrary, choose public-private-civic network as their partners for resource exchanges, although they also collaborate with the private sectors in various activities.

4. The Differing Patterns of Policy Instruments

What explains why certain instruments are chosen? What to say about a region with a certain selection of policy instruments? Cities in the Yogyakarta and Denpasar region, in particular, share a great deal of similarity in selecting and deciding the policy instruments. Surabaya, on the other hand, have lack of coherence in all policy instruments. The tendency that we found is that the more coherent local policy instruments observed, the more cities actively advocate collaborative activities in their plans. From the perspective of power relations and policy instruments, in a realm that power relations tied to how local governments conduct their intergovernmental and cross-sectoral relations as well as internal political relations hypothetically cities with strong coherence will have a higher probability of stronger intergovernmental relations and closer local political interaction and vice versa.

Table 6: Classification of adopted collaboration-supportive policy instruments.

Instruments	Mean	Surabaya (n=7)	Yogyakarta (n=3)	Denpasar (n=4)
Exhortation				
Advocated in Master Plan	65.5	71.4	100.0	25.0
Advocated in the midterm Development Plan	62.7	71.4	66.7	50.0
Advocated in the long-term Development Plan	59.5	28.6	100.0	50.0
Advocated in the Program	80.9	42.8	100.0	100.0
Direct provision				
Shared local budget to state enterprise	80.6	100.0	66.7	75.0

Sub-district and village collaboration	30.2	57.2	33.3	0.0

Note: *n* is number of cities in the region.

Source: Author (2014).

As observed in the classification of adopted policy instruments (Table 6), three sample regions appear to exercise different policy approaches to collaboration. Cities in Yogyakarta are very keen on having incentives put in place to encourage collaborative governance while Denpasar and Surabaya choose in-kind transfer as their most preferred fiscal instruments, followed by grants. Observed regions also seem to have different perspectives on regulation and contract instruments, with Yogyakarta posts as the biggest proponent of these types of instruments. The majority of cities in Denpasar and Surabaya prefers to adopt regulation administering collaboration from the higher levels of government, mostly from the provincial government, than to enact their own regulation. However, cities in Denpasar assent with Yogyakarta in term of the importance of having consolidated contract issuance and evaluation scheme while cities in Surabaya have mixed preferences.

Cities also have differing perspectives on regionalism and ways to manage their resource sharing scheme. Surabaya, the biggest metropolitan region among the observed regions, exhibits the least coherence among its member cities in administering budget allocation for managing regional collaboration. Only four out of seven cities allocates budget for implementing regional collaboration programmes. However, they are more eager to share fiscal means to the state enterprise as part of resource sharing activities. Cities in Surabaya region also favour more to provide instruments for third parties to develop and manage their infrastructure than Denpasar and Yogyakarta as shown in the infrastructure transfer and management of local assets instruments. These two instruments are quite recent to be introduced in Indonesian cities to encourage public private partnership in governing urban infrastructure. Infrastructure transfer instrument provides local governments with a scheme and regulation to transfer privately built urban infrastructure to cities as public assets with exchange of compensation such as tax relief and permit for developers.

As most of direct provision instruments is intended for encouraging nongovernmental actors to participate in the collaborative activities, our results show that cities in Surabaya region lean toward the cross-sectoral collaboration more than intergovernmental ones. These cities also have reluctant tendencies to govern their collaborative perspective to be more regional oriented as they opt to not provide budget on activities related to regional collaboration. On the other hand, cities with regional approach tend to collaborate more with their neighbours as observed in Yogyakarta. All of three cities in the Yogyakarta region allocate yearly budget for managing regional collaboration programmes and provide fiscal instruments that allow them to transfer financial means to other local governments for implementing urban infrastructure projects.

Further grouping of sample cities were conducted according to the reliance level to instruments and the presence of procedural guidelines and regulation of a collaborative arrangement in order to identify further policy characterisation. Cities with high reliance (enacting more than 2/3 of instruments in a group) are sorted into one and the remaining city in another group. The means of total interactions –in total and according to major collaborative activities– were measured to grasp the interaction level of cities according to their reliance to a specific policy instrument.

The results show that the higher instrument reliance on exhortation prompt cities to collaborate more with an average of 40 percent. These cities also produce higher interaction of all collaborative activities. While it is considerably higher in all collaborative activities, it is especially higher on the joint policymaking activities. Cities with a higher reliance on fiscal/subsidy/tax and contract instruments also pursue more interaction than cities with lower reliance. The exception comes with the presence of regulation in collaboration with nongovernmental actors. Cities which adopted regulation of the higher levels of government have higher interaction than cities which enact their own regulation on both joint policymaking and resource exchange activities. Cities without procedural guidelines also perform better in developing activities with nongovernmental actors. This finding implies that regulation at some extent hampers local government to conduct collaborative arrangement with nongovernmental actors.

Table 7: Means of the local policy design.

	With other local government actors		With nongovernmental actors	
	Joint policy making	Resources exchange	Joint policy making	Resources exchange
Max score	12.00	9.00	32.00	24.00
Exhortation				
Cities with high exhortation usage*	6.85	4.15	5.07	4.62

5. The Role of the Institutional Structure and Policy Instruments

Our findings indicate that establishing a multistakeholder process of policymaking and resource exchange for delivering the urban infrastructure varies according to the types of policy instruments and institutions adopted in the local jurisdiction. Although in general the presence of policy instruments encourage collaborative activities, at some extent it shapes local government's preference of collaborative partners. The adoption of certain policies could also encourage or limit intergovernmental and cross-sectoral policymaking and

resource exchange. Cities with stronger preferences toward nongovernmental actors tend to nurture local environment that support cross-sectoral collaboration through the enactment of nongovernmental-friendly policy instruments. Cities preferred to collaborate with their neighbours, however, enact policies to support their intergovernmental collaboration.

Our results demonstrate that policy instruments concerning exhortation and contract positively affect collaborative joint policymaking and resource exchange regardless local government's choice of collaborative partners. To a certain extent, this means the greater the use of these policies, the greater the extent of intergovernmental and cross-sectoral collaboration of a city. Moreover, direct provision and fiscal instruments are partial to the local government's preference of collaborative partners as well as its outlook toward regionalism. From the financial perspective, this can be explained that seeking, acquiring, combining, or leveraging resources, particularly with nongovernmental sector, demands a great deal of government financial support.

Local government's inclination in choosing the flagship regulation that specifically enacted to address collaboration procedures plays an important factor on their governing of collaborative policymaking and resource exchange. The use of regulations negatively influence the collaborative policymaking and resource exchange with nongovernmental actors while positively boosting intergovernmental collaboration. Cities which preferred to adopt regulation from higher levels of government exercise more collaborative activities with nongovernmental actors compared to cities which enact their own regulation. The corollary is that in Indonesia the process of enacting local regulation requires approval from the local assembly which in most cases through a lengthy and costly process. In cities which the majoring political party differs from the mayor or regent, the transaction cost of enacting regulation is even higher. To avoid a high transaction cost, local governments often opt to adopt similar regulations from the central and/or provincial government. Those regulations usually less detailed and broader in essence as well as more open in term of interpretation.

6. Conclusion

In general, from the perspective of the institutionalisation of policy instruments through policy process and institutional structure, the instruments selection and policy choice affect the state of the intergovernmental and cross-sectoral collaboration in a city. The variation between sampling cities in the cross-sectoral collaboration is wider than the intergovernmental collaboration. Policy instruments in Indonesian collaborative governance, thus, offer a means of structuring a space of selective cooperation and a space for exchange through negotiations and agreements.

Policy instruments also set an expansive platform with multiple actors, thereby allow for a sectoral and case by case cooperation rather than ambiguous and metropolitan-wide consensus. Policy instrumentation for cross-sectoral collaboration is built upon a short-term exchanges and the state of power relation between government and nongovernmental actors through the use of authority and regulative instruments. The extent of intergovernmental collaboration, however, is influenced through the selection of available policy instruments.

The findings presented here are indigenous to Indonesian cities. Even under similar governing system, one city is clearly different from the other. The administrative, political and fiscal decentralizations greatly influence the way local governments manage cities as demonstrated through their selection of policy instruments. However, although policy selection shapes the collaborative approach of local governments in policymaking and resource exchange, the effectiveness of collaboration is a critical question remained unanswered in this paper. Enactment of a certain type of policy instrument may result on wider coverage of collaboration through region-based collaboration, yet whether it results in better policymaking and resource exchange activities cannot be answered. Future research should develop on these findings by building more comprehensive measures.

Devolution as a way out of planning legitimacy crisis - why sharing planning power matters for the CEE countries

Lukasz Pancewicz, PhD, Gdansk University of Technology, Faculty of Architecture, Municipal Planning Office of Lodz

Abstract

The paper focuses on experiences of sharing planning power as a way of reinventing planning in transition countries in Central and Eastern Europe. The planning in CEE countries shares many similar challenges, including the hollowing-out of the welfare State in a wake of rapid privatization, weakening of the institutional capacity of planning apparatus and the rise of the planning 'chaos' due to strengthening of private interests over collectivist planning. In such context the role of typical command and control planning is often weak and reduced to the development of limited public projects. Devolution of planning through delegating decisions to the resident groups may not solve all problems of planners. Nonetheless, in the wake of legitimacy crisis of planning it may provide a necessary impulse to reignite the debates on the necessity of changes to the system. It also may provide a much needed room for experimentation with new, rejuvenating planning concepts. Still, the current formulas and methodologies of planning need to be substantially updated, to accommodate greater degree of sharing the decision making process. This requires going across the embedded real estate interests. Also, the institutional and political skepticism towards sharing powers is the other potentially a limiting factor in that case. The paper reviews the latest experiences with both new tools, including experiments with citizen panels and extended public consultation, with more fundamental change, brought about by recent societal and political changes. Above all, the important one was the steady transition of members of so-called 'urban movements', former activists, towards mainstream local politics and growing interest amongst general population towards urban planning issues.

Introduction

Rapid political change in the Central and Eastern European (CEE) countries a quarter century ago resulted in reinstating strongly market-friendly, representative democracies in place of failing, Communist governments. The change started a long term process of transition for many aspects of life, including town planning. The timing of the changes varied vastly. In planning the political change, such as establishing the local governments and new legislation frameworks outpaced the ability to create the effective planning system that complemented these fundamental, power-shifting transitions. Even though the city planning started to work in the new realities of the weakening State and growing role of the private sector, the creation of a planning system, that responds to this highly decentralized, negotiatory context today is still largely an incomplete and on-going project for many countries in the CEE.

The next step in evolution of the system may become increasingly possible now, with the maturing of the civil society, particularly the rediscovery of the urban issues by the residents. For planners, embracing of such change may be vital as a way out of the legitimacy crisis that the profession is struggling with now, due to impotency of current regulatory planning in a face of rapid privatization and weakening of the State intervention. The opportunity to modernize planning may be triggered also by the rise of urban challenges that cannot be met by standard practice and will undoubtedly need significant urban policy

prototyping, such as urban regeneration. In the text, I argue that enabling more decentralized, innovation-focused approach may bring the delayed and much needed further evolution of policy making and planning system itself.

Methodological note

The comprehensive overview of changes on planning systems is by nature a broad topic. In the text I focus primarily on the Polish experience with references to other countries in the region. The issues addressed in the text refer mostly to the regulations on the local level. After the governmental reforms of 1999 in Poland and majority of other CEE countries in the region the territorial self-governments became key actors as the planning was delegated largely to this level of governance (Simpson, Chapman 1999). In the text I review the challenges to the system from the perspective of the planner. Even though I make a strong case for delegation of the power to the residents and resident groups, such change does not necessarily mean the removal of the planning profession from the broader discussion.

The “local” nature of the difficulties witnessed by planners in the CEE countries, offers also useful insights into broader, world-wide discussion on the future direction of planning. The crisis of the CEE countries reflects the broader challenges faced by planners in the countries in transition. The paper also addresses the issue of changes facing the regulatory, formalized planning in the wake of market-friendly deregulation in the representative democracies.

Evolution of planning in CEE post-1989 as a slow adjustment to Western deliberative model.

Central and Eastern European countries have gone through a major change, caused by dismantling of the Communist State and reinstating the free market and representative democracy almost a quarter of a century ago. The political change was rapid but other changes, such as establishing the comprehensive planning system, took much longer to adjust or was not particularly successful in modernizing itself. For example, Poland witnessed at least two major changes in planning legislation (in 1995 and 2003) with numerous minor changes. Even though the need for planning, understood broadly as ensuring the rational land-use, protection of the natural environment, balancing the private and public interests amongst many other objectives of spatial planning (UnHabitat 1972) did not diminish. The practical nature of the planning activity has changed substantially towards market-oriented, regulation-based and negotiatory.

Two effects of the change in particular significantly weakened the powers of the planners. Firstly, creation of the private property market, property titling and privatization had severely limited the freedom of arbitrary decision making. The rights and protection of property rights were established as a foundation of the new systems which granted constitutional protection in the early nineties. Other legal protections quickly followed, such as the limitations in the use of compulsory purchase orders for the public needs and, more importantly, rules of compensating for the loss of property value as a result of planning decisions. At the same time, the local planning, through land use designation has become an important tool in securing the land value and providing the development capacity for the private sector. In that sense planning from activity closely related to implementation, as it was in “command and control”, top down modernist planning, became a largely regulatory tool. The abilities to *masterplan* by planners became severely diminished. This happened as a result of privatization of actual city development as well as the built-in limitations in permitted actions of the local governments. As in Western countries, such tasks were transferred mostly to private sector architectural companies, who represented particular clients. Important changes were put into legislative acts made further changes, strengthening

the role of property rights. Here proposals such as “as of right” development of suburban single family housing or exceptional, fast-track planning permissions for infrastructure, independent of formal zoning were prime examples of erosion of planning controls.

Equally important factor was the shifting role of the local governments from the position of active providers of urban development, especially in the field of public housing, to the one of regulators. This position changed due to access to the EU funding, directed towards new member States since 2000 pre-accession funds, which dramatically expanded the ability to provide large infrastructural development in all aspects of built environment. The EU funding did modernize the regional and spatial dimension of planning, as the regional governments were necessary in managing the redistribution of EU structural programmes. On the local level the investment planning became separated from the reality of urban development as many “plans” remained in the domain of regulation of land use. In practical terms, many products of such planning became code based zoning documents with little powers to intervene in urban matters other than rudimentary planning regulations.

These two changes, amongst many others, pushed planning towards the operational and normative context shared by Western counterparts, namely shifting towards negotiatory and deliberative models, introduced and discussed in the West since seventies (Healey 1997, Forrester 1999). The very nature of change in the CEE, facilitated through unprecedented, massive privatization of former State assets and corresponding changes in regulatory landscape, constituted a major difference between the West and the transition countries. This situation also left planning in fairly precarious situation, as the reforms had weakened its practical capacity to ‘plan’. As a result, in general social and political legitimacy of planning was severely hampered. Planners’ actions were often unfairly hailed as obstructionist and non- efficient. Growing marginalization was reflected by recent changes in legal status of the planning profession. In 2015 in Poland planners were officially deregulated en bloc with other regulated professions, raising little or no political and public opposition. The official register of planners at the time of deregulation counted 1200 no. members of the planning institute for a country of 38 million inhabitants, according to the Polish CSO data in 2012. In that sense, the true discussion on the social or deliberative turn in planning in CEE still did not fully materialize.

Market-oriented and statutory planning as a challenge in the CEE

The issues mentioned above put validity of planning, shaped by the combination of privatization and regulatory land use, into question. The resulting abandonment of planning as integrative action had significant effect on urban space. The geography of the cities became reshaped to the larger extend by fragmented privatized development, leading to growing perception of the urban chaos as a visible, spatial effect of the property development of many cities in CEE region (Kowalewski et al. 2013, Kusiak 2013). Probably one of the biggest and ongoing failures as a result of such dramatic changes is real inefficiency and inability of such system to meet its basic obligations such as provision of a balanced land use and sustainable development (Planning and Development Act, 2003). In Poland, the pressure of the private market and weakness of planning led to severe oversupply of zoned land, vastly outstretching the demand and realistic capacity to absorb the land for material development. The structure plans of all local governments established the reserves of new development land for the equivalent of 167-229 million inhabitants, based on 2012 statistics, the financial costs resulting from legal obligations vastly outstretch the ability to cover them by the local government’s budgets (Kowalewski et al. 2013). Such process can be attributed to process of land speculation land with attempts to secure and capture the assumed land value by prospective owners as well as individualistic market-driven logic of recent city development. As a result, the inefficiency of planning has become an economic issue.

Previous attempts to fix the system focused on comprehensive, top-down legislative action were unsuccessful as they resulted in further reduction of the effectiveness of the system. Reform of the Planning and Development Act in 2003ⁱ discontinued the pre-1989 plans, as non-compliant with current legislative context, and introduced fast-track planning procedures, for the areas without zoning plans. The current planning coverage in 2013 was still at the level of 28%. Many zoning plans are situated in the suburban areas of urbanization pressure. The most recent attempt to create the comprehensive planning code, akin of German *Baugesetzbuch*, that started in 2012, produced a project of the regulation in 2015 (MIR, 2015), but it is still unclear how such project will be implemented. The stop-gap solution, the so-called “small improvement” of the 2003 Planning and Development Act, based on the new Code has been prepared and awaits implementation.

As a result planners became isolated with the problems at hand. With legislative actions put the primacy of the individual property laws over the common good, the local governments often became focused on facilitating private developments. The authorities considered planning through the lenses of administrative procedures of pursuing the broader public aims. Planners, who had little to offer in terms of short term material gains and benefits to the local communities besides creating regulations, have been put in difficult situation. On one hand, they failed in fulfilling their obligations to plan efficiently on behalf of the public good on the other hand their actions could be seen as unnecessary burden or limitation on fulfilling the economic potential of the individuals. Such precarious condition led to marginalization and irrelevance of planning professions in broader discourse on the necessary changes in managing the cities.

Giving the room for the new discussion on planning – role of the urban movements

As a result formal planning in countries such as Poland acts is in impasse. What changed however in the post-1989 landscape, was the rise of the general discussion on the condition of the cities. The academic and professional discourse maintained through the post-1989 era, yet many of such debates had limited audience outside its constituent circles. Such debates in the public sphere intensified again in post-2009 Poland, with the mobilization of so-called urban movements. In Poland the process occurred as a result increasing activity of non-governmental organizations and groups of activists that focused their actions around issues such as participation in planning, environment protection, transportation (Mergler et al. 2013). Their steady formalization allowed for forming of the more organized forms of cooperation, such as ‘*We, the inhabitants of Poznan*’ in 2011, which made successful forays into local elections. Such change was in a way mirrored by other CEE countries where emerging urban movements engaged in actions on issues relating to housing, such as tenant protection initiatives in Budapest – “City is for all” or coalitions of activists .

One of the major successes of such initiatives was forming of the Urban Movements Congress in 2011 which gathered approximately fifty activists from all country and resulted in first set of independent urban policy proposals, the so-called ‘Urban Theses’ (pol. “Tezy Miejskie”)ⁱⁱ, devised as a way of bringing together organizations that had represented a broad spectrum of various ideological positions but in their activities they all focused on the urban issues. The movements quickly formed a non-formalized alliance that started to hold regular meetings in various cities of Poland. The connections between organizations were often based on interpersonal relationships and ad-hoc initiatives rather than formalized structures. The fluid nature of the alliance allowed for many different organizations to blend in under the umbrella of the Congress. The joint position taken by the allied movements were the results of the collaborative, horizontal cooperation. Also the high public visibility of the movements was often based on initiatives of the most prominent members and leaders of the particular organizations. Lack of stronger structures and open-ended, non-ideological nature of the

alliance was a deliberate position. It allowed for creation of multiple, parallel sources of the discussion on cities in a context of the stagnant debate on cities. Also, the movement intended to support the growth of local civic capacity to discuss change in cities without falling into particular position already held by established political parties (Poblocki 2014). Such open-ended position was debated within the Congress, in a wake of local political elections. The lack of strong ideology was seen as potentially diffusing the potential to facilitate necessary change and risking falling into populist centre-right conservatism that prevailed in local politics during recent years (Erbel 2014).

The important step in development of the civic movements was the 2014 local elections. The independent joint election committee "Urban Movements Alliance" (pol. Porozumienie Ruchów Miejskich) was formed to provide a media and campaigning support for the candidates to local governments in eleven cities in Poland. The growing presence of the movements led to limited success in gaining a foothold in a few cities. This included Poznan, one of the major Polish cities, whose residents voted for competing candidate - a former member of urban movements who joined the ranks of the leading mainstream party - Civic Platform. New mayor appointed a prominent member of a local urban movement, My-Poznaniacy as a vice-Mayor. The greatest political victory of urban movement backed candidates were elections in Gorzow – a mid-sized municipality in the Western Poland where independent city Mayor took its office after a landslide election. Even though the electoral effect was limited the movements left a lasting impact on the national political debate on the urban issues. This was facilitated by a strong media presence and localized, direct action of the members of the urban movements. The resulting social and political mobilization put growing pressure on the government to act. This facilitated a much delayed grass-root response to the pressing urban issues that was stymied by the early stages of market-friendly transition in the late nineties and rampant privatism of that time.

The interplay between NGOs, urban movements and the State in the context of urban policy forming illustrates the works of processes of collective urban policy prototyping and informal, symbiotic relationship on the pragmatic level. It is the key to understand the potential opportunities that may comprise potential way-out of the current planning stalemate.

Shaping National Urban Policy as opportunity to test new system-based planning as a new opportunity for planners

In 2012 Polish government undertook first steps towards the creation of the coherent National Urban Policy (NUP), since the 1989 transition, to address several urban issues, including the difficulties mentioned above. It became (Trojak 2014) the main driver of modernization of the initial change was the intention to improve the modernizing leverage provided by the UE structural funding in the 2014 - 2020 (MIR 2012a). The work on the policy corresponded with other, parallel debates on the state modernization such as the National Framework of Urban Development (KPZK 2030) – a high-level, large-scale national masterplan for the spatial and functional structure of the State.

The draft document has been published in May 2012 and contained progressive set of actions addressing several issues. This document, heavily inspired by the Leipzig Charter, included the recommendations on the issues such as urban regeneration, sustainable transportation, planning for ageing, planning for climate change (MIR 2012a). Even though it failed to become a fully adopted official State document, at the time of the writing, it has become a form of guidance. Ideas elaborated in the MUP started to take shape as a "road map" to a series of potential changes in a system of managing Polish cities. Even if the long term political viability of the actual MUP document will be tested by the upcoming elections in October 2015, the core concepts expressed in this document most likely will transpire into practice of the cities. As the grounding ideas of the document are addressing vital planning challenges of the cities. In the preparation the document was inspired by expert input

including the OECD team (OECD 2011) which worked on the basis of Polish guidance documents (Węclawowicz 2010) and expert-led workshops. The document became influenced by the discussions expressed by the NGOs including the members of the Urban Movements Alliance, who discussed the Policy during II Urban Movement Congress, via Res Publica Nova and Magazyn Miasta, one of the leading, independent urban related magazines in Poland. The ideas expressed in the Policy in a way included many postulates of the activist groups.

The overlap between expert-led State policy making and informal deliberation may be growing stronger in the upcoming perspective as the government started to implement changes on foot of the Draft NUP. One of the most substantial results of this initiative entails the creation of the comprehensive system of urban regeneration (MIR 2012b). Here the actions of the State comprised preparation of the new legal proposals coupled with pilot projects. The major change, proposed by the Draft NUP brings to the fore the social aspect of regeneration, stipulated by the EU Strategy Europe 2020. For the Polish context, where these policies were focusing on infrastructural, urban development based on integrative systems approach (i.e. taking into account social, economic and spatial issues) and operational planning (i.e. with focused timeframe, detailed aims and budgeting) is a major change in current practice. Making such leap forward will required substantial amount of new thinking and testing of the solutions. This opens up the window for traditional planners to fit in as one of the expert groups involved in implementation of the new proposal.

Summary – devolution of planning as moving forward

The way out of the planning impasse may lead through “prototyping” of the new planning policies where planning expertise meets the social capacity to act and negotiate. Such field has been slowly building up as a result of resurgent of civic society in Poland and growing focus on broadly defined urban issues. Here lies potential to rejuvenate planning as the interaction between “bottom-up” activism and State-led modernization often lies in exchange of new ideas and directing the possible actions of the State. For the planning it meaning giving up the position of an expert and moving more into the deliberative model, familiar with mature Western democracies. In that sense the “devolution” of planning power, means abandoning the old ways of regulatory, reactive planning and switching towards fluid, system-based policy prototyping and enacting. It will most likely mean the necessity to take more negotiatory and partner based relationship with other actors that are already present in the space of urban policy making.

Enhancing Urban Socioeconomics, Looking beyond Conventional Mixed-use Development Model

Maged Zagow, PhD Candidate in Illinois institute of Technology, USA - and
Assistant Lecturer in Tanta University, Egypt

1. Abstract

One of Urban planning foci is redevelopment of existing cities to improve their quality and efficiency. Many redevelopment programs has been applied through over 60 years ago in Illinois State, since the Housing Act of 1949 to New Urbanism, Smart Growth, which targeting transformation of the built environment on land already containing structures and has occurred under both national and local guidance. These programs perpetrate injustice even while their supporters claimed that they were intending to benefit the poor and people of color who increasingly were the occupants of inner-city neighborhoods.

This research investigates how planners can implement successful mixed-use development, given Social justice fundamentally shaping urban development; social justice in terms of the distribution of wealth, opportunities, and privileges within a society. Current housing policy favors high-density, mixed-use development on previously developed urban land. It is frequently cited as a development type that can address a variety of social problems and has enjoyed a recent surge in popularity in redeveloping cities by providing more affordable housing opportunities and choices, reducing auto dependency, and a longing for the sense of place and community. However, its physical design and affordability outcomes are highly variable. This paper outlines the development of a theory of social equity in relation to urban form and presents empirical research based on this to test the case of mixed-use urban form. We are particularly interested in whether and how the distribution of mixed used impact on the social and economic configuration of the built environment. Using multi-level data from 1382 zip code to 102 counties representing all Illinois State with contrasting implementation methods of mixed-use development and different cultural and historical backgrounds, this research proposes a novel graph-analysis framework in which mixed used patterns can be represented under realistic constraints of urban geometry, and land use distribution.

The findings suggest that, in certain respects and with certain qualifications, the mixed use development has the potential to promote social equity. Likely benefits include reduced car dependency and lower levels of social segregation, while the main problem is likely to be a lack of affordable, decent-sized homes. Positive effects are emerging in response to cities which most support equity appear to be those that have a large proportion of medium-density housing and a large quantity of locally provided services and facilities.

2. Introduction

Aristotle was the first to develop a theory of justice, which he identified in two basic kinds of justice: *justitia directiva* and *justitia distributiva*. The first kind of justice refers to the fulfillment of contractual obligations, while the second kind manifested in the "distributions of honor or money or the other things that fall to be divided among those who have a share in the constitution".

This research focuses on the latter - distributive justice - that is, the just allocation of goods and responsibilities through communities. This is often referred to as the issue of "social justice". A subject has increasingly become a hot common issue. *Urban justitia distributive* lacks a stable set of criteria. Identifying these criteria is the subject matter of theories of urban justice, which assume various concepts, implement various applications and apply various justifications, which produce different principles.

Jane Jacobs advocates a mix of architectural and functional diversity in the city. A variety of types of buildings that are created at different times is true, authentic diversity. She also says

that having a mix of commercial and residential buildings together that grows organically adds to the city's variety and beauty. One last point she makes about the diversity of the city being beautiful and economically sound is the fact that in New York, the landmarks are mixed in with the rest of the buildings. This richness of life and culture mixing is a feature that Jacobs advocates as the standard for urban planning. Not only does it make the urban space special, but it also brings business and tourism into the neighborhood.

The main hypothesis of this paper is that the distribution of facilities can enhance social justice through communities. It leads more positive socio-economic effects: poverty prevention, equitable education, and labor market access. The reasons of involving social indicators, first in practical terms, it is describing the state of society, analyzing social change, forecasting the future, evaluating social programs, setting goals and priorities, and developing a system of social accounts. Second, the philosophical and normative reasons are emphasizing the reduction of inequalities and the furthering of the principles of equity and social justice to create a good or well society. Social well-being is thus seen as a condition in which the needs and wants of the population are satisfied.

land use, is important component of urban planning, can contribute significantly in addressing the major urban challenges if led by well-informed policies based on sustainable development principles, social justice procedures and supported by well thought out and managed follow up actions and investments.

3. History and background

Illinois is a state in the Midwestern United States. It is the 5th most populous state and 25th largest state in terms of land area. With Chicago in the northeast, small industrial cities and great agricultural productivity in central and northern Illinois, and natural resources like coal, timber, and petroleum in the south, Illinois has a diverse economic base and is a major transportation hub. By 1900, the growth of industrial jobs in the northern cities and coal mining in the central and southern areas attracted immigrants from Eastern and Southern Europe. Illinois was an important manufacturing center during both world wars.

The Census Bureau estimates Illinois population is 12,880,580 on July 1, 2014, a 0.39% increase since 2010. Illinois is the most populous state in the Midwest region. It has three major geographical divisions. Northern Illinois is dominated by Chicagoland, which is the city of Chicago and its suburbs, and the adjoining exurban area into which the metropolis is expanding. Chicago metro area includes several counties in Illinois, Indiana, and Wisconsin, and has a population of over 9.8 million people. It is a cosmopolitan city, densely populated, industrialized, and the transportation hub of the nation, and settled by a wide variety of ethnic groups. Chicago is the third most populous city in the United States. Chicagoland, as known locally, comprises only 8% of the land area of the state, but contains 65% of the state's residents. The city of Rockford is Illinois' third largest city and center of the state's fourth largest metropolitan area. The Quad Cities region, located along the Mississippi River in northern Illinois, had a population of 381,342 in 2011. By the early 2000s, Illinois' economy had moved toward a dependence on high-value-added services, such as financial trading, higher education, law, logistics, and medicine. In some cases, these services clustered around institutions that hearkened back to Illinois' earlier economies.

Illinois state pass through different urban development stages starting from seventies, city governments continued to confront lean budgets and tax resistance that inhibited them from using their own capital budgets to finance development projects. In that time, there were two movements; first, the Uniform Relocation Assistance Act finally ensured that displaced residents would receive adequate relocation payments. Large-scale urban renewal projects aimed at downtown regeneration continued, through land use, transportation, and environmental systems that would provide the template for urban improvement. Overall the balance between justice and injustice changed, with more equitable outcomes occurring even while demolition of communities and subsidies to developers continued (Fainstein,

2011). Second, by middle 1970s business departure to suburban office parks and shopping malls accelerated, while housing abandonment turned central areas into vacant lots. Tracts that had been bulldozed by urban renewal still awaited private investment. Chicago (Squires, 1987) was able to achieve redevelopment success by employing TIF financing to enlarge its CBD and nurture the new service economy, enabling it to boast of new and lively downtown. Until the 1980s redevelopment efforts in Illinois had largely targeted central cities. Suburbia, however, has increasingly become the site of poverty, deteriorated housing, and abandoned commercial buildings. Uneven development has transformed the earlier condition of impoverished inner cities and wealthy outlying areas into Chicago metropolitan area, wherein some suburbs became ghettoized, older shopping malls were vacated, and low-income people of all races moved into outlying areas while metropolitan center witnessed gentrification. In the ninetens till now, the centerpiece of urban policy provided federal tax forgiveness and deregulation to entice private investment and also injected federal funds into social services. It was limited to a handful of cities; evaluation indicated that “zone initiatives had little impact” (Oakley, 2006). Even parks, long assumed to be a public responsibility, were expected to be self-financing as a consequence of revenues produced by adjacent real-estate development.

From this brief historical overview of the use of urban development, determining the justice of urban policy requires scrutinizing its consequences by examining the resulting distribution of benefits not only evaluating the circumstances under which it was made. Social justice indicators do not set goals and establish priorities. They measure progress towards goals set in the public arena. In this research we will be focusing on such problems, where urban spatial configuration contributes to social diversity by constraining access to socioeconomic opportunities:

1. Scarce in integration of activities networks with social networks and neighborhoods, which create a lack of urban opportunities to enhance local and city-wide cohesion.
2. The decision rules for planning in Illinois become hazier as there is less focus on the appropriate groups of concern. The majority discusses the problems of limited or low income, but rarely does it specify “minorities,” communities of discrimination because of race, color, religion, national origin, familial status and disability.
3. Urban Policies by state focuses on problems and activities for those who already choose—for example, housing for a high-tech workforce, not for low-income families, or transit as an alternative to driving, rather than for those who cannot afford a personal vehicle.
4. As a result of the decentralization of development and the decline in transit service, an increasing number of activities, especially employment opportunities, are totally inaccessible to the transit-dependent population. Obviously such restraints upon mobility lead to, or support, the narrowing of choices in employment, housing, recreation and health care.

4. Social Justice and urban Form:

For a city to be deemed fair or unfair, it should deliver a range of costs and benefits to its inhabitants, where are distributed that governs whether or not it promotes equity. Distributional justice may be viewed in terms of both the fairness of the outcome of distribution (the end result) and the fairness of the actions and procedures that bring this about. Our focus in this research on the fairness of the intended end result of urban form policy and practice. An appropriate theory for judging the ‘fairness’ of the distribution and satisfaction of the needs which impact of different land uses was selected by identifying the most common understanding of social equity within urban development literature. Distributive justice concerns the nature of a socially just allocation of goods in a society. A society in which incidental inequalities in outcome do not arise would be considered a society guided by the principles of distributive justice. The concept includes the available quantities of goods, the process by which goods are to be distributed, and the resulting allocation of the goods to the members of the society.

Figure 1 the conceptual framework of the relation between justice related and urban form.

This idea of social equity is linked to the concept of equality of needs, facilities, and activities, and may be considered to encourage a ‘fair’ distribution of costs and benefits if they are associated with benefits for the conditions or life chances of the disadvantaged, so reducing the gap between the advantaged and the disadvantaged. This definition is similar to Rawls’ difference principle, according to which: “All social primary goods—liberty and opportunity, income and wealth, and the bases of self-respect—are to be distributed equally unless an unequal distribution of any or all of these goods is to the advantage of the least favoured” (Rawls, 1972). ‘The disadvantaged’ are defined, for the purposes of this research, as those on low incomes, that is, those worst off in terms of the possession of one of the social goods identified by Rawls. Improving the life chances of low-income groups will therefore involve an increase in their share of social goods.

According to Merkel and Giebler, the three dimensions of poverty prevention, equitable education, labor market access and Social cohesion and non- discrimination carry the most conceptual value (Merkel, 2009). Under conditions of poverty, social participation and a self-determined life are possible only with great difficulty. The prevention of poverty is in a certain sense a condition sine qua non for social justice, and thereby takes precedence to the other dimensions from the perspective of justice theory. Equal access to good-quality education is another essential factor in providing equitable capabilities and opportunities for advancement (vertical mobility). Social or cultural background must not be allowed to adversely affect educational success. The labor market’s degree of inclusiveness is likewise of considerable importance to social justice, as an individual’s status is defined in large part by his or her participation in the workforce. Exclusion from the labor market substantially limits individual opportunities for self-realization, contributes to an increase in the risk of poverty, and can even lead to serious health stresses: “So long as gainful employment remains the primary means by which not only income, but also status, self-respect and social inclusion are distributed in developed societies, inclusion in the labor market must be a high priority for a just society” (Merkel, 2009). Community-level social capital is dependent on the demographic makeup of the community (e.g., race, poverty, adult educational level). All three fields can play a role in the creation, facilitation, and maintenance of social capital.

5. Interaction between Mixed used development and Social Injustice

Architects and Planners think mixed use development is more about the dynamic activities occurring within the public realm that it is about the built quality of the space (buildings, physical amenities, etc.). Mixed use development concerns more with the concept of “Inevitably,” writes Jan Gehl, “life between buildings is richer, more stimulating, and more rewarding than any combination of architectural ideas.” (Gehl, 1980). Mixed use development target is to ensure that urban space retains the capacity for quality urbanism, and encourage designers take steps to avoid precluding it.

This research will adopt the Douglas Wheeler Associates (2009) mixed use definition which are clearly influenced by the ULI definition when they say: “Mixed use’ is generally loosely defined but can encompass single developments with two or more revenue-producing uses

('vertical' mixed-use development) and mixed use neighborhoods with physical and functional integration including real physical connections between uses within a five minute walk ('horizontal' mixed-use development)". Although all these kind of wide range of different concepts of mixed-use different communities choose mixed use for different according to expected consequences. Different communities choose mixed use for different reasons. Some see it as an excellent way to incorporate a mix of housing types on a small scale while enhancing traditional town character. Others see it primarily as a vehicle for revitalizing struggling areas and spurring economic development. Still others use it to create or enhance village centers. Listed below are some of the many benefits of mixed use development:

- Preserves and enhances traditional village centers
- Promotes a village-style mix of retail, restaurants, offices, civic uses, and multi-family housing
- Provides more affordable housing opportunities and choices
- Promotes pedestrian & bicycle travel
- Reduces auto dependency, roadway congestion, and air pollution by co-locating multiple destinations
- Promotes a sense of community and place
- Encourages economic investment
- Promotes efficient use of land and infrastructure

6. Research hypothesis

First, U.S. Department of Housing and Urban Development suggested that exogenous location factors like (income, education, age, and race) influence facilities types and location choices. We expect the influence of exogenous factors to be especially pronounced in urban contexts, since facilities in a city are embedded amidst other land uses and an omnipresent influence of urban form. This leads us to the following hypotheses addressing the impacts of social context on land use pattern. We therefore specify as below:

- 1) *Mixed use is positively related to income equality, and preventing poverty.*

We examine each possibility, operationalizing Critical Mass both as (1) the number of people of all ages in poverty 2013, as well as (2) unemployment rate

Second according to (Niemira, 2007) suggests that an establishment's location decision can be strongly influenced by the location choices of education. We therefore specify our third hypothesis as follow:

- 2) *Mixed use is positively related to offering more education opportunities.*

We examine each possibility, (1) the number of educational organizations within an area, as well as (2) the number of adults with education.

Third, economic theory suggests that land-use location preferences depend on the type of goods sold. Facility size is not the sole factor; the frequency of patronage that the Facility attracts also plays a role. Grocery stores, for example, offer goods that are demanded frequently by their customers, but hardware store, in contrast, are visited rarely. Typical urban Mixed-use project have no legal mechanisms in place to keep unwanted facilities away from anchors. At the same time a large agglomeration of Mixed-use Buildings with relatively low patronage frequencies can collectively also start producing demand externalities that benefit Mixed-use Centers. Unlike a mall, we expect a Mixed-use Centers can be composed of facilities who value the presence of other facilities in the cluster and stores who do not. Rather than collaboratively optimizing the facilities mix to attract the largest possible demand to the cluster as a whole, we expect the uncoordinated urban facilities to exhibit a stronger preference towards locations with advantageous exogenous conditions. This leads to our first and second hypothesis:

- 3) *Uncoordinated facilities locations exhibit a stronger preference towards customers rather than collaboratively optimizing facilities mix.*

4) *Mixed-use diversity is positively related to job opportunities*

For the purposes of this paper, we test two mixed use the vertical and horizontal models which included in the definition of mixed use. Also include (1) average unemployment rate, (2) the Civilian labor force 2013.

7. Methodology

With just a few cases, we cannot build a theory. But with a large N (1382 cases), US Census provides us with sufficient data including 1382 Illinois zip codes, every zip code can consider such a social and economic case to study and to know where is the level of such kind of facility in such zip code regarding to nation records.

Table 1: Descriptive Statistics for Core dependent & Independent Variables

Variable	Definition	Mean	Standard Deviation
Dependent variables			
LAND_MIX index	distribution of several land-use types within the region		
Retail Trade	Num. of Retail Trade facilities	24.84	47.46
finance	Num. of finance facilities	12.76	36.41
Education	Num. of Educational Services facilities	4.83	17.68
health care	Num. of health care facilities	21.16	43.77
art, entertainment	Num. of art, entertainment facilities	2.90	6.02
food	Num. of food facilities	17.78	34.84
Housing Units	Num. of Housing Units facilities	3825.21	6171.24
Independent variables			
Poverty Prevention			
POVALL_2013	Estimated percent of people of all ages in poverty 2013	1356.44	2440.59
Income inequality	household income	6197.57	22755.46
Equitable Education			
LHD 09-13	adults with less than a high school diploma	790.81	1476.48
HD 09-13	adults with a high school diploma only	1680.92	2581.77
CA 09-13	adults completing college or associate's degree	1986.62	3721.32
B.Sc 09-13	adults with a bachelor's degree or higher	1787.11	2808.05
Labor-market access			
CLF	Percent of Civilian labor force 2013	1102449	3445269
UNEMP	Percent of Unemployment rate 2013	184.64	10298.53

From 1994 to 2012, the Census collects comprehensive information about the total number of establishments in every zip code. It called "Zip Code Business Patterns," it presents for example the number of restaurants and religious organizations per zip code. It offers also more data using Number of Establishments by Employment-size class which provided which describe the employment level as well as employment dynamics stratified by firm size which can be used as value for each type of facility. Zip code demographics are effective, because they generally create a clear image of how a city is broken up. Zip code demographics make it very easy to compare trends in the city to trends in the suburbs. Zip code data are designed to make connections between the past, present, and future as easy as possible. It also can provide us with social characteristics like income, education.

7.1 Measuring mixed-use development

Amenities may capture abstract qualities of the neighborhood, such as the ability to meet one's day-to-day needs and the sense of a complete neighborhood (Douglas, 2008). As this

research adopted the definition of mixed use using Farr Douglas definition, he also adopted concept of diversity to describe mixed use in quantitative method. Following Frank et al (2004) (L. A. Frank 2004), this is an entropy measure reflecting the evenness of distribution of several land-use types within the region. The LAND_MIX index is calculated as follows using the n categories of land in each region:

$$(LUM = - \sum_{i=1}^n p_i \ln p_i / \ln n)$$

Where n is the number of different land use type classes in the region and Pi is the proportion of land in type i in the region. This index is calculated separately for each zip code. The resulting variable LAND_MIX is the land use mix entropy index, which varies from 0 (homogeneous land use, such as in rural areas or suburban subdivisions) to 1 (most mixed, such as diverse city centers) land use. The land uses is using the proportion of estimated square footage obtained from zip code Data (proportional to the size of the network buffer), controls for land uses within the network buffer that were not considered to have walkable destinations within them included industrial, for example.

This method of measurement prevents an area that is evenly distributed with respect to the four land uses, but has a relatively small area occupying this mixed use to have the same value as an area that is also evenly distributed with respect to the four land uses, but has mixed land use over a relatively larger portion of the network buffer. All measurements were made within a 1-kilometer roadway network distance of each participant's place of residence. Land use mix ranges from zero to one, with zero representing a single land use environment, such as a purely residential neighborhood, and one representing a perfectly even distribution of square footage across all four land uses with several destinations within walking distance. Mixed land use has been found to be a good predictor of pedestrian travel.

7.2 Two mixed use models:

First (Model A): the conventional mixed use model which includes retail store, entertainment, food, and housing. This model is what usually developers offer in their project and this model is more convenient with the 'vertical' mixed-use development'.

Second (Model B): mixed use development model includes retail store, finance, education, health entertainment, food, and housing. This model is what usually mixed use neighborhoods with physical and functional integration including real physical connections between uses within a five minute walk 'horizontal' mixed-use development".

7.3 Research variables:

Tracking different land uses over time and space provides a history of their development, the dynamics of which, once understood, can be useful for future urban planning. There are a number of factors that are important in determining land use patterns:

8. Discussion:

This research adopts John Rawls work with the work of Amartya Sen, the 1998 Nobel Prize for Economics winner who emphasizes the distribution of those goods that play a special role in the developed societies of the 21st century. Sen focuses on the just distribution of individual capabilities rather than on a society's institutional order, which is Rawls' prime focus. For Rawls, the point is to provide all individuals with an equal set of primary goods that correct the inequality of life chances. In a just society, an individual's rich or poor parents, intelligence or dullness, sheltered or neglected family background, are not the determining factors in his or her life plans or opportunities for achievement. Institutions must distribute such primary goods that are relevant for creating equal chances in life. Most important

among these primary goods are rights, freedoms and opportunities, income and wealth, and the social conditions for self-respect.

The most recent urban programs recognize the equally important role of local authorities and civil society in improving the lives of the urban poor. They simultaneously address issues of decentralization and social equity and promote partnership between municipalities and communities. Decentralization devolves wide responsibilities to local facilities in districts, cities, and villages. They are responsible for providing health, education, public works, communications, and the management of land and other environmental resources, as well as support of agricultural, manufacturing, and commercial activities. The laws do not specify which functions are mandatory for each category of local authority and which are optional or shared with other authorities. This lack of clarity notwithstanding, local governments have to take the lead role in addressing the needs of lower income communities.

Regression analyses make a strong claim: it attempts to demonstrate the degree to which one or more variables potentially promote positive or negative change in another variable. Regression analysis allows to model, examine, and explore spatial relationships and can help explain the factors behind observed spatial patterns. By modeling spatial relationships, however, regression analysis can also be used for prediction. Building a regression model is an iterative process that involves finding effective independent variables to explain the dependent variable trying to model or understand, running the regression tool to determine which variables are effective predictors.

At this level we are able to test our hypotheses within the same model, allowing us to measure each hypothesis's individual effects and their relative strength in predicting mixed use development. Hierarchical modelling allows us to nest mixed use model within its larger census. More information on our model is provided below.

Table 2: Regression analysis

Independent variable	Model	R ²	Sig. F	P-value	Coefficients	
					Inter.	
Poverty prevention						
People in Poverty	A	0.48	0.0	0.0	23.54	0.04
	B	0.89	0.0	0.0	602.18	2.44
Income Inequality	A	0.22	0.0	0.0	64.14	0.003
	B	0.47	0.0	0.0	2729.3	0.19
Equitable education						
adults with less than a high school diploma	A	0.47	0.0	0.0	26.27	0.07
	B	0.90	0.0	0.0	708.57	4.05
adults with a high school diploma	A	0.54	0.0	0.0	8.38	0.05
	B	0.94	0.0	0.0	-79.69	2.37
adults with college or associate's degree	A	0.54	0.0	0.0	10.25	0.04
	B	0.95	0.0	0.0	1.63	2.19
adults with a bachelor's degree or higher	A	0.49	0.0	0.0	25.40	0.03
	B	0.91	0.0	0.0	709.87	1.61
Labor market access						
Civilian labor force	A	0.29	0.0	0.0	57.17	0.0
	B	0.62	0.0	0.0	2319.96	1.44
Unemployment rate	A	0.50	0.0	0.0	16.81	0.0
	B	0.94	0.0	0.0	236.11	0.04

9. Results:

Table 2 summarizes the stepwise results for the independent variable LAND_MIX percentage of two mixed use models, for about 1382 cases with complete data; a model with reasonably good predictive powers was obtained.

9.1 Poverty prevention

The indicator “People in Poverty” corresponds to the sum of persons who are “at risk of poverty or severely materially deprived or living in households with very low work intensity” and income below the risk-of-poverty threshold, which is set at 60 percent of the national median equivalized disposable income (after social transfers). The concept of this indicator extends far beyond a simple measure of relative income poverty. It refers to the deprivation of basic human needs, which commonly includes food, water, sanitation, clothing, shelter and health care in the neighborhood which provide educational and healthcare facilities. According to the regression analysis, around 48 percent of “Model A” are at risk of poverty or social exclusion otherwise “Model B” exist in 89% of these area. “Model A” is presenting the conventional real state model of mixed use development which targeting high income people. This may interpret the following results because “Model A”, 22 percent are in area with income inequality which refers to the extent to which income is distributed in an uneven manner among a population on the other hand “model B” present 47%, which means that the gap between the rich and everyone else, has been growing markedly.

9.2 Equitable education

Equal access to good-quality education is another essential factor in providing equitable capabilities and opportunities for advancement (vertical mobility). Social, political and economic participation depends in large part on this public good. To this end, the state must take care that genuinely equal educational opportunities are available to every child. Social or cultural background must not be allowed to adversely affect educational success. This dimension considers efforts to provide early-childhood education, the role of socioeconomic background in students’ educational success, and, finally, a qualitative expert assessment of educational policies, focusing particularly on the provision of high-quality education and equitable access opportunities. Assuring equity in education opportunities is primarily an ethical imperative, since weak access to education and social poverty generate a vicious circle in which those lacking education access are denied opportunities for social betterment, and the socially disadvantaged are denied access to education. Breaking this vicious circle is a matter of solidarity and key to maintaining the social fabric of society. At the same time, it makes good economic sense to nourish and apply the talents and abilities of everyone in society, as much as is possible. With the limitation of applying “Model A” because it targeting city centers and density areas on the other hand “Model B” is more exist in suburban areas which attract more population and higher educated people with more facilities and prosperity

9.3 Labor market access

The labor market’s degree of inclusiveness is likewise of considerable importance to social justice, as an individual’s status is defined in large part by his or her participation in the workforce. Exclusion from the labor market substantially limits individual opportunities for self-realization, contributes to an increase in the risk of poverty, and can even lead to serious health stresses: “So long as gainful employment remains the primary means by which not only income, but also status, self-respect and social inclusion are distributed in developed societies, inclusion in the labor market must be a high priority for a just society” (Merkel 2009) . Alongside the overall employment rate, the specific rates for 55- to 64-year-old workers, for foreign-born workers as compared to natives, and for women as compared to men are considered. In addition, the labor market inclusion dimension examines the overall unemployment rate, and is supplemented by the long-term unemployment rate and the degree of labor market exclusion experienced both by young and by low-skilled workers. According to U.S. Bureau of Labor Statistics (BLS) Civilian labor force definition is describing the subset of Americans who have jobs or are seeking a job, are at least 16 years old, are not serving in the military and are not institutionalized. “Model A” doesn’t attract population

comparing to “Model B”, so “Model B” has more Civilian labor force especially with more education levels. The problem is although “Model B” has verities of facilities, it doesn’t offer more jobs opportunity.

Conclusions

The research reported in this paper suggests strongly that the development of mixed use that supports the idea of an urban renaissance has impacts on social equity. Financing, tenure and management are not the only aspects of mixed use that influence the life chances, opportunities and well-being of the least well off in Illinois towns and cities. For designers and mixed use developers seeking to promote social equity, the implications of the research are that higher-density facilities such as retail, education, health, art, apartments and terraces are the best forms of mixed use, especially if they are developed on derelict land in areas where there are plenty of locally-provided services and facilities. Encouraging people to move back into towns and cities seems to improve social equity generally, leading to increased public transport use, better mental health and reduced segregation of low-income groups. For urban policy makers, although the potential benefits of mixed use development, including increased walkability, job opportunities and good access to facilities, it may have negative impacts, such as small dwellings, lack of affordability, shortage of green space, risks to respiratory health and increased crime, need to be addressed.

How to rework the productive city?

Investigating the Effects of Industrial Cluster Development Policy on the Performance of Urban and Regional Old Industries

Zahra Ahmadipour, Central Tehran Branch- Islamic Azad University, Iran

Abstract

Cities and regions represent the most powerful economic engines in the world. A major portion of economic dynamism of cities is basically attributed to its industries. Numerous transformations in various fields of global industries has brought some issues for some cities and regions' old industries that have industrial background and are suffering from inadequacy of capital, technology and labor and brought these industries on the wane. Development of these old industries is often neglected in urban and region development plans. Industrial clusters development model is one of the major recent models which has enjoyed lots of attention for industrial development in cities and regions. The model seeks to help renovate urban and regional economic endeavors, development of new industries and encouragement of economic collaboration among regional networks and firms, government, academia, research and development centers, local expert workforce and entrepreneurs and ultimately provide a new organization of industrial and economic development. Against this background, the purpose of this paper is to discuss the effects of policies based on the development of industrial clusters on transformation of old industries of the cities.

Keywords: industrial clusters, old industries, urban and regional development, Policy

1. Introduction

Cities and regions represent the most powerful economic engines in the world(Shanghai Manual, 2010:2).since throughout the process of globalization, cities and their local authorities have become almost independent units, and their goals have been reformulated in ways that are consistent with the global economy (Guzey, 2009, 27). Meanwhile, major portion of economic dynamism of cities is basically attributed to its industries. Therefore, each city will need an industrial development strategy. On one hand Numerous transformations in various fields in global industries has brought some issues for some cities and regions' old industries that have industrial background and are suffering from inadequacy of capital, technology and labor and

brought these industries on the wane. Development of these old industries is often neglected in urban and region development plans. The overall policy objective for these urban and region has been to find ways to re-position them away from the traditional sectors in decline and to install new drivers for economic growth (Skokan, 2009:772). In recent decades, Industrial clusters have been introduced into urban and regional policy as a strategy for creating and strengthening local development, competitiveness and performance in the globalized economy and also are one of the major models which have enjoyed lots of attention for industrial development in cities and regions.

The geographical concentration of related manufacturing and service firms that is referred to as clusters, is as dated as economic development, but it has drawn renewed attention in the last third decades in the wake of the spectacular growth of regional economies such as Silicon Valley (South San Francisco Bay), Route 128 (greater Boston area) and the “discovery” of numerous other manufacturing districts from Denmark and Italy to Thailand and Japan (Desrochers, 244:233) .A cluster is define as a geographically proximate group of interconnected companies and associated institutions in a particular field, including product producers, service providers, suppliers, universities, and trade associations. They are increasingly recognized as an effective means of industrial development and promotion of small and medium- sized enterprise. The model seeks to help renovate urban and regional economic endeavors, development of new industries and encouragement of economic collaboration among regional networks and firms, government, academia, research and development centers, local expert workforce and entrepreneurs to ultimately provide a new organization of industrial and economic development. Much like with clusters, it provides a better lens to understand economic dynamics and can be a useful level for policy action. Against this background, the purpose of the paper is to introduce industrial clusters model in a theoretical context as an appropriate alternative for reconstructing, rework and developing new industries in old industrial cities and regions.

2. Industrial Clusters Approach

In recent years, clusters have become an object of interest for academics and policy makers alike (uyarra& Ramlogan, 2012:5). Michael Porter, the Harvard Professor of strategy who developed the cluster concept, defined cluster as (1990) “industrial clusters are formed by firms and industries linked through vertical (buyer/ supplier) or horizontal (common customers, technology etc.) relationships and with the main players located in a single nation/state. Geographic concentration of rivals, customers and suppliers in a region will promote innovation and competitiveness in a

cluster” (Porter, 1990). Their two key characteristics are thus the proximity of individual activities in terms of (1) geography and (2) value creation. Porter, through extensive research, came to the conclusion that economic success does not occur in single industrial branches, but in clusters (Porter 1990, 1998, 2000). These clusters are made up of actors from related branches and sub-sectors. Once a cluster has evolved, intensive exchange within the cluster starts. This interaction leads to the diffusion of new technologies, increased availability of trained specialists, rapid dissemination of innovations through the channels of subcontractors and clients, to the discovery of new possibilities for competitiveness and new market opportunities, and more(Beaker& others, 2014).

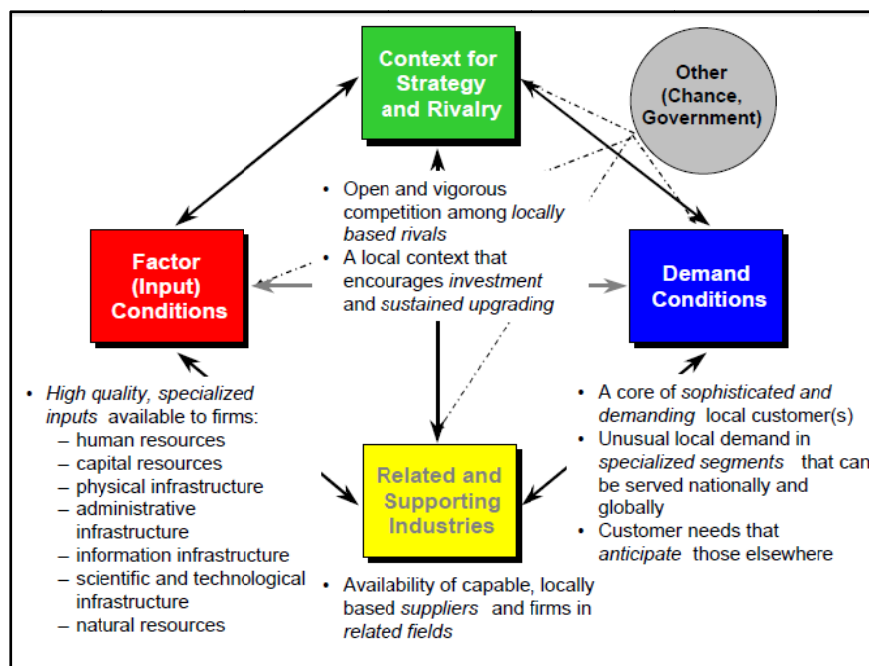

Figure 1 : Determinants of cluster competitiveness(Linde, 2003:143)

Clusters can be characterized as networks of production made of strongly interdependent firms (including specialized suppliers), knowledge producing agents (universities, research institutes, engineering companies), bridging institutions (brokers, consultants) and customers, linked to each other in a value generating production chain. The cluster approach focuses on the linkages and interdependences between actors in the network of production that are producing products and services and creating innovations (Roelandt and Hetrog, 1998:5). As the space industry organization forms to create a competitive advantage, it enables information and technology acquisition more convenient, relatively lower relatively; transaction costs savings, and encourages new enterprises to join to form a competing and cooperative relationship. Hundreds of cluster initiatives have launched involving virtually all regions of the world and the number is

growing (Skokan, 2009:772). Cluster initiatives, the organized efforts to increase the growth and competitiveness of cluster, in many countries are becoming an important way to structure economic policy and strengthen ties between industry, government and academia (Skokan, 2009). Cluster development initiatives are an important new path in economic policy, building on earlier efforts in macroeconomic stabilization, privatization, the opening of markets, and reducing the costs of doing business (Setz·2004). Clusters arise because they increase the productivity with which companies can compete. This approach to economic development generates significant benefits by enabling cities and regions to gain comparative advantage from the increased economies of scale of businesses that co-locate and collaborate in knowledge transfer, investment opportunities, and industry development. Generally, industry clusters are recognized by their significant role both in urban and regional economic development and in improvements in quality of life.

Porter witnessed that cities and regions could attract a significant focus from competitors, customers and suppliers that not only leads to efficiency and specialization but also information centralization and visibility of competitors. Therefore, in his latest formulation, Porter concludes that most of the successful international businesses are located in a city or specific region within a country (Dadashpor, H, 2011). He refers to steel industry around Dortmund, Essen and Düsseldorf, machine tools industry in Stuttgart and kitchen equipment industry in Solingen as examples of locational agglomerations. Porter states that “regions compete to create the most productive space. Industries do not matter, but it’s the method of competing and the way that they benefit from environment that matters” (UNIDO, 2009: 55). Porter stresses that space adjacencies among firms in what he refers to as industrial cluster building, plays an important role in improving productivity and encouragement of continuous innovation. Therefore, development of clusters reveals the role of location in competitive advantage. Porter (2000) states that competition among clusters in regions is influenced in various ways or in other words, clusters influence competition in three general ways that reflects and consolidates different parts of the diamond model: 1. increasing current (static) productivity of companies or member industries; 2. Increasing the capacity of cluster members for growth of innovation and productivity; 3. Stimulating formation of new businesses that support innovation and increase the domain of cluster (Porter, 2000: 11).

Given the varied theoretical perspectives regarding industry clusters, it is important to delineate the characteristics of clusters that are agreed upon in the literature. Steiner (1998) asserts that there are key features common to all theories of industry clusters. First, clusters are based on

specialization that results from a high division of labor within the economy. This naturally leads to a high degree of interdependence among economic actors, which leads to increased cooperation. This cooperation can take the form of inter- industry transactions between firms, knowledge exchanges between individuals and institutions, or linkages between public and semi-public institutions. These linkages can be based on either formal contracts or social, cultural and political ties. Second, specialization and interdependence is partly based on proximity in both economic and social space. Proximity in economic space entails firms producing similar goods or services. Proximity in social space entails firms sharing similar cultural, political and normative traits. This combination of specialization and proximity results in synergies that increase the competitiveness of the urban and region, which results in higher productivity, stabilization and wealth creation for both the firm and region (Peters, 2004:2-3).

2.1 Six key elements form the economic foundation that supports the development of industry clusters.

- a. Networks and alliances are formal and informal associations and mechanisms that facilitate the exchange of knowledge, information, ideas, and trade between companies and businesses involved in specific types of economic activity within an area. (These networks and alliances may expand between areas and sub regions, and some are global.)
- b. Skilled and adaptable human resources, for example, multi skilled, multilingual, and contract labor, must be available.
- c. Technology availability is important in improving production efficiency. The wide use of CAD, CAM, and GIS systems to assist manufacturing and analytical processes is important in improving the efficiency of production and the delivery of value-added producer services.
- d. Advanced physical and information infrastructure, for example, fiber-optic cable systems, data processing centers, efficient transportation systems, waste management services, and education, training, and community facilities have a significant impact on equipment and human performance in supporting the development of industry clusters and attracting new industries to regions.
- e. Access to financial capital, such as equity, venture capital, or debt financing, is an important economic foundation supporting investment in industry clusters.
- f. Taxation and regulatory environment has a significant impact on the cost of business and economic performance. Regions that offer taxation incentives for R&D, flexible building codes,

sound policies on environmental performance, and support for cleaner production provide the kind of economic foundation that foster industry cluster development.

3. Why cities and regions are important for development of industrial clusters?

Industrial clusters are a topical issue in urban and regional development and have become the main form and method of urban competition in the world (Shuqin& Hong, 2008). Many countries and cities take the industrial clusters as an important source of urban competitiveness under globalization (Shuqin& Hong, 2008) since cities and regions are well positioned to benefit from future industrial market opportunities. Much of both past and recent literature on urban growth begins with the premise that cities succeed because they promote agglomerations that raise the productivity of firms locating within the city's boundaries. There is a couple of reasons for this fact. Firstly, more than 50% of the global population now resides in cities and cities are gaining more economic importance and provide a specific context for the broader economic development challenges. Secondly, cities seem to be attracting a growing share of economic value, not just of population. With value creation increasingly driven by innovation and knowledge, cities' relevant advantages play out: density, absolute size that allows a portfolio of related activities to be present, proximity to benefit from local knowledge spillovers, a deep labor pool, amenities that attract a wide variety of human skill, and the traditional role of cities as homes to core educational and research institutions. Thirdly, cities – metropolitan centers in particular – play an increasingly critical role in a policy approach that aims to upgrade microeconomic competitiveness from the ground up. Hence, clusters are designed to restructure economic activity in a city or region, develop new industries and foster models of economic coordination involving localized networks of entrepreneurial activity and alliances between local governments, universities, skilled labor and firms. This model has drawn much interest from governments, multinational corporations, and local businesses in many countries as a means of strengthening and diversifying the urban and regional economic base. Generally, cities are able to provide the framework and physical infrastructure needed by industrial clusters if they are to thrive. Urban regeneration undertaken by city administrations and their partners provide businesses with a suitable environment whilst improvements in quality of life can lead to talent attraction and retention. In addition to leading physical urban development, cities can also bring together multi- sectoral partners by developing "technology". These provide clusters with structures to support the creation and development of incubators, startup centers and business centers (Euro, 2009:11).

Figure 2: Conceptual Approach and Goals of Cluster- Based City Economic Development

Ultimately, urban and industrial agglomerations have several advantages. Economies of scale (i) make it more efficient and effective to share market information, knowledge, new technology, product design and service innovations, and common research and development (R&D) facilities or centers; and (ii) lower the costs of doing business. This is the key phenomenon behind the concept of *cluster-based city* economic development. City clusters can offer shared access to common infrastructure, geospatial proximity for supply chains and networks, and concentrations of human resources and skills, and thus help to lower production and transaction costs. Industry clusters are significant drivers of local economic development (Choe & Roberts, 2011:3).

4. How Industrial Cluster policy can best contribute to the economic development of older industrial cities?

The study of the role and importance of clusters in supporting local economic development has undergone considerable research and development since Porter (1985, 1990) first wrote about them. According to Marques et al. (2005), the importance and impact of clusters in the processes of urban transformation, due to their potential as a possible economic and urban development tool, has been widely observed. Most developed countries, and an increasing number of developing countries, have embraced the concept of clusters as a matter of new economic policy.

The policy emphasis on clusters appears to be replacing the traditional supply-driven sector plans of governments, as these have failed to achieve sustainable economic outcomes for cities and regions. Clusters can become centers that generate urban redevelopment in processes of productive restructuring, due to the strong impact they have in their surroundings (Marques et al., 2004). Clusters evolved from productive agglomerations as districts or development poles, and are nuclei of small/medium interrelated entities in complementary productive sectors, which cooperate with research institutes, trade associations, local governments, etc., establishing synergies and linking agents in the same geographical location (Igliori, 2001). (3 Without any doubt, the Technology Center, the Technology Park, and universities key elements of successful restructuring and recovery in economic terms after the collapse of traditional industries in recent decades. In general, firms located in industrial clusters are more productive than those not located in clusters. The higher productivity of firms in clusters has long been explained through agglomeration effects, which refer to positive localized externalities: Knowledge transfer and innovating ideas among densely agglomerated workers, alleviating matching through thick labor markets, or reducing transaction costs by transacting with proximate firms. The authors stress out that this happens especially in areas that have undergone a restructuring process, where Clusters have been transformation agents of the urban fabric, acting as regeneration producers, not only from a morphological, but also from a socioeconomic point of view. This new type organization is an alternative to the development of contemporary cities, which have had part of their territories disqualified, in the restructuring, re-industrialization and deindustrialization processes, over the last 30 years (Marques Nunes and other, 2010:4).

5. Conclusion

The cluster-based economic development approach is a relatively new approach with the goal of creation of business clusters and development of competitive urban economy. There is an assumption that since no city (or country) does not have advantage in all sectors of industries, there would not be industrial clusters in every field. Hence, when there is an advantage for a city in specific field or industry and there are exist clusters relevant to that industry; policies could focus on development of these clusters. In fact, in such conditions it is expected that development of these clusters lead to development of the urban economy. There are numerous advantages for agglomeration of industrial clusters: economies of scale, sharing of new information, knowledge and technology, product designs, innovation in providing service and facilities and joint centers for research and development become more effective and more efficient and decrease in transaction costs and business operations costs. This is the major

phenomenon that lies within the concept of cluster-based economic development for cities. Since urban and regional economy is the result of the performance of relevant industrial firms on regional scale, business clusters are key units for understanding and developing regional economic performance as co-location of industrial units and related governmental institutions and bodies in a specific geographical location contributes to more dynamism and efficiency for production chain.

Creating Industrial Estates of the Future: Case Studies from Singapore

Li Jie CHOO, JTC Corporation, Singapore

1. Introduction

Industrial estates are typically perceived as hard, concrete landscapes devoid of aesthetic or 'human' factors. One would not expect the 'ballet sidewalk' espoused in Jacob (1961) to play out in such a place – often large, sprawling estates ploughed by heavy vehicles and segregated from the rest of the city. Traditional conceptualization of city development such as Burgess's or Hoyt's models also advocate that industrial activities should be segregated from residential and other uses, to avoid pollution or nuisances from causing disamenities to city dwellers.

The nature of today's industrial or manufacturing activities is, however, undergoing change, with the advent of the "Knowledge Economy", the "Digital Economy", or the "Creative Economy". Increasingly, the boundary between manufacturing and service are being blurred, giving rise to a wide array of economic activities and needs. In order to capitalize on these new relationships between economic activities and actors in the city, this paper seeks to argue that industrial estates of the future should be planned as workplaces with strong connections to the rest of the city (be it economically, physically, aesthetically, etc.), rather than merely places for machinery; industrial estates should as far as possible be guided by 3 key principles of city-planning: 1) Compactness, 2) Mixed-uses, and 3) Connectivity.

The paper will be divided into the above sections, using case studies and examples from Singapore. The first, on Compactness, explores how the city should make full use of available industrial land, in the context of land scarcity and competing uses. The second principle, on Mixed-Uses, explores how the city can plan for a fine-grained urban fabric even in the context of manufacturing spaces. The third principle, on Connectivity, is what ties these compact, mixed-use manufacturing spaces or districts with the rest of the city.

2. Case Context: Singapore

As a city-state with a small land mass of only 718 km², equivalent to almost half of London, Singapore presents itself as a apt case study of the dynamics between urban land and economic growth, magnified by the acute limitation in land resource. Early Singapore started out as a colonial port in the 1800's. Upon independence in 1965, the country moved into labour-intensive industries such as textile and wood products, and in the 1970-80's, into higher-value added industries like wafer fabrication and electronics. Today, Singapore's economy has diversified into various sectors, from banking and finance, tourism, biotechnology, petrochemicals, shipping etc. Unlike many other post-industrial cities, production remains a significant role in Singapore's economy, with manufacturing contributing to 28% of GDP. At the same time, there is a need to also address needs of a growing population - currently 5.4 million and projected to grow to 6.5 million by 2030 – with pressures for more land for residential, commercial, amenity and other uses.

Using Singapore as a starting point, the subsequent sections explores how a productive city of the future can be planned for.

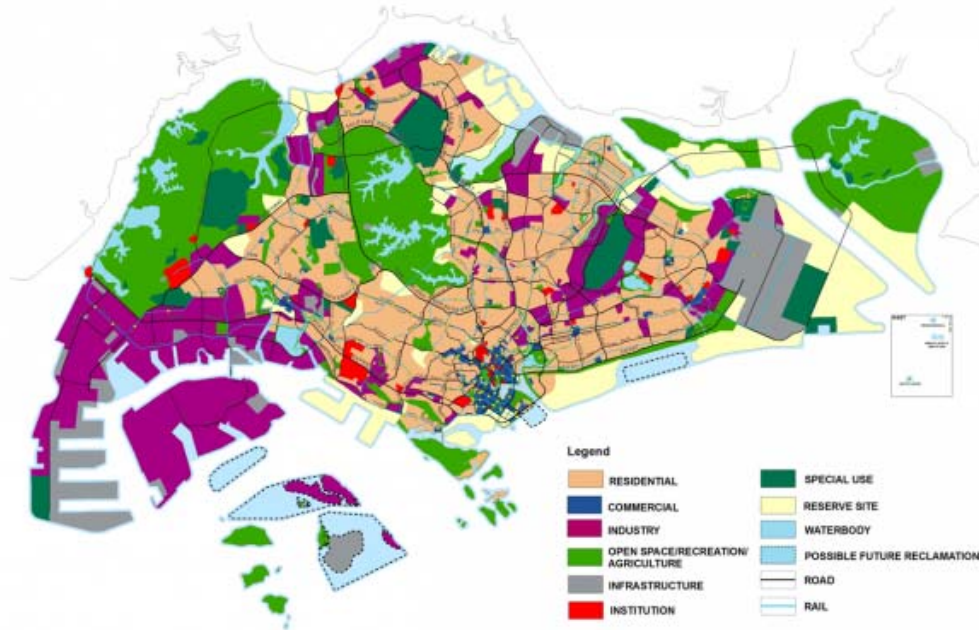

Figure 1: Profile of projected land uses in Singapore beyond 2030
(Source: Ministry of National Development)

3. Principle 1: Compactness

Today's post-industrial cities are hard-pressed to justify and safeguard industrial land, given the low value as compared to residential, retail or other uses. London, a major manufacturing centre in the 19th - 20th century, saw most of its manufacturing activities phased out and replaced with office, retail and residential developments, with almost 604 hectares of industrial land lost from 2006 to 2013 (Jones, 2015). Some of London's business districts today such as Canary Wharf, Battersea, and Croydon, have seen multifold increases in land values as a result of this replacement of industries with more 'valuable' uses. The hard truth is that urban land is scarce, and the city's land market is extremely competitive. In the face of strong pressures address housing and other needs in the city, industrial estates, often sprawling and low-rise, are often first to be foregone.

For cities to be able to accommodate and justify for industries to be located in the city, new forms of compact industrial developments needs to be embraced. Land issues aside, there are also strong reasons why industrial developments should be compact. Cities are engines for economic growth as they sit at the confluence of knowledge exchange and innovation. These interactions thrive on proximity and clustering, which is a key reason why writers such as Glaeser (2011) and Swinney and Thomas (2015) advocate for high-density forms of development. The concept of economic clustering or agglomeration is not new (for instance, as put forth by Marshall in 1920) - but there needs to be a paradigm shift that manufacturing activities can too be housed in compact urban forms.

3.1 Industrial Clustering in Specialized Industrial Parks

In Singapore, clustering is a key strategy to leverage on synergies from proximity and the sharing of utilities and facilities. The congregation of many big and small actors located within the same estate brings about locational advantages. On Jurong Island, a curated group of companies is carefully planned to be co-located such that one's outputs can be quickly and easily transported to another as an input. Through sharing of common facilities and

eliminating duplication of infrastructure, clustering is used as a tool for planners to minimize land take of industrial activities. Simultaneously, companies benefit from the provision of these shared infrastructure and amenities, for instance pipes for the transfer of chemical goods, security and safety services, training centres and R&D centres.

Figure 2: Jurong Island, a dedicated offshore island for the petrochemical industry in Singapore (Source: JTC Corporation)

At the same time, clustering helps to manage constraints posed by industries, for instance, height constraints from aerospace companies, health and safety buffers imposed by chemical companies, hygiene and cleanliness requirements from food and biomedical companies, and non-vibration environment required by wafer fabrication companies. In the 1980's, the need to manage these constraints gave rise to a new form of industrial development – specialized parks. These are now located at various parts of the island such as the Seletar Aerospace Park, Jurong Island, Tuas Biomedical Park, and Woodlands Wafer Fab Park. By clustering companies from the same industry together, land use constraints imposed by these industrial activities are limited only within these designated areas.

3.2 Intensification in High-rise and Multi-tenanted Facilities

Clustering takes place not only on an estate level, but on a building level. For a small, land-scarce city like Singapore, the move towards denser, more intensified forms of industrial development is a perennial quest – closely related to achieving higher land productivity to rationalize industrial land in Singapore. Policy-wise, the state requires industrial developments to meet minimum Gross Plot Ratio guidelines, depending on the needs and operations of the various industrial sectors. Industrialists are also encouraged to consolidate their developments, alter manufacturing operations or adopt new technologies to achieve higher land productivity through a Land Intensification Grant.

The state also leads in the development of high-rise, multi-user buildings catered to specific industry sectors, to encourage industrialists to move from land to space. The first multi-storeyed “stack-up” factory built achieved a Gross Plot Ratio of 2.05, as compared to 0.8 for older low-rise factories. Today, multi-storey industrial developments have since become the norm in centrally located or newer industrial areas in Singapore, with some of them being able reach as high as 10-storeys (even for heavier production activities that require ramps to access upper floors, for instance warehousing). Moving forward, developments are doing away with the traditional ramp-up typology and adopting alternative ways to transport goods and achieve even more land savings. For instance, JTC Space@Tanjong Kling, dubbed the ‘Small Footprint Factory’, facilitates vertical goods movement via lift, hoist and crane system. The Cluster Industrial Complex with Mega-hoist (CICM) was conceptualized to make use of a megahoist system within the building to facilitate transportation of goods from lower to upper floors. Others that house clean and light production activities, for instance R&D, can go even higher. These different types of multi-storey industrial developments are crucial in providing choice and supporting diversity of economic activities in the city.

Figure 3: Illustration of the CICM megahost system (Source: Government of Singapore)

Moving forward, the state is continuing to develop such high-rise, multi-user buildings for industry sectors that traditionally operate on ground floor. Instances include the JTC Surface Engineering Hub @ Tanjong Kling, a 4-storey development with a shared wastewater treatment plant for surface engineering companies, JTC Food Hub @ Senoko, a 7-storey development with a centralized coldroom for food manufacturing companies, JTC Furniture Hub @ Sungei Kadut, a 10-storey development for furniture manufacturing companies, and JTC Medtech One @ MedTech Hub with a shared sterilization plant and warehouse for medical technology companies. What is apparent from this is that it is possible to ‘densify’ a wide array of industrial activities through innovative development design, and at the same time reap benefits from this fine-grained clustering, where companies are similarly able to benefit from shared facilities and synergistic collaborations or tie-ups between each other, made possible by their close proximity to each other.

Figure 4: JTC Surface Engineering Hub, JTC Food Hub @ Senoko, JTC MedTech One @ MedTech Hub, JTC Furniture Hub @ Sungei Kadut (above left, clockwise) (Source: JTC Corporation)

3.3 Creating Space in Underground and Air Rights Development; Co-locating Uses

Besides the above, there are other ways to densify industrial developments.

With limited land resource, one strategy to create space is to go underground. For instance, what is being explored now is to use underground space as a ‘science city’ or for logistics and warehousing. Another strategy is to create space in air, through air rights development over major transport expressways, particularly in research and science parks. An outcome of this is the provision of linkages between separate developments.

Figure 5: Underground Science City (left), Air-rights development (right)
(Source: JTC Corporation)

Additionally, industrial developments are increasingly co-located with other types of uses to optimize site potentials. For instance, the Multi-Utility Hub located in one of Singapore’s knowledge cluster, one-north, houses a variety of uses and infrastructure within one complex – carpark, district cooling system, and park space. Another plot in one-north sees a 66kV substation integrated with park space. These typologies give flesh to the fact that industrial developments can be compact and dense developments that ‘fit in’ well and even enhance the city’s urban fabric.

Figure 6: Multi-Utility Hub at one-north
(Source: CPG Consultants)

4. Principle 2: Mixed Uses

A compact, dense city is able to capitalize on the social and economic synergies brought about from a large number of diverse activities congregated in close proximity to each other. For Jacobs (1961:155), the interweaving and interaction between different activities, is what generates vitality and vibrancy of city districts, what she terms the “essential phenomena”. Due to the low population density and the nature of industrial activities, one does not tend to

associate industrial estates with mixed uses. In fact, the traditional planning approach would be to segregate industrial uses from other uses as far as possible to avoid conflicts or disamenities caused.

In Singapore, the need to manage and plan for sustainable development within the city-state has warranted deviation from traditional planning. The city is adopting a decentralization strategy to establish 'regional centres' across the city, rather than isolating or congregating jobs in areas. This is to avoid congestion and provide businesses with alternative and more affordable spaces, and to bring jobs closer to homes and amenities (Tan, 2008). In that vein, production activities are increasingly situated closer to residential, commercial, and other uses.

The ability to support such activities near to neighbourhoods is complemented by the shift towards the knowledge economy, geared towards activities highly involved in innovation and research. Some of the identified industries for Singapore were healthcare, biomedical sciences, ICT, education services, photonics and nanotechnology (Wong and Millar, 2013:4). A more recent trend is servisation, or the "service encapsulation" of manufacturing products to include design, consultancy, diagnosing, repair, financing and product delivery activities within the value chain (OECD, 2001:63). With technologies such as additive manufacturing and robotics allowing more customized production, servisation is expected to "gather pace" in Singapore (MTI, 2014). The nature of production is transforming, in tandem with the types of spaces required.

Additionally, expectations for one's working environment are also altering. Spurred by Florida (2002)'s arguments on the "rise of the creative class", several cities have adopted place marketing strategies to attract a larger talent pool to work in the city or in a particular district. This goal to provide quality and vibrant working environment where people will be attracted to work in applies not just for commercial areas in the CBD, but also for production and manufacturing-related business districts. There is thus a need to provide a quality working environment, with sufficient amenities, open spaces, and other uses industrial estates, as illustrated in the following case study.

4.1 Case Study: one-north, Singapore

one-north, named after Singapore's geographical location one-degree north of the equator, is located in central west region of Singapore. The estate houses R&D and hi-tech clusters like biomedical sciences, physical sciences, engineering, infocommunications, media, as well as financial and business services. The planning of one-north was primarily conceived with a work-live-play-learn concept, to create an environment where a diverse mix of institutions and professionals are able to exchange knowledge and spur innovation. This knowledge and institutional networks within one-north and its vicinity comprise of a mix of economic and research-related players, from MNCs like Shell, Novartis, and Procter and Gamble (P&G), local companies like Infinite Studios and Lucasfilm, start-ups housed in a multi-tenanted incubator, academic institutions like INSEAD and ESSEC Business Schools, Singapore University of Design and Technology (SUTD), and National University of Singapore (NUS), as well as research institutions like the Agency for Science, Technology and Resesarch (ASTAR). This mix of economic activities situated in close proximity provides opportunities for synergistic collaborations. P&G for instance has signed a 3-year agreement with ASTA on biomedical research (ASTAR, 2013).

Figure 7: one-north, a 200-ha business park development (Source: JTC Corporation)

To create a vibrant work-live-play-learn environment and meet the needs and lifestyle preferences of the creative community, a fine-grained, mixed-use strategy was adopted in the masterplanning and programming of uses and activities in the estate. Both horizontal and vertical mixed use is encouraged. ‘Work’ spaces are distributed near key transport nodes of the MRT or potential People Mover System stations to enhance business accessibility within and beyond one-north. ‘Live’ spaces are typically located adjacent to green spaces such as the linear one-north Park or low-density heritage estates. ‘Play’ and ‘Learn’ elements are carefully distributed between the ‘Work’ and ‘Live’ components to act as bridging elements. These include recreational and retail programs (sport centres, media theatres, museums, clubs, cafes and restaurants) and educational institutions and libraries.

The Vista area for instance serves as the “heart” of one-north, acting as the gateway into the estate. The area includes housing, lifestyle, and business-related uses including residential developments and commercial developments housing event halls, retail, hotel, etc. In particular, Rochester Park, consisting of colonial bungalows refurbished into gastronomic venues, has come to be a popular destination for Singaporeans. Detailed attention has also been paid to the design and use programming to create a vibrant urban environment. Ground floor spaces of most developments are activated with retail uses, ranging from cafes, restaurants, childcare centres to shops. There is also generous provision of public and green spaces and street furniture particularly along key pedestrian pathways. To promote permeability throughout one-north, urban design guidelines are put in place to ensure developments are fenceless and make provisions for public spaces and linkways both on ground and upper levels to connect to adjacent developments. Echoing Jacobs’ principles for “exuberant diversity” in urban districts (1961:155), the provision of such a fine-grain mix of uses imbued with a highly open and porous open space fabric is designed to encourage social and economic interaction.

Figure 8: Diverse land uses in one-north (Source: Urban Redevelopment Authority)

Figure 9: Public Space in Star Vista development (Source: CapitaLand)

5. Principle 3: Connectivity

The third principle, on Connectivity, is what integrates these compact, mixed-use manufacturing spaces or districts with the rest of the city. Movement of people and goods is a key driver for economic synergies. Today, urban agglomerations like Europe and China are pumping billions of investment into high-speed rail networks, airport and port infrastructure, highways etc. With this comes the ability to plug into global, regional and local circuits of capital, what Sassen calls the 'global city'. Manufacturing spaces today thus has to be well-connected by land, air or sea to other economic zones.

In Singapore, extensive study is being embarked on the movement of goods across the city. One idea is for an automated underground goods mover system, connecting the future mega-container port on the Western end of the island, to other industrial estates in the city. This is expected to reduce the need for heavy vehicles and therefore road congestion, and at the same time cut short time needed for goods to reach its destination. These ideas seek to reconfigure the way goods and freight is distributed, making it easier, faster and more sustainable to support production in the city.

On a less macro-scale, connectivity is also crucial for accessibility and integration with surrounding areas. An industrial estate that is disconnected or fragmented from its surroundings cannot be a liveable one. Industrial estates need to be accessible by various modes of public transportation to homes and facilities to bring the working population to their workplaces. Often, this aspect may be neglected in industrial areas due to the low density of working population that is unable to financially justify investments in transportation infrastructure to serve the area. Even then, there are other affordable transport options that can be provided to serve industrial estates.

This section uses the same case-study of one-north to understand how these considerations were factored in in the planning and implementation of one-north.

5.1 Case Study: one-north, Singapore

When one-north was conceived, the flow of people and accessibility into the business park was an integral factor to ensure the estate was an attractive location for investors and companies. The first phase of the development centred around an existing rail station served by the East-West Line, Buona Vista Station, where the Vista area is located. At the same time, the estate capitalized on the upcoming Circle Line creating a circular route around the central fringe area of Singapore. Today, the estate is served by another dedicated station, one-north station, in addition to Buona Vista Station. These stations are crucial in ensuring that the prospective working population and visitors are able to access the estate, offering a direct route to the city centre, the airport, and residential areas in Singapore. At the same time, the estate is well served by road connections, with direct expressways linking to the western industrial region, city centre, and the airport.

Within the estate, strategies are also explored to facilitate workers to get to their destination in comfort and with speed. For instance, the Land Transport Authority (LTA) in conjunction with JTC Corporation (JTC) will be test-bedding driverless Autonomous Vehicle in one-north (LTA, 2015). Pedestrian networks and covered linkways are also planned in to provide users with a convenient and comfortable walking route to destinations.

6. Conclusion

Industrial development needs to be re-conceptualized and recast in a new light, to take into account changing trends in the economic landscape and diversity of economic activities, and be thought of as part and parcel of the city's urban fabric, rather than an unvalued, invisible and isolated fragment of the city.

As Glaeser (2011:6) writes, "cities are the absence of physical space between people and companies. They are proximity, density and closeness". These traits are an economic and social resource, which a compact, mixed-use, and well connected district can capitalize on, as illustrated using the one-north and other industrial developments in Singapore. By understanding how the city works best and how might it be possible to apply these mechanisms or principles even for industrial developments, planners can create industrial estates of the future – one that holds a strong narrative in the city's pursuit for social and economic sustainability.

Urban Circular Economy

Lieve CUSTERS, Buro Boris, Belgium

1. Abstract

Citizens are not concerned about circular economy. Because research on this particular form of economy mainly focuses on the larger streams that are running through the city like energy, waste, water and cycles between larger companies.

However, an urban variant of circular economy currently arises out of local entrepreneurship. Young entrepreneurs come up with new goods or services that push forward a recycle or a lease or share economy. For this purpose they are focusing on the small-scale personal needs of citizens (food, fashion or products). This process will change citizens, even beyond the status of consumers of solitary consumers of goods and services. They will become users. How will this process of moving towards an urban circular economy affect the daily life in the city and what will be the spatial impact on the structure of the city? What if these young entrepreneurs grow from niches towards a mainstream market? What will be the influence on (public and private) urban development? And how will citizens, as users, get more involved in an urban circular economy?

The designers (Lieve Custers for Buro Boris and David Dooghe) from the project Urban Circular Economy had interviews with several circular entrepreneurs from Antwerp and Rotterdam. These entrepreneurs focus on the profit that can be acquired from their consumers through sharing or leasing products instead of selling and/or valorizing the latent value of domestic waste. In addition to the interviews an interactive workshop was organized with a group of early adopter users.

This process resulted in three spatial future models that will be explored. Whereas in "business almost as usual" the focus will be on making existing production more green with no or minor effort of the user, "sustainability as pocket money" will be about valorizing the latent value of domestic waste (ex. upcycling, repairing...) and in "sustainability as Lifestyle" the community aspect, leasing and sharing will be the main facets. These three models will be described in this paper and the first conclusions will be drawn. What are positive or negative effects of an Urban Circular Economy on the city and urban development in the ¹future?

2. Introduction

In 1968 the Club of Rome warned about it already, but now it is becoming truly tangible: there is a limit to the growth and raw materials are becoming scarcer ^{1,2}. In addition, due to the current interest rates, it (almost) does not pay off to save money and therefore the family budget stabilizes. The scarcity of raw materials and the average family budget force consumers to take more informed choices and emphasize that our current linear economic system is under pressure. This is not a threat; on the contrary, by questioning the system itself, space for a system change is created.

One such system change is the emergence of circular economy. Companies are seeking to keep their raw materials in balance by optimizing material flows, water, energy, waste heat ... Today this optimisation of different flows is mainly used by and happening between large companies because they are benefited by their large concentrated masses. Thereby, the circular economy is still a long way off the daily life of the average consumer and the profit that can be found by the consumer is not gained yet ³. This applies both for economic profit as the gain in resources.

But recently some circular entrepreneurs have been focusing on the profit that can be acquired from the consumers. They aim to share and lease rather than to buy products or valorise the hidden value of household waste. In addition, these businesses are especially interesting for the impact they have on their customers. Whereas the industrialization made consumers of their customers with waste as a byproduct⁴, the Urban Circular Economy turns customers into users with more social contact as a byproduct. For users, it is no longer the possession, but the use that is important⁵. The cost of the use is lower than the cost of the purchase and maintenance of the products. This allows the user to maintain his lifestyle without increasing the share out of the family budget invested in these products. And once the products are used, they go back to the chain; ready to use again.

This system change offers a great challenge for the design team and the central question of the research is: what would the city look like when the Urban Circular Economy is mainstream, starting from the current circular users and entrepreneurs in the city? However, before the design team can define the spatial impact, is it necessary to specify the economic and social structures of a user driven society.

3. Principles

The project Urban Circular Economy centralizes the design of the new relationship between user and entrepreneur. Hence, the design team decided to investigate the development of an Urban Circular Economy from three products which contribute to fulfilling the daily needs of consumers: food, clothing and utensils. Neither consumer nor user, can get through the day without these products. In addition, these products have a different “run trough time” and therefore a different spatial impact (highly dynamic or rather static).

To change the system from a niche to a mainstream user market a sufficient concentration of users is needed for the economic model to be successful. Cities as hotspots of creativity and innovation offer this concentration. And because the relationship between the entrepreneur and the user will become more important, many entrepreneurs want to be close to their users. However, the attractiveness of cities has an influence on the land prices (they will increase) and space is a scarce commodity in the development of a new economy. As a result the tension between space and economy will be the highest in the city and therefore it is interesting to study the circular economy in an urban area.

The project examines the Urban Circular Economy in two cities: Antwerp and Rotterdam. These metropolises are very similar on the one hand: number of inhabitants, presence of a port, in full transformation due to high population growth and hotspots of creativity. On the other hand, their creative sectors are very different, the ownership structure is different and the policy on waste is organized differently. This offers the opportunity to examine which aspects of a transition to an Urban Circular Economy are location specific and which are generic.

4. Methodology

This research particularly focuses on the spatial impacts in a city where it is mainstream to lease or share instead of buying but where waste is seen as raw materials as well.

4.1 Prelude (July to December 2014)

First the design team collected data through interviews with experts, urban circular entrepreneurs and a through workshop with early adopter users. These data were used to work out the methodology.

Discussions with experts have led to the conclusion that scarcity of raw materials and resources will disrupt the current system and that it is important to build a circular economy within a network so that one is not dependent on one link to close the chain ⁶. Also, concluding agreements between companies is actually opposed to free market operation which makes companies reluctant to participate. Finally it was indicated that current technology does not yet make it possible to close the circle completely, but we can try to get as close as possible.

The interviews with fourteen entrepreneurs ⁷ gave insight into their company, the space they use and their relationship with their customers, both now and in the future when a user society will be mainstream. We learned about the background of their current and future planning decisions. Why is their business centrally or decentrally organized? What is the purpose of the present collective space? Do they desire visibility at the public space? How close to their suppliers or customers do they want to be located? How do they organize storage, transport, work and office space?

Finally, needs of the users were examined by organizing a workshop with early adopter users. In this workshop we asked the users how they can validate the value of waste more efficiently, what the underlying motives are when they buy, lease or share a product and which products or services can enhance the development of a circular economy in their neighbourhood.

The data collected in this initial phase is the hardware from which the spatial indicators are distilled which are important for the development of the methodology.

4.2 Approach (January to December 2015)

The design team is aware of the fact that an urban circular model, applicable in all cities, simply does not exist. Depending on the spatial and economic profile of the city, the ideal opportunities for the development of the city should be sought including both growth and decrease.

From the analysis of the data gathered two distinct questions have emerged. Will the ownership or use of products become mainstream? And will the increase of sustainability of the economic system be driven by producers or by customers? When these questions are plotted in a coordinate system, four quadrants are created. In each of these quadrants, the customer has a different role: a passive or active role in the closing of the chain and the owner or user of the products. The role of products, suppliers or governments on the other hand may be similar in some quadrants. If we expand the companies from the interviews in the coordinate system, three squares are filled. The fourth, could not be filled because this quadrant focuses on business to business and therefore falls outside the scope of the research. The three filled in quadrants are developed further into three perspectives.

These three resulting perspectives are implemented through research by design into the urban fabric of Rotterdam and Antwerp. As a result, the opportunities for users, businesses and governments will be set clear, but also the spatial impact of a user society. It provides a vision for both cities in which Urban Circular Economy is mainstream.

From these images of the future we will look back at the situation of today. This retrospective makes it possible to define strategies for the development of an Urban Circular Economy. These development strategies include steps that clearly indicate: who? what? where? when? and wow? both for the user, the entrepreneur and the policy. What is the low hanging fruit and what are the long-term investments? Thus, the development strategies provide an insight into the future and this gives the entrepreneur and the policy the flexibility to respond to changes that occur on the path to a user society. By comparing the development strategies for Antwerp and Rotterdam it will become clear which of these strategies are generic and which are specific to the unique economic and spatial situation of the city.

5. Three perspectives

5.1 Influential trends

The design team acts on two important questions: will the ownership or use of products become mainstream? And will the increase of sustainability of the economic system be driven by producers or customers? These questions are not the only aspect playing a part in a shift from consumer society to user society. There are trends, developments and processes that have an impact on an Urban Circular Economy. The design team is aware of this and will, for each perspective, consider how these influences contribute to both making the perspective mainstream and how they affect it.

So will there still be products contributing to the self-development and/or the expression of identity ⁸ of the buyer or user? Online shopping, apps, social media, ... remain a part of our purchase or usage. However, to this day, a growing group is already opposed to excessive online use or uses it in a more conscious way : "If I share everything, what remains of my uniqueness?" ⁹. The "offline world" will not disappear and interaction in the public space remains necessary ¹⁰. The migration to the city is continuing provided that the city remains a concentration of employment and meets the requirements of a good living quality (facilities, green and self-development).

Producers will continue to operate according to the formula of supply and demand. From this, they want to ensure economic freedom by minimizing interdependencies in a chain and they will pursue profit maximization ¹¹. Clarity in legislation and policies will be a key requirement for producers to develop new business models ¹². Creating room for experimentation within legislation and policies is essential to test the grassroots perspectives ¹³. With new products and/or services, producers will focus on the sustainability of the economy. However, depending on the perspective, the use of the product can also be sustainable.

5.2 Three perspectives

The three perspectives are all an extreme effect of a specific relationship between customer and producer. Each of the perspectives starts from a shortage of materials and the average family budget. However, each perspective leads to a different ratio of urban dwellers compared to the products a person uses or consumes on a daily, weekly or yearly basis.

In the perspective "Business (almost) as Usual" the customer is a consumer and owner of the products he/she buys and afterwards disposes. The sustainability of the supply chain (and goods) depends on the producer (Unilever, Colruyt). This perspective is closely linked to the strengthening of a circular economy between companies. In the perspective "Sustainability as Pocket Money", the customer will still buy the product, but as the owner of the product he/she will rent out its temporary use (Airbnb) or lend it (Peerby). When the product is at end of its life the owner shall return it (Marktplaats) or sell the materials (Afval Loont). As more products are in circulation and being reused, the user will play an active role in the sustainability of the product and the supply chain. These two perspectives focus as much as possible on resolving the waste problem afterwards. The third perspective "Sustainability as Lifestyle" goes a step beyond in trying to avoid waste at the source. Here, the customer no longer buys the product but will, through for instance the establishment of cooperatives, regulate the use of the product from a supplier (Greenwheels, Cambio). Besides cooperatives, other forms of cooperation are possible. Again products circulate longer and at the end of their lives the materials are still reused as a result of which the user also plays an active role in increase of the sustainability of the product and thus chain. In this perspective, different principles of the Sharing Economy can be found.

To illustrate the prospects more clearly a brief sketch will now be explained presuming the self driving car would be mainstream. In the perspective "Business (almost) as Usual" cars are bought for private use and besides the owner, no one else uses the self driving car. In the perspective "Sustainability as pocket money" cars are still bought but the owner lends the car to others if he/she does not use it him/herself. In the perspective of "Sustainability and Lifestyle" a supplier (whether or not the producer) owns the car and the users will share its use. This example also demonstrates that the different perspectives are robust enough as such to apply on new technological developments.

For every perspective both the role of the various parties (who) as the economic model and the possible spatial and policy implications (what) will be outlined briefly. Only after applying the perspectives on actual locations in Rotterdam and Antwerp the how question can be dealt with.

5.3 Business (almost) as Usual

In this perspective, the customer is the consumer and the owner of the product. He/she buys the product and throws it away at the end of its life. The sustainability of the chain (and thus also the city) is the responsibility of the producer. "Locally what is possible, globally what must be" will become the credo of more and more companies.

Producers have known for a while that sustainability has economic benefits: in addition to the positive image to the consumer, there are lower energy costs, lower CO₂ emissions (and thus less tax)... To have more control over and to get greater profits from the supply chain, companies will try to oversee the whole chain and, where possible, incorporate it in the activities of the company. This can be done by acquiring suppliers or by making clear mutual agreements¹⁴. Recycling companies will be important players to overcome the shortage of raw materials. They will collect the garbage from the city and other industries (and thereby take over tasks of the government), process raw materials and reduce the chain. These recycling companies are not location dependent and can settle in the proximity of the producers in order to get direct and on demand delivery. In addition, more recycling businesses are mainly located in less politically sensitive areas than many mining companies. Recycling companies can organize themselves locally (at a pre-separation of waste) or centrally (in post-separation of waste). In a centrally organization it is possible that a monopoly is created.

If the consumer does not value his/her waste, recycling companies can easily obtain raw materials and process them. A specific recycling will only be economically viable when there is a sufficient mass of waste and therefore these companies will settle in urban regions. Due to the proximity of consumers and producers, transport costs are lower and together with a more sustainable supply chain these sustainable products will be able to compete in price with the less sustainable products. This allows the customer to consume more products with an equal budget.

The spatial translation of this perspective strongly depends on the organization of recycling companies. When these companies are decentrally organized special waste collection systems may be set up at district level. Local businesses can use specific waste to power their business. This already happens but these entrepreneurs often run into some problems (such as logistics, destination...) which makes it difficult to make this system profitable.

When the recycling companies are centrally organized these companies will settle in strategically infrastructural places in the urban regions. The spatial requirements are good accessibility, far away from dwellings to avoid nuisance and enough storage space (for various raw materials so that they can be stored safely after recycling) and the ability to deliver them to other companies on demand, regardless of a centrally or decentrally organization.

Example

The Antwerp fashion designer Katrien van Hecke ¹⁵ has incorporated the entire production process in her business in a way that waste practically does not exist. She buys raw uncoloured fabrics and colours them herself with natural pigments according to the clothing designs for that season. Because of this, she only produces the material she needs. The remains of the fabric are carefully collected to be used in later collections as a patchwork.

She also cuts the fabric herself. Only the effective production of the garments is outsourced, be it nearby. She shares her knowledge with the trainees who help her. She hopes to inspire them to increase the sustainability of their own collections as well.

Katrien Van Hecke is more durable than many other fashion designers without compromising on her creativity. Moreover, by having control over the whole process she broadens her possibilities. As a consequence, the end result remains as exclusive as for other designers, because clothes are mostly bought because they are beautiful and not so much because they are produced sustainably.

Conditions

- The urban dweller is still a consumer, has his/her waste collected and continues to pay for waste disposal. In order to collect as much waste as possible the effort required from the consumer should be as limited as possible or should have a certain fun factor.
- Producers increase the sustainability of their supply chain.
- Recycling companies become a stronger player. For a successful economic model recycling companies must optimize and refine their process to meet the specific requirements of materials demanded from the producers and the price of their recycled material must remain lower than mining.
- Governments reduce their waste tasks and allow more space for recycling companies.
- The local waste flows must be known to set up a decentralized recycling system.

Advantages

- This perspective is easy to implement and is already applied by young entrepreneurs and established firms ¹⁶. The manufacturer increases the sustainability of the chain without radical investments on the short term or without deviating from its current main activity.
- By adding recycling companies in the product cycle a new economy with new jobs is created together with a new need for innovation.
- The retrieval of specific waste or post-separation of waste will require the presence of (cheap) labour. It is therefore easy to create a link between social initiatives and entrepreneurs ¹⁷.
- Companies can specify them by responding to local residual flows.

Disadvantages

- A lot of energy is lost in the conversion of waste to high-quality raw materials.
- Producers and recycling companies become more powerful in their relationship with each other (at a central organization they may grow into a monopoly), and their consumer.
- The consumer has a passive role and is not actively connected to the process. This can result in the loss of a lot of material.

5.4 Sustainability as pocket money.

In this perspective, the customer will still buy the product, but as the owner of the product he / she will temporarily lease the use (Airbnb) or lend it (Peerby). When the product is at the end of its life, the owner will return the product (Marktplaats) or sell the materials (Afval Loont). The buyer will have different expectations from the products (durable and robust), but can also choose to purchase a product based on the rental of the use ¹⁸. In addition, it can also have an impact on the purchasing behaviour of consumers when more expensive and more robust products are bought or, from an economic perspective, responding to the needs of the neighbourhood or its clients. This perspective goes beyond what the current

mainstream consumer does. There is a shift from consumer to user and in this perspective the market is not only lead by large producers but also by many small suppliers (individual users) who are offering the use of their products as an extra income.

The owner of the product sells the use of his/her products to other users (Snappcar), with or without additional services (Uber). As a result the owner of the product acquires extra income to supplement the unchanged family budget and retains his/her purchasing power. The user is both consumer (when he purchases a product) and producer (when he lends the use of the product to users). Once the product is at the end of its life, he/she will return the product for reparation (Iphone Doctor, Repair Café), sell it to others as a whole (Marktplaats, Kapaza) or sell the residual value of the product (Afval Loont).

In this perspective products are used longer. This results in fewer products in total, but it also takes longer for a product to return to the chain for recycling. Due to this, the producer will change his business model. The producer will not exclude selling products but will also provide services (repair e.d.).

When the used product is sold, there will be a quality inspection in order to determine the value of the materials. Different services, specializing in the collection and, if possible also the reuse or fast recycling of materials, will also emerge. This collection of specific products makes recycling easier. For example, mobile phones can be recycled perfectly, but it takes a lot of effort to collect them. Large-scale recycling companies will mainly be used for the difficult and labour-intensive recycling processes.

Given the economy that forms itself around the use and residual value of the product, the spatial interpretation of this perspective will focus on both the long-term use of the product (warehouses and workshops for repairs or adjustments to the product) and the residual value (second hand stores, strategically located collection points). To show the potential to the multitude of suppliers (use) and buyers (residual value) the initiatives be bundled in a “neighbourhoodapp” so one does not need to consult any other app for each product. But also physically, bundling can strengthen the initiatives: together on one location where many people pass by, offers great potential. This perspective leans towards multiple use of space and densification ¹⁹.

Also, in this perspective a smart mobility is essential to keep the cost of the use and transport of the residual product as low as possible. As sales and collection points are the same or lie in close proximity to each other, transport for the collection and delivery can achieved in one ride back and forth.

Example

Buurman ²⁰ is a DIY store for used building materials, located in the Rotterdam Vierhaven area and located next to a traditional DIY store. The building materials Buurman sells, come from industrial areas, demolition of buildings, exhibitions etc. At the moment, the materials are brought to the shed, but the goal is to organize the sale online so that the materials are immediately picked up on the construction site. This allows to save on transport which is the biggest cost.

Besides the (online) store Buurman will also become a public workshop where workbenches and equipment can be rented. The products can be made with free advice from a professional. The goal is to use their outdoor space to create a meeting place around the 'production process'. The user is more connected to the product through knowledge sharing, renting tools and space and organizing events. They are co-creator of their product which ensures a longer use of the product in the future. The goal is to roll out this formula to different cities and making each Buurman depend on material from their own city to keep transportation also as local as possible.

Interestingly, in the formula of Buurman matching supply and demand is paid for and not so much buying materials and selling. By focusing solely on matching, Buurman also saves from unnecessary transport.

Sharing knowledge, organizing events in collective space and the user/co-owner are also aspects that can be found in interviews with other circular entrepreneurs, for example from the food business (Uit Je Eigen Stad ²¹, Stadsvers), and are also strategies that are heard in the fight against vacant shops ²². If users can bring their waste back to shops in exchange for discounts (Shop & Drop app ²³) shops will also restore their important role as a physical place in the city.

Conditions

- The user is an active player in the economic system.
- The frequent and prolonged use causes long lasting products to be preferred to the rapid consumption goods. Producers must make their products robust and will also have to provide more services (repair / return).
- The bottlenecks are insurance, law and licensing. They are not adapted or leave no room for new revenue models. More opportunities should be provided ²⁴.
- The true cost of a product (including the impact on the environment) must be passed on to the customer. This makes recycling and/or upcycling competitive with finite resources ²⁵.

Advantages

- All parties are actively involved in the increase of the sustainability of the city.
- By renting products less waste is produced and therefore less energy is lost in the recycling of products.
- Because waste is sold in collection points, the recycling company saves on transportation costs (pick up at the various waste containers in the street) and the separation. This profit is the minimum value of the waste. Litter will decrease because waste is given a value
- The multitude of users implies a greater "demand and offer"-operation whereby not only the price but also the additional service will play a role. The multitude of users is a driving force for innovation in specific areas. The quality of the product and/or service is rendered transparent by a real-time rating system.
- In this model profits are distributed among producers, recycling companies and users.
- In the trade-offs resources connected to labour can be traded. By eliminating money as intermediate means (and therefore fiscal policy), labour is cheaper and the potential labour force in the city can be better employed.

Disadvantages

- The presence of many players may lead to a fragmentation of the market.
- In competition with others acquired social rights and obligations may be violated (e.g. discussion about Uber). Producers and suppliers need to adapt their organizational and business models to this situation.
- If the user gets paid for returning his/her waste, the price of recycled materials could also become higher. So, the model is only economically viable when the price of mining is also rising sharply.
- Due to the sales of the use of products, there is less need for products. Hence, the demand for recycled material and also the price will decrease. This will translate further into the price of the waste so that the economic model is under pressure in the long term.
- Furthermore, it may also increase theft because waste has a value.

5.5 Sustainability as Lifestyle

In this third and final perspective users are seeking to avoid waste. Here, the customer no longer buys the product but will (through the establishment of cooperatives) regulate the use of the product from a supplier (Greenwheels, Cambio). Other formal or informal partnerships are also possible. In this perspective, the customer has thus become a full-fledged user. The user (independent or part of a group) makes an agreement on the use of a product (e.g. a

washing machine) or a service (e.g. clean clothes) with the producer. If the agreement is made by a group it becomes easier to stipulate on price and service. In return, the user will have to accept that he/she has no sole rights to the product.

While this prospect may seem far-fetched, it is already very real. There are already cooperatives or platforms for energy (solar energy), mobility (Greenwheels), entertainment (Spotify), knowledge (Leeszaal West), workspace (Flexpackerz), landscaping (Stadstuin), financing (Crowdfunding and alternative currencies), food (Rechtstreex, Uit je eigen stad, Stadsvers), and products (Peerby). In addition, sharing experiences (for example, during physical and digital events by social media) with your peers is a clearly identifiable trend ²⁶.

As the producer remains the owner, he is responsible for the maintenance of the product. Depending on the service of the manufacturer and of the cost of use of energy, the user will determine with which producer he will close the deal. It is therefore important for the manufacturer to provide solid and durable products. Because the customer is no longer a consumer, but shares products several times, a possibility to improve products is created for the manufacturer. Today producers often have to compete with the continuous consumer demand for new products (for example, different clothing collections per year) and as a consequence the quality of the product is currently under a lot of pressure ²⁷. Instead, a product library gives the user the opportunity to try something new without buying a new product.

Although there are fewer products made, many customers who use the products will remain. So, the overall use does not change. In order to enable such use the producer will have to change his current space into space for repair and reuse of parts in the long term. As the producer remains the owner he has the possibility to recover and improve the parts and/or products at all times. The service does not stop with the products but along with other products packages can be assembled (washing machine and detergent (Bundles)) so that on the occasion of proper use, the products will also have a longer life.

Because of its focus on use rather than ownership, the service-economy will take a flight compared to the production-economy. Because everyone pays just for the use it is possible to have access to different services instead of saving money for the purchase of different products separately. The higher prices for housing gives the young customers for example less opportunities to buy products ²⁸. The choice of the type and grade of service is expected to be based on the frequency and duration of use, hygiene, investment and identity (exclusive or not) of the user ²⁹.

The success of this perspective results from combining various sub-platforms (mobility, nutrition, and so on) in order to create a sufficient mass to force change. This has the added advantage that the customer need not have a lease and/or weekly subscription by different services when he/she is offered the comfort of a total package ³⁰. Subscriptions are interesting for the producer as this ensures certainty of income. The subscriptions also represent a certain value, and should also be introduced as equity when applying for a new loan for further investment ³¹.

Besides products, you can also rent work (e.g. employment agencies). What if education, labour and health come in a package? From a certain age, you register and you become educated, someone will be looking for a job for you and will also regulate standard things such as health insurance, pension... This relieves both the worker and employer ³².

To lease and/or share products, less products are required causing the spatial effects in town for this model to be the greatest. Car sharing can save up to a third of the fleet ³³. This gain is even higher if working hours are flexible, so that not everyone needs a car at the same time ³⁴. This reduction of cars has a huge effect on the need for parking spaces in the city and provides space for e.g. an individual green spot such as a front yard or collective

playgrounds. Neighbours or neighbourhoods can make agreements about the use of products which enhance social cohesion. Furthermore, people do not need to have a storage room for tools, because it can be sufficient to salvage it at neighbourhood level. This will allow opening up the dead plinths of buildings for other functions to create more liveable streets. It is therefore expected that from the sharing and/or lease of a new product (social) meeting spaces will arise. These spaces will ideally go together with the clustering of several initiatives and the distribution centres will be working as new stores and will also be at more central places in the city.

Example

The vision for further development of their business of Peerby ³⁵ fits the "Sustainability as Lifestyle" thinking. Peerby allows you to borrow stuff from people in your neighbourhood. Place a call on their platform and Peerby will look around for you in the neighbourhood. Their business philosophy is accessibility: everywhere, everything, everyone. Peerby works demand-driven (out of a need) and not from offer (i.e. Marktplaats, Kapaza) and also enhances the neighbourhood feeling. The borrowers of Peerby are mainly people from the age of around thirty. These people come in a new phase of life (family, child....) and the acquisition of all new stuff is too expensive. They often do not have the space at home to store stuff either. On average, the lenders are older than sixty: they have bought a lot of stuff and have their experience and attained prosperity but also feel that they want to give something back to society. When we take these averages further, in several decades from now, there will be a situation with more and more borrowers and less lenders because no one will buy products anymore. In this way, Peerby sees a further development of sharing economy to slow and/or lease economy. The platform can then bring together users who demand better products from producers. The products are no longer purchased but rented or leased. So, use and not property will be paid for.

Because the users themselves share, it is interesting to lease the product so that the responsibility for maintenance lies with the producer and not with the group of users.

Conditions

- This perspective is strongly linked to the further development of cooperatives, platforms or other collaborations.
- Given the social importance of the expression of one's identity a possibility for the user to share a product with others or to have a monopoly on the use must always be extant.
- Producers will have to change their business models. This requires a change from current mainstream financing (banks) or laws and regulations (insurance and risks, destinations, and so on) so that new business models will be possible.
- Next to production, producers will also include services and repairs in their tasks. At the same time this requires changes in the design phase. The products must be designed and manufactured modularly so that components can be changed quickly.
- Governments must continue to provide basic public services to those who choose not to take part in a cooperative for their need for transportation, energy, education....
- Governments will have to support sustainable alternatives through tax system, targeted investments and sustainable alternatives.

Advantages

- Increase of sustainability for products, users and producers.
- By leasing and/or sharing products less materials will be used and the products will be more robust.
- The user needs less storage space which creates more living space in the house.
- For the producer this means a steady income and a closer relationship with the user

Disadvantages

- This model requires a lot of changes (social, economics, finance....) so it is not immediately implementable. Because of these major changes, effects are difficult to predict.
- The system depends on social structures, trust and good use. When products are shared people must also bring them back in time so that they are available for others.

6. First conclusions

The interviews with urban circular entrepreneurs and feedback from early adopters have made clear that mainstream Urban Circular Economy can still go in different directions. From this point of view three perspectives were defined by the design team, each having a different spatial effect. These are theoretical models and a further elaboration in practice is necessary. The perspectives will be further developed in practice through collaborations with circular urban entrepreneurs, early adopters and users of the municipality of Rotterdam and the city of Antwerp in the coming months. The importance of this project is high. Once scarcity of resources makes itself felt more strongly the common consumer, designers and governments will have to have in mind how an Urban Circular System can be given direction.

This research is part of the open call: "Tinkering with the metabolism of the city" of the Fund for Creative Industries. The design team consists of David Dooghe (Rotterdam) as project leader and Lieve Custers for Buro Boris (Antwerp). It is conducted in cooperation with the municipality of Rotterdam, Antwerp and R'damse Nieuwe.

Rejuvenation of the Productive Area in the City: E4 Subzone of Delhi

Dr. Meenakshi Dhote; School of Planning and Architecture, Delhi; India

Dr. Kusum Lata; India

Gargi Singh; India

Synopsis: The paper elucidates the inherent problems of unplanned and unregulated industrial development in developing countries and its social and environmental implications on the quality of life of a city.

1. Introduction

The Industrial sector plays an imperative role in the economic and social development of a city. Despite productiveness of a city being a major economic driver, it often causes a stir due to its negative environmental impact. These unwelcome consequences are mainly the product of lax in the implementation of norms due to want of administrative and political will, and poor planning practices. This not only threatens the physical environment but also disturbs the social fabric and economic welfare of the city of an area.

In the developing countries, undesirable mix of land uses especially the presence of small scale noxious industries among congested high density residential areas have been a major concern. Though the presence of industrial units in residential areas proves to be quite a comfortable choice for the owners and the workers, but its negative environmental impact often overrides this favourable setting.

India has many such areas where industrial activities have infringed the residential areas and Delhi itself has over 20 such pockets. The scattered growth of industries and the undesirable mix of land use in Delhi has been a major concern for last five decades. The three master plans of the Delhi (1962, 2001 and 2021) have recommended the segregation of confirming and non-confirming industrial uses and detailed the relocation strategies, yet its implementation remains a work in progress.

2. Growth of Industrial Mixed Use in Delhi

Delhi has undergone a rapid process of urbanization and industrialization with growth of industries beginning towards the end of 19th Century. In the span of about four decades there was a scattered growth of industries and by the beginning of World War II (WWII), nearly all the areas in the city had some industrial concentration. After the WWII gave fresh thrust to the process of industrialization, the number of registered factories increased from 111 in 1939 to 227 in 1945, with a corresponding increase in the number of workers from 17,400 to 37,000 respectively (GOI, 1997). However, the unforeseen growth of industries in Delhi was due to the influx of refugees in 1947, after the partition of India and Pakistan. The refugees from West Punjab (in Pakistan) brought with them mechanical skills and the ethos of entrepreneurship. By 1953, the number of workers in registered factories was about 44,000 and most of them (>85%) were working in small scale industries (GOI, 1997).

Due to the sudden surge in the number of establishments in one decade, majority of them were operating in improper and overcrowded structures as there was a lack of planned industrial space in the city. Prior to 1962, about 258 Ha, i.e.1.6% of the total area was covered by industries (GOI, 1962), most of which were scattered all over the city and few of them were in 2 planned industrial areas. 8000 industrial units were lying in non-conforming areas, especially in densely populated areas (GOI, 1962). Also, inefficient enforcement of structural and operational factory regulations coupled with inadequate (or lack of) zoning enforcement and environmental laws created a chaotic condition in the city.

First Master Plan for Delhi-1962 proposed industrial use while keeping in mind the lack of planned industrial areas and the objectionable locations of the industrial units scattered all over the city. Hence, new industrial areas were developed, so that the non-conforming industrial units could gradually be shifted there. However by 1981, which marked the end of the first master plan period, the industrial mix was still an issue as more than 20,000 industrial units were operating in residential area, as shown in Table 1.

Table 1: Location of Industrial Units in Delhi, 1981

Type of Area	No. of Industrial Units	Percentage
Planned Industrial area	8,330	18%
Residential Area	20,025	44%
Commercial Area	9,710	21%
Industrial Cluster	7,013	15.2%
Others	904	1.8%
Total	46,000	100%

Source: (Saigal et al 1994, pp. 35)

The issue of non-conforming industries became a matter of serious concern in the aftermath of oleum gas leak from a fertiliser industry in Delhi. This gas leak occurred soon after the infamous Bhopal gas leak and panicked the residents of Delhi. The oleum gas leak resulted in one fatality and few causalities. Thereafter, a court case was filed by an environmentalist lawyer, M. C. Mehta, for closure of non-conforming industries in Delhi. The lawyer claimed that these industries were taking away 'right to life' from the residents due to their polluting nature. Subsequently, in 1996, the Supreme Court of India directed the closure of industrial units functioning in residential and non-conforming areas of Delhi.

The subsequent master plans made provisions for the relocation of the industries but the strategies never materialized. Though the factories in pre-existing structures are under-maintained and over-utilized but these are significantly less expensive on per worker basis than any new space would be. It saves not only commute expenses for the owners and the labourers but also proves to be time efficient. These facts motivates the manufacturers to stay put in these old localities and not shift to the allocated plots in the industrial areas.

3. Redevelopment of 22 Non-Confirming Industrial Areas

After the failed attempts of the first two master plans, the third Master Plan of Delhi (2021) proposes to regularise 22 non-conforming areas of Delhi with over 70% industrial concentration. The prerequisite for regularisation is to adhere to the redevelopment norms, which pertains to road width and services. Rest of the non-notified industrial areas were ordered to shift within three years. However, these non-notified, non-conforming areas continue to exist in the residential areas.

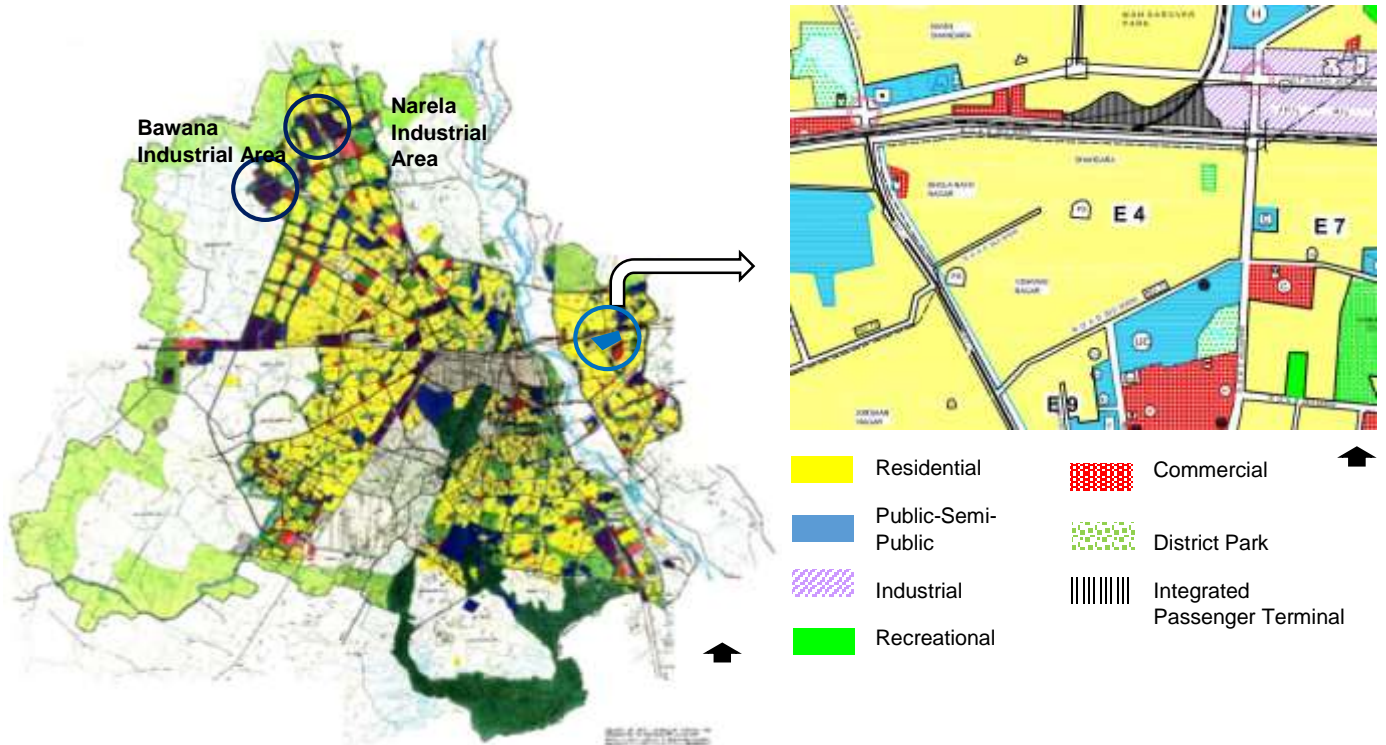

The present scenario of Delhi is such that three types of industrial area exists, namely, the planned industrial area, the 22 unplanned redeveloped non-conforming areas and the transitional non-conforming areas which are yet to relocate to the designated planned industrial areas. The third category of industries causes maximum damage to the residential environment as they're not bounded by norms of an industrial area, hence the pollution remains unabated. They are in transition stage for last eight years and not much has changed except the environmental quality of these residential areas, which has further deteriorated.

4. Introduction to Case Study Area: Sub-Zone E-4

One such case of transitional area is located in the planning sub-zone E-4 of Delhi. The case study area is located in Shahdara. Shahdara, literally means "door of kings", is one of the

oldest localities of Delhi. It was used as a passage from a neighbouring city of Meerut to Delhi during ancient times and developed around a small market called *Chandrawali* village dating to the 16th century. Soon, Shahdara grew into a major grain wholesale market and is still considered as a major marketplace in the east of Delhi.

Figure 1: Case Study City: Delhi, Case Study Area: Sub-zone E-4

Source: Master Plan for Delhi, 2021 and Zonal Development Plan, Division E, 2010

Sub-zone E-4 covers an area of 270Ha and accommodates 94,000 population as of 2014. Though it is designated under residential land use but industrial units are operating in the dense lanes of this urban village (shown in Figure 2). The area does not fulfil the 70% industrial concentration criteria and is therefore ineligible for redevelopment and subsequent notification. The majority of the industrial units, about 2500 are accumulated in 56Ha, known as Vishwas Nagar which is a regularised unauthorised area of the sub-zone.

Figure 2: Land Use Distribution of the Sub Zone

Source: Primary Survey, 2014

Unlike the old Shahdara, Vishwas Nagar came into existence later in 1950s and has distinctively orderly parallel streets. Vishwas Nagar started as a residential area, but in 1970s, a playing card manufacturing unit of medium scale was established here which changed the character of this area. Though the factory relocated to the outskirts within few years, but it triggered the mushrooming of small scale factories in the area. Land owners grabbed the opportunity to make money and rented out the flats to the industrial owners.

Vishwas Nagar started as a residential area, but in 1970s, a playing card manufacturing unit of medium scale was established here which changed the character of this area. Though the factory relocated to the outskirts within few years, but it triggered the mushrooming of small scale factories in the area. Land owners grabbed the opportunity to make money and rented out the flats to the industrial owners.

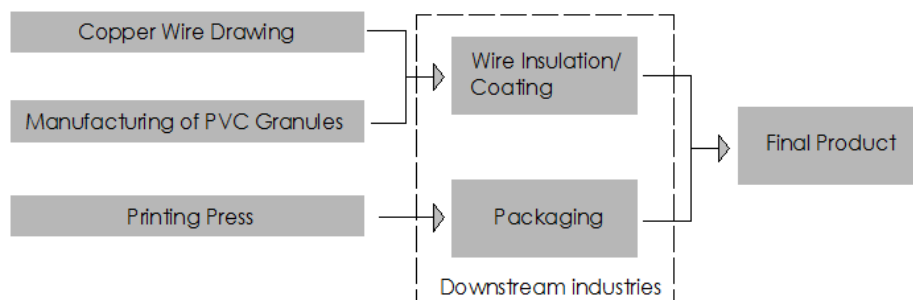

Figure 3: Industrial Units in Vishwas Nagar

Source: Survey by Delhi Pollution Control Committee, Govt. of National Capital Territory of Delhi and Primary Survey

Presently, Vishwas Nagar is well known for its industrial mix. In this maze of choked lanes, one can notice small manufacturing units dominating the area. Though 784 plots in the planned industrial areas of Bawana and Narela (Figure 2) have been allotted to the factory owners for relocation, but the industries continues to operate here. The industrial mix has been languishing here for past four decades and the owners are not planning to leave, albeit their number has been dwindling slowly. The allotted plots in the planned industrial areas have either been sold or rented out to other industries. They're mostly being considered as back-up option for the worst-case scenario, that is, when the municipal corporation seals the factories.

Figure 4: Types and relationship of the major industries in Vishwas Nagar

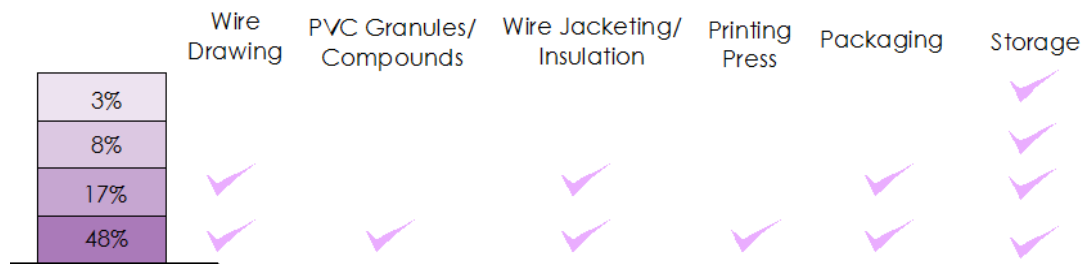

Wire manufacturing industries are flourishing in Vishwas Nagar. Since the area isn't classified as an industrial zone, the industrial units usually hide behind the closed shutters.

Ironically, the area is a stone’s throw away from the Karkardooma District Court. Most of the industrial activities take place at the ground and first floors, and the floors above are either used for storage or for residence by the owners or workers of the industrial units (Figure 5).

Majority of the factories here are orange category industries, which are significantly polluting in nature and hence unfit to operate in residential areas. In spite of that, a review petition has been filed in high court by the factory owners for Vishwas Nagar to be declared eligible for redevelopment. The factory owners have even offered to give up their allotted plots in planned industrial areas if Vishwas Nagar is notified under industrial use.

Figure 5: Floor Wise Activities in Vishwas Nagar

Source: Primary Survey, 2014

Figure 6: Built Up Land Use Distribution in Vishwas Nagar

Source: Survey by Sub-Divisional Magistrate office, Vivek Vihar, Survey by Delhi Pollution Control Committee and Government of National Capital Territory of Delhi, Primary Sample Survey 2014

According to the Master Plan for Delhi (MPD) 2021, “Non-conforming clusters of industrial concentration of minimum 4 hectare contiguous area, having more than 70% plots within the cluster under industrial activity/use may be considered for redevelopment of area identified on the basis of actual surveys”. Though master plan suggests a plot wise survey, but the Delhi Pollution Control Committee (DPCC) takes into account of the whole built up area (floor wise activities) in its survey. Vishwas Nagar has been surveyed thrice by the concerned authorities but the share of industrial units comes out to be less than 70%, both plot wise and built-up wise (Figure 6).

Moreover, according to DPCC, industries falling under the F-27/33 categories of MPD 2001 are not allowed in non-conforming areas. The PVC compound making industries (F-27) and wire drawing, coating, electric cables (F-33) fall under this category. As more than half of the industries in the area comprises of these two categories, the concentration of permissible non-conforming industries falls to approximately 12%.

Figure 7: Bars Showing Industrial Concentration in Vishwas Nagar Residential Area

Source: Primary Survey, 2014

Table 2: Categories of Industries Operating in The Area

Manufacturing Type	Units		MPD 1962	MPD 2001	MPD 2021	DPCC
	Number	%				
Wire Drawing	673	26%	Extensive	Group F	Permissible in Industrial Area	Orange
PVC Compounds	441	17%				
Wire Jacketing/ Insulation	336	13%				
Packaging/Cardboard	492	19%	Flatted & Work Industries	Group A	Household Industries	Green
Printing Press	597	23%	Flatted & Work Industries	Group B	Group B – Permissible in Commercial Areas	
Sanitary Fixtures	53	2%	Light and Service			
Ice Cream & Water Cooling						
Electric Fittings						
Helmet (PVC) Manufacturing			Extensive	Group E		
Machine Assembly/ Small Machine Parts				Group F		
					Permissible in Industrial Area	Orange

Source: Primary Survey, 2014

Apart from the orange category industries, a red category (heavily polluting) industrial process is also taking place in Vishwas Nagar. The manufacturing of PVC compound is also done by reprocessing of waste like glucose bottles, discarded PVC toys, pipes, etc. Hazardous waste processing viz. hospital/ medical/ industrial waste are prohibited in Delhi due to their extremely polluting nature. However, industries in Vishwas Nagar take the leverage of the residential status and carry out the process during weekends

5. Factors behind persistence of the industry owners

There are various factors which come into play in the existence of these industrial units despite the owners having an available alternative from the government. These are:

5.1 Economic dependency of the residents on industrial activities

These industries are the primary source of livelihood for many families residing in the area and its vicinity. Owners of about 32% of the industrial units and 20,000 workers reside in the sub-zone and the rest are living in the vicinity of 2-5km radius. The location is best suited for them as it saves time and money on commuting. Moreover, 36% of the residents in Vishwas

Nagar are engaged in the ancillary activities like service/repair, lamination which are product of industries and will not survive without them.

5.2 Underdeveloped Planned Industrial Areas

The planned industrial areas where plots have been allotted to the owners are about 35-40 kilometres away from this sub-zone (refer Figure 2) and commuting to such far flung areas is time consuming and costly. Moreover, since Vishwas Nagar is not a planned industrial area, it offers few perks of its own. Illegality comes easy as the “transition” area doesn’t come under the scanner of the pollution board and the revenue department. Hence, the taxes aren’t paid and the environmental norms are more often than not are flouted. Furthermore, labour laws aren’t followed, the workers slog for more than 12hrs a day and power theft is rampant. These factors end up minimising the manufacturing cost for the owners. The owners of wire drawing industries here earn up to Rs.50 lac (USD 80,000) per annum, which will reduce drastically if they operate in a planned industrial area.

5.3 Lax on the part of government

The Supreme Court order dated 07-May-2004 (M. C. Mehta v/s Union of India and others) states that “*the water and electricity connection of the industrial units found operating after the due date closure shall be disconnected*”. Due to lack of cooperation among the municipal corporation, electricity and water board, the implementation is stuck in a vicious cycle where one is waiting for the factories to be forcefully shut and the other is waiting for the utilities connection to cut off. However, in reality, the authorities have been shying away from their responsibilities and a blame game is on. Corruption in the authorities is one of the major reasons in the delay of implementation. The industries are being benefitted by this and the residents are bearing the brunt of it.

6. Impact on the Residents

Owing to the presence of these non-conforming industries, this subzone has deteriorated in terms of physical and social environment. The area witnesses smoke, noise, odour, obnoxious gases, illegal dumping of untreated industrial effluents and waste (refer Table 3). To make matters worse, fire incidents and chronic diseases are constantly on the rise. Moreover, due to these flourishing industrial units, ancillary non-conforming activities have also mushroomed in the area in the commercial mixed use streets, which causes further nuisance due to the incompatibility of the land uses.

Residents are compromising on their basic human need like clean air to breathe and a peaceful environment. There’s no relief even at night. The scenario gets worse during the weekends, as red category manufacturing process is executed during holidays, when there’s no probability of government surveillance. Social nuisance coupled with physical deterioration of the environment is taking toll on the quality of life of the residents.

Table 3: Nuisance caused by the industries

Manufacturing Type	Air	Water	Noise	Odour	Dust	Vibration	Fire Hazard
Wire Drawing	Severe	Severe	Moderate	Moderate	Moderate	Negligible	Moderate
PVC Granules	Severe	Severe	Severe	Moderate	Severe	Moderate	Moderate
Wire Jacketing	Severe	Moderate	Moderate	Moderate	Negligible	Negligible	Moderate
Printing	Moderate	Moderate	Severe	Severe	Negligible	Severe	Severe
Packaging	Negligible	Negligible	Moderate	Moderate	Negligible	Negligible	Moderate

■ Severe ■ Moderate ■ Negligible

The least nuisance causing industries in the area is that of packaging, which is categorised under household industry by DPCC. Wire drawing and PVC compound manufacturing are

the most polluting types and are blameable for the deterioration of the environment and health of the residents over the years.

Figure 8: Problems identified in Primary Survey

6.1 Air Quality

Table 4: Annual Air Quality of Shahdara and Delhi

Parameters NAAQS Standard	SO2		NO2		PM2.5		PM10	
	50		40		40		60	
	Shahdara	Delhi	Shahdara	Delhi	Shahdara	Delhi	Shahdara	Delhi
2007	5	5	50	44	87	84	195	188
2008	5	5	58	45	89	85	210	198
2009	2	6	43	49	77	72	224	243
2010	5	5	31	55	85	89	375	259
2011	6	6	59	61	91	95	486	222
2012	5		56				253	
2013	4		62				246	282
2014	4		57				272	318

Source: Central Pollution Control Board, WHO

The air quality of Shahdara is one of the poorest in Delhi and the city itself is the most polluted city in the world. The parameters of PM₁₀ is doing the worst among the parameters due to the presence of industries. Apart from the air polluting manufacturing process, the industrial waste is burned at night and early mornings which further add to the pollution. The quality is observed worst during the weekends, when the industrial owners take the leverage flout the norms by carrying out prohibited activities like reprocessing of PVC waste. The air quality has taken a toll on the health of the residents.

6.2 Noise Level

Table 5: Noise Levels observed during Primary Survey

Location	7:00 AM		2:00 PM		8:00 PM		10:00 PM	
	dB(A)							
	Min	Max	Min	Max	Min	Max	Min	Max
Vishwas Nagar	67	73	71	74	77	82	72	78
Near School	58	64	61	69	-	-	-	-
100% residential	42	49	46	52	49	54	39	51
Standard	55				45			
Market	44	52	68	75	48	56	42	55
Standard	65				55			

Noises in the industries are mostly the result of impact, vibration, friction, or turbulence in air. PVC granules and printing industries are most nuisance causing in this regard. The factories operate whole night and makes it difficult for the residents to sleep peacefully. The loading and unloading of trucks aggravate the problem. The noise level in Vishwas Nagar is over the prescribed limit throughout the day.

6.3 Odour

Though the factories hide behind closed shutters, but one can easily comprehend it because of the unpleasant smell lingering in the surrounding environment. The odour is mostly strong during the weekends when it can be sensed in the whole sub-zone.

6.4 Ground Water Quality

Ground water quality is affected by human beings both directly and indirectly. Direct impact is when the water is contaminated through discharge of pollutants, known as anthropogenic pollution. Indirect impact is due to water table depletion, which results in geogenic contamination, that is, elevation of concentrations of certain elements which affects human health negatively.

Table 6: Geogenic Contamination

	pH	EC (uS/cm)	Total Hardness (mg/l as CaCO ₃)	Fluoride
CBD Shahdara	8.41	5084	1190.95	0.38
Delhi Avg.	8.69	3285.26	938.09	1.30
Indian Standard	6.5 – 8.5	2250	300	0.6 to 1.2
WHO Standard	7.0 – 8.0		100	

Source: Central Ground Water Board

Factory owners (especially wire manufacturing units) use bore well. The constant need of water change during the manufacturing process has made the owners opt for a cheaper alternative even if it is not legal.

Table 7: Anthropogenic contamination

	Chloride	Sulphate	Nitrate	Nitrite	Calcium	Magnesium	Sodium	Potassium	Silicate	RSC	% Na	SAR
CBD Shahdara	1234.9	569	24.2	0.01	176.1	180	741	28.9	71	- 19.3	56.7	9.34
Delhi Avg.	622.77	387.3	98.6	0.09	130.3	163.9	479.5	61.9	48.0	- 14.6	43.5	5.59
Indian Standard	250	150	45		75	30	-	-		2.5	60	26
WHO Standard	250	150	50		75	30	200	-				

Source: Central Ground Water Board

The parameters which are exceeding the standards are the reflection of the raw materials that are used in these industries. Chlorinate Paraffin Wax (CPW) and Calcium Carbonate, the raw materials of PVC granule, have contributed to the shooting level of the chlorine and calcium. Sulphuric acid, used in wire drawing, when reacts with water forms sulphates. Moreover, the lubricant used in wire drawing industries is Sodium Nitrate. These raw materials have contaminated the ground water quality due to the negligence among the factory owners, labourers and the suppliers. The suppliers of the raw materials in this area

store chemicals like sulphuric acid in an underground water tank. The chemical can easily leach and contaminate ground water.

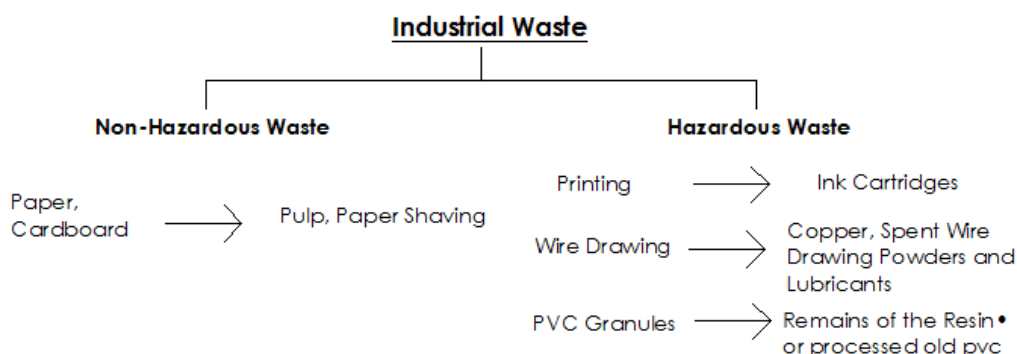

The lack of sense or indifference towards the disposal of waste is another major reason. The untreated chemical effluents of the industries are drained in the storm sewer, which contributes to the contamination of the ground water. As the industries here have a high demand of cooling water, processing water and water for cleaning purposes, the effluents are drained very frequently throughout the day. For instance, water is used to cool down the semi-melted PVC wire and because it gets up heated quickly, the warm water is replaced with fresh cool water to maintain the correct temperature. The phthalates can easily leach out of PVC because they are not chemically bound to the plastic. So, when dumped down the drains, these phthalates eventually leach into water. Similarly, wire drawing process builds up a toxic sludge of heavy metal when the water mixes up with a cleaning solvent. The sludge also contains minute particles of copper. This heavy metal sludge is also thrown in drains without being treated. Lastly, the industrial solid waste is dumped in undeveloped open lands in the vicinity and during rainfall the toxic waste seeps underground, causing ground water pollution.

6.5 Solid Waste

Figure 9: Industrial wastes are either dumped in drain or burnt on barren lands at night

The non-hazardous industrial waste in this area are the paper wastes from the printing press and packing industries. These wastes are recycled later when picked up by the local paper scrap dealers. However, the hazardous waste is illegally dumped by the factories. Industrial units located adjacent to the Shahdara drain take the leverage to dump the solid waste and effluents in the already polluted drain.

The vacant plots in the sub-zone have turned into dump yards for the industries. For instance, the CBD ground in the vicinity is yet to be fully developed, so the factory owners take the leeway of using it to dump and burn waste (Figure 9). Burning of wastes is a common practice and it worsens the already deteriorated air quality. Though the rag pickers collect the waste from these areas, but more or less the dump is always there.

6.6 Fire Incidents

Fire incidents have become fairly frequent in the clusters which have an industrial mix. On an average, 4-5 minor fire incidents are reported in the sub-zone every month. Though these fire incidents are mostly minor but due to the orange category industries and congestion in the area, there’s always a risk of a major fire outbreak in the area.

Vishwas Nagar has witnessed a major fire breakout in past. On December 7, 2005, a garment factory witnessed a major fire initiated by a sparkling machine kept near a 20 litre inflammable solvent can. The raging fire took lives of 12 workers and many were injured. Many workers ended up injuring themselves after jumping from the third floor of the building in desperation due to want of a fire escape and absent building byelaws.

Figure 10: Fire Incidents in Sub-Zone E-4

Most of the fire incidents (>70%) are reported from Vishwas Nagar. Though fire incidents due to factories comprise only 23% of the share (Figure 10), but other causes of fire hazards in the area are indirectly due to presence of the industrial activities. According to the Delhi’s Electricity Board, the area is classified as high theft prone. The fire in electric meters and transformers occur due to power theft and consumption of power beyond the sanctioned load, which puts stress on the distribution, equipment and network. Fire in rubbish occurs mostly due to the dumping of inflammable industrial waste like printing ink. The situations get worse as the narrow and congested lanes delays the emergency response in spite of the fire department being in the vicinity.

6.7 Occupational Hazard

Occupational hazard is one of the major concerns but is much underrated over here. Working behind the closed doors exacerbates the impact of manufacturing processes on the health of the workers (refer Figure 11). They work in an environment which is laden with chemical dusts and fumes and the concept of air change is unfamiliar here. One of the PVC recycling unit owners justified the condition by stating that residents are against the exhaust fans as the fumes and odour end up inside their home. Safety gears and safety measures are an outlandish concept in these accidental prone factories.

Figure 11: Despite the fumes, the workers operate in behind the closed shutters and nil ventilation

Furthermore, the factories are prone to fire hazard, and the vulnerability is amplified by the fact that there's no proper exit and the major gates remain locked from outside. The minor openings in the backyard don't suffice in the dire situations. To add to their plight, the medical first aid and fire aids are absent from the premises.

6.8 Health Hazards

The impact of the air quality has been confirmed by the primary survey of the residents and interviews with the local doctors. 45% of the health complaints pertained to Vishwas Nagar. According to the local doctors and primary survey outcome, airborne diseases like tuberculosis, thyroid and bronchitis/asthma are rampant here. Moreover, waterborne disease of kidney stones, which occurs due to high fluoride level in water, is fairly common among the residents. Diabetes and arthritis is prevalent among the workers due to irregular meal consumption and prolonged standing, respectively.

6.9 Other Issues

Due to industries, lots of impermissible ancillary activities like auto repair shops, scrap dealers have mushroomed in the area which cause nuisance. Loading and unloading activities and movement of commercial vehicles cause parking problem, congestion and other forms of annoyance in these narrow lanes. Since these industries are operating illegally, the products are transported every day rather than storing in their premises. As a result, about 1400 commercial vehicles like autos and truck frequent the area every day. Heavy vehicles are allowed in the city only between 10pm to 7 am, but one can see trucks plying in the area all day.

7. Root Cause of the Present Scenario

Environmental quality refers to the natural environment as well as the built environment. The built environment of the area is already compromised in unauthorized areas, such as less open space and built up ratio, inadequate right of way of roads, quality of structures, etc. Hence, it wouldn't be fair to say that the presence of industries has deteriorated a perfect residential environment. The following issues need to be addressed for the betterment of the area:

7.1 Delinquent Authorities

There is lack of co-ordination between the concerned authorities, i.e., Municipal Corporation of Delhi, Water and Electricity Board, which is delaying the implementation of the recommendation of Master Plan for Delhi, 2021. The lack of political will in the implementation process is a major setback which has resulted in the current scenario.

7.2 Relocation but no Rehabilitation

The industries require a developed site rather than a barren plot. Moreover, the plan does not include provisions for accommodation for workers and their families. Since the workers are usually in-migrants and don't have permanent residence in the city, it is necessary to provide accommodation as daily commutation and rent is a big cost for them.

7.3 Socio-Economic Dependency

About 60% of the residents are directly or indirectly dependent on these industries. Hence, shifting the economic base of the residents is a multifaceted issue and it's hard to tackle with a mere relocation strategy.

8. Possible Scenarios

Two future scenarios based on different assumptions can be built as recommendation for the area, as shown in Table 7. The first scenario is projected as a residential area with permissible household industries. The second scenario is planned with due consideration of the socio-economic dependency of the residents and allowing all the green category industries including household industries to operate in the area with their respective abatement procedures. In both the scenarios one can see the potential changes in physical environment and socio-economic status of the area.

Table 7: Two possible future scenarios for Vishwas Nagar

	Existing	Scenario 1	Scenario 2
Land Use	Residential + Industrial Mix	Residential	Residential + Industrial Mix
Type of industries	Household (19%), Green (23.5%), Orange (57.5%)	Household (Packaging) = 492 Units (19%)	Green (Packaging + Printing) = 1089 Units (42.5%)
Environmental Impact	Air Pollution, Effluents, Noise, Odour, Solid Waste	Impact Noise, Solid Waste, Fire Prone	VOC Emission, Effluents, Noise, Solid Waste, Fire Prone
Hazard (Fire, Occupational Hazard, Health Hazard)	High	Low	Low
Traffic congestion	1410 Vehicles/Day	140/Day (90% reduction)	395/Day (72% reduction)
Abatement Procedures	NONE	Acoustic Measures (a thicker under layer of sub-floor or shock absorber pads/pedestal/foundation under the machinery), Fire Extinguishers	Waterless Offset Printing, Water/Vegetable based Ink to Reduce VOC Emissions, Fire Extinguishers
Workers	19,900	1968 (10% retained)	5053 (25% retained)
Issues and Challenges		Loading/un-loading space need to be designated. Highly dependent on printing industries	Mildly polluting industries, so strict regulation on permissible industries required.

8.1 Proposal for the Remaining Industrial Categories

Out of the 1400 orange category industries, plot would be allotted to remaining 616 units as well and incentives to all 1400 would be accorded. Incentives could be like blanket tax concession for 5-10 years like SEZs. Moreover, developing rental housing for the workers

along with physical and social infrastructures. Moreover, the red category process would be ceased.

8.2 Provision of Loading/Unloading Space

Firstly, heavy commercial vehicles wouldn't be allowed in the area during day time. Secondly, the route of the commercial vehicles would be restricted along with a designated loading and unloading space.

8.3 Redevelopment Norms for Non-Conforming Industrial Areas

Master Plan's criteria for selection of non-conforming cluster based on 70% criteria need to be reassessed as everything boils down to the socio-economic dependency. Moreover, the redevelopment norms listed out by master plan clearly lacks the concern for physical environment and mostly pertains to social environment. Moreover, regular monitoring to be done in those 22 notified areas.

9. Conclusion

These transitional areas are often neglected and thereby continue to deteriorate the quality of life. Wiping off the industrial units from the area is not a suitable solution because the socio-economic dependency of the residents cannot be disregarded. These areas are complex in nature and require more than a mere relocation strategy. Therefore, a sustainable approach needs to be adopted so that the small scale compatible industries can exist without being a health hazard in the area.

Reworking London as a productive city: Challenges of implementation

Jessica FERM and Edward JONES
Bartlett School of Planning, University College London, United Kingdom

Abstract

This paper examines the challenges that planners face if industry is to survive and thrive in a successful city. It does so in the context of London, where the difference between the value of land for residential and industrial use, and the pressure to address the housing crisis, is leading to the loss of industrial land and premises at an increasing rate. The paper first challenges a common perception that the loss of industry in London is not a problem, as well as assumptions around the decline of manufacturing. We highlight the symbiotic relationship between industry and the city, why many industries depend on a city location, and the important supporting role played by industry for the wider economy, London's communities and the vibrancy of city life. The paper then explores current approaches to planning for industry in London, identifying impacts of a policy framework which anticipates and plans for the decline of industry. It then focuses on the critical question of how to plan for a productive city: we explore the arguments in favour of integrating industry into the urban fabric and set out the challenges posed by this approach, identifying some of the benefits of separating out uses and retaining employment land designations. We argue that if London is to continue to prosper, and meet the needs of all Londoners, then we need to think more carefully about how to plan for a productive city, experiment with innovative ways of integrating industry and other city uses, whilst protecting the existing land for industry. We put forward a critical research agenda to enable the planning system to effectively meet this challenge in the future.

1. Introduction

Our cities need to cater for the industries of the future, as well as the industries of the past. We need to create the conditions for new industries to flourish, whilst holding onto traditional industries that enable the city to function, provide essential goods and services to businesses and residents, and provide employment for the many, not just the few. This paper explores this challenge in the context of London. Measured in terms of GVA (Gross Value Added), London is one of the top five most successful cities in the world, achieved through a shift to higher skilled, higher productivity employment (London First, 2015: 16). However, there are two strongly voiced concerns about London. The first is around London's global competitive position, which shows that the city's economic growth has slowed since the 2008 recession; it is no longer ahead of its rivals, "but has now fallen back to being one of the pack" (ibid: 18). This is leading to a strong sense that London cannot take its growth for granted, and that it needs to rebalance the economy and build its economic resilience through supporting growth in a broader range of productive sectorsⁱ. The second is a concern that, as the city's population grows and residential property prices escalate, "the city is eating itself"ⁱⁱⁱ. London is losing much of what makes it interesting and special, including well occupied and functioning employment space, suitable for both new and traditional industries, as well as

start-ups and small and medium sized enterprises (SMEs) that seek more flexible, affordable space.

Ideally, we need to facilitate the provision of adequate land and premises for all these diverse productive activities to thrive in the future. But at the same time, we have to find ways to build more housing for a growing population. London's government is exploring a range of possible scenarios to accommodate future housing (Robson, 2015: 23-24), but in the absence of more radical answers, it has been turning to the mixed-use redevelopment of employment land. At face value, this seems like a win-win solution. London's shift towards a service economy means that more businesses are compatible with residential in a mixed-use environment. Even modern manufacturing no longer requires large factories, but can be accommodated in small and discreet buildings (Marsh, 2015), more easily integrated into a mixed-use environment, with housing and other community uses alongside. However, in practice, this approach is not achieving much success. This paper therefore challenges some of the optimism around mixed-use redevelopment of employment land, and points to a critical research agenda if we are to move forward.

One of the questions commonly posed is 'why should we be concerned about the loss of industry in London'? 'Industry' in this context usually refers to traditional industries that are perceived as out-dated and better suited to parts of the country (or world) where both land and labour costs are cheaper. The first section seeks to provide an answer to this by considering what sort of industry a city such as London still needs, and in turn, why industry might need, or thrive better in, such a city. The second section then goes on to explore the question of how we best go about 'planning' for industry in the contemporary city, where there are also other pressures on land use. Here, we start by looking at existing policies, both at the regional and local level, which encourage mixed use redevelopment. These policies are critically discussed in the context of the ideology of mixed use and what it is trying to achieve, against what is actually achieved on the ground. The reasons for failure in implementation are explored, and an argument made for the benefits of continued spatial separation of (some) industry and housing, alongside experimentation with new typologies and strategies for mixing industry with housing. The extent to which separation is still required depends on our ability to find solutions to the mixed-use dilemma (both in design terms and the way land value is calculated). The third section concludes and reflects on implications for future urban policy.

2. Why industry in London?

Productivity can be achieved in many ways, through producing things, ideas and services. However, in recent years, the balance of the economy in post-industrial cities has shifted away from primarily producing things, and increasingly towards producing ideas (the 'knowledge economy') and providing services (especially financial, legal, and business). The focus of this section will therefore primarily be on the value of continuing to pursue material production – or making things – in cities such as London.

First, however, some myth busting. There is a widely held perception that manufacturing is in terminal decline in the UK, and certainly in London. The Greater London Authority's employment projections, upon which it bases major decisions in the London Plan, are that there will be an 88% loss of manufacturing jobs from 129,000 in 2011 to just 15,500 in 2050 and substantial loss of other jobs in industry, utilities, transport and warehousingⁱⁱⁱ. These

projections are based on extrapolating past employment trends; by this methodology it is only a matter of time before this is reduced to zero. However, there are already indications that this trajectory will not simply continue – official figures show that employment in manufacturing in London has increased slightly between 2010 and 2015 (London Datastore, 2015) and this is echoed (as a rise in industrial employment generally) by the Industrial Land and Economy Study (AECOM, 2015). The GLA's interim employment projections (GLA Economics, 2015) treat this as a 'blip', but this is debated and it is possible we might have reached a critical threshold. A report by PwC (2009) argues that focusing only on employment and manufacturing's contribution to GDP is misleading. The UK picture in terms of employment is that 1 in 10 jobs were in manufacturing in 2008, compared to 1 in 4 in 1980. In terms of its contribution to national GDP, manufacturing is in 'relative' decline because of the growth in service industries, but it has continued to grow overall as GDP has increased roughly fourfold since the 1950s. Advances in technology mean that, although jobs have been lost, there has been a steady rise in productivity in manufacturing, so that its outputs (measured by GVA) have risen.

There are also spatial variations. Mass production in large factories has generally moved away from high value locations in inner cities to lower value land on the edge of cities, in other parts of the country, or in emerging economies; in short, places where both land and labour are cheaper. Such trends follow the logic of *bid rent theory*^{iv}, whereby the location of land uses and their values are determined by a competitive bidding process, where those uses that benefit most from being located in the centre will outbid other uses. However, some industry has remained. As Curran (2007: 1429) argues in the context of New York: "Those businesses that could, left the city long ago; those that remain are the ones that need to be there or have a business advantage because of their urban location". There are broadly three reasons why businesses might need to be in an urban location: to be close to other businesses, to be close to their markets and to access labour.

2.1 *Industry needs the city*

Other businesses can be clients, customers, suppliers, service providers or subcontractors. The volume of business-to-business (B2B) transactions is much higher than business-to-customer transactions – there may be multiple B2B transactions in a supply chain - and proximity is often key for speed of service. In Charlton Riverside in southeast London, there is a collection of complementary companies working in lift manufacturing and repair. Here, lift manufacturers and repairers are located next to specialist steel stockholders and electrical fitting suppliers. Working in close symbiosis, these firms can offer a rapid lift repair service to firms in the City and Canary Wharf, as well as to local residential high-rise blocks (JSEP, 2014).

Proximity to other businesses in the supply and production chain is an important feature of the benefits of agglomeration – as famously described by Max Weber and Alfred Marshall – but other benefits include the availability of labour and ability to share equipment and premises. Scott (1982) argues that this is particularly important for businesses in the incubation phase. New, small firms tend to seek out the mutually supportive environment provided by a concentration of other similar firms, with similar needs. As firms grow, they become more self-sufficient and less dependent on other firms or the availability of such externalities, and can take advantage of lower land costs in more peripheral locations. This has been the trend in mass manufacturing, where the processes of design and production

can be easily separated. However, in mature economies, where we are seeing a growth of smaller-run manufacturing for niche markets, it is harder to separate from the manufacturing process, since design and manufacturing choices are closely intertwined. As the CEO of the design software giant, Autodesk, explains:

During the period where people tried to exploit offshoring and outsourcing, manufacturing and design got divorced from each other. Now companies are realizing that if you get too divorced from making the product, you don't understand how to improve it. (quoted in Leber, 2013).

What the implications of such change are for land use and design of premises is so far little understood and not reflected in land use classes. For example, in England, a single premises is categorised as either an office, a factory, a warehouse or a retail unit, whereas in reality there is increasing hybridity within a single premises (Ramidus Consulting, 2012).

Industry has traditionally sought a city location to be close to its markets. As documented by Peter Hall (1969), London was historically home to industries at the end of the production chain: clothing manufacturing rather than textiles; furniture, rather than woodworking; printing rather than paper production; and jewellery and watchmaking rather than metal manufacture. For these industries, their location was driven by proximity to the market (in London the large pool of potential customers and their relative wealth was an attraction - as well as access to the national and international markets). The increased use of road-based deliveries and the decreased cost of transportation has meant that industries no longer need to be cheek by jowl with their markets. Nevertheless, some recent trends are re-emphasising the importance of proximity. First, the rise of niche, bespoke production means that producers need to be close to their markets, to understand and effectively respond to them. Second, customers are becoming more demanding in terms of speed of delivery and service, and there is also a trend towards integration of manufacturing and retailing, where customers can buy products straight from the site of production. In New York's Industry City, this has been a key driver for flexibility of use classes in the development (Kimball, 2015). Increasingly, a separation between places of production and consumption can undermine business models and proximity to markets appears more important than ever.

The fact that London has been home to traditional industries toward the end of the production chain, means access to skilled labour has always been important. In new manufacturing, there is a closer symbiosis between production and design, research and development, which again relies on access to skilled labour. In London, there has been ready access to both skilled and cheap labour, due to it being a first point of call for most immigrants into the country (Hall, 1962). Scott (1982) argues that throughout history, there has been a tendency for labour-intensive firms to seek central locations (with access to the greatest 'pool' of labour), and for capital-intensive firms (those who depend more on larger premises or machinery) to seek peripheral locations, where land is cheaper. With improvements in technology, we have seen over the course of history, a displacement of labour (people) by capital (machinery) in manufacturing. Thus, over time, we have increasingly seen firms disperse or decentralize. However, the nature of labour in manufacturing is changing:

The manufacturing of the past was characterised by long production runs and repetitive manual labour. It was used to make goods that varied little between one day and the

next. The focus in the industries of the future will be on fast changing products, created to high specifications, often through mixing a range of technologies, from electronics to biotech. Next generation manufacturing will be tailored to individual requirements and fabricated in short runs. (Marsh, 2015)

This will require more skilled labour, proximity to centres of research and development, and other technology sectors. This all suggests that, for industries of the future, it will be increasingly important to be near other businesses, to be close to markets, and to have access to skilled labour – all of which are more accessible in cities than their peripheries. This all suggests that we are likely to see continued agglomeration in the materially productive sectors of the economy as well as the knowledge industries, hitherto well documented. In short, for industries of the future, cities will be more important.

2.2 *Cities need industry*

Conversely, cities also need industry. The most obvious reason is because there are industries that are essential to keep the city functioning, to provide goods and services to its businesses and residents, to deal with its waste, to provide materials for its construction, and so on. A consultants' study of industrial premises remarks:

Just consider the diversity of services and products consumed by the average office building: catering; cleaning; furniture; maintenance and fit out; office equipment and supplies; print and copy; security; waste disposal and many others...Much of this support activity is located away from the central area, often clustered around the central area and in outer London... Often the activity is "low key", but is vital to the efficient functioning of the city and in supporting its global role (Harris, 2013: 1).

The importance of activities on industrial land as a support function for London's businesses and residents seems obvious but is often overlooked. The demand for a wide array of just-in-time goods and services is increasing as London's residential and business population becomes increasingly wealthy, lifestyles are changing and the internet facilitates the delivery of such services at the touch of an app button. An employment study for a central London borough (Roger Tym and Partners, 2011a) identifies a number of examples of such businesses providing goods and services with a short 'shelf life', including florists serving small retail outlets in stations, Asian fast food kitchens, and taxi firm 'Addison Lee' which needs a central administration and vehicle garaging centre, to enable quick dispatch of vehicles to respond to market demand. A central location for such businesses is important as they are required to guarantee timed deliveries to customers or their own retail outlets.

The construction industry, which has supported London's property boom, depends almost entirely on industrial land available within London, particularly the manufacture and supply of construction materials, but also related services such as plumbers' merchants, scaffolders, trade wholesalers etc. Facilities like aggregate yards may be unattractive neighbours for nearby residents, but nevertheless form part of the essential infrastructure for London's construction industry.

The imperative for London to sustainably deal with its waste means that there is a demand for sites to accommodate this essential element of London's infrastructure. For example, Powerday building waste recycling centre occupies a site in Park Royal, and makes use of rail and canal infrastructure to transport waste thus reducing lorry movements (GLA, 2014:

72). Similarly, work by Cass Cities^v has shown that recycle production is increasing in London and is becoming a significant element of manufacturing. For example, the Dagenham gasification plant will turn 180,000 tonnes of waste each year into 19MW of energy, while producing metal, aggregate and glass recycles. Newer businesses, such as Closed Loop who produce food-grade plastic recycle out of plastic bottles, wanted to be in London because of its stream of waste.

The increasing demand for just-in-time goods and services, and increasing opportunities in cities for green industries, suggests there is a strong environmental argument for supporting industry in the city. If space for manufacturing and industry can be incorporated into the city, travel distances between production and markets can be reduced, and green industries can grow. So it can be argued that cities need industry in order to move towards a more environmentally sustainable future.

Cities also need industry in order to be more economically and socially resilient. It has long been known that diverse economies, i.e. those that do not rely on a narrow range of economic sectors, are more resilient (Chinitz, 1961). In London, there is a concern that the city has become overly reliant on the financial and business services sector, such that one of the three stated goals of London 2036 (London First, 2015: 4) is to increase London's diversity and resilience, promoting strong performance across more of the economy, with no single sector contributing more than 40% of GVA or jobs growth. Promoting resilience also requires ensuring a balance between imports and exports. At present, the UK imports more goods than it exports, but it exports more services. In 2012, the Chancellor George Osborne set a target to double UK exports to £1 trillion by 2020. London has a long history as a trading centre; its demography and international reach means it is well placed to lead the UK's exports drive (Theseira, 2014). However, its potential is limited by availability of suitable premises and land for new manufacturing activity (Marsh, 2015). Solving this issue would support the economy, but it would also promote social equity in the city, by providing a greater range of jobs, both skilled and unskilled, but with the potential for higher wages, job progression and satisfaction than the service industry. Camden's Core Strategy (LB Camden, 2010: para 8.12) explains:

Premises suitable for industrial, manufacturing and warehousing businesses provide jobs for people who would otherwise be at high risk of being unemployed or workless. The Camden employment land review 2008, using data from the National Employer Survey 2003 and the Annual Business Inquiry 2006, found that the skills required for these sectors are fundamentally different from other sectors with similar qualification level requirements, such as retail, leisure and hospitality. Therefore, it is unlikely that the retail or hospitality sectors will provide straightforward alternative job opportunities for people losing industrial/warehousing jobs in the borough.

Increasingly, it is becoming clear that the so-called 'knowledge economy' has not solved the problems of post-industrial cities, the gap between rich and poor has got worse and long-term unemployment remains a major issue (Madanipour, 2013). Therefore there is increasing interest in the potential of new urban manufacturing to bridge the gap.

Finally, another argument - currently underdeveloped – is that industry makes for a more interesting and vibrant city. As stated in the urban lifestyle magazine, *Monocle* (Tuck, 2009):

City streets need to be pleasant places to live but also home to small businesses, craft makers and even the odd car mechanic. They might be unsightly, noisy and lower the tone of the street but they are what make a neighbourhood thrive. And anyway, too much peace and quiet can be bad for you.

Such ideas underpinned arguments made in the 1960s by Jane Jacobs in her seminal book, *The Death and Life of Great American Cities*, later an inspiration for Sharon Zukin's (2010) *Naked City: The Death and Life of Authentic Urban Places*. Jacobs (1961) argued: "City diversity itself permits and stimulates more diversity" (p.145). The same conditions that create diverse commerce, she claims, also promote other types of city variety; diverse cultural opportunities and "a variety in its population" (p.148). Such ideas underpin the enthusiasm for mixing land uses in cities, which is discussed in the following section, but there is by no means a consensus about how we should effectively incorporate production into our cities.

3. Planning the productive city

The evidence suggests that if London is to continue to prosper, whilst meeting the needs of all Londoners, then we need to think more carefully about how to plan for a productive city. Before going on to discuss future options, it is helpful to explain how London currently plans and what the key challenges are.

3.1 Current approaches to planning for industry in London

Manufacturing and industry in London is protected through area-based designations at both the regional and local levels. Strategic Industrial Locations (SIL) afford the highest degree of protection, with losses only allowed as part of a coordinated process of consolidation. Locally Significant Industrial Sites (LSIS) require regular reviews of supply and demand to justify continued protection, and 'Other' industrial sites are not protected strategically but managed by borough policies. (GLA, 2015: 160; GLA, 2012: 7). Approximately half of London's industrial capacity falls within SIL, just under a fifth within LSIS and a third within 'other' industrial sites, with no policy protection (URS, 2010). The existence of these protective policies suggests that the elimination of these uses is resisted by the planning system, but overall the decline of physical production is anticipated and planned for. The evidence base supporting the London Infrastructure Plan predicts an 88% loss of manufacturing jobs by 2050, leaving only 15,500 jobs in this sector (GLA Intelligence, 2013). Policy documents refer to the historic structural change in London's economy, moving away from 'traditional manufacturing industries' to the 'service sector' (GLA, 2008: 14). Similarly, the Mayor's Economic Development Strategy (GLA, 2010) presents a potted history of London's economic growth where industry and manufacturing are portrayed as part of London's past. This narrative presents a justification to dispense with the protection of industrial sites and instead provide infrastructure to support growing sectors of London's economy, such as business services. These sentiments are echoed in many consultants' studies, for example one observes that "land use planning designations have lagged behind economic change and consequently too much land has been allocated and protected for industrial use in London" (URS, 2007: 82). The document *London 2036: an agenda for jobs and growth*^{vi} anticipates:

that large-scale manufacturing will not return to high-cost cities like London, even if re-shoring brings some manufacturing employment back to advanced economies as a whole. Changing technology may drive some pockets of growth, for example in close-to-market creation of prototypes through 3D printing. However, these pockets are unlikely to generate significant employment; particularly since the economic reasons to locate outside high-cost locations will become more compelling if employment grows. (London First, 2015: 22)

However, this view does not chime with that of writers on the 'new industrial revolution', who argue that "the world is on the cusp of a manufacturing revolution" which is only just gathering force, and that advanced industrialized nations are well placed to take advantage of this (Anderson, 2012; Marsh, 2012). Strategic policy does not recognise this potential adequately and rather plans for the continued decline of manufacturing and industry through the use of benchmarks for the managed release of employment land. Furthermore, planning practices - in response to development pressures - appear to be speeding this decline, over and above the benchmarks set out in policy. Between 2001 and 2006, 90 ha of industrial land were lost each year to other uses, approximately double the proposed benchmark in policy (URS, 2007: 9, 82). For the period 2006-16, the benchmark remained roughly the same at 48 ha per annum (GLA, 2008: 7), while in reality 86.75 ha industrial land was released each year between 2006 and 2010 (GLA, 2012: 8). Reasons for the unanticipated were explained through interviews with planning officers from six London boroughs, undertaken as part of a study for the GLA (Roger Tym & Partners, 2011b: 19):

there is very little understanding of strategic employment land issues in development control teams ... most policy officers reckoned that their development control teams had no familiarity with the benchmarks or with the GLA evidence base in general. They might understand the general strategy, but not the detailed benchmarks, rationale or technical detail behind the numbers.

Substantial losses of industrial land, over and above the benchmarks, has led to a lower benchmark of 36.7 ha per annum for the 2011-2031 period (GLA, 2012: 8), but the overall approach of managed decline remains. This is despite an understanding that the official figures are likely to underestimate the scale of loss, not taking into account transactions that take place under the radar, or that which is in the pipeline due to policy changes. The key question is to what extent demand is affected by supply, in other words has the loss of jobs in industry and manufacturing been accelerated by the inability of companies to secure suitable space in the capital? If this can be demonstrated, then a strategy of managed release to match declining demand does not stand up as a rationale.

At a local level, it is becoming common practice for London boroughs to give more flexible mixed use designations to their locally significant industrial sites. For example, the London Borough of Brent in northwest London has identified one such industrial area (Alperton) as a growth area, which needs to accommodate a proportion of the borough's housing targets over the next 10-15 years. As part of this process, sites that were protected for industrial use are being given a 'mixed use' designation, in order to be able to accommodate housing (LB Brent, 2011). In Lewisham, southeast London, several such sites have been given a designation of Mixed Use Employment Locations (LB Lewisham, 2013), but it is unclear how the Council will secure any significant employment on these sites. Many more examples across London could be given. Of course, in addition to the sites that were previously

protected by policy for industrial use, approximately one third of London's industrial capacity falls outside areas that are protected by policy and therefore they are much more vulnerable to redevelopment. In some cases, these are sites that are in local authority ownership, but ripe for disposal. For example, in Camden, there are a significant number of industrial sites and premises in Council ownership that are being sold to fund its Community Investment Programme^{vii}. The fact that local authorities are under pressure to sell off their own industrial sites in order to fund basic community services adds another dimension to the potential scale of loss in the pipeline.

3.2 Mixed use as an ideology

Underpinning this trend that is seeing employment sites re-designated as mixed use is an ideological argument against separating industrial from other land uses, which suggests that zoning (or separation)^{viii} is an outdated, now irrelevant way of managing cities, which does not support compact, diverse and vibrant mixed-use city environments, and is therefore unsustainable. The loss of manufacturing in industrial cities of north America and Europe has prompted many to question the logic behind the continued physical separation of employment land from other city uses and housing, the assumption being that businesses in the knowledge economy no longer seek traditional employment locations, but are more attracted to the mixed-use environments typical of city centres. Promoting more 'mixed-use' also allows employment land to accommodate housing development, and meet the pressure for housing growth. Aside from the practical considerations, mixed-use environments - whereby a range of different commercial, residential, leisure and community land uses are accommodated together within a building, site or district - support the environmental sustainability agenda of compact cities and have been promoted, following the traditional European model, by the European Commission in the 1990s (CEC, 1990), and the UK Labour Government in the early 2000s (DETR, 2000) as part of its drive for an Urban Renaissance. In many places, it is now the norm rather than the exception (Foord, 2010). The trend towards mixed-use and urban renaissance has its parallels in the 'new urbanism' and 'smart growth' movement in the US. Building on the success of the traditional European model, smart growth enthusiasts promote non-industrial over industrial activities; on the basis that they promote compact development, increased jobs, attracting residents to the city centre and increasing local tax revenues.

There are others who actively support industry in the city, but argue that it should be much more integrated into the urban fabric. Cotter (2012) argues for the integration of light industry into mixed-use urban development in Atlanta, in the US. London's Deputy Mayor for Business and Enterprise suggested that we are going to have to find ways to integrate housing into industrial areas and intensify the built environment: "The idea of an industrial park is really a modern phenomenon" and "what we will return to is a 19th Century model, where industry is mixed around housing"^{ix}. Although this agenda is no doubt also driven by the urgent need to find more sites for housing in London, it resonates with the concept of the "industrious city" promoted by the Urban Design Group, which supports bringing more industrious activities into cities, as well as re-appropriating our business parks. This is driven by a desire to support and celebrate manufacturing activity in cities:

There is an opportunity to move away from the rooted practice to design these sectors out of our towns and cities. Let's make them visible again and stop housing them in anonymous sheds. Let's re-appropriate industrial estates and districts

through raising the quality of their design and maintenance. As a result, local communities could have a better understanding of how their local economy is formed and develop a sense of ownership. Let's celebrate manufacturing industry again. (Urban Design Group, 2014: 2).

This challenge was explored in an Urban Design Framework for the Blackhorse Lane industrial estate in northeast London (LB Waltham Forest, 2011). Building on architects Gort Scott's survey of the industrial land and businesses on the estate, design proposals are presented that integrate existing businesses and buildings into a commercially viable development plan. The approach is to creatively adapt and re-use buildings, to retain and build upon the existing diversity of uses in the area by enabling local businesses and industries to remain in-situ wherever possible. The framework insists that "extinguishment of businesses is to be avoided at all costs." (p.40).

The concept of a future "industrious city" might well entail overlap of land uses that are often deemed 'incompatible'. But the enthusiasm for reintegration is driven by revolutions in technology, which mean that traditional industries are cleaner and quieter than they used to be. There is also an enthusiasm for embracing the potential of the 'new industrial revolution', where production no longer entails large factories capable of mass producing goods. Nonetheless, in many peoples' eyes, there is a long way to go yet and the prospect of integrating productive activities with other uses can present a range of problems. The next section first sets out some of the counter arguments to promoting such integration.

3.3 The case for continued protection of industrial land

Despite enthusiasm amongst architects, urbanists and urban designers for increased mixing, there is still strong support in policy circles in the US and UK for continued protection of industrial land (Dempwolf, 2010; Leigh & Hoelzel, 2012; GLA, 2015). In London, the Mayor has been advised to continue protecting industrial land on the basis of both economic efficiency and social equity (see Roger Tym & Partners, 2011b: 5-7). It is argued that land use allocations based on the price signal alone would not take into account long time horizons or negative externalities such as the pollution caused by relocating further from London. Even if markets did work perfectly, there is no reason why they should produce a fair distribution of the wealth generated, or take into account the costs of generating it.

Heikkila and Hutton (1986) summarise the range of arguments in support of industrial zoning, which include the fact that it promotes a diversification of the economic and employment base, helping to ensure a range of different types of businesses can thrive and a range of different types of jobs are provided for the workforce. In particular, it supports the location of small, new firms in central locations, important in the 'incubation' phase, when firms rely on the agglomeration benefits of the inner city. It also makes the provision of public services and infrastructure required by similar types of businesses more efficient and less costly. Chapple (2014) has further argued that the availability of industrially-zoned land contributes to the regional economy by providing flexibility, specifically offering a reserve of relatively large sites that can accommodate a range of businesses. Whereas startups (in their very initial phases, as low-overhead home-based businesses) can locate in residential areas, firms that expand – whether in production, distribution, and repair or information-based services – benefit from the ability to spill into available space in large buildings. Industrial

zones facilitate this more effectively than commercial zones, she argues, perhaps because they have more of the 'flex' space that allows firms to grow and shrink readily.

Property agents acting for the industrial sector have argued against 'vertical separation', where business uses are accommodated on the ground floor, with residential uses above. In a report to Camden, a central London borough, consultants Roger Tym & Partners (2011a: 14) state that although occupiers are generally prepared to compromise on the quality of the building stock and price, they generally do not compromise on key locational features such as proximity to customers, unencumbered access and sufficient distance from residential neighbours to enable 24 hour operation without complaints. They report many new mixed use developments with industrial space on the ground floor that remain un-let and argue that developers tend to pay little attention to the design and specification of the industrial part of the development, treating it as a 'loss-leader' and may even have in mind a future change of use to residential.

Furthermore, mixed use environments are not without their problems (see Foord, 2010) and presumptions about the benefits need to be balanced with the important function of employment land being to protect lower-value commercial uses from the rising land values of the inner city and competition from higher value land uses, in particular housing. To date, there is no effective mechanism in the UK context to protect employment land values within a mixed-use area. Rather, there are likely to be knock-on effects of the loss of employment land to mixed-use. First, new employment floorspace created within mixed-use redevelopment schemes tend to be let at significantly higher prices than the employment floorspace it replaces (Ferm, 2014). Second, the expectation by developers that mixed-use redevelopment can be achieved raises land values across the industrial area and means that new commercial development is less viable (Roger Tym & Partners, 2011a: 13). Designated employment land provides a 'reservoir' of affordable space, relatively insulated from the high and rising land values associated with mixed use areas. Our next phase of research will explore the nature of planned mixed use redevelopment on employment sites in two London Boroughs, in terms of the imperative to increase the supply of housing and the kind of employment floorspace re-provided.

Arguments against planning control and interference are often made on the basis that this interferes with the market-led mechanisms that promote agglomeration^x. However, due to the susceptibility of industrial uses to displacement by higher-value land uses, a counter argument to this is that we need to protect industrial land if we are to create the conditions for industrial agglomeration to occur at all.

A successful industrial district requires a critical mass of business, and the existence of that critical mass depends on the availability of industrial land. Rezoning not only shrinks the amount of available land legally available for industry; it drives up prices in broad areas where industrial businesses are located, produces uncertainty about long-term capital investments in industrial operations, and invites conflict with nearby residential and retail uses...If urban industry is to survive, not to say thrive, it needs protection from market forces... treating industry as a relic justifies the conversion of industrial land to other uses, thereby further weakening the possibility of industrial revitalization. And like farmland, once lost, industrial land is gone forever. (Bronstein 2009: 30)

Critics of the smart growth agenda (Bronstein, 2009; Leigh & Hoelzel, 2012) also argue that protecting industrial land is wrongly seen as undermining sustainable land use. On the contrary, sustaining urban industry “fends off urban sprawl” (Bronstein, 2009: 28) caused by outward movement of industry. It also promotes more sustainable transportation between businesses occupying industrial land and the other businesses they serve and interact with.

4. Conclusion

This paper has explored the challenge of how to facilitate the provision of adequate land and premises for diverse productive activities to thrive in our future cities, whilst at the same time building a sufficient quantity of new housing for a growing population. We have argued that, for industries of the future, cities will become more, not less important. At the same time, we need both traditional and new industries to be able to locate in our cities – many are essential for London’s functioning, others play a crucial role in contributing to the economic and social resilience of cities and urban vitality.

The paper has grappled with the divisive question of whether or not the continued separation of industrial land is desirable. We have asked, whether it is possible, through clever urban design, to accommodate businesses currently occupying industrial land within a higher density mixed use context? Such optimism is prevalent and its potential should be explored, particularly as industries become cleaner and quieter with improved technology. But ultimately it does not address a fundamental problem, which is that there is currently no effective mechanism within the UK legislative and planning system to manipulate land values within a mixed-use context. Even if one could address – through design or legislation - the concerns of industrial occupiers regarding the proximity of housing and the resulting restrictions on their operations, how could one prevent the ongoing loss and displacement of the lower-value industrial land uses within such a mixed-use context? To date, employment-led mixed use has been notoriously difficult to achieve and negotiate. Rather than try and redevelop the whole of London into new mixed-use quarters, we need to acknowledge the importance of industrial land as a vital component of a compact, smart city, not a barrier to achieving it (Bronstein, 2009; Leigh & Hoelzel, 2012). Therefore, although we believe there is scope to experiment with greater mixing in some urban locations, we believe that - in London at least - the imbalance of land values and the strength of the residential property market means that we now have little alternative but to protect the industrial land we have got. A positive approach to industrial land is required, which acknowledges its importance as a vital component of a compact, smart city, not a barrier to achieving it.

It is clear that reconciling different views on this matter is far from straightforward and in order to better understand the potential impacts of any proposed policy in this area, we suggest that there are four areas of fruitful research to be pursued. First, we need to better understand the workings of industrial areas and their businesses, through utilising more qualitative and ethnographic methodologies^{xi}. Second, we need a better grasp of the impacts on land values of introducing residential land use into industrial areas. Third, a finer-grain understanding of the types of activities and uses that can co-locate with residential uses is required. This could be effectively informed by international examples, for example in San Francisco and Los Angeles, there are said to be effective models of co-location of residential and high-tech manufacturing. Finally, we need to do further research on how to protect land values within a mixed use context, with a view to reforming the planning system to facilitate this.

Acknowledgements

We wish to thank the Bartlett School of Planning for providing the seedcorn funding to support this project. Inspiration and valuable contributions, which have informed this paper either directly or indirectly, have come from members of Just Space Economy and Planning (in particular Elena Besussi, Mark Brearley, Eileen Conn, Michael Edwards, Myfanwy Taylor and Roy Tiindle), and a seminar on the Productive City organised by Mark Brearley at CASS Cities with European colleagues Jan Zaman and Joachim Declerck (April 2015). We are also grateful to Mike Raco for supporting our research and commenting on an earlier draft.

^{viii} In the UK, planners can identify areas where industrial uses are protected (designated as strategic or locally important industrial land in local plans). However, this is not akin to zoning in the US as it is not bound by law. The UK's discretionary planning system means that developers can submit a planning application for a change of use on such land, and each case is considered on its merits against relevant planning policy and 'material considerations'. These differences are worth keeping in mind. In this paper, we refer to industrial 'zoning' as a generic term used to describe both mechanisms (statutory and non-statutory), but acknowledge that there is technically no 'zoning' in the UK.

Reuse of economic freckles in urban tissue, the case of South West Flanders

GHEYSEN Maarten, intermunicipal development agency Leiedal, Belgium

Recently in South West Flanders the transformation of economic freckles in urban tissue into allotment areas is increasing. But seen from an urban point of view this transformation is unnecessary and more over leading to problems on different levels. The intermunicipal development agency Leiedal is studying this phenomena and developing instruments to counter this transformation process. Among these instruments, a series of design studies is carried out, leading to different spatial strategies and demonstrating the benefits of reusing economic freckles in urban tissue.

1. The spatial context of South West Flanders

A strong mixture of dwelling and working is a continuity in the spatial development of South-West Flanders. The absence of topographical or hydrological restraints combined with a fertile soil made it possible to open up the territory early in history (De Meulder & Dehaene, 2001). Some even state the Flemish countryside vanished somewhere in the 12th century (Declerck, 2012).

Economic growth in South West Flanders was grounded in the agricultural development. South West Flanders isn't characterized by mining, heavy production or steel-industry. In contrary the region specialized in flax, linen, home-based production,... making it possible to combine living and working in a domestic environment. Our spatial condition is characterized by small economic freckles in urban tissue.

This resulted in a sprawled patchwork pattern combining small cities, farms, housing, factories in a seemingly random configuration. The so called horizontal metropolis (Secchi, 2013) or peri-urban (INSEE Première, 2009) condition. Although strongly contradicting the model of a compact and dense city, the sprawled patchwork pattern offers high living qualities and proximity but also mobility problems and environmental issues.

Figure 1, Aerial showcasing the mixed character of the South West Flemish territory © luchtfotografie Henderyckx

Until present this mixed land use is strongly present. In 2002, 80% of all economical activities was established outside an industrial or business area (Strategisch Plan Ruimtelijke Economie, 2002).

2. A paradigm shift

Recently we notice a shift in this model. Vacant factories in urban tissue are no longer reused by economical programs but are replaced by housing developments. (New) economic development is almost exclusively (re)located on industrial zones and business parks (IDEA, 2014). This shift has different origins:

An ideological thought.

Industry used to be polluting and noxious. Originating in a modernist endeavor to build healthy cities, industry was displaced from city centers to specialized industrial zones. This way of thinking led to a planning discourse of spatial separation, specialization, zoning plans and the disappearance of industrial activities in cities and towns.

In Flanders this reasoning was transmitted in 'gewestplannen', the construction of large specialized industrial zones and the relocation of economic activities. Up to now this is the main discourse when thinking on economic development.

Profit driven motifs.

Profit driven motifs are amplifying this paradigm shift. The reconversion of abandoned industrial sites into housing developments is a profitable business. The conversion can triple the ground value.

Path of least resistance.

Erecting or expanding an economic development in a build environment is complex. A strict set of rules and legislation (fire safety, soil remediation, insulation,...) is contrasting with the 'easiness' of building on greenfield.

A survey amongst 50 entrepreneurs indicated a significant price difference between an allocation in an urban setting or industrial zone. Causes can be found in higher ground value of urban locations combined with higher standards and demands concerning (architectural) quality of the buildings and surroundings, extra measures in terms of good neighborhood, the cost of renovation, efficiency issues on irregular parcels,... (Leiedal, 2014). So instead of going through the difficulties of re-using existing sites the path of least resistance is preferable and a new location is developed.

Intolerance.

Neighbors become less and less tolerant for (potential) nuisance due economic activity and potential leading to heavy traffic, irregular hours or unwanted activities. The transformation of economic activities to housing, commerce or services is therefore seen as positive by the neighborhood and by extension by the policy makers.

3. Problem setting

As stated, the mixed character of our territory is gradually declining due an ongoing demix of functions and a continuous transformation of greenfield into specialized zones. But where this paradigm shift at first seems beneficial, it becomes clear after a closer observation there are several problems connected with this transformation.

Space is scarce

Firstly, available space is scarce. The continuous transformation of greenfield into housing or industrial zones is increasingly becoming difficult due to the negative spatial, environmental and social consequences (Fishman, 1998).

A growth based economy in which a continuous greenfield transformation is applied causes conflict. Our spatial reasoning is often narrowed down to a mathematical equation in which each agency claims its hectares of 'nature', 'agriculture',... The sum of all these hectares doesn't fit in our territory.

This is expressed in a growing resistance against greenfield development. Large scale developments are frequently contested and often subject of jurisdiction.

Not enough specialized zones.

Secondly, the existing available surface on specialized zones is limited. More than 2/3 of all economic activities in West Flanders is based in so called 'residential areas'. Industrial & business areas only contain 14% of all economic activities. (Pom West-Vlaanderen & Dienst Economie Provincie West-Vlaanderen, 2011)

Knowing South-West-Flanders has 3.500 hectares of industrial & business areas, this simple figure demonstrates the impossibility to relocate (if even wanted) all economic activity to specialized zones. Furthermore, since there is a scarcity in industrial & business zones a more selective policy on allocation should be recommended.

Livability of municipalities.

Thirdly, the separation of working and living has a negative impact on the livability of municipalities. Businesses departing from inner-city location often leave behind empty sites and buildings. Combined with an eventual pollution this (could) lead to long-term vacancies. This is harmful in terms of perception and quality for both the site and its surroundings.

Moreover, the absence of economic activities leads to mono-functional living areas. This again has an impact on the livability of municipalities.

Mobility

If economic activities relocate to specialized zones, distance between work and living is increasing. The number of daily movements increases leading to both a reduced access to labor for less mobile people and a energy and time consuming living pattern for the commuters.

No programmatic need.

A clear need for the reconversion of vacant industrial sites to housing is missing. The comparison of growth in the number of households until 2030 versus the unbuilt surfaces in residential and residential reserve zones indicates only 1/6 of these areas is needed (Leiedal, 2015). To keep up with the growth in number of households no new zones need to be created.

Research by design on the station area of Anzegem demonstrated the building possibilities in existing build-up tissue. By reworking and densifying the existing parcels and structures the number of houses could be doubled within the compact and existing village, leaving the surrounding landscape untouched (Heirman, et al., 1 Ma Ar 2014-2015).

Figure 2, study on building possibilities in Anzegem station by Jelle Heirman, Camille Degroote, Inès Van Ransbeeck

So if the existing building possibilities already cover more than sufficiently the actual need for housing, it is obvious there is no argue to transform built up economic tissue in housing development.

Preliminary Conclusion

As described above on the one hand the conversion of greenfield into new and sufficient industrial & business areas is becoming more and more contested. On the other hand, there is no clear need to transform the existing economic freckles into housing areas. Moreover, these transformations generate a series of disadvantages in terms of urbanity, mobility and so on.

4. Opportunities to reuse economic freckles for economic activities

Where large scale greenfield development has become increasingly difficult, a number of tendencies and changes in both the nature and size of the economic activities combined with a legal framework create opportunities to reuse existing economic freckles.

First of all, our type of economic activities has changed over the years. The polluting and unhealthy production industry has been replaced by a clean manufacturing economy. In this manufacturing economy, 90% of all activities is no longer polluting at all. The logic need to separate living and working is gone.

Next to this policy makers recognize the need for mixing. Different spatial policy plans and instruments confirm this tendency by stressing the multifunctional use of sites, stimulating reconversion to economical programs and the ambition to build 'space neutral'. A set of laws has been created in order to encourage the mix of working and living.

Finally we notice the majority of businesses in industrial zones are SME's. 44% of all surface is used by firms having less than 20 employees, 75% of all surface by firms having less than 100 employees (IDEA, 2014). It is obvious small scaled companies are much easier to integrate in urban tissue

The combination of these three opportunities and the crisis of the paradigm shift gives the opportunity to think on reusing economic freckles in urban tissue. A model in which living and working is combined, a model of vivid municipalities. In this model existing economic freckles are kept, new types of economic activities are introduced and brown-fields are converted into living and working areas.

5. Kameleon

To pick up this opportunity and to counter the paradigm shift, Leiedal (an intermunicipal development agency in South West Flanders) launched a project called 'Kameleon'. This project is supported by the Flemish government and runs from 2014 till 2016.

The aim of Kameleon is multiple: to maintain economic activities in urban tissue, to stimulate economic development and eventually to create new economic development in build environments.

Since the problem setting is complex, Kameleon is focusing on different instruments/solutions/... to tackle the issue of reusing urban freckles in urban tissue.

Central in the study is a dual track. Firstly we examine the way governments deal with questions on the reuse of abandoned economic freckles. By setting up a LEAN-traject they should be able to provide a quicker, completer and clearer answer when confronted with redevelopment questions.

Secondly we develop a pro-active policy on economic freckles. Not all of them are suitable for reuse while others are extremely valuable for reuse. By setting-up a reflection on: "what kind of activities are organized where and under what conditions?" a long term pro-active policy is developed.

To inspire this long term pro-active policy a series of design cases is carried out. The cases for these workshops are grounded in real-life sites, some of them already vacant, some still having activity. The cases are tackled both by a design team at Leiedal and a collaboration with the first master year at the Faculty of architecture of KU Leuven (Gheysen, et al., 2014-2015).

The goal of the design cases is to develop a vocabulary of tools and methods, to generate inspiring examples en to deploy strategies for the reuse of economic freckles.

6. Lessons from the design cases

At present 17 designstudies have been carried out. They differentiate in location, size, context and activity. The design interventions can be organized in 3 scale levels: interventions on the site but effecting the whole community, interventions on the site that changes the relation with the context and finally interventions having effect on the site itself.

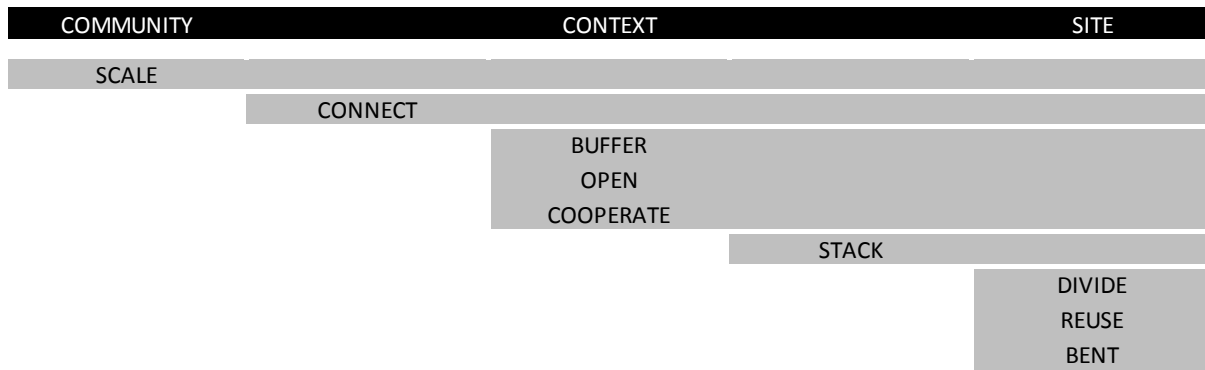

Figure 3, Organizing the design cases

The strategies are documented and described in such a way they become both an inspiration for future designs but also a tool to unravel themes and topics that are crucial in the debate on reuse.

The strategies have a pedagogic meaning in terms of countering the first reflex on transformation of the economic freckles into dwelling. Combined with the other Kameleon-tools they will influence the decision making process in municipalities.

Community

Group 1 (community) focusses on those interventions redefining the spatial relation between the economic freckle and the community. When redeveloping a new economic activity on the site, sometimes opportunities arise to inscribe the site as being part of the community instead of being an isolated and locked-of island in the community. To do so we noticed it is important to (a) give limits or *scale* down the economic activity so it balances correctly with the dwellings and public domain in the surroundings and (b) create connections so the economic freckle is opened up for pedestrians and cyclist thus giving meaning to the site besides the economic activity.

(a) Deknudt is a typical historically grown factory. Started in 1923 it grew from a small atelier to a specialized company. Because of this growth the oldest sites in a buildup environment are now abandoned in favor of a new site on an industrial zone. The historical atelier has grown over the years from east to west thus consuming the whole building block and diminishing dramatically the living qualities in the environment.

Figure 4, Scale: the original build up monolith (l) is broken up in smaller units (r)

By evaluating the build in terms of heritage, isolation, stability, renovation costs,... we came up with a proposal to split up the monolithic factory in smaller units. Each of them is no longer 'served' from the streets but from in-between open spaces to reduce the use of the

public domain by the economical function. More-over, the in between open spaces are designed in such a way the operate as a farmers market during the weekend.

(b) In some cases the redevelopment of an economic freckle has the opportunity to connect missing links in the pedestrian and cyclist network in the surrounding urban tissue. In the case of Douterloigne we noticed the development of the economic freckle could connect the creek in the south with a new playground in the north of the village. This connection becomes a new spine, linking the school, municipality centre and the church with the two green elements and thus forming an alternative for the east-west road crossing the village.

Figure 5, Connect: the development of the economic freckle connects the northern and southern part of the village

Context

Group 2 (context) deals with the direct relation between the site and its surroundings. Economic activity is too often something hidden, something being part of another world. This results (partly) in the intolerance to economic activity as described above. Unknown is unwanted. Group 2 strategies stress the importance of intermediates such as collective spaces, buffers, fringes,... They can play a role in giving limits and scale to the economic activities, organize and divide where necessary or open up possibilities in attracting secondary programs (market, playgrounds,...).

By working on the proximity and visibility we restore the contact between the context and the economic activity. This is done by (c) opening the industrial box, (d) a multiple use of the buffer and (e) stimulating cooperation between neighborhood and economic activity.

(c) Economic activity is 9 times out of 10 completely interiorized. Anonymous and cheap prefabricated concrete boxes block of all connection with the outside world. In his research, on the building, urbanity and public space Jan Gehl (Gehl, et al., 2006) discovered a strong link between the scale of the façade en the use of space. Made simple, small scale facades have a bigger contribution to urbanity when compared to large scale facades. So if we want

to increase the relation between economic activity and the urban issue, the usage of large scale blind facades is not done.

Figure 6, Jan Gehl, comparison in scale

In her inside/outside studies, Radka Vilímková (Vilímková, 2014-2015) explores different activities and their relation with the exterior. These relationships vary from a simple window to see through, an outdoor terrace or an exterior showroom. The, sometimes literally, creation of relationships increases the appreciation on the economic activity and should decrease the level of intolerance.

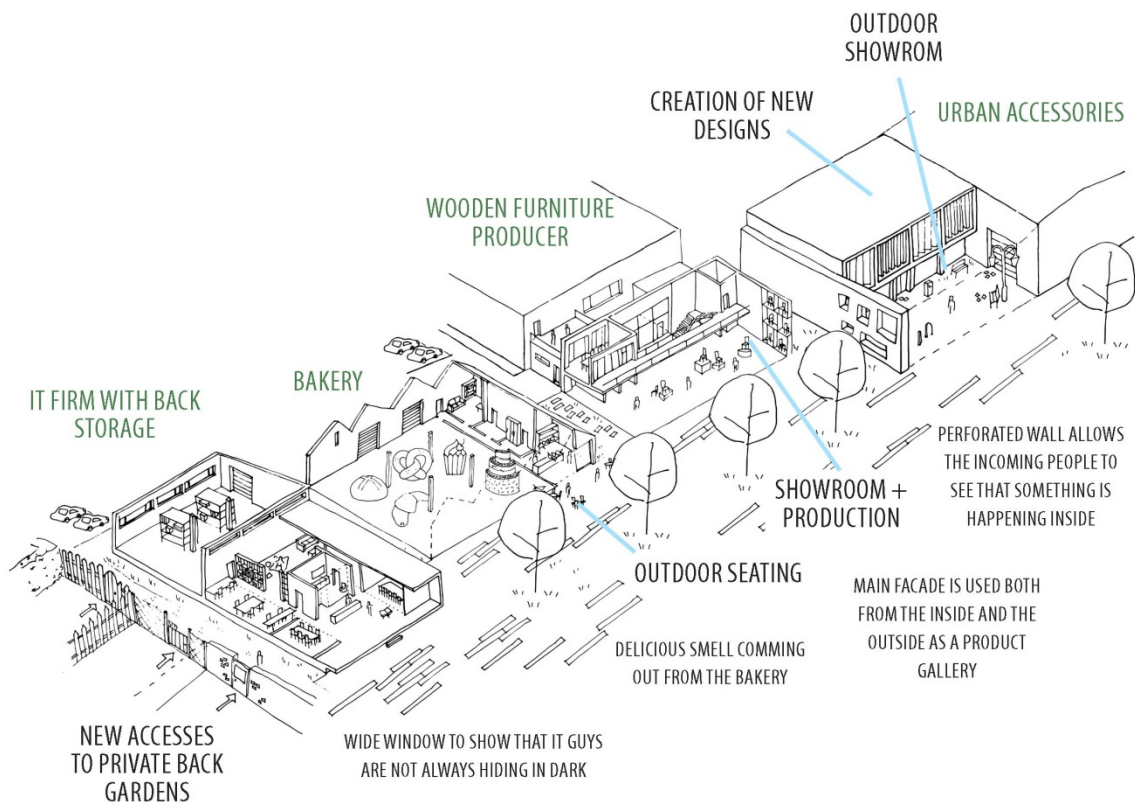

Figure 7, Study on inside/outside relations by Radka Vilímková

(d) Legislation obliges to create *buffers* between economic activities and dwelling areas. These buffers vary from 10 meters to 50 meters, depending on the kind of activity. . Different scales, different rhythms, different interests,... could cause conflict so buffers are created to absorb the friction between economic activity and dwelling.

But buffers are rarely interesting and most of the time a mono-functional 'greenish' area.

By putting in a figure, literally a fringe, between housing and working an in-between figure originates. This in-between element can be programmed so both working and dwelling can use it. The docking station being a playing ground after hours. Or the rainbuffer becoming a pond for the neighborhood. Parkings could be used for both housing and working. Just like the collective garden (Leiedal, 2014).

(e) Economic freckles or not seldom heavily build up. The absence of open space is often a reason to relocate the activity (lack of expansion possibilities) and a cause of friction with the surrounding neighborhood (no intermediate between the economic activity and dwellings). When redeveloping the economic freckle, *stacking* should be considered. By doing so, the plot is opened to introduce buffers, shared spaces and shared programs, other functions,... All these operate as an intermediate and offer an added value when redeveloping the economic freckle.

Site

Group 3 is composed by strategies who work on the level of the site itself. These interventions of course have an impact on the context but there merits are mainly located on the site. This group consist of strategies that introduce a multiple use of the public domain (f) *Share and divide*, the re-use of (parts of) the building (g) *Re-use* and benefitting from existing topographical differences on the site (h) *Bent*.

(f) As long as the economic freckle was an enclosed entity, open space could be considered pure infrastructural; a buffer, parking, road or docking bay. When redeveloping and opening the economic freckle, the infrastructure gets a new role, it becomes public domain. This public domain both acts as a *sharing* mechanism by its use for both the site and the context but simultaneously can *divide* the activity form the context (the public domain acts as a buffer). This strategy has potential when dealing with sites with a mixed program.

Figure 8, Share/Divide, between dwelling (S) and SME's (N) a multifunctional public space is introduced containing circulation, parking, water buffer, grass field and trees

Figure 9, Reuse: the wooden construction in this warehouse proved to be an unique feature. The site is going to be reused as a covered farmers market in the nearby future.

(g) Reuse: the buildings in economic freckles have a history. Some of them are simple concrete structures, other are interesting brick construction with unique features. When redeveloping an economic freckle, the evaluation of the existing build is a crucial element. Since the economic function is no longer production, the qualities of the build are having an increased importance. They can make the difference in the search for unique working conditions. 'A building with a history' has proven to be an asset when redeveloping.

(h) Industrial sites are often characterized by large horizontal surfaces. These were needed to ensure a horizontal production process (for instance weaving). But in a landscape that gently folds, these horizontal planes are disconnected from the surroundings. The horizontal plane easily gets under or above the surrounding ground level. When reusing these industrial sites, the horizontal surface is a benefit. It is in many situations very easy to develop a second level by using the difference between the topography and the horizontal surface.

7. Conclusion

In a context that has always been characterized by a strong mixture of working and housing the concept of zoning and division is difficult to implement. Moreover, the strict need to divide polluting industry and housing has vanished since our production methods changed and became cleaner. The strict division between working and housing has proven to be less beneficial because of a decrease in urbanity due to a mono-functional character of the urban centers and an increase in mobility, transformation of greenfield and loss of biodiversity.

To preserve the mixed character of our territory and to stimulate the re-use of economic freckles in urban tissue a trend reversal is needed. Economic freckles are too often transformed into dwelling areas due to different reasons.

By the development of different policy making tools and by testing and designing different cases, Leiedal demonstrates the potential economic freckles have. By reusing them for economical purposes both the site, context and community benefit in a direct (spatial) way. The redevelopment of these sites also contributes in the larger picture to no longer consume greenfield and fully work on reconversion of existing areas

City Logistics Vienna

Transport challenges in urban areas within a disordered institutional framework

Vincent NEUMAYER, TINA Vienna Ltd., Austria

Synopsis

Production moved out of cities and goods consolidation takes place mostly on green-fields at the fringe of cities. This paper examines in the context of the City of Vienna ways of both, bringing (green) logistics operations back into the city and defining opportunities for a holistic freight transport concept.

1 Summary

This paper examines possible solutions towards a CO₂-free commercial traffic in Vienna, but at the same time reveals the lack of institutional framework setting for an inclusive and efficient stakeholder-integration for the purpose of decarbonizing city logistics. The public institutions in Vienna have confidence in private initiatives to establish CO₂-free cargo transport. Still this confidence is contradicted by rising cargo transport demand to and from Vienna and extensively underlined need by hauling companies for central cargo hubs within the borders of Vienna and clear incentives for greening city logistics processes. Despite this need the city of Vienna administration and political decision makers hesitate to start establishing an overall city logistics concept for Vienna.

Results of this paper are based on a research project conducted under the co-funding of FFG (Austrian Research Promotion Agency).

2 Introduction

New opportunities by e-mobility, greening of logistics processes, industries on the basis of 3D-printing production, significantly growing e-commerce supported by just in time parcel deliveries, innovative non-motorized ways of cargo deliveries for the last mile, and cooperative cargo consolidation are just a few key fields of future transport operations within the metropolises and cities in a world of globalized goods flows. Especially in socially and environmentally sensitive but economically powerful areas of cities and towns new solutions for cargo transport are demanded. These developments offer new chances for urban brownfields and areas in conversion. Despite strong (economic) pressure on central locations in urban areas, a rethinking has started, whether residential and office use is the only sustainable way of meeting the needs of future urban growth.

These general conditions Europe and the world will face during the upcoming decades. This is the starting point of this project which has been conducted under the public call of the Austrian Research Promotion Agency (FFG-Forschungsförderungsagentur) for the support of research projects in the field of “mobility of the future”. As part of the overall objective of “How to reorganize mobility of goods?” within the urban context, the project team – Austrian Institute of Technology Ltd., Econsult Consulting Ltd., Port of Vienna Ltd. and TINA Vienna

Ltd. – has strived to identify opportunities of a public inland port in a well-connected location for future activities in city logistics. The objectives of this project study are to find out whether inter- and multimodal hubs like the port of Vienna can serve its cities as urban logistic center for a regional and local distribution hub of goods. What kind of technological and organizational measures are necessary to render such a function possible and efficient? What kind of companies is interested in such a concept?

The port of Vienna is located in close vicinity of the city center of Vienna (about 10 km), combining three main modes of transport: rail, road and inland waterway (Danube river), hence it offers various theoretical options in hosting enterprises which operate in city logistics.

The design of the project didn't pursue a demand- or supply-driven approach towards the development of concepts, but it has been based on four specific tasks for the port of Vienna in order to assess the possibility to establish city logistic operations:

- A positioning concept: how to promote the port of Vienna within the counterbalance of demand and supply for logistic services?
- An organizational concept: how and where to position city logistic services on the area of the port of Vienna?
- A functional concept: how to adapt processes of operational planning to requirements of city logistics under the consideration of using vehicles with alternative driving technologies?
- A technological concept: how to integrate the means of new technologies for port superstructure and IT-supported processes?

Essentially, for assessing future opportunities to organize last-mile transport, a first analysis of the legal, process-related and planning-related framework conditions for urban transport in Vienna has been conducted. Deduced from the overall project objective, of which a first glance at stakeholder involvement in urban transport planning has been integrated part of the elaboration, a closer look is taken to the institutional framework in Vienna within this post-project paper. The leading questions to guide this analysis are:

- Who are the key players and how can city planning support sustainable and future-robust urban freight transport solutions?
- Which mechanisms have major impact on city logistics?
- How does the city of Vienna contribute to private measures of greening logistics?

Starting from the overall content of the project mentioned above, the intra-municipal processes of Vienna are dissected for a deeper understanding on how to bring the logistic sector back into the city.

3 The Project IMPALA

3.1 Context and Setting

At the beginning of the project IMPALA (Intermodale Knotenpunkte als Urbane Logistikzentren) which serves as a trigger for my analysis of players in city logistics in Vienna, the project team needed to define certain most important terms for the topic of urban freight transport. For the purpose of this paper a few play a major role in the identification of players and stakeholders in Vienna city logistics, for instance *freight village*, *smart urban logistics* or *urban freight mobility*.

As a *freight village* we consider a concept for a central freight distribution system in which logistic providers and transport services cooperate in a geographically and access-related

convenient location. Usually areas and superstructure are leased from a central administration unit of this freight village which guaranties neutrality and open access towards independent and interested companies. Besides business-as-usual functions (e.g. commissioning and handling of goods) supplementary services (e.g. packaging, cleaning etc.) can be offered by the administration unit of the freight village or additional service providers (Malina, 2014)

Smart urban logistics is the tag for future freight transport. For the purpose of Vienna smart urban logistics is considered to be: the implementation and development of new, sustainable and efficient good distribution schemes for metropolitan agglomerations with focus onto the last mile in order to reduce overall inner-city traffic (IMPALA 2015).

Urban freight (cargo) mobility is defined as the potential of movement of persons and goods in a physical, urban space in order to change place of being. This potential of movement goes beyond the understanding of traffic which describes the actually realized movement (BMVIT 2012).

These three definitions partly contain already who to address when talking about changing conditions for goods deliveries within a city framework in order to reduce the carbon footprint of transport operations. Especially the concept of smart urban logistics is open enough to consider a variety of measures with two focuses, technology and organization.

For a clear identification of stakeholders in city logistics three sections have been identified for a closer look on how to integrate an inland port into urban freight mobility for a whole agglomeration, as well with regard to the transport chain: freight village – delivery (chain) – city/metropolis. This threefold approach combines commercial and public aspects and integrates both sides into the stakeholder analysis. The project additionally analyses international good practice examples and interweaves the results of the analysis – an overview of supporting and limiting influential factors (drivers & limits) – with statements of public and commercial stakeholders who have been interviewed with respect to city logistics as such, to planning responsibility of the public administration and to commercial operations of businesses.

An overview of drivers and limits and their interlinkage with each other can be seen in figure 1.

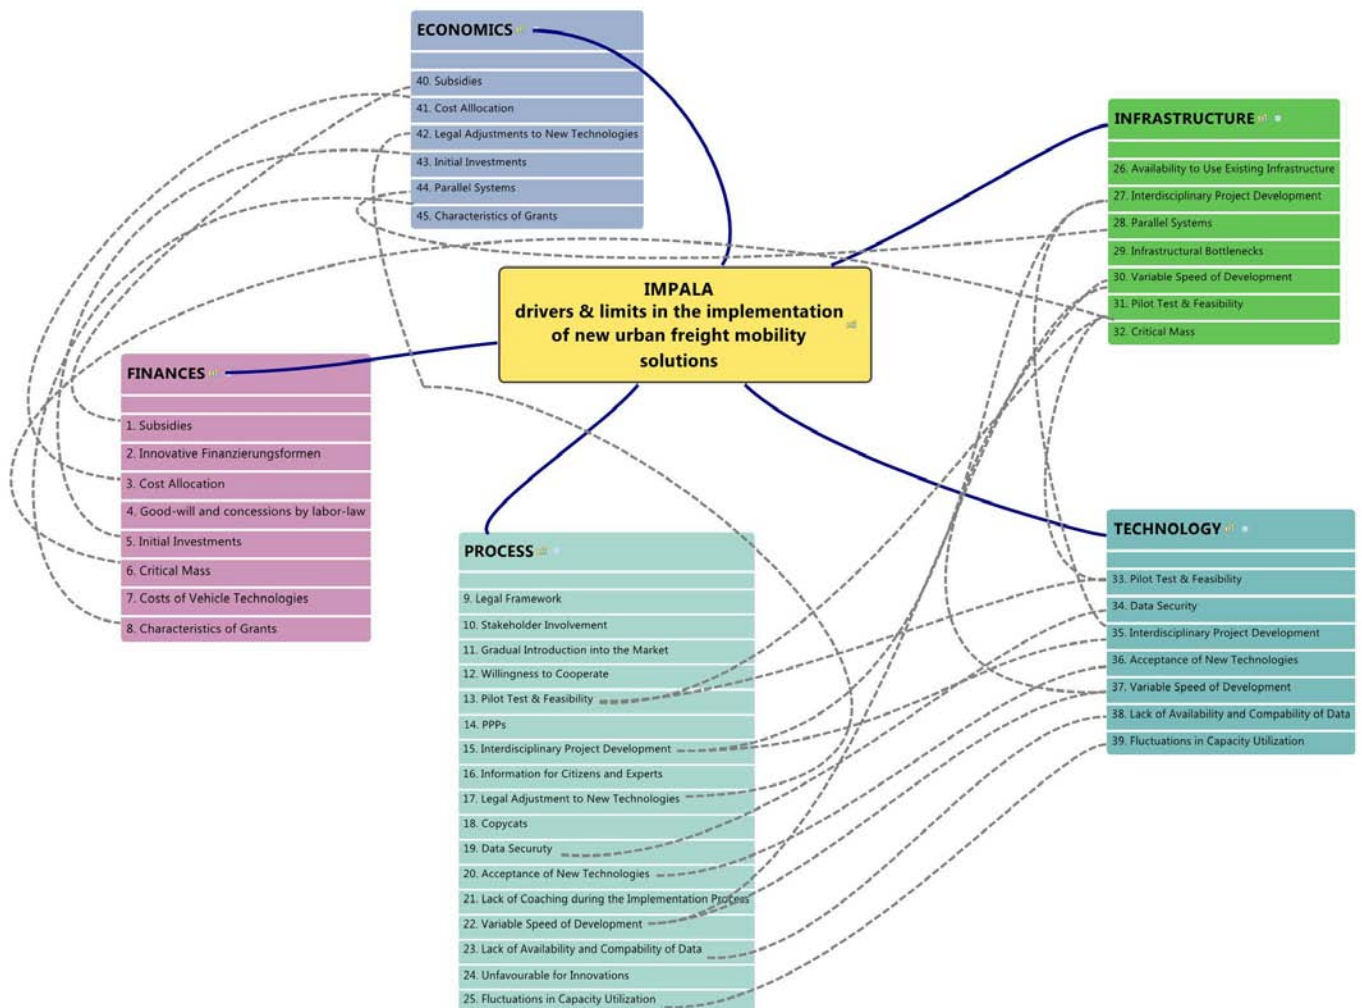

Figure 1: drivers and limits in the implementation of new urban freight solutions (IMPALA 2015)

The identification of drivers & limits for new urban freight mobility solutions, deriving from success factors of good practice examples and statements of stakeholder interviews, facilitates to have a first idea about which stakeholder plays a vital role in certain influential fields for city logistics. Some limits & drivers need to be taken into account from different perspectives; hence an impact description is provided from certain angles, as shown in the figure above in repeated entries in different fields.

The stakeholder interviews showed a broad range of opinions on necessary measures towards a coordinated freight distribution scheme. Several stakeholder statements from fields like research, politics, logistic operators and shippers anticipate already obstructions and an unclear setting of responsibilities within the city of Vienna, e.g.:

- “Well coordinated single measures shall be favoured over a holistic urban freight distribution scheme.”
- “Citizens need to become aware of their responsibility in influencing urban transport.”
- “An urban freight distribution scheme is considered a command-driven economic interference in commercial processes.”
- “Additional road infrastructure mitigates future transport bottlenecks.”
- “Urban development areas are planned without regard to local goods distribution.”
- “Flexibility in labour law regulations mitigates peak stress in urban transport systems.”
- “SME commercial traffic is the main originator for urban freight transport need.”
- “Commerce should be the driver in a future city logistic concept for the city of Vienna.”
- “Currently there is no urgent need to realize a holistic urban freight distribution scheme.”

- “External and neutral coordination of district distribution schemes is welcome.”
- “Urban spatial planning needs to take logistic processes better into account.” (IMPALA 2015)

Following these statements and first research results this paper will evolve around a deeper stakeholder analysis in chapters 4 and beyond.

3.2 Further results of IMPALA

Besides a first stakeholder screening the project IMPALA developed a catalogue of requirements which a variety of stakeholders within a city expect and wish from an urban logistics hub like the multimodal terminal port of Vienna. These requirements are structured along the categorization city – client – operator of a city logistics terminal – logistics operator. These requirements from stakeholders to stakeholders show whose responsibility is expected in case of different management assignments within city logistics. E.g. logistic operators demand public electricity charging stations in case of (legally) enforced use of electric vehicles for inner city freight transport (for instance within a limited transport zone). These statements and research results add their contribution to a first stakeholder-analysis of the institutional framework.

In a positioning concept results from all the work done so far in IMPALA - growing demand for transport services, increasing e-commerce and future challenges - are taken into account to frame a picture of future needs to city logistics. The method morphological box has been used to extract on the basis of three particular (pilot) examples, which conditions are necessary to render city logistic operations feasible from the point of view of the port of Vienna. The organizational concept has analyzed current conditions at the port and put them into the context of the demand/supply situation for logistic services in the agglomeration of Vienna. Summarizing, these two concepts showed potential for city logistic services operated from the port of Vienna despite non-ideal current conditions for warehousing and transshipment for the three scenarios (pilot examples) which were considered within IMPALA (IMPALA 2015 [2]).

Furthermore for the three scenarios technological and functional tests have been run with regard to suitability for electric vehicle use for transport operations, range of vessels and vehicles and technical feasibility of transfer of good practice examples to Vienna.

4 Stakeholders in Vienna urban freight transport

The range of interview partners in the project IMPALA has been a first attempt to identify different groups of stakeholders, important to urban freight transport in the city of Vienna. A categorization into politics and public administration, logistic operators, shippers and research institutions gives a first trajectory for stakeholder identification. Within politics and public administration, necessarily a more precise classification is needed. Directly and indirectly public administration is guided by politic and political decisions, additionally the system of Sozialpartnerschaft (social partnership) plays an important role in terms of public impact on economic operations. It comprises a cooperative check and balance relationship between social partner organizations which represent associations of employers and employees. Social partners are the Austrian federation of trade unions, Austrian chamber of labour, Austrian chamber of commerce and the Austrian chamber of agricultural businesses. Additionally other chambers and representing bodies of employers are accounted as social partners. Hence the public dimension is split into politics, public administration, lobbying groups (transport associations etc.) and social partners. Research is extended into organizational and technological research, including innovation. Taking these and one more group of important stakeholders (population) into consideration, a first picture of stakeholder categorization can be drawn (see figure 2).

Figure 2: Stakeholder Groups in Vienna Urban Logistics (own research)

These stakeholders are embedded in the overall framework strategy of the city of Vienna, called Smart City Framework Strategy, which demands to render “by 2030 commercial traffic originating and terminating within the municipal boundaries to be largely CO₂ free” (Vienna City Administration 2014). This significantly excludes the transit freight traffic but sets ambitious goals for a medium-term time horizon under overall development paths like: reduction of emissions, optimized deploy of resources, increase of efficiency, improved integration of cargo transport, increased transparency and enforced sustainability. The EU white paper on transport sets less strong goals by halving the use of conventional carbon fuels in urban transport by 2030 (European Union 2011)

The influence of stakeholders in urban freight transport oscillates between logistic demand and logistic supply. These two poles and their detailed aspects determine ways for influencing in a multiple stakeholder effort future city logistics (Climate and Energy Funds Austria 2013).

Logistic demand is differentiated by:

- | | |
|--|---|
| <ul style="list-style-type: none"> • Consumer • Commerce • Catering • Production | <ul style="list-style-type: none"> • Construction sites • Services and craftsmen • Maintenance & repair • Medical and care services |
|--|---|

Logistic supply is differentiated by:

- | | |
|--|---|
| <ul style="list-style-type: none"> • Store Logistics • Courier, Express, Parcel Services • Factory traffic • Trucking services | <ul style="list-style-type: none"> • Waste management logistics • Construction material logistics • Service traffic • Special shipment (e.g. heavy cargo) |
|--|---|

transport)

By the identification of general stakeholder groups in city logistics we reveal slowly the specific stakeholder constellations in Vienna. This only includes Viennese stakeholders, although it is clear, that federal decision makers and administrative bodies, but as well European legislation have a strong impact on urban freight transport organization. In figure 3 the main stakeholders of Vienna are mentioned.

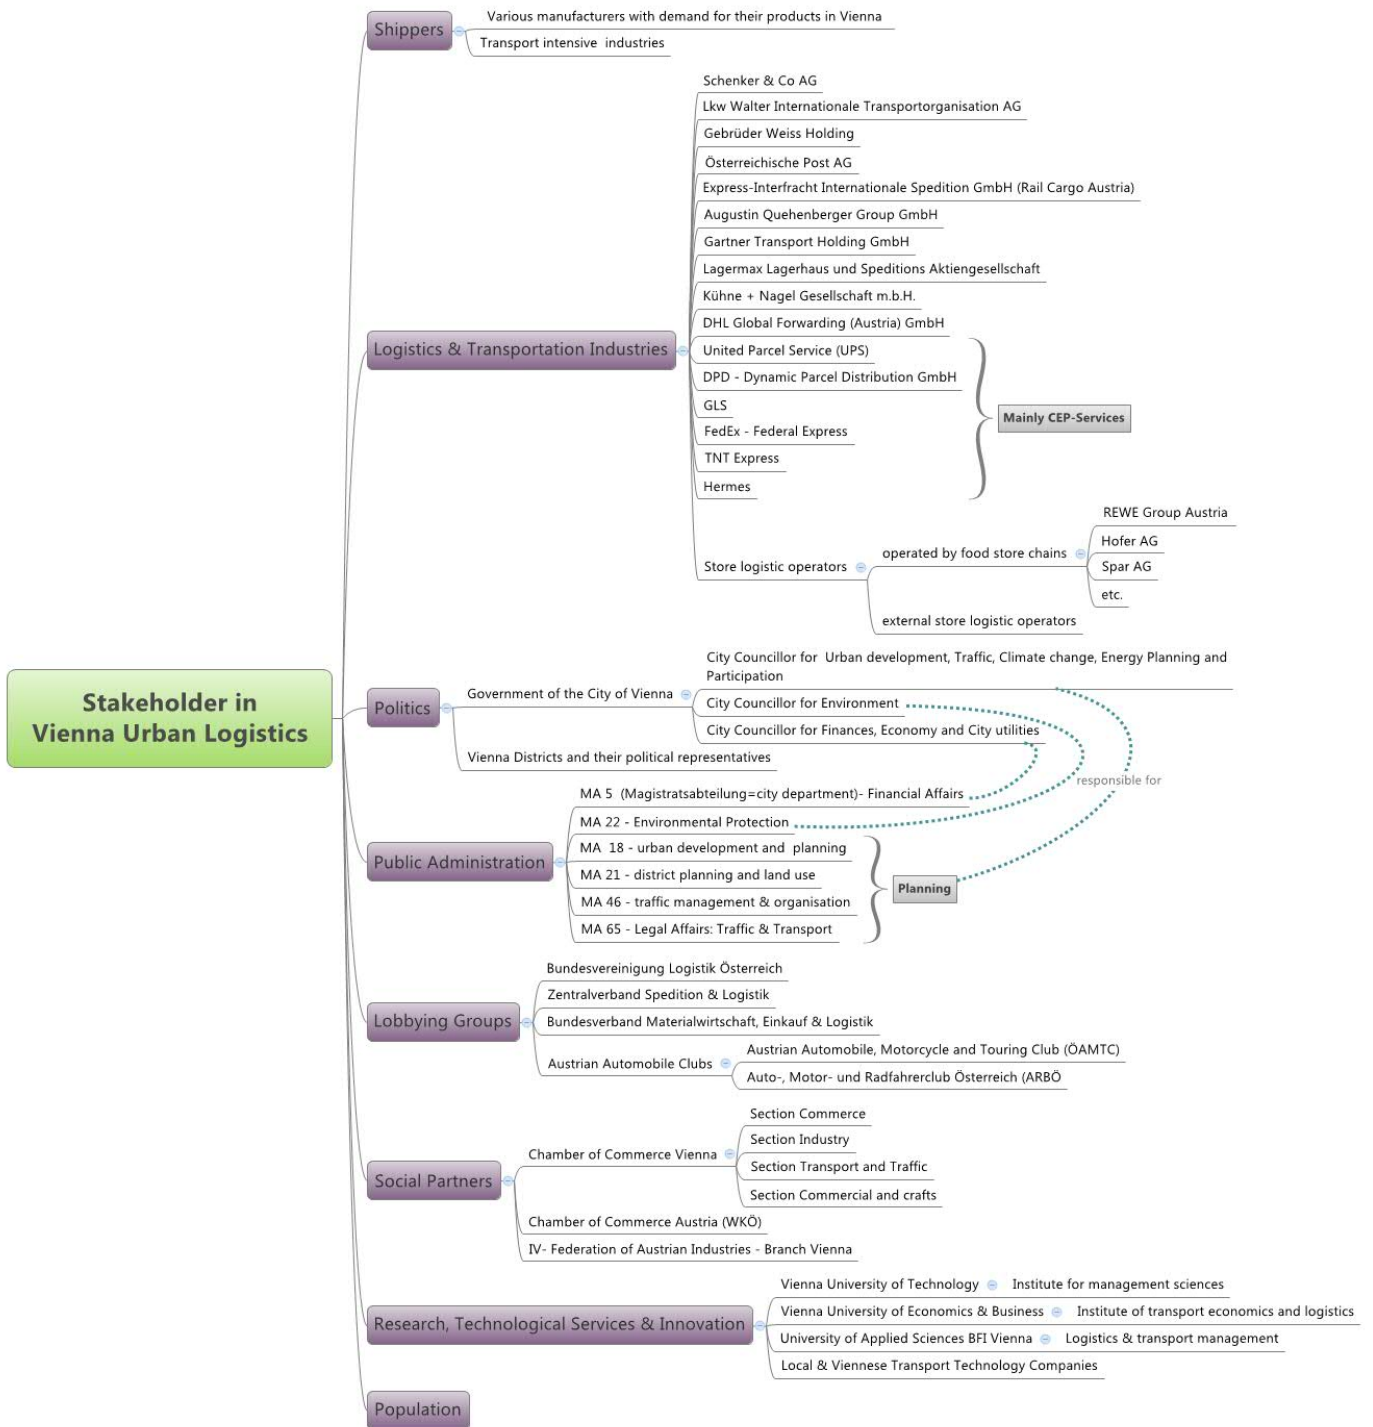

Figure 3: Stakeholder in Vienna Urban Logistics (own research).

Of all these stakeholders the regulative power is concentrated mostly with the public administration units (MA) which elaborate urban freight transport related measures and actions on the basis of policies of governing parties in Vienna. Additionally, social partners may have influential impact on city logistics concepts due to their assignment of representing sectoral organized business branches. The actual process of the (currently hypothetical) creation and coordination of a city wide city logistics concept would be accompanied by social partners and additional stakeholders with informal influence (e.g. chamber of commerce, district administration, public transport organization of Vienna), although not all of these stakeholders are mentioned in the overview chart (figure 3), due to their informal role in processes. Nevertheless, overall political determination in Vienna can finally overcome strong veto by important stakeholders without relevant legal obstructive power to fight such concepts.

Chapter 5 gives a brief overview of ways how to regulate urban freight transport in Vienna.

5 Measures for and influence on city logistics

The City of Vienna hasn't adopted an overall city logistics concept. Only single measures like limited traffic zones for good deliveries in pedestrian areas (e.g. in the inner city), nominated parking lots for cargo loading and unloading as part of the city wide public parking network, small subsidies for the purchase of an e-vehicle for cargo transport etc. are implemented. Such single measures often have the focus on managing local challenges triggered by goods deliveries but they don't pursue a strategy for the whole economic eco system metropole. Stakeholders within the city administration legitimate a missing city logistics concept with a lack of actual need. Neither the articulation of the population or the lobbying groups, nor politicians underline the need of better regulated goods distribution.

The city administration unit MA 18 – urban planning & development is responsible for strategic questions of traffic and transport development in Vienna. This MA defines – together with a variety of stakeholders – the overall development trajectories for transport in Vienna. The actual implementation and legal realization of new regulations is duty to the MA 46 – traffic management & organization. Usually such a motion (for a city logistics concept) is initialized by politicians, elaborated by the MA 18, coordinated with the stakeholder groups as described in Figure 2, decided about by the municipal parliament and implemented by the MA 46.

But both of these MA don't anticipate the topic of city logistics as important although in overall strategic goals action towards zero-emission logistics are demanded. Even when considering aspects for future city development areas, logistics, and neutral cargo consolidation centers for new settlements within the city of Vienna, or certain needs of logistic operators and CEP-services, are only minor topics within the district planning. As well the city planning doesn't save space within the city of Vienna, in order to establish a neutrally operated consolidation center. Rival functions and "more valuable" uses of space easily overcome the currently rather weak wish to render city logistics green.

Who will be then the driver for a freight transport scheme in Vienna? Is it commerce and store logistics which voluntarily transform their logistical processes towards zero emission? Will the branch of commerce demand new ways for the last mile of good distribution? Is it the local chamber of commerce as representing body of thousands of businesses both in the logistics sector, and in the commerce sector? Will the social partnership demand more regulations both for the employees being represented and the employers?

The Viennese strategy "Fachkonzept Mobilität" (development concept mobility) discusses commerce traffic but only mentions concessions for further support for production businesses in order to concentrate their logistic flows. Additionally the strategy considers stronger financial support for the purchase of e-cargo-vehicles; the multimodal hub port of Vienna shall serve together with a new rail/road terminal (Inzersdorf) as local freight village/distribution center; local distribution boxes for urban blocs shall serve as reduction

measure for CEP-service-trips; commonly used loading yards may trigger cooperation between different logistic operator; good conditions for cargo bicycles shall green the last mile transport and the introduction of an overall truck-toll on federal level for every street but not only motorways is supported by the city of Vienna (Vienna City Administration – Urban Development 2015). Still there is no holistic strategy on how to pursue the goal of greening logistics in Vienna but merely single measures.

6 Conclusions

As described in the elaboration above, the management of city logistics is rather complex in urban areas, due to a big variety of stakeholders involved but as well due to various influencing parameters like environmental sanctions, supranational agenda setting and specific local stipulations. The city of Vienna is no exception, but even presents a few unique circumstances which need to be faced by future efforts for the establishment of an urban freight scheme. These are mainly the integration of social partnership and framework strategies which need to be translated into concrete management plans for transport related policies.

The (theoretical) realization of a city logistic concept needs to integrate requirements and wishes of both transport industries and the population. Still the current status in Vienna places this topic on a minor level of the agenda of urban planning issues. This circumstance shows already that city logistics is considered to be a topic of urban - and strategic mobility planning. Additional dimensions of city logistics like economic growth and economic stimulation, diversification of business branches within a city, raise of awareness for the impact of actions of single citizens in terms of transport or legal challenges due to new ways of (private) goods transport – as operated by checkrobin.com or planned by amazon.com Inc. (Gassmann 2015) – are treated as secondary and less relevant in the discussion.

Interviews with stakeholders and the analysis of planning documents show that urban freight transport is not a burning issue for Vienna. There is potential for optimization and certain local problems (e.g. for single shopping streets or particularly congested dense areas of Vienna) severely need to be tackled for individual solutions, but there is no overall need articulated by neither the public administration and the population, nor the transport industries for a city wide concept to manage freight transport in Vienna. Chances to meet future challenges in economic development and related transport operations by setting proactive measures and concepts are ignored so far, despite the self-proclaimed goal to make transport (commercial traffic) within Vienna “largely CO₂-free by 2030” (Vienna City Administration 2014). This gap between goal setting and actual action towards achieving a change in the logistics cityscape is the main indicator for a lack of clear institutional responsibility in Vienna. Hence the disordered institutional framework for city logistics in Vienna bears responsibility of missing the chance to present the city of Vienna as a role model smart city and paragon for a city wide logistics concept.

Intra-Urban Labor Mobility: New Perspectives for the Use of Big Data in Urban Analysis

Filipa PAJEVIĆ, McGill University, Canada
Richard G. SHEARMUR, McGill University, Canada

Abstract

In spite of the great interest in Big Data, very few studies have been carried out to assess the validity and usefulness of Big Data in social scientific research, and fewer explore methods through which existing data types can be combined with Big Data to produce richer analyses. One social scientific area in which Big Data could be very useful is that of daytime labor mobility at an intra-urban, or city, scale. Given the role that mobile telecommunications play in enabling this daytime labor mobility, and given that mobile telecommunications generate huge amounts of geolocated data then it is interesting to explore which of these data can shed light upon the new geography of economic activity.

1. Introduction

ICT, and in particular their data-gathering and geographic tracking capacities, are altering the way society functions in ways that remain little understood: behind the headlines on the privacy, surveillance, marketing and productivity advantages and dangers of the Big Data gathered through ICT, it is still unclear how it is actually impacting our daily lives.

Indeed, the very notion of Big Data remains ambiguous. On the one hand, Big Data are information, usually derived from users of particular technology or from sensors, without people being aware of the data collection. On the other hand, Big Data are a tool: their quantity, and the rapid rate at which they are refreshed, enable them to be used in feedback loops, altering the behavior (or at least the networks that underpin the behavior) in almost real time. Although data have always had this dual aspect – observation of a phenomenon and input for action – the speed and scale at which this can now be done are leading to qualitative changes in the feedback mechanism: from being a fairly slow, deliberative process, open to analysis and debate, it is becoming a real-time phenomenon guided by algorithms that are often opaque.

The opaque nature of Big Data algorithms, and of the underlying data themselves, is due to their operational, and often private, nature. These data are not gathered by statistical agencies or through surveys, which focus on a pre-conceptualized population and for which adequate sampling is important. They are usually gathered opportunistically from users of particular networks or technologies: the data are massive, can be used to influence (and, hopefully, improve) the particular function for which they are gathered, but their use in a social science context, to further understanding of social processes which are multidimensional and which extend beyond users of particular technologies, remains unclear.

One social scientific area in which Big Data could be very useful is that of daytime labor mobility at an intra-urban, or city, scale. Indeed, people- particularly in intellectual or service-oriented jobs- are increasingly able to work from a variety of locations, arrange meetings and meeting places in real time, and it is less and less realistic to suppose that they have a fixed place of work. Thus, traditional approaches to the study of employment location- using census data or establishment registries-

are decreasingly useful as ways to understand where economic activity actually takes place.

Given the role that mobile telecommunications play in enabling this daytime labor mobility, and given that mobile telecommunications generate huge amounts of geolocated data (phone users can be tracked, the intensity of data and line use can be geolocated and tracked throughout the day, twitter posts can reveal activities taking place at a particular place and time, etc.) then it is interesting to explore which of these data can shed light upon the new geography of economic activity.

This is of particular importance in cities, where the nature of traditional office space, the use of public meeting places, and the economic function of places such as restaurants and cafes, even transit, are all evolving fast in ways that remain little understood. Meanwhile, policymakers and urban planners continue to focus their attention on factors that, in light of these changes, may be less relevant.

The daytime mobility of labor has rarely been studied, since most studies of employment location rely on business surveys or census place-of-work data that essentially records the administrative location of jobs. Big Data, without replacing the need to understand where companies are physically located, open up the possibility of understanding where work - or value creation - is actually performed in cities, be it in offices, factories, cafés or subways. Although Big Data have been used to track the movement of people within cities, these analyses have not so far been able to produce policy recommendations beyond transportation, and have done even less to produce a comprehensive image of the city and its uses (Graham and Shelton 2013; Batty 2013). Big Data are a powerful lens, which, if looked through to study labor mobility, could produce a richer, more informative portrait of the city. Understanding where people work in the Information Age will not only provide new knowledge about the spaces where people actually perform their work, it will also contribute to our understanding of how the city is changing, and how planning and governance can help support the activities that are rooted in space.

The purpose of this paper is to, first, briefly outline the way in which the economy-jobs and job location in particular- have evolved over the last 30 years or so; second, to highlight the possible impacts of mobile communication technologies; and, third, to assess the extent to which Big Data can renew our understanding of labor mobility, job location and of the economic function of different places in the city.

2. Unprecedented flexibility and mobility of labor: the new role of location

By the 1970s the increasing technological prowess of developed countries had, on the one hand, enabled a massive outsourcing of manual labor to developing countries; and on the other, induced structural changes in the local economies, with changes in production processes, value-chain organization and employment conditions. Stagflation, in combination with rising markets in Asia, led to an unwinding of the production system. The shift from Fordism to Post-Fordism left in its wake large pools of unemployed and precariously employed people, and a fiscal situation that called for a structural and institutional change. Neoconservative reforms in the UK (Thatcherism) and the US (Reaganism) accelerated the rollout of neoliberalism, and, effectively, a more flexible form of production (Harvey 2007; Harvey 1989; Scott 1988). With more options for production also came a new configuration of relations, or networks, between economic agents. This required new regulatory measures, as well as new forms for industrial co-operation (Frenken, Van Oort and Verburg 2007; Maillat et al 1995). The main objective of this new configuration was the reduction of uncertainty, or risk aversion, as well a systematic

search for new resources and technological innovation (Harvey 2005). Pressures in the economy (whether cost or regulation related) were resolved by geographic arbitrage, i.e. increased mobility of capital across geographical scales, now enabled through innovation in transport and communication technologies (Howells 2005). This internationalization of capital (associated with considerable restrictions on labor mobility, and with the continued prevalence of regulation at the national scale) intensified the speed and expansion of information transfer, affecting not only the manner in which work was carried out, but also the location, or rather locations, of the production process (Dicken 2007; Sassen 2002; Sassen 1990). In turn, this allowed for rapid changes in productivity, as well as the ability to produce a variety of goods, all through the increasing computerization and externalization of the production process. The cyclical nature of the techno-economic system, as presented by Kondratieff (1925), reveals a strong link between the economy and the need to innovate and generate new demands; also, it warrants the need for an entrepreneurial mentality in the face of a crisis (Schumpeter 1942).

More and more places are able to house production processes, driving down costs (wages in particular), and increasing the need for a speedier, more efficient generation of ideas as competitive advantage shifts towards quality and uniqueness rather than cheapness. This means that labor itself needs to be more versatile, more flexible, in order to compete with labor pools elsewhere. This has led to greater uncertainty within both the global and local labor markets, as wages decline as a proportion of value-added and contractual arrangements shorten continuously. Essentially, the neoliberal economy is both a bonanza and a curse, as opportunities have never been greater, but with grave uncertainty (Piketty 2013). In order to secure jobs, workers are expected to exhibit high adaptability to systemic changes, as well as a willingness to work longer hours in various locations. Old divisions of labor are no longer apt at depicting broader trends (Malecki 2010). The very nature of the knowledge intensive economy is non-routine and unpredictable, and is not distributed equally everywhere.

3. Labor mobility and locating where value-added occurs

Labor mobility can be defined as the ability of workers to move across geographical scales (Sassen 1990), across industrial sectors (Massey 1984), as well as within firm structures (Farber 1999). Reasons for mobility include levels of education, higher income and career opportunities, but also the changing costs of labor, heightened competition, the local economic and political conditions, and personal reasons (Hübler 2015; Piketty 2013; Turok and Mykhnenko 2007). Notwithstanding the importance of assessing mobility determinants of workers so as to develop a better understanding of regional economic inequalities, this paper is concerned with the movement of labor at an inter-urban, or city, scale as a result of increased uses of ICT and as a reflection of global trends.

On the subject of the location of labor in cities, earlier studies stressed the importance of the local milieu in attracting firms and capital (Storper and Venables 2004; Krugman 1998; Porter 1998). Theories on factor endowments, or location factors, were widely accepted and translated into policies seeking to create local competitive advantage. These policies favor clusters and agglomeration economies, valuing proximity and space, as well as the presence of certain physical attributes such as infrastructure and cultural amenities. It has been important to understand the wider institutional framework, historical context, and numerous endogenous and exogenous factors, but also the level of technological progress and ICT infrastructure as elements affecting firm location. However, as advancements in the latter stirred a debate on the relevance of distance, academics called for a more in-depth

exploration of factors that make places *stickier* in an increasingly unpredictable global economy and a virtually borderless world (Huber 2012; Urry 2012; Gallaud and Torre 2005; Markusen 1996). It has become important to understand that firm location no longer depends solely on Christallerian (access to services) and Webberian (access to production inputs and markets) factors, since both of these can now be accessed from a wide variety of points in time and space.

Even if the benefits of agglomeration and physical proximity have become unclear, space remains a fundamental dimension of human activity – people, and economic activity, are necessarily situated, and necessarily involve face-to-face interactions, even if these are temporary. Thus, space continues to have a role as support for meetings, and also as support for the transport networks that enable the mobility of agents who attend these meetings (Rainie and Wellman 2012; Agrawal, Cockburn and McHale 2006). To use Castell's terminology – physical space undergirds not only the nodes, but also the flows, of a networked society (2011). Whilst this much is a given, the way in which this undergirding occurs, and the functions that take place along the networks or at the meeting places require exploration, since physical networks and physical meeting places need to be designed, built, and maintained.

4. An ecosystem for knowledge creation: the impacts of mobile communication technologies

Meanwhile, the digital divide is closing. Studies show that 85 out of 100 people have mobile phone subscriptions (Steenbruggen, Tranos and Nijkamp 2015; Miller 2010). It is important to note here, however, that despite the proliferation of mobile telecommunication technology, the level of access to Internet infrastructure varies across geographies. Accessibility to the Digital Economy remains the privilege of larger cities, most especially in the West (Tranos, Reggiani and Nijkamp 2013). Notwithstanding the uneven distribution of ICT infrastructure, technology is becoming increasingly embedded in our daily lives. In a growing number of places gaining access to the Internet is no longer as problematic, and the ability to access and control household and work appliances through the Internet is improving. Portable *smart* devices are essentially enabling individuals to carry their personal and professional networks in their pockets (Greengard 2015; Rainie and Wellman 2012). Never before has the world been this connected, and this, in turn, affects individual perceptions of time and place, presence and connectedness.

Whilst daily lives have been fairly routine and linear in the past, with established times and places for work and socializing, today the work and life balance has been disturbed, and personal and professional times and places overlap. Even waiting time has become productive as work can be carried out while in transit, or from locations other than the office. In other words, mobile communication technologies fill virtually all time slots with all sorts of activities. Documents, spreadsheets and correspondence are increasingly stored in the *cloud*, and through *smart* applications we can access them from anywhere, analyze them anywhere, edit them and send them to others via email, instant messaging, or discuss them via Skype or FaceTime. A significant portion of the population is always online, available, and with access to information shared through the Internet. We learn and create new knowledge simultaneously- online, on the go (Rainie and Wellman 2012).

People who can move and act faster are those with the most power in the contemporary global economy (Bauman 2013; Sassen 2002, 2001). Access to networks enables a speedier response to a problem or a glitch, and heightened mobility enables the expansion of current networks, the formation of new ones, and

the uncovering of new opportunities (Granovetter 1973). Mobile communication technologies allow us to be connected to various networks and build new ones at the same time (Castells 2008). Social networks such as LinkedIn, Facebook and Twitter play a dominant role in forming and maintaining these networks, and are constantly evolving to produce new markets (Zervas, Proserpio and Byers 2014). While LinkedIn and Facebook connect people, other peer-to-peer platforms such as Airbnb and LiquidSpace connect people to flexible living and workspaces. In response to losses instigated by the global crisis, these networks generated alternatives to existing service and goods providers. Airbnb, a home-sharing platform, continues to drive down short-term accommodation process, and is changing the economic function of homes and hotels in the city. In response to the sharing economy, Marriott has launched a program that provides workspaces on demand with state of the art facilities that promote collaboration and networking (Meister and Willyerd 2010).

Doreen Massey (2005) has shown how cities have become spaces of interlinked trajectories. As companies and people grow more mobile, and most of our social interactions take place in cyberspace, the ideas of a pre-arranged rendezvous become virtually obsolete; and yet, geography remains important in maintaining these networks (Stephens and Poorthuis 2014). Space is not dead, the office –and, for many jobs, the specific work location - is. The workplace has become an abstract concept: not only is there no grasp on where work¹ actually takes place but there is very little understanding of how and when existing workspaces are being used. Defining the right design for workspace of an increasingly interconnected and mobile workforce has become a challenge. It is important to re-evaluate present social and economic functions of places in cities, and better understand the factors that keep networks rooted in space.

Essentially, understanding where people live and work these days calls for new conceptualizations and new methodological approaches. And as planning theory shifts from agglomeration and density studies to notions of edgeless cities (Lang 2003), to edge cities and places in between (Garreau 2011), new studies are needed to rethink present theories and develop more accurate understandings of modern urban life.

Meanwhile, the communication and transport networks supporting daily mobility are generating vast amounts of passive data (Mayer-Schönberger and Cukier 2013). Researchers have begun to investigate ways in which this information, or Big Data, can be transformed into knowledge that could be applied to problem solving (Miller 2010). They are investing heavily in the development of data mining techniques that could lead to new knowledge (or at least to uncovering unsuspected relationships that require understanding and theorization). This could undoubtedly be a tremendous opportunity for spatial sciences. Telecommunication patterns can be used for real-time urban analysis, e-ticketing can provide new information on commuting patterns, and participatory GIS and social networks can offer insights into the new uses of space. Many are quick to claim that we are now in the position to see, perhaps for the first time, the mechanics of the global economy as well as to better understand society (including the city and its functions) (Mayer-Schönberger

¹ This does not apply to all types of work. It is higher-order service work (Reich's (1992) symbolic analysts) for whom work location has become very ambiguous – and these activities are predominantly urban, traditionally concentrated in and around the CBD. Other person-to-person service jobs sometimes require a fixed location (e.g. restaurant work), sometimes do not (e.g. hairdressers and cleaners can travel to their client's location to perform their work). Production work, on the other hand, still requires interaction with equipment that is not mobile on a daily basis.

and Cukier 2013; Tranos and Nijkamp 2013); furthermore, as individuals we have been enabled to more actively participate in political, economic and urban processes through the widespread uses of technology and the growing number of links between society and the government (Goldsmith and Crawford 2014; Townsend 2013). Notwithstanding the usefulness of Big Data to transit analysis and better participation in governance, it is difficult to assess the extent to which Big Data enable the understanding of (as opposed to tracking and real-time optimization) underlying layers of the global economy and the generation of knowledge on changes in our society and cities. Even though the global economy is dependent on ICT, and we are using these technologies to extract Big Data to help track behavior and reveal social patterns, very little is known about and how their uses are affecting urban life. Whilst certain general theoretical frameworks have been developed, (see Castells 2011, 1996; Batty 1995; Massey 2005, 1991) there has so far been limited empirical investigation and theory testing.

5. Big Data and cities

Big Data, and harnessing them in order to understand social and urban change, have not yet become mainstream research. There is much speculation about the capabilities of Big Data analysis, and actual studies have been limited to few researchers at MIT, UCL and the University of Tartu. The technical nature of Big Data is one of the main causes for the lack of new knowledge on its applicability and usefulness (Tranos and Nijkamp 2013; Miller 2010). As it is so closely tied to digital infrastructure, researchers feel that their lack of technical knowledge will limit their understanding of Big Data: indeed, much current research is focused on statistical techniques that enable the extraction of information from Big Data rather than on what Big Data can tell us about social processes and how accelerating feedback mechanisms structure and alter these processes. Many believe that once these technical issues are resolved, research using Big Data will help improve cities by offering real-time explorations of the city, providing information and helping identify patterns that could be used to predict future problems (Batty 2013). Furthermore, there is widespread belief that Big Data can support better decision-making by helping identify the right partners and form relationships, thereby enabling cities and city planners in better addressing the needs of multiple actors (Goldsmith and Crawford 2014; Townsend 2013). Policymakers are increasingly drawn to the Smart City framework without definitive proof of its actual benefits to the city (Kitchin 2013). And as Big Data become increasingly more embedded in decision-making without proper understanding of what it can or cannot do, or thorough exploration of analytical tools and methods used to extract new knowledge, cities are at risk of misinterpreting causality (Graham and Shelton 2013). Even though there are opportunities for Big Data, they must not be treated as panacea (Steenbruggen, Tranos and Nijkamp 2015). Furthermore, the complexity of urban environments demands an approach that consists of a mixture of data sources and methods.

Let us consider the benefits of Big Data. First and foremost, they are real-time, fine-grained and ubiquitous. Second, Big Data can be extracted from surveillance technology and sensors, or indirectly through the use of smart devices (records of transactions and interactions stored in the device's history), or volunteered by users through their exchanges on social media outlets such as Twitter and Facebook. Third, unlike traditional data sets, such as the census, Big Data are varied and produced frequently over wider spatial scales (Tranos and Nijkamp 2013). They promise to fill existing knowledge gaps and produce richer analyses of social and spatial phenomena given their spatial attributes. Moreover, they promise more sophisticated studies in terms of methods, models and theories (Kitchin 2013;

Graham and Shelton 2013). Finally, due to these inherent traits Big Data has the potential to reflect dynamic processes in the city.

As a result, cities are scanning Big Data for knowledge that helps deal with complex, multi-scalar- wicked - problems, and continue to invest in smart technologies to both produce and analyze Big Data (Townsend 2013; Morozov 2013). However, there is a limited body of work that addresses the effectiveness of Big Data analysis in addressing, and unraveling, this complexity. MIT SENSEable City Lab and the University of Tartu have pioneered research on the urban metabolism with the use of Call Data Records (CDR). This data provide the origin and destination of calls, as well as their timestamp, the duration of the call, and identify the status of the caller (worker, non-worker, or student). CDR promises information on population clusters, travel patterns, and temporal clusters of activities, which, when combined with demographic data and land-use plans, can produce an image of the city and how it is being used by certain groups of individuals (Jiang, Ferreira and Gonzales 2012; Jiang, González and Ferreira 2011; Becker et al 2011; Calabrese et al 2010; Ratti et al 2006). However the quality of CDR depends largely on the presence of cell towers within the desired area of study, and data is generated only when an exchange or transaction occurs. Furthermore, the data is not open source, and privacy regulations grant limited access to researchers. Also, it is very difficult to determine the type of activity or exchange (personal or professional, and in what sector) taking place through CDR alone.

Access to Big Data is one of the main challenges to researchers. Other challenges include the design, development and testing of new methods capable of handling the volume and versatility of the data. Traditional methods are no longer applicable, and researchers will increasingly need to acquire skills in coding, statistics and modeling. Companies are working hard on developing new data mining techniques, and are exploring other sources of data, such as noise and mobility sensors. Scholars question the impacts of such changes on social science on the whole. The rise of computational social science is based on the need to collect and analyze massive amounts of data on human behavior, but little is known about what all of this can actually tell us about society, politics, economy and space (Kitchin 2013). Furthermore, the drivers behind computational social sciences are private tech companies such as Google and IBM, and government surveillance agencies (Morozov 2013). If computational sciences become the exclusive domain of the tech industry, the knowledge created will address a specific set of questions and problems and ignore wider concerns, especially in terms of understanding social and urban change. Finally, without an anchor and other more static data types, Big Data are poorly adapted to uncovering change. Big Data should not go to waste, but in order for them to generate more concrete knowledge on the changing urban dynamic it would require careful matching of new and existing data types (Steenbruggen, Tranos and Nijkamp 2015; Becker et al 2011; Frias-Martinez et al 2012).

Studies on the spatio-temporal patterns of human mobility across different neighborhoods are scarce (Isaacman et al 2012). So far these studies reveal commuting distances and patterns, and identify hotspots and population density. They do not, however, indicate real-time land-use patterns, the types of activities taking place, and new economic functions of places in the city. It is difficult to ascertain the benefits of Big Data, using current methods, in tracking social and spatial changes such as increased labor mobility and changing job locations in the city. Undoubtedly, a better understanding of how, where and when people move and where they rest on a daily basis could lead to better planning policies. But adding to the equation places of work and leisure could produce new information for better urban design, infrastructure provision and environmental impact assessment.

The widespread use of ICT, namely mobile communication technologies, has signaled a point of no return: the data exists and will be used, whatever the quality of the knowledge generated from them. Notwithstanding the issues concerning privacy and surveillance, it is important to assess the benefits of data that is generated -and analyzed for other purposes already- to the creation of new knowledge on, and the understanding of, social and spatial changes occurring at the city scale. Adding to the equation the study of social networks through tags could gain insight into wider social and economic trends (Rainie and Wellman 2012) and how they play out on the ground (Castells 2011). Encouraging voluntary information (geographic and otherwise) could not only eliminate privacy concerns, but also enable bottom-up data creation to fill gaps previously generated by static, more traditional data collection and analysis. Furthermore, this would build a sense of inclusiveness on the part of the users in decision-making processes. Also, opening up Big Data to academic researchers could balance out corporate interests. Combined with census data, surveys, and voluntary geographic information, Big Data has the potential to provide an elaborate, detailed portrait of the city and its current uses. It is important to contribute to existing studies on Big Data and urban analysis, and explore more ways in which these data types can be matched to produce new knowledge on job location and inter-urban labor mobility.

6. Conclusion

Technology is undoubtedly changing the face of the city. The creation of cyberspace, or cyberspace (Batty 1997), has led to a detachment of certain, more mobile economic activity from physical space. Today, people can work at an office, or from their homes, or at a café, or from a subway or train station. It has become more difficult to pinpoint where work takes place, and, essentially, where innovation occurs as business is conducted on the go. As the idea of an office grows more abstract, urban planners need to concern themselves with the fate of fixed places that are no longer desirable, nor affordable, for firms as well as individuals.

Meanwhile, networks that enable this greater flexibility and mobility of labor, are created and supported by technologies that generate vast amounts of information, or Big Data, that could be used to better understand the dynamics of these networks and how they impact the use and configuration of space in cities. In spite of the great interest in Big Data, very few studies have been carried out to assess the validity and usefulness of Big Data in social scientific research, and fewer explore methods through which existing data types can be combined with Big Data to produce richer analyses.

The reasons for this, in addition to the general reluctance of social science researchers to engage with data types that require more specific technical skills, include inherent biases that make the data unsuitable for the analysis of population as a whole and/or for targeted subgroups, and the lack of access of Big Data to researchers as a result of strict regulations and privacy laws. And yet, the penetration of private tech companies in the field of computational social science raises concerns over the extent to which these regulations actually protect privacy, and, what is more, the extent to which the information produced reflects social and spatial trends and not just corporate interests. If Big Data remain within the realm of private companies, the debates necessary for knowledge creation will be stifled. As a result, the “knowledge” produced will be geared towards questions of efficiency and competitiveness to the exclusion of a myriad of other types of knowledge such as inequality, identity, land-use, personal mobility and other that are unrelated to markets.

Furthermore, the distinction between correlations and knowledge is an important one: at the very least, knowledge requires theory and an understanding of social mechanisms. Correlations can support and confirm theories, but can rarely produce them. However, inductively, correlations can help build new theory, which then needs verifying and testing by means that extend beyond just more correlations. Big Data present many opportunities, as well as challenges, for research, and more attention should be paid to ways in which Big Data can be paired to theory and matched to other data types to produce more concrete images of changing urban dynamics.

Inter-urban labor mobility is a reflection of wider global economic trends, and the economic function of places in the city carries implications for future planning practices. It is important to understand how Big Data, with their ability to track movement and show real-time urban mobility, can be used to grasp both of these increasingly dynamic processes.

Finally, distance is not disappearing as a basis for human organization, but the parameters that define its importance are changing. Widespread use of the Internet has altered the geographic organization of our economy, sense of identity and how we interact with places in which we live and work. At the same time it has also served to reconnect us with place, as social and economic networks have geographic properties, and are essentially rooted in space. It is important to understand these changes at a city scale, and use this information to improve planning practices and policy.

Heterochrony in Architecture

Simone BACK PROCHNOW, Uniritter Laureate International Universities, Brazil.

ABSTRACT: Architecture allows us to experience places that go beyond our own existence. As a testimony of our development and our way of inhabiting them, cities are naturally composed by different parts, built in different times. That is the paradox that makes it so interesting: cities have to stay as well as continuously advance and change. Permanence is becoming harder in this context of hurry and missing values that our society lives in and therefore our memory concepts nowadays are somehow vulnerable. But this permanency still has several ways to happen - to turn architectural heritage and obsolete industrial pieces into creative and alive places is the real challenge. Different ways of reusing existing buildings demonstrate legitimacy as far as they allow us to enjoy these buildings, use them and recognize them as transmitters of artistic, cultural and historical aspects of humanity. This heterochrony in architecture is the theme of this study, that rethinks the architectural project as an important tool for heritage preservation in most varied forms, and existing buildings as part of a bigger and continuous live process - the city.

Key words: memory; architectural heritage; architectural design; heterochrony.

1. Foreword

Life is a continuous process and in many ways our cities are a reflex of what is happening in our lives. Hurry is the global command now, and this makes a big difference in every item that composes our places and our thoughts. Everything must be done and answered in seconds, most of the things should not last for a long time - we do not have time to lose thinking about reasons in life and about ourselves. And when we think about heritage, in special architectural heritage, this hurry effect turns into a sharp edge - dangerous and harmful.

Concepts as post-modernism, cognitive capitalism and liquid life are presented to us daily, in a frenetic way and somehow they try to explain this strange sensation of lack of time. According to Françoise Choay (2006), in 1913 Giovannoni is already worried about the innovative role of the "new techniques of transport and communication", foreseeing exactly what we are living nowadays. Thomas Carlyle in the middle of the XIX century, speaking about the Industrial Revolution, says that not only the physical world was then organized by machines, but also our spiritual world, our thoughts and our sensibility. Men have turned so mechanical in their spirits as in their hands. (CHOAY,2006). Considering the hyperconnection and the virtual revolution that we are living now, if we think in the same proportions of Carlyle, how is it actually our world, our way of living, our material places, our architecture future?

Our relation to the past as to our memories is also being redefined. The attitude towards old buildings suffers in a paradoxal way too. Neglect is one of the possibilities, since we do not know the history, we do not know the buildings and their reasons, so we do not care about them. Creativity is the other side, when so many different manners are possible to rehab old buildings and enjoy them, learn with their histories and in so many different scales and approaches.

This study seeks to identify the project lines that guide this creative types of reuse in our architectural industrial heritage, making its permanence not only possible but also economically viable. There are several interesting ways to design this that can be found in many different places around the world.

How has this heterochrony (Comas, 2010) - a concept brought from biology, defined as a developmental change in the timing or rate of events, leading to changes in size and shape of species according to its needs during its evolution through time - worked out?

How is this time passage being noticed in our cities? It is a consistent worry if we consider that the perception of places also change along time. According to Lineu Castello (2007), several different places were criticized but some of them, due to the popular appropriation,

due to its real use, ended changing peoples minds and becoming recognized as nice places to inhabit.

As pre-existences are the taxable event of a project, the combination of old and new is the contemporary response to the challenge. Even more instigating is the fact that some of the old industrial buildings were not even noticed, and after rehab are in a much higher level of recognition in the cities.

2. Ways to Rework Industrial Architecture

Ruth Verde Zein (2014) says that our memory is made of "rememberings" and "forgettings". Both are fundamental for us to be healthy people living in society. We are what we remember but also what we forget. And forgetting is another kind of art - that means, an ability that can be acquired and so, improved. To forget is not a defect, is the condition for us to create new memories, new spaces, and even a better city.

How can architecture stay through time? Being updated and used permanently is one of the main answers. The mixture of different times is a very important ingredient in an architecture that uses pre-existences. The heterochrony in these projects must deal with special conflicts, for example, the ones that will exist between the *Zeitgeist* and the *Genius Loci* of that "place" that will be reused.

The concept of place, following the research of Prof. Lineu Castello (2007), varies according to the experimentation of each person in it. The perception of new places, when designed to fulfill the needs and practices of each society defines them as being places of urbanity or not. This perception can be transmitted in a visual, sensorial or informational way. A space turns into a place as long as it acquires definition and significance.

When Charles Bloszies (2012) defines historical buildings as architecture comfort food, he signalizes important aspects for preservation: their esthetic appeal, as known and with simple forms that comfort the views, as well as their participation in the city legibility. In the example below, working and living are places under the same roof (a common desire in our society nowadays). A glass box is put inside the brick shell.

Figure 1: Walden Studios, California

Françoise Bollack (2013) mentions in her book *Old Buildings New* the *as found* theory. Since Marcel Duchamp, responsible for the *ready-made* concept, the barriers between art and normal life can be eliminated. The reuse of a building in its ruin state is also possible - and is one of the highlights at the moment.

Engaged with this way of thinking appears the upcycling concept, that goes beyond recycling since it suggests to reuse materials as they are, not expending energy to rework them. A radical recycling *in situ* of a building, for example - uses what exists and gives it a new meaning. Taking as most important sustainable actions that will result in a new esthetic language.

This old deposit in Bund District in China, for example, was transformed in a luxurious hotel. The concrete carcass is kept and corten steel walls are added to it. From the interiors people can experience both old and new parts together.

Figure 2: Exterior and interior of The WaterHouse Hotel, Bund District Shanghai .

A very important item to be considered when reusing old industrial buildings is the scale that connects them to the city, making a different relation to pedestrians. According to Carlos Eduardo Comas (2011), recycling a building redevelops its function in several dimensions: symbolic, operational, spatial and technical, all together. An important sample of this kind of reuse is the SESC Pompeia in the city of São Paulo, Brazil. An old drums industry was transformed into a cultural center, allowing the community to live the place and appreciate the historical construction.

Figure 3: SESC Pompeia a great example in São Paulo, Brazil.

All these ways of manipulating the pre-existences reinforce a very important component of memory that is evolution. This evolution registers the art will of each time, the *Kunstwollen* as defined by Alöis Riegl (1903). Evolution and development are conditioned to changings. Heritage cannot be frozen in time. For some authors the best defense of an authentic historical architecture is the complement of an authentic contemporary architecture; an architecture that transforms and preserves at the same time. An architecture that transforms exactly by being recognized as part of the historical process, a time dialogue between them, not submission from one towards the other.

"Good architecture of a certain period always goes well with good architecture of any other previous period, what does not match with anything is the lack of architecture."

Lúcio Costa

The greatest deal is also to search the conversation between old and new, floating between autonomy and codependence. In a form and time speech as says Fernando Diez em Summa +128 (2013). Not to accept new, just for being new is the same as defend the past and deny contemporaneity its right to history - says already in 1903 Alöis Riegl in his book "Der Moderne Denkmalkultus".

Françoise Bollack (2013) in her book divides the reuse design strategies in five categories: *wraps, weavings, juxtapositions, parasites, insertions*.

Figure 4: Categories of Intervention following Bollack in her book *Old Buildings New Forms*.

An example of insertion is an interesting case in renowned Tribeca, Nova York. A cheese industry was transformed following this strategy. Built in 1871, it became an office building through an insertion of a new structure, which is a little bit smaller than the old building, creating a porch. This allows the interior to be illuminated and the separation between them is like an interstitial place some meters wide. Just like a mask, the metal skin covers the new glass brick wall. This new wall works like a neutral background to the old, and this game between them permits an easy reading of the composition.

This way of working the new "floating" inside the old enhances the perception of what contains and what is contained. The urban scenography is kept, since the scale and the relation with the street is the same as when the building was erected.

Figura 5: Old façade as a mask in front of the new one and illuminated interiors.

Interiors are designed in a contemporary way, unmatching old levels and new ones. A grid is made to play with the strong hierarchy of the old classic facade and the new used places. A void space was left illuminating even more the longwise inside.

In the juxtaposition cases of intervention, the addition stays next to the existing building, but in an interesting way, not in an obvious conversation. The original stays completely legible and no frontiers are mixed up. The contribution of each part is done in a relatively distant way. A visual separation is clear by the use of different materials, colors, textures or even a formal abstraction - this increases the individual values of each part. This is somehow the way a case was developed in South Brazil.

3. A Case in South Brazil

In South Brazil, specifically in the city of Porto Alegre, as several port cities in the world, there is a brownfield that nowadays is turned into a focal point for real state production. It is close to historic downtown, has a flat geography, is well served by public transportation and has some interesting green areas, but is full of abandoned industrial buildings that turn it into a not well seen area. The government is trying to update the place, but their actions are not enough. Private investments are needed to obtain the aimed results in a larger scale and in a shorter period of time.

The example shown here is an old textile industry that has left the buildings empty for decades. It is not yet ready - part of it is a work in progress - but it shows already how results can come in this kind of project. It is a large scale project that involves a big area inside this District (around 36 thousand square meters). It is called Rossi-Fiateci.

The permanence of architectural industrial heritage was enabled through a strong negotiation between the interested parts. Some advantages were given by the city planning team, in order to get main buildings restored (and most important: making possible for the community to reuse them and somehow live inside them again). Permission to build sixteen storage buildings, for example (for living units and offices). With completely different use, now the historic buildings receive commercial and service businesses.

Figure 6: The heterochrony of the construction and its site.

A complex strategy of placemarketing was elaborated, selling the idea of revitalization and new places to live and work in the city. Its success was proved when after three months of launching the project, more than 50% of the units were already sold.

Figure 7: Image used in the marketing campaign of the project

This shows how *placemaking* and *placemarketing* have the power of shortening the time needed to create and to form an urban place. With a shopping center, a museum, open areas, it is possible to duplicate the aura of urbanity found in other city areas that are alive and full of people according Lineu Castello (2006). Architecture office Brasil Arquitetura (2014) which is used to work with rehabilitation projects say that the reuse of buildings must respond to the need of new uses, and also to a clear way of a spatial situation that already existed in the same place. Even more, should create new places of living together based on the local history and the contemporary values administrating situations that are around it as

different social classes, conflicts, tensions, searching for tolerance and cohabiting. This is what is promised by Rossi-Fiateci project.

Its importance is huge when we think about turning alive such a big area as the IV District. There are steps to be followed and the first one is exactly reactivating specific important points in the whole net.

After that, other points should be resolved also, then all of them should be connected to "healthy" parts and after that, they should connect themselves to the others, making a strong configuration of ways to bring people to the part of the city to be renovated.

Figure 8: Diagrams from the author explaining the steps of rehabilitating an area.

A positive point is the fact that the city of Porto Alegre has a plan for establishing new central places - and that will be surely increased by this project. As mentioned by Lineu Castello (2007) in his research, the imagetic force of some elements in the city stay even when they are useless. This is how industrial buildings with their specific building constructions and chimneys work in peoples mind. These symbols have the potential to receive new elements in their images regenerating the places, bringing them back to life.

Figure 9: The image in collective memory: chimney as an important landmark in the project.

The impact that the new towers cause in the city skyline, since the major number of buildings in that area are two floor buildiconstructions, is huge. If analyzed as urban acupuncture, as part of a whole strategy based on several points that will be connected, it can produce a positive effect (Casanova and Hernandez, 2014). But part of the global project should necessarily be the improvement of open green areas in between, as well as buildings that allow visual interest for people that walk in the streets (Jan Gehl, 2013). What is seen in this project in Porto Alegre is a small conversion: the space in between the buildings will be part covered, used as internal squares and meeting point for the users. The streets around the new buildings will certainly feel the improvement of new users in their economy, but also are somehow not connected to them. Very few entrances are positioned to let the pedestrians flow across the block.

Figure 10: Internal squares created by covering the void spaces between buildings.

4. Some conclusions

It is possible to say that only the real use and its dynamics can prove the success of heritage permanence as a place in the cities. Its permanence through time is justified by being inserted in everydaylife as a place for working, enjoying, meeting and living. As a great point is the fact that old buildings perception (the perception that stays in peoples minds) works as a positive influence for the companies that reuse the buildings and have their images connected to them.

What is not recommended is the use of same strategies and plans in every city, turning the solution an "urbanalization" (Munoz, 2008) since every history and every place needs according solutions to its reused areas.

Cities in developing countries are merging from industrial era to information economy. It is urgent to define ways not to neglect the historical industrial buildings, but somehow with creative and sustainable projects bring them back to activity. Since there is a noticed need of places for the new kind of living and working, why not take them as basis for renovating but also preserving methods? Heterochrony is part of architecture itself. It is important to learn

how it can be pro development used and studied. Special connections to the whole city are primordial action to obtain success in conversion projects.

The plight of the "Chinese-style peasant economy" in the transformation of urban industry

Jing QIAO, Huazhong University of Science and Technology, China
Hong GENG, Huazhong University of Science and Technology, China

Keywords: Chinese-style peasant economy, the transformation of urban industry, farmers' interest, informal economy

Abstract:

The urbanization of China has already entered a period of industrial restructuring and upgrading, whose major direction is speeding up the development of service industry. As the significant branch of service industry, rural tourism industry brought many undisputable economic benefits to Chinese villages and farmers, which accounted for nearly a third of the economic benefits of the total Chinese tourism market. However, rural tourism has brought intense impact to the "Chinese-style peasant economy" structure, which is the China's rural stable reservoir in the development of Chinese modernization. The rural tourism development pattern, including scale development, diverse planning and market-oriented, have a conflict with the "Chinese-style peasant economy", which is characterized by management dispersion, landuse fragmentation and villagers self-administration. Therefore, "Chinese-style peasant economy" structure has the features of informal economy. It has made great contribution to the transformation of the urban industry. The paper researched that how to incorporate the informal economy which plays an important role among precarious populations into the transformation of the urban industry and protect the farmer's interests. Firstly, the necessity of the "Chinese-style peasant economy" structure which is characterized by informal economy in Chinese villages was proposed. Secondly, the traditional production pattern was broken due to the non-coupling between the rural tourism and the "Chinese-style peasant economy". Therefore, the peasant lost the elastic space and flexible choice in the transformation of urban industry. Finally the responsibility of planning in protecting the "Chinese-style peasant economy" structure and incorporating the informal economy were discussed. The multiple interests should be harmonized in rural tourism by planning. In particular, farmers' interests could be guaranteed and maximized by means of clarifying the land right, protecting rural space and guiding the cooperation.

1. Introduction

Along with the rapid industrialization, China has acquired obvious achievements. But also, many problems not allow to neglect have appeared. Against the background of the global rebalancing and the re-adjust of the industrial pattern, global supply structure and demand structure have been changed profoundly. The contradiction between the strong production capacity and the limited market space is prominent, and China will face more intense competition. Therefore, China has faced up with great challenge in economic restructuring and industrial upgrading. Especially, accelerating the development of service industry is the main direction of industrial upgrading. As one of the most important branches of service industry, rural tourism is a new attempt for modern tourism extending to traditional agricultural. It is a new form of industry, which combined eco-agriculture and eco-tourism organically by the promotion of tourism. Rural tourism originated from Europe and has a history of more than 100 years. China's rural tourism sprung up in the late 20th 90's. It has played an important role in optimizing rural industrial structure, narrowing the income gap

between urban and rural areas, promoting the rural employment, driving the development of related industries, accelerating the cultural exchange between urban and rural areas, and so on. In the 21st century, rural tourism has entered a period of comprehensive development. The increasing attractions, the expanding scale, the extending distribution, all show a good momentum of development. Data show that China's rural tourism income reached 300 billion yuan in 2014, accounting for one-third of its economic benefits of the tourism market. The "first document", signed by the Central in 2015, pointed out the importance of rural tourism development for increasing farmers' income with a large space. And pledged to give full support from land, finance, banking, taxes, etc. Therefore, the development of rural tourism has become an important industrial form for increasing peasant's income.

However, the development of rural tourism is a game process among multi-stakeholder. Developers, government, farmers, tourists and other groups all want to pursue their own maximal interests in the process of rural tourism development. But in the process of the game, farmers are often in the inferior status, and their rights can't be protected properly. So, although the development of rural tourism brought great material benefits to some extent, the obtained benefits are not sustainable. Considering the reason, it is directly related to the "Chinese small-scale peasant economy" in the Chinese rural society. The "Chinese-style peasant economy" has the same characteristics, including the small scale and separate management, as the informal economy. Especially, it has not been involved in market management and urban strategy. Thus, the peasants participation in the development of rural tourism is lack of fundamental protection. Therefore, this article hopes to study based on the necessity of the "Chinese small-scale peasant economy". Then the conflict between rural tourism development and the "Chinese small-scale peasant economy" was analyzed concretely, and dissect the root causes of farmers' interests being damaged. Finally, we discussed how to use plan to dilute the conflict in the rural tourism development and incorporate the informal economy into the strategy of urban industrial transformation. Thus to protect the fundamental interests of farmers.

2. The necessity of the small-scale peasant economy

Before the industrialization process, small-scale peasant economy exists throughout the countries and regions all over the world. China is a typical small-scale peasant economy country since ancient times. Small-scale peasant economy has existed for thousands of years in the history of China, and is the economic foundation of Chinese civilization's continuation. It has experienced the transition of system, forms and features since the formation. From modern times to the founding period, small-scale peasant economy shows an overall change from closed to open. What's more, due to the impact of Chinese economic development, it presents the transition character from tradition to modern in recent years. Although "Chinese-style peasant economy" has certain common characteristics with the informal economic, and many western scholars have predicted the inevitable demise of the small-scale peasant economy. It still exist in the Chinese rural society, which has a profound impact on farmers' living and production.

2.1 The main characteristic of Chinese small-scale peasant economy

The concept of "Chinese-style peasant economy" is a long-term study by Professor He Xuefeng, which proposed to describe the agricultural business and rural livelihoods mode, structure on the basis of "semi-cultivated in the intergenerational division of labour based semi workers" in the current stage of China. In particular, with the development and urbanization of China's economy continues to accelerate, a lot of young labour force move into the city for their livelihoods from rural. They leave the countryside temporarily or permanently, making the countryside has become a "three Left groups" (stay for the elderly, women left behind, left-behind children) habitat. These groups are also left to become the

main practitioners of the rural economy at this stage. Therefore, the current peasant economy shows different from the one emphasis on family as the main production unit of the peasant economy expressed by the classical theory, but also different from ranch business model by capitalist agriculture. It performs to form a reproduction of labour power mode, based on the peasant economy family and inter-generational division.

2.1.1 Basic characteristics -- "semi-cultivated in the intergenerational division of labour based semi workers"

With China's urbanization and industrialization, more and more farmers choose rural migrant to increase the income of workers for family, in order to improve the overall level of income. For rural households, rural migrant farmers are mostly in young or middle-aged labour force. According to statistics, 80% of farmer families have the phenomenon that young children work away from home, whose parents farm in rural. This structure of "semi-cultivated in the intergenerational division of labour based semi workers" begins form national flow of rural labour since the reform and opening up in the 1980s. The earliest (1970s) appeared in the southern township enterprises. Farmers farm in busy season and work in the other time. This division formed "institutionalized half work half farm" by Professor Huang Zongzhi. Due to the rapid development of township enterprises, the policies allowing farmers to engage in trade and industry. Some labour move into the cities and move into the business. It makes the labours liberating from traditional agriculture. It improves the efficiency of agricultural production, but also improves the lives of farmer level. By the 1980s, migrant farmers began to increase, predominantly male scale. Mostly elderly, women and children are left behind. In the 21st century, the vast majority of young rural labour force have moved into the city for work or business, who become important part of the urban labour force and important means to improve the living standards of the rural population. On the other hand, after the main labour force flowing out of rural, women's farm, elderly agriculture and peasants planting operations and other forms become the main mode of food cropping. Some carry out featured planting or breeding and some elderly and women who are still strong search opportunity to do "odd jobs" to make money. They farm in busy season and work in leisure day in the towns. Or even do manual processing in the home of the operations. Such as the development of rural tourism is one of the ways to increase revenue for villagers who stay in the village.

2.1.2 Essential character -- a stable reproduction form of rural labour

Although with a large number of rural labour outflow, the phenomenon of rural hollowing tends to be serious. Production began to be done basically by old people and women in agricultural. However, the current structure of "semi-cultivated in the intergenerational division of labour based semi workers" remains a stable workforce reproduction mode. Firstly, from the "semi-farming" perspective, the household contract system is the basic agricultural management system in China, and agricultural production is the fundamental mode to maintain income and it is also the guarantee to maintain stable development of China. And with agricultural industrialization and modernization developing, labour for agriculture will be required less and less. The development of industrial diversification, rural tourism and other tertiary industries also led to increasing the added value of agriculture. The basis of agriculture development will further reinforce, and farmers can likely be achieved "income-place" increasingly, therefore staying rural farmers on agricultural production still remains great enthusiasm. Even the old people are not suitable to continue to engage in agricultural production and labour, due to the lands transfer and implementation of contracting policy, the people also can contract and transfer the lands to the other residents of the village to carry on the sustainable agricultural production. Therefore, the structure of "semi-farming" is very stable. On the other hand, from the view of "semi-working", along with the urbanization process promoting, the gap between urban and rural areas is actually still growing. In the

current situation, many rural areas cannot satisfy the demand for improved their living standards by simply engaging in agricultural production, due to tensions between people and land. Therefore, the labour force is bound to liberate from the limited arable land resources out into the city to engage in secondary and tertiary industries, which has more productive rate of return. Statistically speaking, the proportion of the structure has been rising steadily when it appears in rural since the 1980s. In the 1980s the proportion is about 20%, and the regional distribution is unbalanced, mainly in the coastal areas; In the 1990s the proportion should be about 40% or more, and the region have been all over the country; After 2000, the proportion rose to 80%, and it has reached a relatively stable maximum value. Such a high percentage may be maintain for 20 years or even more. Because, after 20 years, the parents whose children were the first of the young migrant workers out of business are too old to do farm work. And the young man's children have grown up and start migrants. When they are no longer young, they would return home to take over the farming parents. This realize the reproduction of the structure of "semi-cultivated in the intergenerational division of labour based semi workers", which is very stable.

2.1.3 *Spotlighted issues -- the small scale of Chinese-style peasant economy*

The small scale of Chinese-style peasant economy mainly shows in two aspects. Firstly, from the macro perspective, the underdeveloped Chinese agricultural modernization and the lack of technological innovation and technology promotion capability have led to a small scale of China's peasant economy and inefficiency of land management. In recent years, to improve the level of agricultural modernization and industrial development has become a great concern of the Chinese government. Since 2004, the first policy document has focused on the "three rural issues" and emphasized the issues of concerning increasing farmer's income, agricultural modernization, rural planning and construction, and social issues. Rural Tourism Development which will be discussed in this article is one of industrial development path to increase the added value of agricultural production and land management benefits.

From the micro perspective, most of the Chinese current peasant families are running small-scale production and management activities. This is mainly because the farmers' production-scale is restricted by land and capital. Compared to peasant population, China's arable land is extremely inadequate. Besides, the accumulation of farm families is limited. It is difficult for the peasants to have sufficient capital and advanced technology to expand production scale.

In addition, studies have shown that: because a variety of agricultural production factors have good divisibility, modern agriculture did not show obvious scales economy advantage within the family compared with other sectors. Therefore, farmers lack sufficient power to expand family business scale internally. Therefore, the traditional idea of "self-sufficiency" and our household land contract system have made our land management become fragmented. And this is the biggest problem faced by the Chinese Agricultural operators at present. Fragmented land management has eventually lead to excessive inputs of invalid labour, poor land management efficiency, and lower output efficiency.

2.2 *The necessity of Chinese-style peasant economy*

2.2.1 *Chinese small-scale peasant economy always ensure the agricultural income of farmers*

Although with the developing of industrialization and urbanization, more and more of the agricultural population will join into the urban population, rural industry is also gradually tend to diversify and farmers' income structure will change. But agriculture has always been the

fundamental industry of farmers. China has 800 million farmers living in rural areas, accounting for nearly 60% of China's total population. It's an important safeguard for Chinese stable and healthy development to ensure that 800 million peasants' lives. The main form of peasant economy as a traditional agricultural production to ensure the continuation of the agricultural economy, ensures the ultimate source of income for the 800 million farmers and provide sustainable basic living guarantee for them.

2.2.2 Chinese small-scale peasant economy is the ultimate protection for migrant workers returning home

With the accelerating process of urbanization, China has about one million migrant workers working in cities, become the resident population, but did not enjoy the urban population as a welfare policy should not be the domicile of the urban population in the true sense, no really integrate into the city, so that employment which 200 million people are always at risk. But this is the part of migrant workers to complete reproduction of labour power by the "semi-cultivated in the intergenerational division of labour based semi workers" structure. So that migrant workers at risk of unemployment, you can choose to return the countryside, continue to engage in agricultural production, ensure the overall income of the family. In other words, the vast majority of migrant workers did not sever ties with the countryside. As long as the current agricultural basic management systems stable, staying in the country farmers can still guarantee their life and production stability through diversification of agricultural production and industrial development path similar to rural tourism development, and they may fail to migrant farmers Workers provide a smooth passage to return home.

In addition, for the reproduction of small-scale peasant, the failure migrant workers into the city don't have to stay in the city. Compare to the average of developing countries, Chinese farmers are much more fortunate, because they can return home to work in agriculture. The so-called rights, first and foremost is the right to choose. The choice rights of farmers into the city or return reserved, is to give farmers the most basic human rights. Because the city failed farmers can choose to return home, so when migrant cannot survive in a decent city, they will choose to return home.

2.2.3 "Chinese-style peasant economy" structure is the China's rural stable reservoir in the development of Chinese modernization

Any developing countries in the development are impossible not to meet the economic, financial, social, and political aspects of the crisis that occurred in the city and its most highly developed structure. Once the urban structure of crisis, whether this country has the ability to deal with the crisis or not, has become the key to the country's modernization can be completed. Chinese urban crisis, if the centre of gravity in rural areas remained stable, the Chinese-style crisis manifested in the city, then under the stable centre of gravity of the role of the countryside, and soon stabilize. China Rural fairly stable and provide support for the city of migrant workers huge peasant economy was stable social structure where the centre of gravity of China, is one of the key for Chinese stability in any complex situation.

3 The present condition of the "Chinese-style peasant economy" in the development of rural tourism

In recent years, the development of rural tourism is increasingly prosperous. First of all, in the circumstance of the experience economy, profound changes have taken place about the idea of the consumer's consumption and the way how they consume than before : In terms of the structure of demand , while the tourism consumers focusing on product quality, we find out the increasing proportion of emotional needs among them; In terms of consumption

content, Popular tourist products are losing their advantages, consumers begin to pursue the products and services which can reveal their personalities ; In terms of the value and target , consumers have changed from paying attention to the products itself to value the feeling when accepting it; In terms of the way receiving products, consumers are willing to participate in the product design and manufacturing initiatives. Consumers are increasingly emotional, personal, perceptual, changing their core demands from the pursuit of practical to pursuing the experience. Along with the improvement of the traffic conditions and the quality of life of visitors, domestic existing hot spots become crowded, and the environmental quality of urban living people falls down. Cities and traditional sights is no longer able to provide proper and comfortable experience for visitors. While the vast country with diversity natural landscape and rich cultural connotation, acting as a major carrier to the original idyllic scenery and traditional way of life, can provide tourists with multi-level diverse experiences of visual, hearing, and further interaction. Therefore, the rural tourism development has been developing rapidly in recent years, followed with the considerable economic benefits. As too many Subject of interests are involved in the development of the rural tourism, including the government, farmers, corporations and tourists, and farmers are vulnerable groups whose interests will always be subject to a strong sense of market competition. As for the reason, it is because the "Chinese-style peasant economy" structure On behalf of farmers' management characteristic is impacted by the rural tourism development.

3.1 The characteristics of the rural tourism development

3.1.1 Multi- subject of interests participation

There are four main relative subject of interests of rural tourism development: farmers, governments, corporations and tourists. The process of the development rural tourism is actually the process of the four subject of interests pursuing their own interests maximally in the game play. Government determines the development orientation of the whole rural area, guiding rural development, strengthening the infrastructure, attracting foreign investment to build a platform to enhance regional influence by taking charge of the rural tourism planning. The development corporations of rural tourism hope to do some development activities with taking advantages of the rural land, agriculture, ecological resources to obtain maximum profits by cooperating with the government. Meanwhile tourists hope to attain their expected travel experience form the ecological environment and the rural landscape in the countryside with the cooperation projects and activities set by the government and corporations. For rural residents, the priority is to improve the quality of life, by changing the traditional mode of production through the development of rural tourism, increasing the added value of agricultural production and increasing the income of "semi-cultivated" part. Meanwhile farmers hope to improve the environment, improve infrastructure, and improve the living environment through the development of the rural tourism. Therefore, based on the demands of different subject of interests, the process of rural tourism development becomes a multi-subject's participation and game.

3.1.2 Large-scale of the development and management

Large-scale of the development and management is mainly reflected in two aspects: land resources and projects. Rural Tourism Development Project is generally based on ecological or agriculture, thus requiring a large area of land, so in order to meet the needs and benefits of large-scale operation of the project, brings out the need for rural development to integrate the existing land resources management.

Those common picking garden, organic food cultivation, leisure farms and other development projects, all need the land resources which is centralized, larger scale, and the

better ecological basis to meet the needs of project development. On the other hand, even a single project area may not need a large area of land, such as a simple farmhouse, simple handicrafts, and other specialty products for sale, but because the government vision for the positioning and development of the whole area generally requires companies and enterprises to form an industrial chain forming a sustainable driving force, therefore the scale effect among similar enterprises and the cooperation among heterogeneous enterprises and also need to be gathered on the development and operation of the project is running, to form the whole area of the scale. As used herein, select research Huaijiu road Area Rural Tourism Development Area of Fanchang County, Current situation is there already exists some picking based enterprises, but they business their own way, be independent to each other, there is no agglomeration of scale, and cannot form the entire Area core competitiveness and foreign brand.

3.1.3 Government-led, market operation

Development of rural tourism refers to the original landscape has not been carving, the beautiful natural landscape and historic folk culture and tourism with the appropriate resources and tourism products in rural areas, including the Integration and development to rural bucolic, rural architecture community, rural natural environment, traditional farming village farming, rural traditional rural folk culture tourism resources. It is the technical economic activity to meet and attract urban population come here to travel.

Therefore, as tourism development, within a certain range land, it is a comprehensive social and technical and economic activities in order to attract and reception of tourists with tourist facilities conducted training and other construction of tourism environment. Thus, the tourism development is a systematic project, mainly premised by the development of tourism, market demand-oriented, tourism resources as the core, focused on improving and enhancing the appeal tourism resources to the tourists,

Reaching around a lot to attract tourists and meet their, visit, study, entertainment, or simply relax contains a certain technical content of various needs of economic activity. Therefore, the government leading of unified planning and market demand as the leading factor is one of the important characteristics of rural tourism development.

3.2 The impact on the farmers' interests of the rural tourism development

According to the analysis of "Chinese-style peasant economy" and the characteristics of rural tourism development, it is easy to find that there are some conflicts and contradictions on the main feature. The conflicts of the characteristics will impact and even violate the different interests of farmers in different ways which includes the land rights, sustainable economic benefit and environmental benefit.

3.2.1 The landuse right

The characteristic is widespread in the peasant economy that the land management is a small scale, which conflicts with the characteristics of scale management in rural tourism development under the market economy. The conflicts and contradictions are reflected in farmers' land rights. In particular, the land is the most elementary condition for the development of rural tourism, some enterprises and developers ignore the local actual. Therefore the rural collective land is often expropriated. The resources including the land in the development of rural tourism are generally owned by villagers collectively. According to the nature and process of the rural tourism development, expropriation of land is an essential link for most of the rural tourism developments, unless it is spontaneous for farmers to run

their own range of small-scale rural tourism model. Land is the most basic factor of production and the basis of survival and development for farmers, and the land right is the farmer's most important property right. So if the farmers lose their land, they not only lose the right of management, usufruct and some disposition, but also a lot of relevant rights and interests attached to land. In the actual development of rural tourism, because the government is engaged in the profitable business activities of tourism market, it has become one of the main beneficiaries in the development of rural tourism. However, countryside and farmers have become spectators, instead of enjoying the economic benefits from rural tourism, they have to endure a series of adverse consequences. The government seized a large amount of revenue because of the wide difference between expropriation compensation and land price. As the developers, the enterprises or individuals will also grab the high profits. As a result, the landless farmers will lose much.

3.2.2 The sustainable economic benefits

Farmers in the small peasant economy have relatively free production autonomy, while the rural tourism development has the obvious market rules that it determines the direction and content by the market demand. Therefore, the independent production and the market operation have a certain conflict in the "Chinese-style peasant economy" which will affect the sustainability of the economic interests of farmers.

The limited space determines the risks when the farmers participate in the development of rural tourism. If the farmers' land is used as a rural tourism development, the agricultural production of farmers is bound to be impacted. Because the limited land cannot simultaneously meet the demands of the scale of rural tourism and agricultural production. Also, the market is always risky, the rural tourism and agricultural production have a strong seasonal and random characteristic. In the rural tourism season, farmers may obtain substantial revenue because of the successful development of rural tourism. But in the low season of tourism, farmers' incomes cannot be guaranteed, because the land has been occupied by tourism development, they have been out of agricultural production.

On the other hand, project development of rural tourism requires an accurate assessment of enterprises and need to analyse the demands of the market. Once the analysis fails, the fragile ecological space has altered substantial construction and development, its recovery will be very difficult, and it will take a very long period. Therefore, farmers will suffer greater economic losses during this process. Instead of obtaining benefits through the development of rural tourism, farmers lose their land in the construction and development. The reproduction of agricultural land is very inelastic, and the land is poor of reversible. Therefore, after the production independence of peasant economy is destroyed, the economic interests of farmers in the market operation may be only temporary, is not sustainable.

3.2.3 The environmental rights and interests

Development of rural tourism is essentially a process during the period of destroy and rebuilt. In particular, in order to obtain economic benefits from the development of rural tourism, the destructive behaviours must have done. This destroy is not a pejorative concept in the narrow sense. In the long term, destroying is the first step and prerequisite to benefit. It can seem to ignore the temporary economic losses caused by the destroying while the damage caused by destroying and the harvest are compared on the economic benefits. But from the point of view of social and ecological benefits particularly the environmental, the countryside is an area with very advantageous ecological. And some countryside also assume the functions of eco-conserving division and ecological conservation areas. Therefore, once the rural ecological environment has been destroyed by the tourism development and construction, not only the primitive rural scenery will disappear, but also the ecological value

of the countryside will reduce. It is an obvious manifestation that the farmer's living environment quality greatly diminishes. On the other hand, the rural carried rich and varied cultures and the history is long, industry modernization invasion will inevitably erase the traces of traditional culture, including traditional houses, traditional settlements and so on. And then the traditional architectural culture, neighbourhood atmosphere and long farming culture will disappear. Nowadays, the city's living environment and culture has been buried by the rapid development of urbanization and industrialization. As the last pure land of environment and cultural heritage, countryside assumes a more important and extraordinary ecological, social and historical significance.

4 The responsibility of planning-- protecting the "Chinese-style peasant economy" structure and guarantying farmers' interests

"Chinese-style peasant economy" is the production and management of Chinese farmers'. Production and life interests of farmer concentratedly reflected in the structure of "Chinese-style peasant economy". The development process of rural tourism attacks the "Chinese-style peasant economy". In fact, it attacks the structure of existing production and living of farmers. The peasant economy is not without problems, but the main features of the peasant economy still determines the necessity of the existence of it as the above analysis.

Therefore, planning as government action, should effectively slow down the impact of rural tourism development to peasant economy, to ensure the interests of farmers and to achieve maximum benefit of farmers in rural tourism development.

4.1 Large-scale of the development and management based on clarifying the landuse right

The scale operation of rural tourism development is the inevitable requirement under market economy. To protect farmers' land rights and interests as well as to follow the laws of the market competition of rural tourism development, the main way is to operate on a large scale on the basis of making clear of the land rights of farmers, the main means is a diversified land circulation form. Land circulation refers to the transfer of land use rights. Land use right transfer means farmers transfer their land management rights to other farmers or economic organization through subcontracting, transferring, investment, cooperation, lease, exchanging and some other ways. Government encourages farmers to transfer contracted land to professional investors and cooperatives, to develop the scale of operation in agriculture. Diversity land circulation promotes the appropriate scale of operation of rural land, improves the land utilization ratio and output rate; brings about the agricultural structure adjustment, improves the economic efficiency, promotes the transfer of rural labour force, increases the income of the farmers. It is conducive to agricultural technology extension and the formation and development of the agricultural industrialization management. Diversity land circulation ensure the farmers land ownership and the rights and interests in the rural tourism development.

Resulting from the comparison of various ways of land transference economic performance, and land circulation patterns which has higher degree of marketization brings greater economic performance than the lower one. However, from the comparison of the results of social performance, the result is completely different. Land circulation patterns which has relatively low degree of marketization may have a greater economic performance than the higher one. Different patterns of rural land transfer bring different transfer performance. Brought a kind of rural land transfer modes of economic performance and social performance and better than other rural land circulation patterns. Economic and social performance of one rural land circulation mode may not be better than other modes. Therefore, in the practice of

rural tourism development, the land transfer mode should select according to the characteristics of their own country, balance the economic and social benefits, select the most appropriate way of circulation, and meet the needs of the scale of operations, farmers' economic benefit and land rights.

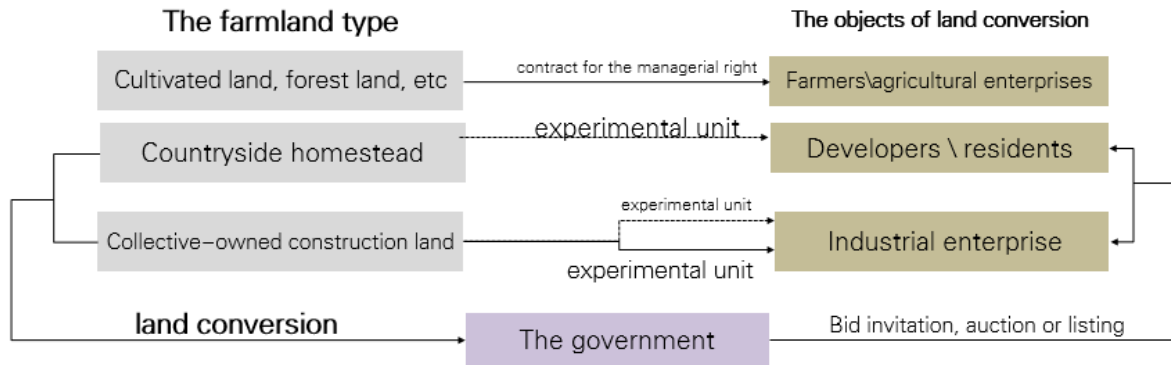

Figure 1. The sketch of land conversion route

4.2 **Build a control system dominated by respecting the original appearance to ensure environmental interests of farmers**

4.2.1 **Low-impact construction of the ecological management and control**

The ecological environment in rural areas is the focus of farmers living environmental protection. Including water, mountains, forests, lakes, farmland, biological, atmospheric resources, etc., all of them are the important elements of the rural ecological base. Firstly, urban planning has a duty on building control system about ecological management, clarifying the control limit, formulating the control regulation. Furthermore, urban planning also need to supervise behaviours of tourists and enterprises in the development of rural tourism. Especially for the enterprises, which should be controlled strictly in environmental protection standard. It is important to control the pollutant emission in countryside. The most significant issue is protecting the farmland strictly, because China's grain production is the basis of urbanization and modernization. Removable architecture can be used in construction to reduce the destruction to the farmland. It will be more flexible and sustainable. On the other hand, special planning of environmental protection is essential for rural tourism development areas. The construction of paths about infrastructure and environmental hygiene facilities should be included. In addition, the overall image in countryside should also be paid attention. For example, the environment of waterfront, lakeside, riverside, hillside, etc. . All in all, low-impact construction of the ecological management and control should be the main principle to achieve the goal which is keeping the rural original appearance and make the construction integrated with nature.

4.2.2 **The rural dwellings protection**

The significance of the rural dwellings protection lies not only in protecting farmer's human settlement, but also protecting the traditional style of rural image and residential architectural culture. It has great social significance. Including the whole village appearance, for rural residential use and transformation. For the whole village appearance as example, urban planning and design should maintain the mutually relationship between the village and natural environment in harmony. Controlling the skyline from far view of villages to emphasize the outline of mountain. Moreover, controlling the rural buildings and public buildings along the street interface, conducting regular inspections of the village environment,

and prohibiting non-standard construction practices to maintain the overall image of village. From the aspect of rural residential using, urban planning can choose the utilization patterns from the whole lease and self-management, etc., which depend on farmers how to participate in Rural Tourism. As for the transformation of rural houses, urban planners must evaluate the rural dwellings to decide to demolish, enhance or protect.

4.3 Guide benign cooperation between farmers and enterprises to ensure the sustainable economic interests of farmers

4.3.1 Cooperation and win-win mechanism

Rural tourism development involves a multi-party including government, enterprises, farmers, etc., so in the development process, development is not the only one goal. It is also significant to protect the interests of farmers in the market behaviour. Therefore, in planning practice, the appropriate business model should be chosen based on the characters of rural tourism development area to achieve the common interests of farmers, businesses and governments. Common cooperative business model including "community + company + farmers" model, "government + company + farmer tourism association + travel agency + farmer" mode, autonomous mode of operation, the overall leasing mode. "Government + corporation + travel agency + tourism association of farmer + farmer" mode, for example, Ping Ba County, An shun City, Gui Zhou Province Tian Longtunbao Cultural Village adopted this business model in sharing of benefits to avoid excessive commercialization. Government is responsible for the planning and construction of infrastructure, and optimizing the development environment. The company responsible for the management and business operation. Rural tourism association is responsible for organizing villagers to participate to opera performances, guided tours, crafts, provide accommodation and catering services, and maintenance and repair of their traditional houses. Travel agencies responsible for market development, organization source, effectively avoid the farmers in the tourism industry may cause excessive commercialization atmosphere to maximize their local cultural authenticity, so that visitors feel real and natural simple folk. The proportion of income allocated as follows: 11% government, 10% of the village committees, 14% of farmers tourism associations, travel agents, 11%, 54% of the company. Because of government intervention and management, and constantly expand the brand effect, so cooperative model has been protection policy, thus greatly ensure the stability and sustainable economic benefits for farmers.

4.3.2 Optimize the revenue structure of farmer

With the flourishing development of rural tourism, the revenue structure of the villagers presents different characteristics under the influence of the "Chinese small-scale peasant economy". It can be divided into three categories: the first category is migrant income based; the second is farming income based; the third is mainly comes from the tertiary industry developed by rural tourism. The planning should respect the existing revenue structure, as well as the living and production style under the "Chinese small-scale peasant economy". And do not break the structure of "semi-cultivated in the intergenerational division of labour based semi workers". Then further enhance and improve them according to their own characteristics. For the first category income structure, on the one hand, we should ensure the creation of the living space for the rural staying residents, especially the children's growing space. On the other hand, try to attract them to participate in the project operation by a variety of ways. Thus to increase the overall income level for them. For the second category, on the one hand, the cooperation mechanism between enterprises and farmers in agriculture can be promoted. On the other hand, the tertiary industry which has bigger degree of relation with agricultural production can be increased properly. This can really maximize the value of agricultural products, increase their income other than traditional

agricultural production, and make the rural development diversified and sustainable. For the third category, the projects of rural tourism development should be guided to form a good win-win cooperation mechanism. We should focus on the management of the market order, and effectively protect the interests of farmers in the market behaviour.

5 Conclusion

This paper researched how the "Chinese-style peasant economy" was impacted by the rapid development of rural tourism, as well as what we can do to mitigate the effects by planning. Since "Chinese-style peasant economy" stands for the Chinese farmers' production and living style, farmers' interests, including the landuse rights, the sustainable economic benefits and the environmental interests, are damaged to a variable extent. Therefore, the paper further studied the contributions of planning in guaranteeing and maximizing farmers' interests by protecting "Chinese-style peasant economy" structure in the development of rural tourism. The conclusion can be divided into three parts. Firstly, large-scale of the development and management is necessary. The point is to clarify the landuse right by diversified land conversion patterns. Secondly, urban planners should control and protect the rural space morphology effectively, including ecological environment and rural dwellings. Thus to guarantee the farmers' environmental rights and inherit the rural traditional culture. Finally, to ensure farmers' sustainable and maximized interests, benign cooperation between farmers and other stakeholders in the development of rural tourism should be guided by planners.

Reinventing a Philippine City Through Vision 2020 Plan

Haydee Jacklyn M. QUINTANA MALUBAY, University of the Philippines
School of Urban and Regional Planning, Philippines

1. Introduction: *Bahala Na!*, Serendipity and Candelaria

The western idea or construct of Planning is rather opposed to how Planning is perceived in the Philippines. This iterative process is defined by John Friedman as “primarily a way of thinking about socio economic problems, [principally] oriented toward the future, is deeply concerned with the relation of goals to collective decisions and strives for comprehensiveness in policy and program.”

To some extent, *Bahala na!* defines planning in the Philippines. Literally translated, *Bahala na!* means *come whatever may*, strictly anathema to planning. It leaves the future to fate or some fatalistic view.

Philippine mythology considers “Bathala” the highest-ranking god of ancient indigenous peoples, the creator of all things. The people’s dependence on Bathala for all aspects of their lives, from agriculture, to livelihood, to marriage, to death, to war and peace, may be responsible for the **Bahala na** (also “let whatever happen”) attitude of Filipinos. It is a philosophy construed by many as one of resignation and passiveness, but also of recklessness on one hand, and even bravery, on the other, of brazen forging ahead driven by faith that Bathala will eventually be in charge.

Irony describes the planning narrative of Candelaria, the subject of this paper. It is a premiere municipality/city in a first class province of the Philippines. In essence, it is quite serendipitous that through its updated Comprehensive Land Use Plan (CLUP) – Vision 2020 – Candelaria and its major industry – desiccated coconut processing – raison d’être for its productive city status, inadvertently realize new insights and propositions to reinvent itself. Serendipity is quite a contradiction to planning which is a conscious and deliberate undertaking. Consequently, this planning “accident” or story helps illustrate that an already “working” city can, in fact, still be “reworked.” Indeed, there is always room for improvement.

Chartered in 1878 by the Spanish colonial Queen, Candelaria, relative to most Philippine *pueblos* and *ciudades*, is considered a young local government unit. From its inception, Candelaria was then, and is now, a modest but prosperous town largely defined by its agricultural lands. Eventually, at its half century of existence, its economy is characterized by the steady pace of growth of its major industry. Though young, it has been very fast-growing. It is developing dynamically in the economic sense manifested by commercial entities rising continuously in its central business district. Geographically speaking, it is in the path of

significant growth, not only in the province of Quezon, but in Region IV-A's CALABARZON, as well.

However, its current track in terms of industry growth dates back to the World War II, and is thus considered "aged." From that historical juncture, Candelaria was like a phoenix rising from the ravages of war. It then picked up the pieces and set itself up to become the "dessicated coconut capital" not only of the Philippines, but also of the world. Coconut is called the tree of life with each and every part of the tree containing proven benefits to health. Dessicated coconut is processed coconut that finds its way into a myriad of goods ranging from food to cleaning products and everything else in between. Other coconut industry players in Candelaria manufacture coconut oil.

Candelaria is in the cusp of progress and development. All necessary ingredients in terms of all possible resources -- natural and human -- are present in this landlocked town. Hazards commonly faced by majority of Philippine localities are next to non-existent in Candelaria. Growth is, and had mostly been, incremental. But the decision to make it phenomenal is likewise within easy grasp.

Vision 2020 paves the path to get to real progress and meaningful development. It can now take advantage of the many opportunities currently and widely available. Newly passed laws and innovative arrangements on public-private partnerships provide the structural support for attaining the seemingly abstract translation of the vision embodied in the Plan. Armed with this blueprint for sustainable development, Candelaria is on the right track. However, it still struggles against the prevalent cultural tendency relative to planning and its implementation where *Bahala Na!* looms large as a communal psyche.

2. Problem

Still and all, local government units are required by law to undergo a comprehensive land use planning process. Section 20 (c) of the Local Government Code (Republic Act 7160) and the National Land Use Act (Executive Order No. 72) specifically provide for this. The Local Government Code mandates it from the law's inception in 1991, initially to cover ten (10) years and then subsequent revisions every three (3) years.

Pursuant to the Local Government Code of 1991 and other pertinent laws, it is imperative to reassess the state of Candelaria’s land resources and determine whether they should be reallocated, as many developments have since then taken place that have rendered some assumptions of and policies in the last CLUP insufficient, irrelevant, or obsolete to keep up with the dynamics of the ever-changing space and time, within and outside it. The Plan does not aim to be an all-inclusive document, but rather endeavors to be as comprehensive as time and other resources allow.

For most localities, compliance to the law is wanting. Contributory to this perhaps is the lack of punitive or incentivizing mechanisms. For instance, even sans CLUP, local government units can still access their Internal Revenue Allotments which the national government has control of.

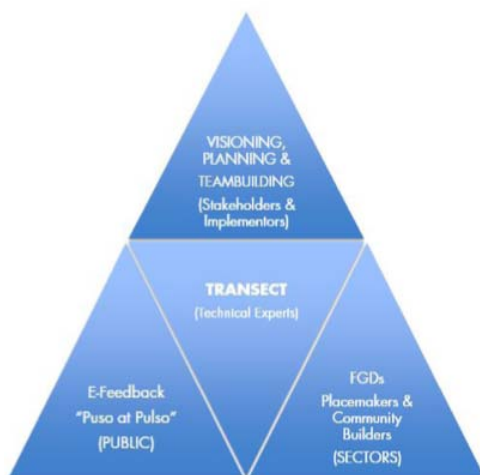

Furthermore, this could probably be due to the complexity of the planning process as prescribed by institutions managing this in the Philippines, whether deliberate or otherwise. (There are several volumes of the “enhanced” manual for the process). This imprimatur impelled Candelaria to rethink its working strategy for a new and enhanced planning policy direction.

With a three-year political term for elected officials – such term is too short for all day-to-day subsistence, operational and maintenance matters of cities and towns. And since Planning is a long and tedious process perceived not to be beneficial to all stakeholders involved and concerned, the logical issue that springs forth is “why undertake such process at all, in the first place?”

3. Background

Vision 2020, Candelaria’s updated five-year plan, endeavored to change this perception and address the challenge. Vision 2020 is Candelaria’s, land use plan. As most land use plans, it has profound effects on diversity as it presents opportunities to tailor traditional land use tools to better address reinvention or reworking requisites of cities as they diversify through multiple temporal and spatial scales and in response to calls for conservation.

With the highly participative, honest-to-goodness, planning process, the program was able to get the “buy-in” of the Local Chief Executive who previously never considered planning a priority. He eventually led the process and endeavored to sustain the gains. (Postscript – the LGU is now implementing the proposed Doables – “government center and pasalubong center”). Furthermore, it brought to fore the stakeholders’ aspirations with hope that these can meaningfully come alive.

Various approaches such as grassroots e-survey, technical transect, sectoral focused group discussions and charrette were conducted as vital components of the planning process. It combined novel, creative and unconventional approaches to maximize resources, effort and time, and to handhold the Planning Office staff and other key local government employees towards capability-building. It elucidates the planning framework, methodologies, review of current prevailing conditions, existing land use and growth trends.

“Beginning with the end in mind,” a one-on-one Visioning and Planning exercise with the local chief executive set the tone and the pace for formulating the indicative planning program.

Planning Framework by Haydee Jacklyn M. Quintana Malubay

Subsequently, the Visioning, Planning and Teambuilding exercise was held for the Executive-Legislative Agenda Team for the purpose of alignment and smooth delivery of outputs expected. This was followed by the same exercise conducted for the *Barangay* (or Village) Development Council to communicate and attain a clear understanding of total Vision and Planning processes. This is purposely intended for the eventual implementation of all programs agreed upon.

To ensure technical viability, the TRANSECT Planning tool was used to determine the feasibility and sustainability of emergent proposals of whole town divided into four locational quadrants (Northern, Southern, Western, Eastern) undertaken by technical experts. These planning specialists include: hydro specialist, geological specialist, geographer, resource management specialist, urban designers/architects and urban planners, with collaboration of Planning Office staff and other offices. The expected output for this was for proposals for general future locations and allocation of categories of land uses.

Another novel planning tool used was E-Feedback: “*Puso at Pulso ng Candelaria*” (Pulse and Heart of Candelaria) for Cross-validation on various issues, namely: (1) Institutional, (2) Social, (3) Industry, and (4) Transport and Communication. Survey tabulation and reports were published in the social media – Facebook – fan page of Candelaria, including charts and interpretation.

Focused Group Discussions engaged the various sectors, namely: (1) Institutional, (2) Social, (3) Industry, and (4) Transport and Communication. Their outputs were presented during the workshops and their reports are made part of the Plan.

Charrette, not often used in Philippine planning, iterated initial processes conducted for cross-validation amongst the different groupings of the total city-zenry. It viewed the challenges not from the vantage point of a specific sector but in its totality.

Interesting alternatives came to fore as this updated Plan embarked on a brave and courageous journey towards 2020. Equipped with participatory approaches that sought to delve into the psyche and sentiments of the cross-section of all stakeholders, and processed through technical eyes, will steer Candelaria more clearly towards what lies beyond the planning timeframe for the benefit of its future generations and rally the current generation into action.

Vision and values, essentially on conservation and conservatism, philosophically underpin the comprehensive plan that stands to benefit industry, in particular, and the whole of Candelaria, in general. Mount Banahaw, a culturally significant landscape protected by law looms large in the planning process conducted. The exercise opened eyes, minds and hearts of technical participants in collaborative modes with the local stakeholders.

Pioneering concepts of a twenty-percent developable land in industry’s identified locational quadrant point to compact development that speaks loudly of sustainability amidst the cacophony of political and economic pressure to open up “new land” for sprawled growth.

4 Quadrants Division Map with the 20% Developable Land

Mixed Uses allocation for each of the twenty-five (25) barangays within the Quadrant.

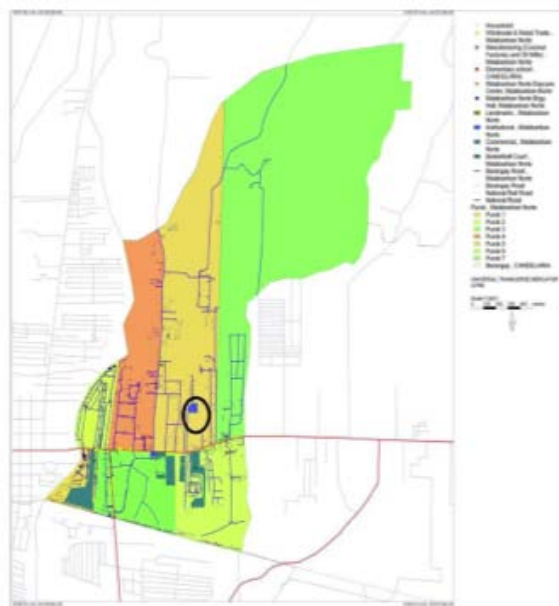

Situated in the Eastern Quadrant are industries and factories. Envisioned eventually are technoparks and cyber parks (that can straddle between Eastern and Western Quadrants), Philippine National Railways (PNR) cargo handling facilities, and employee housing in the mixed-use area of the zone.

Industry location is in the Eastern Quadrant. Barangay Malabanban Norte and Malabanban Sur are villages where the factories are found. For the figure here, the 10% Mixed Use for this Barangay is marked here by a circle where the coordinates are clearly defined.

Through charrette, participatory evaluation of spatial strategies mechanism, Multi-Nodal Urban Form was the most favored spatial strategy that brought to fore the concept of 20% developable land per quadrant and the concomitant 10% Mixed Use component.

The “20% Developable Land” concept was given birth through the value of conservation and conservative planning approach. It, likewise, identifies the 10% Mixed Use areas for every barangay in the locational quadrant. Corresponding maps were drawn to graphically point the coordinates determined through the Barangay Development Council workshop. The determination of the exact location and the computation for the 20% developable land and the 10% Mixed Use area for each quadrant and each Barangay, respectively, are indicated in the Maps and Tables as determined and agreed upon in the technical workshop participated in by all the Barangay Chairpersons.

This new striving towards growth and development branches out from a conservative and conservationist approach, springing forth from a Quezon traditional value of *arimuhan*. It entails harnessing only a small portion of land, i.e. 20% of the Quadrant therein considered “developable”, where there is locator-agglomeration, for the specified use and then reserving the substantive portion of 80% to be “opened up” or released later and much farther into the future. The updated Plan also identifies 10% of the developable 20% for

3. Findings

Candelaria undergoes contending issues familiar to all growing localities in the region and the country. Complex environmental systems are threatened by unchecked sprawl both for the population and for industry, exacerbated by the scramble for needed city revenue. Thus, it is important to put in place a system of checks and balances and oversight. All these contribute to the maturing process of this young and aspiring “model and modernizing” city with its slogan “Can Do,

and modernizing” city with its slogan “Can Do, Candelaria! Kayang-kaya (literally, “easily or very easily”).

Based on 2014 figures from the Philippine Statistics Authority, top five Philippine exports include coconut products worth \$ 1.203 billion; This rose by 19.6 percent from \$ 1.006 billion export receipts in 2013. [2]

For Candelaria, agriculture has been evidently the main source of income for most households where crops are produced for local consumption as well as export commerce.[1] The largest single production facility for desiccated coconut, with a rated capacity of 22,000 metric tons per year and operated by the Peter Paul Philippine Corporation (PPPC), is located in Barangay Pahinga Norte. The PPPC provides a constant supply of fresh premium coconuts year round, maintaining a substantial share in Candelaria’s export products. This company also maintains a coconut plantation. [3]

The level of satisfaction (or could be possibly termed “level of contentment”) had been quite high. Proof of this is that there were no definitive attempts to change what is already a working productive arrangement in terms of dessicated coconut production – this, since the post-World War II incorporation or foundation of the biggest players in the industry.

Peter Paul Philippine Corp. Foundation

On June 29, 1946, a couple of days before the Philippines gained independence from the American rule, and 48 years after freedom from Spanish domination, Peter Paul Philippine Corporation was established in Barrio Pahinga, Candelaria, Quezon Province, making the company one of the corporate forerunners of a then young nation. The plant which was built in 46 days was founded for the purpose of manufacturing desiccated coconut to supply its then parent company, Peter Paul Inc. of Naugatuck, Connecticut, USA, makers of the famous Mounds and Almond Joy chocolate bars. High quality manufacturing standards were established to ensure the reliability and consistent quality of its desiccated coconut supply to the American parent corporation.

Built in the heartland of sprawling coconut plantation in Luzon, which provide the continuous supply of fresh premium coconuts year round, the 13-hectare property is located about 100 kilometers south of the city of Manila.

Peter Paul Philippines Corporation is considered the largest private manufacturing business entity in contributing to the revenues of Candelaria with regard to its gross sales, greatly helping the municipality in their revenues. Thus, more people are engaged in the manufacture of coconut oil and desiccated products due to the increasing demand for such products. [4]

Source: National Statistics Office

process of deduction, Candelaria's latest population census in 2010 yielded a population of roughly 110,000 [6]. There are five (5) major desiccated coconut companies in Candelaria with employees ranging from 2,000 to 2,500.

Conservatively, if the five companies are multiplied to 2,000 employees, this would mean 10,000 multiplied to five (5) which is the average family size. This equals to 50,000. Directly therefore, the desiccated coconut industry in Candelaria impacts on almost half of Candelaria's population. Indirectly, through forward and backward linkages, in agriculture and in industry, conservatively 75% of Candelaria's population is influenced.

Population was not of this magnitude before. Migration from other towns of the province and regions of the country was traced. This is due to the availability of jobs. However, in the Focused Group Discussion (FGD) conducted with Industry, it was determined that spatial location and production processes did not change over the total period of time they were in existence.

Industry had largely located in the Eastern quadrant of Candelaria. Results of the FGD point out to the factors and reasons for this and that is the abundance of water supply

emanating from the watershed in Mount Banahaw.

It is actually serendipitous, that through the Vision 2020 plan, with the comprehensive land use planning process undertaken, Industry was apprised of the gradual depletion of water supply that was critical to their operations. Due to this vital lesson, industry-specific measures are now being undertaken to address these. Proposals to conduct reforestation is already at the program level. Had it not been for the required planning process as mandated by Philippine laws, this serendipitous finding would not have occurred into the strategic corporate processes of Industry in Candelaria.

Given the prioritization extended to this vital Candelaria industry, Vision 2020 Plan seeks to expand Industry but now focusing on those with low-water requirements, namely light industries like business process outsourcing, provision of technical support, and call centers operations. The only concession was extended to proposed bottling or food-processing industries as the backward and forward integration connected to this has a substantive multiplier effect to the remaining segment of the population not directly linked with industry.

Future programs in information technology, business process outsourcing and creative industries can be the next-level focus. The challenges identified above apply to Candelaria's planning environment as these do in most other local government units of the country.

Although most of the current dessicated coconut processing plants cater to the external economy, a balancing focus is now consciously incorporated into the Plan through integrated farming that shall primarily service the local market, the local economy.

One major emergent proposal adopted by Candelaria's *Sangguniang Bayan* (City Council) and the Executive Legislative Agenda was to pursue efforts, initially for cargo transport, for the maximization of the existing and surprisingly still intact Philippine National Railway tracks that traverse Candelaria as a strong support to the needs of Industry.

5. Conclusion

Realizations abound on lessons taught and learned collectively in the oblique and intermeshing roads of the planning process. When shared in a forum such as ISOCARP's, these can truly benefit most practitioners making honest efforts to achieve sustainability for this and the generations to come.

For one, Planning is never done in a vacuum. As the saying goes, “no man is an island.” With increasing globalization and urbanization, everything is now interconnected with everything else. This holds true for framing a comprehensive land use plan. Alignment with higher-level plans is, thus, an ideal that every plan should determine and work for.

Basic to the emergent proposals in this Plan’s agenda is to push for the “DOABLES,” projects that could immediately be launched and deemed to have high impact on revenue and employment generation. Thus, Industry and the Eastern Quadrant play a vital role. This important strategy encourages more interests from other industries as support becomes visible thereby allowing more investments to create more employment opportunities.

Key development opportunities and challenges to regional growth and development were identified during the extensive consultation process. Opportunity areas include: tourism and infrastructure, agribusiness, manufacturing and logistics, information technology, business process outsourcing, and creative industries.

All formal comprehensive land use planning initiatives must apply the “highest and best use” principle. Thus, there is transect and inventory mapping, there is survey before analysis and planning.

The principle of determining the highest and best use of the land requires assessing current uses vis-a-vis potential uses to which land can be subjected. The present use may be the highest and best. The geological viewpoint plays a pivotal role in applying this principle. Moreover, by the very geographical location of the Philippines relative to the “Pacific ring of fire,” disasters and hazards figure prominently in decisions to locate certain uses.

For Candelaria and this Plan’s process, the highest and best use of its land were of fundamental consideration. These were tackled in the key informant interviews, surveys, e-feedback, FGDs, transect, and charrette in coming up with emergent proposals and the adoption of the Plan including the prioritization for the “DOABLES.”

Water resources are also given appropriate attention in this Plan. Their assessment, determination of sufficiency of supply (quantity) and water quality are recommended. Revitalization of dried up water sources were also studied for emergent proposals that include “adoption of waterways” as industry’s manifestation of Corporate Social Responsibility.

In sum, the processes undertaken defined a shared future of the town that will proceed beyond 2020. With the right blending of policies and the appropriate collaboration between planners, policymakers, citizens, stakeholders, industry, public-private partnerships and experts can lead to the establishment of communities better prepared to face the future.

The Plan endeavored hard to stitch together all the components into a coherent ensemble to define the current nature of the Candelaria fabric. All identified factors, issues, concerns, alternatives were equally listened to and considered. The appropriateness of scales in the emergent proposals was treated in all seriousness as the value of conservatism and conservation specifically in pushing for the judicious use of the land and other resources of Candelaria acted as the guiding force.

In undergoing the reiterative processes to formulate the CLUP, all participants, from the e-team (external, i.e. the various technical specialists) and the i-team (internal, i.e. the Mayor, the Executive Legislative Agenda, all participants/stakeholders learned in the two-way processes all throughout. Most important was the cross-validation that took place in every aspect of the Plan formulation.

Despite the myriad and simultaneous developments identified for the Region where Candelaria belongs, this Plan advises to take these at a moderate pace, and not to rush head on, aggressively. In the story of the “turtle and the hare” the one that acts with prudence, and with a PLAN, wins in the end.

Vision 2020 Candelaria CLUP is a very forgiving plan. It endeavors to overlook the misplacement of locators and to make natural shifts and transition towards the ideal state envisioned for the year 2020 and beyond. It recognizes that the town is evolving.

The quadrants, even visually speaking, manifests a strong balancing of the various land use policy purposes, i.e. setting aside for protection, production, settlement and infrastructure zones.

All the processes were undertaken in order to create an urban place that makes sense to the people who will live, learn, work and play in Candelaria.

This “sense of place” is the embodiment of the musings that most people in the e-feedback survey and in the key informant interviews mentioned when they describe a neighborhood or town in which they would like to live.

There is that aspiration for Candelaria to continue to have a desirable, high quality of life; this process was undertaken to make sure that it turns out that way. Without this initiative, this abstract concept of “sense of place” would probably be diminished.

The future is here now, very quickly closing in Candelaria and its people. There is thus the need to work harder on the short-term decisions guided by Vision 2020 to achieve the state envisioned for the long haul - a future that conserves land for balanced development of all of Providence’s creation in the total Candelaria ecosystem.

A feasibility study for a Technological Park undertaken in 2011 by the Municipality of Falconara Marittima, province of Ancona-Italy

Giovanni SERGI, architect and contract professor in Town Planning at the Department
Architectural Sciences Genoa University, Italy
Paolo ROSASCO, lecturer in Real Estate Evaluation at the Department Architectural
Sciences Genoa University, Italy

1. Introduction

In the past few years, the Marche Regional Authority has been involved in the issue concerning the recovery of abandoned productive sites.

The regional legislation on town planning has developed a series of tools and regulations to promote the renewal and redevelopment of these abandoned sites as part of a strategy for the competitiveness and the local territory.

These sites often have abandoned industrial areas, in other case there are abandoned barracks or railway parks which are rarely used.

These areas are owned by entities which have different needs with respect to a possible re-adaptation and promotion of the property.

The Municipality of Falconara Marittima, based on the most updated legislation of the Marche Regional Authority and on the directives of the Master Plan Piano Regolatore Generale PRG dated 2003, decided to carry out a feasibility study in 2011 focusing on an area of 160 hectares that comprises the small hamlet of Villanova.

Figure 1: Location of the project of a Technological Park near the regional airport Raffaello Sanzio, Municipality of Falconara

This area borders the railway line to Rome eastward, it borders the regional airport Raffaello Sanzio southward, the small hamlet of Fiumesino westward and the API oil refinery as well as the railway station of Italian Railway Network RFI located along the coastline.

2. The area which is subject of study

This area is located at the point where the Adriatic infrastructural strip joins the infrastructural strip which goes from the coast through the Esino valley and the Apennines to reach the Tevere valley and connect to Rome. These two infrastructural strips comprise a national road, a highway and a railway line.

The area shows many different functions which include residential areas in Villanova and Fiumesino, production activities and services together with several infrastructures. In this area there are also two railway parks owned by Italian Railway Network RFI, which have been rarely used in the past few years. It is worth mentioning the presence of a purification plant for waste water of Vallechiara, not far from the former Saracini Barracks.

The central position and strategic importance of the area have contributed to the construction, since the 19th century, of infrastructures and military buildings and production plants. As a consequence, the urban landscape is now very complex.

Among these buildings we mention the airport built in the 1920s and the Saracini Barracks abandoned about fifteen years ago. After the Second World War, the construction of an important private refinery, owned by Anonima Petroli Italiana API, was started together with related maritime infrastructures including a wharf for tankers and then the docking on an offshore platform, which have been connected to risks related to the storage and processing of oil products. The airport, whose landing and take-off strip is above Villanova and the refinery, as well as the current crossing of the refinery by the railway line area are risk factors.

It is clear that this area today cannot fully play its very important role based on its geographic location and infrastructures as well as territorial resources. This is due to several evident factors: the excessive presence of different functions, the age and inadequacy of many infrastructures and public spaces, the critical relations between polluting production activities with a high risk of environmental accidents and other functions.

There are serious problems concerning the presence of some polluted areas that require expensive reclamation works.

Figure 2: Photograph of the area involved in the project of a Technological Park in Falconara Marittima

Figure 3: The former Saracini Barracks
(photo 1)

Figure 4: The hamlet of Villanova and the railway
(photo 2)

3. Policies and objectives set by the Municipal Administration

The approach of the feasibility study made reference to the elements contained in the Resolution of the City Council of Falconara no. 7 dated 3 March 2010 “Politiche, obiettivi generali, specifici e azioni da conseguire mediante Variante Generale al PRG” Policies, general and specific objectives and actions to be implemented through General Modification to the Master Plan PRG.

This document shows that the three “Aree a Progetto Unitario” Single Project Areas named APU1, APU2 and APU3 and identified by the Master Plan PRG in 2003 within the municipal territory could still be considered in 2011 as areas “...having potential to become very important centres of redevelopment and development, which can support the role of the city as a hub...”

The area which is subject of Study includes the area APU2. The Municipal Administration decided to delete the API refinery from this area.

Moreover, the three different Single Project Areas defined by the Master Plan PRG “...represent an important opportunity within the vast area to enhance competitiveness, improve the system framework and promote suitable territorial marketing ...”

It is clear that the Municipal Administration considers these three APU as territorial resources that can play an important role, by taking suitable actions to change them, not only for the Municipality of Falconara but also for a wider area defined as the Lower Esino Valley.

Meaningful infrastructural works that have recently completed or that will be completed in the short term in the Low Esino Valley and near the Municipality of Falconara are elements of a logistic platform at national level that may allow these areas to play a more important role in Central Italy. This evaluation is based on the development prospects outlined by the Ministry of Infrastructures and Transport MIT-DICOTER Dipartimento Programmazione Coordinamento Sviluppo Territorio in 2007.

4. Identified planning solution

The objective of this feasibility study is not related to the category of an urban architecture project mainly focused on the morphological characteristics of the built spaces. The objective is to implement a preliminary project for a complex area, which requires an in-depth analysis of the situation in order to outline a project that can effectively be implemented to re-adapt and promote the existing area.

The analysis of the whole area of focus has outlined a project of urban redevelopment in areas which do not carry out their functions anymore or underused areas. Moreover, they do not show an excessive sub-division of properties.

The four identified areas can promote a redevelopment plan which:

- is able to meet some fundamental objectives for the development of the urban system in Falconara;
- can promote opportunities existing within the Municipality of Falconara. This can be achieved by enhancing infrastructures and increasing external business due to a project of a new railway bypass which will increase the speed of connections between the Esino valley and northern Italy. There will also be a connection with new railway freight station at the new interport in Jesi.

These four areas which cover a total surface of 32.4 hectares are:

- area of the former Saracini Barracks, which does not show any problems in terms of reclamation. It is currently managed by the Public Property Agency and has an extension of 8.7 hectares. Between the former barracks and the residential buildings in Fiumesino hamlet there are small facilities that host bars in front of the Flaminia national road and an abandoned hotel called Hotel Internazionale.
- Seaside railway yard Scalo a mare, which together with the workshops Ex Officine Squadra Rialzo has a surface of 4.6 hectares. The railway area borders the coastline and belongs to the state maritime property but has been abandoned for some years. It has pollution problems which required specific reclamation measures.

Figure 5: The coastline in front of Villanova hamlet, Municipality of Falconara (photo 3)

- area Ex Antonelli located between the old track of the Flaminia national road, Monti e Tognetti street and the hamlet of Villanova. It has a surface of 1.1 hectares and belongs to the Municipality. It has pollution-related problems.
- area between the viaduct of the variant to the Flaminia national road and the route of the old national road. The area covers a surface of 11.8 hectares and has a second railway yard of Italian Railway Network RFI called Scalo Squadra Ponti, which might be no more used when the new railway yard built close to the autoport in Jesi starts to be operative. Near the existing railway yard of Italian Railway Network RFI called Scalo Squadra Ponti one of the two lines of the new railway bypass will pass through. Moreover there are large areas owned by private people that need specific reclamation because of pollution.

The outlined redevelopment project includes the railway bypass and is divided into three fundamental elements: the Technological Park, the Seaside Hamlet and the area called Ex Antonelli which is a municipal property and will be used to offer public services.

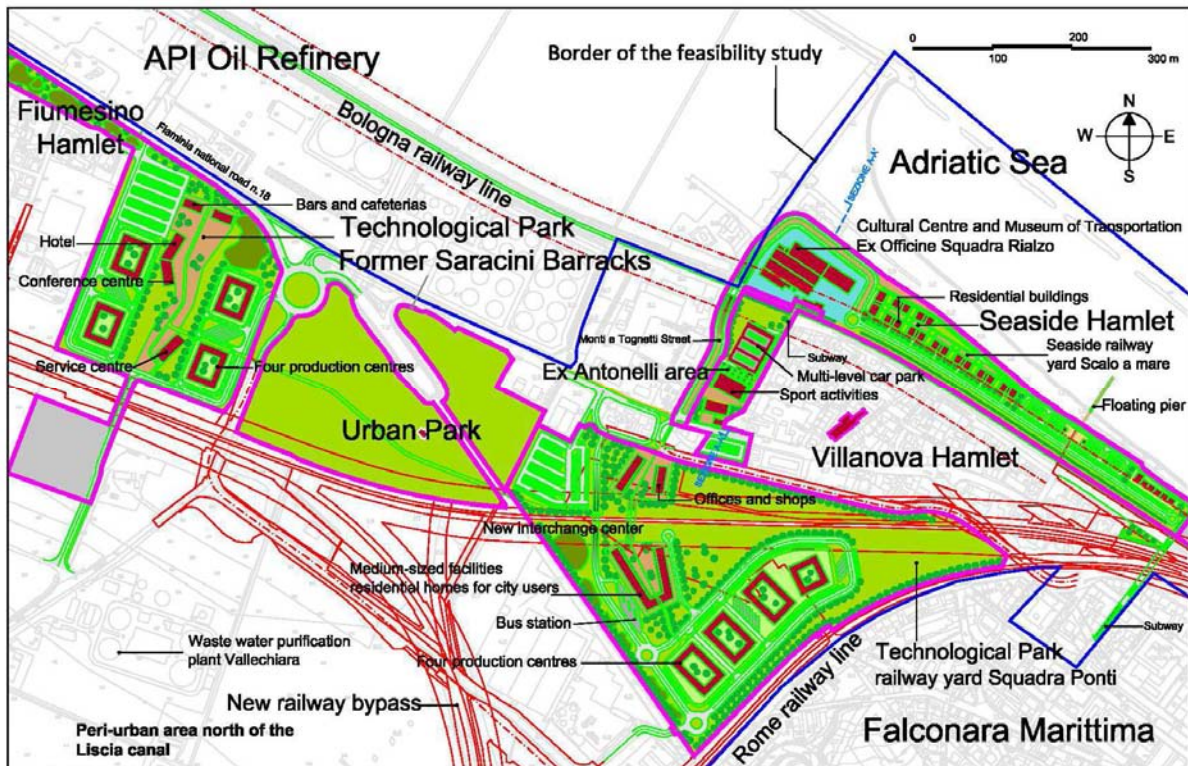

Figure 6: The Project of a Technological Park and highlighted in red the project of railway bypass

These interventions have been divided into two implementation steps:

- first step: implementation of interventions in the area of the former Saracini Barracks, in the City Park and in the area Ex Antonelli as well as in the Scalo a mare belonging to Italian Railway Network RFI;
- second step : implementation of interventions for the area which includes the railway yard owned by the Italian Railway Network RFI Squadra Ponti.

Section A-A'

Figure 7: The Project of a Technological Park. A-A' transversal section: Railway Bypass and Cultural Centre

4.1 The Technological Park

After a careful evaluation, the analysed area has been deemed suitable to host a Technological Park.

Technological Park means an area for small highly-technological businesses, facilities for technological transfer, incubators for new small-sized enterprises.

The reference model is Aree Produttive Ecologicamente Attrezzate APEA Environmentally sustainable and equipped productive areas defined by the Bassanini Law Leg. Dec. no. 11/1998, by the Marche Regional Law no. 20/2003 "Testo unico delle norme in materia industriale, artigianale e di servizio alla produzione" Unified Law concerning plants, handicraft businesses and production services and by the Marche Regional Law no. 16/2005

“Disciplina degli interventi di riqualificazione urbana e indirizzi per le aree produttive ecologicamente attrezzate” Regulations for urban redevelopment and guidelines for environmentally sustainable and equipped productive areas.

To the east of the former Saracini Barracks a large area covering a surface of 6.2 hectares will be reused to host a new Urban Park between the first-step Technological Park that will be built in the former Saracini Barracks and the second-step technological park that will be located in the area of the railway yard Squadra Ponti.

The gross usable built surface in the area of the former Saracini Barracks is 19,140 square meters. The project including the former Saracini Barracks provides for the construction of new buildings and the renovation of existing ones. There will be small facilities hosting bars and company cafeterias, a services centre, four production centres, a hotel and a facility hosting a conference centre and offices.

In the Technological Park Squadra Ponti a new interchange center will be built with a square near the bus station and a park-and-ride with 262 parking spaces. The square will include some medium-sized facilities with three level above ground for distribution businesses, private and public services businesses and, on the third floor, residential homes for city user. In this square will be built a little structure for parking, service and rent of bicycles.

In the Technological Park Squadra Ponti the gross usable surface achieved, according to the project, will be 22,230 square meters.

4.2 The Seaside Hamlet

With reference to a debate among the community of Falconara, the Municipal Administration has considered it useful to design a new area facing the sea near the hamlet of Villanova through a new street network for vehicles, bikes and pedestrians that will be implemented by means of three subways to access the area facing the sea under the Flaminia national road and the railway line. One of the proposals includes the improvement of Monti e Tognetti street, the construction of a subway for pedestrians that connects the multi-level car park in the area Ex Antonelli with the Cultural Centre in the area Ex Officine Squadra Rialzo as well as the construction of a new subway for bikes and pedestrians from Stamura street to the Seaside Hamlet.

The construction of a Seaside Hamlet is provided for in the area Scalo a mare which is owned by Italian Railway Network RFI.

In the seat of the Ex Officine Squadra Rialzo a new important Cultural Centre will be built including a Museum of Transportation, based on the Pre-feasibility Study already approved by the Municipal Administration some years ago.

The Seaside Hamlet will be as follows: a new residential settlement, tourist settlement and commercial area with spaces for free time: a waterfront promenade, equipped green areas, a shelter with two floating piers to host 100 small boats. On the ground, there will be fixed equipment to support fishing activities and activities connected to small pleasure boats. About one hundred underground garage stalls will be built near the residential buildings.

The gross usable surface covers 14,132 square meters including the area Ex Officine Squadra Rialzo.

4.3 The area Ex Antonelli

In this area owned by the Municipality the proposal includes the building of some service facilities that can be play a central role between Villanova, the new Seaside Hamlet and the new Technological Park.

This area, with a surface of 1.1 hectares, will be used for services, hosting three buildings for free time and sport activities, a multi-level car park with 198 parking spaces, besides a community centre to be built in the decommissioned school in Villanova. The total surface services, private car park and community centre will be 10,480 square meters.

4.4 Peri-urban area north of the Liscia canal

The study outlined for the redevelopment project of the whole area has suggested some ideas for environmental regeneration and new use of the territory in the peri-urban area between the track of the railway Bypass and the Liscia canal, bordering the regional airport Raffaello Sanzio.

This area covers a surface of 52 hectares and is characterised by extensive farming of annual crops. The existence of some strict limitations has lowered the attractiveness of building opportunities provided for by the Master Plan PRG. This area nowadays plays a marginal role and the level of maintenance of farming lands is unsatisfactory. As a result social marginality has become widespread in this area.

The first limitation is represented by landing and take-off strip of planes, which restricts the suitability for buildings. These limitations are stricter near the front of the landing track and become less strict far-away from it. Noise pollution here is very high.

The second meaningful limitation is represented by the presence of the consortium waste water purification plant Vallechiara built in the 80s by the Municipalities of Falconara, Chiaravalle, Montemarciano and Ancona.

For this area a consistent redevelopment plan will be implemented according to the Master Plan PRG in force and farming activities. This project may be implemented by the Municipal Administration by using limited funds based on three lines of action.

Area	Intended use established in the Project	Gross usable surface (square meters)	Volume (cubic metres)
Saracini Barracks	Bar –company cafeterias	680	4,352
	Production centres	11,200	56,000
	Hotel	2,280	6,840
	Conference centre -offices	1,200	3,600
	Services centre	980	2,940
	Private firm	2,800	14,000
	<i>Total</i>	<i>19,140</i>	<i>87,732</i>
Railway yard Squadra Ponti	Offices-shops	2,640	9,240
	Offices-shops-residential	7,590	25,300
	Production centres	9,600	48,000
	<i>Total</i>	<i>22,230</i>	<i>94,540</i>
Antonelli	Multi-level car park	7,740	23,220
	Multi-purpose centre	880	8,800
	Gym	900	2,700
	Bar –cafeterias	140	420
	Community centre	820	2,460
	<i>Total</i>	<i>10,480</i>	<i>37,600</i>
Workshops Squadra Rialzo and seaside Railway yard	Cultural centre	4,380	38,106
	Shopping area – residential	8,136	27,120
	Leisure fishing	504	1,512
	Workshops and shops	72	216
	Fishermen Club	240	840
	Restaurants and shops	800	2,800
	<i>Total</i>	<i>14,132</i>	<i>70,594</i>
OVERALL TOTAL		65,982	290,466

Table 1: Intended use and main values of the four areas of intervention

The first line of action concerns ordinary and extraordinary maintenance of public areas such as roads, ditches. These works would increase the opportunity to exploit environmental and landscape values in this area.

The second line of action is based on a systematic intervention by the Municipal Administration to urge private owners to maintain farming lands and farmhouses.

The third line of action includes the implementation of a coordinated network of pedestrian and cycle paths as well as paths for jogging and other sport and free time activities that can coexist with farming activities.

It is thought that a suitable project to promote this area can be consistent with a Technological Park that gives importance to a quality landscape and environment.

5. Town planning procedures

For the studied area the legal and technical framework is typical of complex interventions. This is due to a wide variety of conditions including restrictions, critical aspects and potential of proposed changes in the redevelopment project as well as the heterogeneous range of owners and their expectations, attitudes and capacity to invest.

It is important to identify the most suitable town planning tool in order to implement the initiatives outlined in the feasibility study.

It is hard to work in compliance with the provisions of the General Town Planning 2003, so it is desirable to obtain a partial zoning Variance for the area of the Technological Park. This Variance could be implemented by a Plan Agreement between the Municipality and the Province of Ancona according to the law no. 241/1990.

This procedure can be divided into the following steps.

First of all an Inter-institutional Plan Agreement, which is a typical consultation among institutions, started by the Municipality of Falconara as promoter and open to participation by territorially competent bodies in the field of urban planning, public works, planning, like the Provincial and Regional Authority, as well as local state bodies, i.e. Superintendence and State property. The suppliers of public and private services, like Highways National Agency Anas, Italian Railway Network RFI, Electric Power National Agency Enel and so on could be invited to take part.

The aim of this Plan Agreement is to approve the main aspects related to dimensions and functions of the general reorganisation outline, in its major aspects related to functions and dimensions, indicating performances, expectations, infrastructural invariants, in complexes that will host tertiary activities enjoyed by users resident in the vast area, as well as perimeters of the project areas in compliance with the 2003 Master Plan PRG according to the assessment by the Municipality following the feasibility study.

For each project area Plan Agreements will be added. There can be one or more agreements, based on the opportunities and feasibility depending on the features of the parties involved.

In terms of legal effectiveness, the Plan Agreement approves the urban planning and legal framework of the area, in compliance with the Master Plan PRG or Zoning variance for the feasibility of interventions. In view of the final implementation of interventions, the Plan Agreement identifies individual Sectors where the parties will outline final project solutions.

Following the Agreements, Conferences of Services will be called for by the Municipality. They will deal with the approval of final projects, benefiting from technical flexibility and flexible regulations contained in the Agreements.

6. Implementing parties of the project

In relation to the dimensional scale and the complex interventions, a Company for Urban Transformation Società per la Trasformazione Urbana STU or another joint enterprise with a different legal form could be identified as Implementing Party, where the Municipality of

Falconara can play a leading role in the development and management after private operators have joined the company.

The regulations related to STU sets forth that Metropolitan Cities and Municipalities, with the participation by Provincial and Regional Authorities, can establish joint stock companies to plan and implement measures for urban transformation by applying current town planning regulations.

The companies for urban transformation deal with the prior acquisition of real estates involved in the intervention, the transformation and marketing of the real estates. Acquisitions can be mutually agreed or the Municipality may apply the expropriation procedure. The relations among public bodies as shareholders and the joint stock company for urban transformation are governed by an agreement.

For the management of the Technological Park a suitable company organisation can be identified including private industrialists interested in the promotion and management of the Park, having specific professional skills. The management company may contemplate the participation by the Municipality of Falconara.

7. Financial feasibility

This project has been subject to a feasibility study from an economic and financial point of view based on the four areas analysed by the feasibility study which outlines four potential steps for the implementation of measures in the area. The identified areas are: 1) the area of the Former Saracini Barracks including the westward green area close to the Hotel Internazionale and the area that will be turned into an urban park 2) the area called Squadra Ponti 3) the area Ex Antonelli 4) the area of the seaside railway yard property of the Italian Railway Network RFI.

Since these works and facilities have different intended uses, both public and private, the promoter of this initiative could be a public-private entity, for example a Company for Urban Transformation STU having profitability expectations that are comparable to those of a promoter-real estate investor.

The cost-benefit analysis Analisi Costi Ricavi ACR is based on the implementation that is to say on the determination of the current value of cash flows (cost-benefit) produced by the intervention over time. The cash flows are represented by differences, in each basic period of time, between the revenues obtained from the sale and/or renting of properties and the costs of their construction.

The objective is to find out the economic value of the intervention assessed at the beginning of the investment and defined as Current Net Value Valore Attuale Netto VAN. The feasibility check is achieved when VAN is positive, that is to say when the earnings shown at present value are higher than costs shown at present value.

The second benchmark which takes the invested capital into account, is the Internal Profitability Rate Tasso Interno di Redditività TIR. TIR is the interest rate or discount rate, determined by the profitability of invested capital. In order to calculate its value in percentage, TIR is the rate which cancels VAN, that is to say the rate which equalizes positive and negative financial flows related to the intervention.

For each of the four areas, the cost and benefit analysis was developed based on some development outlooks for the interventions which take into account the different project features and current situation of each area.

To sum up, in the Scenario 0 that will be defined Basic Scenario the following cost items have been taken into account:

- Building of external infrastructures for each area;
- Acquisition of private property areas involved in the implementation of the works according to the project;
- Reclamation of superficial and underground pollution;
- Land conversion costs

Starting from Scenario 0 the values used by indicators of economic and financial feasibility VAN and TIR have been checked. In cases where these indicators do not show economic and financial sustainability of the interventions, other development scenarios have been outlined: Scenario 1, Scenario 2 and so on based on different allocations of costs for some works. This aims at identifying, for each area, the scenario that may ensure a basic economic and financial sustainability for the promoter party.

8. The example of the Scientific Technological Park Kilometro Rosso in Bergamo

A similar experience to the APEA model and the one which is object of the feasibility study is the Scientific Technological Park called Kilometro Rosso created in 2003 in Stezzano, close to Bergamo, based on an idea by Alberto Bombassei, chairman and managing director of Brembo, a leading company in the production of brakes for cars. Other partners among which the Chamber of Commerce and the University of Bergamo were involved. The French architect Jean Nouvel designed the whole complex.

The Scientific Technological Park is hosting buildings on a gross usable surface of 172,000 square meters and is conceived as a park with a total surface of 36.5 hectares located along the highway A4, section Milan-Bergamo.

A red metal curtain with a length of one thousand meters defines the area and is a protection from noise coming from the highway. This metal curtain separates the highway from a large green area where several buildings are located.

In the Park we can find a great number of activities such as research centres, laboratories, institutions, small and big sized companies. Moreover there are also companies in the sector of advanced training, ICT, new materials, biotechnology, mechanics, electronics, automation and so on.

In the Park it is worth mentioning the University of Bergamo which is an official partner of Kilometro Rosso. The objective pursued by the University of to build a Inter-departmental and inter-disciplinary center an ideal meeting place between university and business.

Should I stay or should I go: The role of Colombian free urban housing projects in IDP return to the countryside

Marcin SLIWA

Norwegian University of Science and Technology, Trondheim, Norway

Henrik WIIG

Norwegian Institute for Urban and Regional Research, Oslo, Norway

Synopsis

The new apartments and houses given by the Colombian government for free to the displaced households 'cement' their choice to stay in the cities where they live hence reduces the success of the Land Restitution program, which fosters return of the victim population to rural areas.

Abstract

Over 6 million people were displaced in the ongoing Colombian armed conflict, the majority of them from rural to urban areas. In 2012, the Colombian government launched a large scale social housing program to alleviate the housing deficit caused by conflict and furthermore compensate the IDPs for their losses. The idea of this initiative is in line with the wishes of the majority of the victim families, who prefer to stay in the receptor cities where they settled due to the conflict. The new apartments and houses are given literally for free and are highly demanded. This, however, potentially contributes to the lack of success of another large scale reparation program, Land Restitution, which fosters the return of the displaced households to the countryside.

Basing on empirical data from the field, this paper explains why and how the Free Housing program 'cements' the choice of the displaced families to continue living in cities and further develop their post-conflict urban livelihoods and social networks, as opposed to returning to the depopulated rural areas and reestablishing agricultural activities. However, it is also argued that those housing projects have certain shortcomings and are not the ideal solutions to the problems of housing shortage and the prevailing poverty among the displaced population.

Keywords

Housing, Land Restitution, Reparation, Social Policy, Urbanization, Colombia

Note

This paper was first presented at the 51st ISOCARP Congress in October, 2015 and is based on a Master's Thesis titled: *The boys have lost their love for land: Reparation programs for Colombia's displaced population* by Marcin Sliwa, delivered at the Norwegian University of Science and Technology in May 2015 as part of the M.Sc. in Urban Ecological Planning programme.

Introduction

The ongoing armed conflict in Colombia¹ has resulted in the forced displacement of up to 6 million people (IDMC, 2015a). As much as 93% of them fled the countryside to urban areas (Albuja and Caballos, 2010), contributing to the rising poverty rate and the uncontrolled growth of informal and squatter settlements in Colombian cities. Although a lasting peace agreement has still not been reached, forced displacements are considerably reduced compared to the peak of the conflict between 1999 and 2002 (Unidad de Víctimas, 2013). There are now several reparation and return programs for the Internally Displaced Persons (IDPs). Colombia is perhaps the only country in the world where such measures are being implemented before an official end of the conflict.

This study examines the relationship between the two largest and most important programs currently being implemented for the IDPs in Colombia. The first one is Free Housing, which provides new homes for the displaced in the cities where they settled after the displacement. The second, Land Restitution, enables the IDPs to get back the rights to properties that were lost or abandoned in the conflict, and facilitates their return to rural areas. It is clear that both reparation initiatives represent very different ways of thinking about the migration processes. The first one accepts that once people move from a rural to urban area, whether forcibly or voluntarily, they are likely to adapt and stay permanently. The second is perhaps a more “romantic” idea of returning to the depopulated countryside and engaging into a rural livelihood as before the conflict. Although providing such distinct alternatives for the same target group of IDP households should be considered a great achievement of the Colombian government, the two programs which are part of the same political agenda of Colombia’s President Juan Miguel Santos might actually undermine the success of each other.

Central to the case of those two reparation initiatives is the question, whether the offer of free urban houses affects the willingness of the IDP population to return to the rural area. Indeed, our study found that, to some extent, the Free Housing program further decreases the already small likelihood of the IDP households to return to the countryside. It is argued that by offering free housing and giving incentives to stay in urban areas, the Colombian government both reduces the IDPs willingness to claim land restitution and return to their places of origin in rural areas.

If that holds true, then why does the government continue investing in both programs and keeps offering them to the IDPs? The answer to this question is more complex. First of all, the coordination between the two programs has always been almost non-existent, as both are implemented by the different state entities and are financed from different sources.² Additionally, both initiatives can be characterized as being populist, as they propose radical interventions based on intentions and principles, which seem hard to disagree with, but not necessary possible to implement in practice (Cuervo, 2012, El Colombiano, 2014, El Espectador, 2012, Gilbert, 2013). The low numbers of finalized land restitution cases indicate that the restitution program they only serve as a political “smokescreen” for preserving the status quo in the countryside.

This paper is based on a fieldwork conducted in the Caribbean Coast of Colombia in the summer of 2014 as part the investigation for a Master’s Thesis (Sliwa, 2015).³ The empirical data was collected using qualitative and quantitative methods, including ethnographic interviews with affected IDP households, semi-structured interviews with informants and stakeholders as well as direct observations. We furthermore apply Respondent Driven Sample (RDS) survey data conducted by our collaborators in Colombia and secondary data from relevant literature and media.

First in this paper is a brief introduction to housing production and the IDP debate in Latin America, followed by a review of similar return and housing policies for IDPs in a few selected countries. The next part explains the context and relation between the main reparation initiatives in Colombia. Then, basing on empirical evidence it is shown that the urban IDPs do not want to return and that the Free Housing program is “in line” with their decision to stay in cities. The last section discusses the results of the study, implications and policy recommendations for urban planning and post-conflict reparation policy in the country.

Housing and IDP debates in Latin America

The high population growth in Latin America led to a high influx of migrants to the cities from about 1940. An estimated 70 percent of all new houses in cities were developed informally through land invasions and self-help construction in squatter and irregular settlements (Ward et al., 2015). Such process is normally the reverse of the conventional housing development, which starts with planning, followed by provision of services and infrastructure, construction of a proper house and ends with occupancy. In informal settlements, the occupants move in first, then build a permanent house, and expand it as needed. Once they are established, they may start lobbying the local government to provide infrastructure and services (Baross, 1990, Hamdi, 2010).

Many of the inhabitants of those settlements are economic migrants from the countryside and IDPs fleeing conflict zones. It is difficult to assess whether a hypothetical situation of no conflict would have had a significant impact on the rural-urban migration process in Colombia, but the comparison with other Latin American countries suggests that rapid urbanization was happening in all states in the region, regardless of their political and economic situation (UNDESA, 2014). In some cases it may be problematic to make a clear distinction between the displaced populations and those who voluntarily migrated into the cities, for example to seek employment or education opportunities. Typically, one of the main differences is that the IDPs usually bring no savings which would enable them to start a new livelihood in the city, while the economic migrants come prepared, with a certain amount of cash that facilitates their survival, at least in the first few weeks or months of their stay. As a result, the IDPs are much more likely to enter into extreme poverty than those who migrated voluntarily.

In terms of formal housing, private-sector developers usually target upper and middle-class households. Government-provided social and affordable housing schemes, targeting low-income and vulnerable population in Latin America, were developed in two ways. The first was a centralized approach where the public sector designs, constructs and delivers housing with or without private companies as sub-contractors. This model was most common between 1940s and 70s, where many new public housing projects were built as part of urban renewal and slum clearance policies.⁴ Many of those projects were later blamed for failing to improve the economic situation of the residents and contributing to socio-spatial segregation in the urban areas (Dwyer, 1975, Gilbert, 2001, Hamdi, 1995, Turner, 1976, UN-HABITAT, 2001, World Bank, 1993).

The second was a more decentralized, corporate-friendly model, where the government subsidizes the poor to buy units in privately designed and constructed housing projects. This approach was first tried in Chile in 1977 and was later supported and promoted by such organizations as the Inter American Development Bank and the World Bank (Gilbert, 2004). At the same time, many governments initiated various initiatives and policies to regularize, formalize and upgrade informal settlements, according to the ideas put forth by Turner (1976) and later De Soto (2000). The general principle of all those housing policies applied in Latin America in the last few decades was to promote home ownership, while issues of rental housing were usually ignored (Gilbert, 2013).

The Free Housing initiative adopted in Colombia was also based on the principles and experiences from Chile, although with some differences. In the Colombian program, the units are handed over to the recipients for free, a novelty in Latin America where other countries require some form of contribution from the beneficiaries. Furthermore, the program mostly targets households that were displaced as a result of the armed conflict and, in some cases, due to natural disasters. The generous conditions probably reflect the need to compensate the IDPs for their former losses.

In general, there are three main policy strategies that the governments apply to compensate and help the IDPs: 1) facilitating return to the areas of origin, 2) providing new housing, which may either be temporary (shelters) or permanent (social housing) or 3) improving existing housing (i.e. upgrading self-built dwellings and providing basic services). As it will be explained later, countries which have large numbers of IDPs usually implement more than one of those strategies. However, the academic literature does not compare the different IDP programs within the same country. As explained by Carrillo (2009) and Crisp et al. (2012), literature on displacement is generally focused on the

transitional stage after being displaced and aspects such as humanitarian aid, refugee camps and initial migration into the city. There is, therefore, a need to investigate the more permanent housing and restitution solutions designated for the IDP population, and study how they impact the relations of the displaced families to the places of origin and the eventual decision where to live. According to Crisp et al. (2012), *“urban planners, demographers, and development specialists have not addressed significantly the relationship between displacement and urbanization.”*

Much of academic research on housing and the built environment in Latin America and the Global South is focused on the emergence and consolidation of self-help informal and squatter urban settlements (Bredenoord and van Lindert, 2010, Davis, 2006, Fernandes, 2011, Hamdi, 1995, Hernández et al., 2012, Robbins, 2008, Turner, 1976, Ward et al., 2015). Literature on the general situation of centrally planned housing in Colombia is focused on emphasizing the qualitative and quantitative shortage of affordable and social housing in urban areas (Ballén Zamora, 2009, Escallon G, 2011, Fariás Monroy, 2014, Insuasty Delgado, 2013, Pecha-Garzón, 2011).

Social Housing and Land Restitution in other contexts

There have been a few countries where housing policies designated for the urban poor and – intentionally or not – the IDPs were implemented alongside property restitution programs.

As the civil war ended in Sri Lanka in 2009, close to 90% of the IDPs were resettled or returned to their places of origin (Saparamadu and Lall, 2014). In most cases, the return was voluntary, although the back-then Sri Lankan government has been very reluctant in launching return and restitution programs to support the IDPs, most of whom are from the Tamil minority (IDMC, 2015b). Prior to 2015, only a few externally-funded initiatives existed, such as reconstruction and repair of close to 43,000 houses sponsored by the government of India (UN-HABITAT, 2015).

The situation started to change after the elections in 2015, as the new government has taken a different approach and began developing comprehensive strategies to facilitate return and resettlement of the remaining IDPs and provide the victims with dignified housing, primarily in the most affected Northern and Eastern Tamil provinces (IDMC, 2015b). Due to the geographical concentration of the IDPs, these initiatives are coordinated through one administrative body, the Ministry of Resettlement. The fact that a vast majority of the displaced already returned to their places of origin before the implementation of those new policies, makes coordination of property restitution and housing programs theoretically easier than in Colombia, where few IDPs returned, while the rest are scattered in different urban and rural areas around the country.

When the Bosnian war was over in 1995, there was no demand for new housing due to the decrease in population, although a significant qualitative shortage caused by the destruction of housing stock was present, especially in Sarajevo and other large cities. Therefore, a massive, government-led reconstruction was chosen as the prioritized post-conflict housing strategy (Hegedüs and Teller, 2008). It was hoped that the property restitution and return programs would complement the efforts to reconstruct the damaged housing stock in a successful post-conflict recovery process. However, due to the lack of financial resources, informal character of ownership and construction, as well as the still present ethnic tensions, which discouraged many IDPs from returning to the places of origin, all of those programs were insufficient in providing dignified living conditions for the victims. Though long time passed after the conflict was resolved, there might be a growing need for new housing schemes for vulnerable and IDP groups, particularly those who do not want to return (Hegedüs and Teller, 2008).

Although not originating in civil war, the abolishment of apartheid and the introduction of a multi-racial democracy in South Africa in 1994 led to a similar process. The ruling African National Congress launched a series of policies targeting the poor and the repressed Black population. One of them was a comprehensive land reform and property restitution program. It applied to communities and individuals who were dispossessed of their properties as a result of *“racially discriminatory laws or*

practice" (Sibanda, 2001). Restitution of land in rural areas usually involved group claims, while requests for restitution of plots in urban areas were submitted by individual households and concerned primarily cases of slum clearance and settlement evictions. As restitution of urban lands was usually impossible due to the new development on the sites, most of the claimants received monetary compensation instead of property rights (Sibanda, 2001).

Another initiative of the South African government that targeted the disadvantaged and marginalized groups was the provision of a remarkable 1,155,300 housing units for over 5,7 million people in only five years (RSA Department of Housing, 2001). These total subsidies were meant to alleviate poverty and promote home ownership among the lowest-income earners, the majority of which are Black Africans who suffered from the apartheid regime (Gilbert, 2004). Similarly to Colombia, new formal housing in this case has been distributed to most of the beneficiaries for free (Chiumia, 2014).⁵ Interestingly though, the beneficiaries of the Land Restitution program received special treatment and are eligible for housing subsidies, as opposed to owners of other residential properties (RSA Department of Human Settlements, 2009). Nevertheless, the housing units were criticized of being small, while their poor location further deepened the racial segregation in the country. Moreover, many residents found it difficult to afford paying for public services and decided to move out of the projects (Gilbert, 2004).

Implementation of those policies had mixed results and was context-dependent, as the rural-urban character of displacements, the share of IDPs willing to return, and the political situation, were different in all the cases mentioned above. What is important here is that the institutional coordination between housing, restitution and return policies in countries mentioned above was definitely not uncommon, and in some countries, significantly stronger than in the Colombian case.

The Victims Law and the Free Housing program

In the initial phase of the Colombian conflict, there was little government intervention to provide temporary or permanent housing solutions for the IDPs. The passiveness of the state was reflected in a quiet acceptance of land invasions and indirect support for informal development. Squatting public lands in urban peripheries became a common practice, as the risk of evictions was relatively low during this chaotic period of conflict (Naranjo, 2004). The responsibility to attend the IDPs who just arrived in urban areas was initially given to local governments. The displaced households were eligible for three months humanitarian aid and assistance with education for children under 15 years old (Ibáñez and Moya, 2010a). In some municipalities, local authorities provided land, construction materials, or financial support for families willing to build a house. There were also a number of income-generating and training programs for the IDPs, although not sufficient to permanently alleviate poverty according to Ibáñez and Moya (2010b).

The first attempt by the federal government to facilitate the return of the IDPs to their lands was the Negotiated Restitution in the Law of Justice and Peace in 2003. The victimizers were expected to voluntarily give back the land or compensate the victims in exchange for "*legal and social benefits*" (García-Godos and Lid, 2010). However, hardly any cases were settled in that voluntary way.

A more comprehensive approaches to reparation and restitution were drafted in 2011 in *The Victims' Law*,⁶ which introduced regulations and policies that are meant to "*reduce the injustice and social inequality through economic and moral reparation for the victims*" (Ministerio de Justicia y del Derecho, 2011).

Besides establishing new restitution policies, The Victims' Law recognized the importance of addressing the housing needs of the victims. It specified that the Ministry of Housing, City and Territory (MinVivienda) has the authority over urban housing subsidy schemes for the displaced population and restitution of properties in urban areas, while the Ministry of Agriculture and Rural Development (MinAgricultura) would coordinate housing programs and the implementation of Land

Restitution in rural areas (Ministerio de Justicia y del Derecho, 2011).⁷ In practice, since most of the property dispossessions took place in the countryside and the majority of the displaced households fled to cities, MinVivienda assumed responsibility of social housing schemes for the urban IDPs, while MinAgricultura focused on implementing Land Restitution policies. From that moment, no further coordination between the two reparation programs was present and both ministries developed their own mechanisms to implement these policies.

In order to facilitate attendance of the displaced households and local enforcement of the restitution program, MinAgricultura established the Land Restitution Unit (URT), which opened a number of regional branches across the country. In the first years, the URT is resolving cases of lands located only in the selected areas that were approved by the military as sufficiently secure. Once the legal procedures are over and the property rights are restored, the URT supports the beneficiary household in their return and reestablishment. The landowner is not allowed to sell the property in the first two years after restitution. Monetary compensation is provided only in special cases, when the full restitution of the property is not possible (Ministerio de Justicia y del Derecho, 2011). Funding for the operation of the program comes primarily from the Colombian government and donations from various international organizations and foreign governments.

The social housing schemes for the IDPs followed the recommendation of The Victims' Law, but developed independently from Land Restitution. After a short time of preparations, MinVivienda announced the inauguration of its 100,000 Free Housing (*100,000 Viviendas Gratis*) program in 2012. Construction of the first projects started shortly after. The success of the first stage of the program led to its extension with an additional 300,000 units. The Free Housing projects are operated according to different financing schemes. Some of them are funded entirely from the federal and local governments, while others are subsidized by the National Savings Fund or built in collaboration with private businesses and donors. Regardless of the arrangement, MinVivienda set a limit for the construction costs to 70 minimum salaries per unit. These are usually two-bedroom units in apartment blocks or single-floor row houses in neighborhoods build for 3,000 to 15,000 people on average.

The majority of the Free Housing projects are built in cities that received large numbers of IDPs. Beneficiaries of the program are usually drawn from waiting lists, which are administered locally by Family Compensation Funds (*Cajas de Compensación Familiar*). In many cases, the waiting lists of IDP households willing to participate in the program were created at the local Unit for the Attention and Integral Reparation of Victims (*Unidad para la Atención y Reparación Integral a las Víctimas*), which is one of the first entities where the IDPs go after their displacement as a starting point. These lists are then supplemented with families classified as being in extreme poverty and victims of natural disasters. It is estimated that the IDPs constitute around 72.5% of all beneficiaries of the Free Housing program (Minvivienda, 2014a).

Unlike in the South African case, the Colombian government does not specify whether the IDPs are eligible to apply for the housing subsidy and the property restitution program at the same time. The lack of such regulation may be interpreted as a permission to participate in both. In practice, few apply for both programs.

IDPs are unwilling to return

Data from various sources makes it evident that the IDPs in Colombia want to stay in urban areas. A survey conducted between 1997 and 2004 by the Catholic Church on 43,587 IDP households in different parts of Colombia showed that not more than 11% of the respondents wanted to return to their place of origin (Arias et al., 2014). According to another national survey conducted in 2008 by the Commission for the Monitoring of the Public Policy on Forced Displacement, only 2.9% of the 8,100 surveyed households claimed they would like to return and up to 78.7% would prefer to stay in the receptor city, while 12,2% considered moving somewhere else (CSPPDF, 2008).

Similar conclusions can be driven from our RDS survey conducted in 2014 in Bogotá and Barranquilla on 499 IDP households who own land in municipalities currently eligible for Land Restitution. Although up to 62.5% of the surveyed households are in the process or expressed their intention to apply for the program, only 28.1% plan to return to their land if restituted. Around 22.6% would rather sell or lease the plot to someone else (Wiig, 2015). The lack of interest in returning and farming might be surprising if we consider that the average monthly income of the surveyed IDP households dropped almost by half, from \$935,000 COP before the displacement to around \$500,000 COP in 2013. However, the current economic situation of a given family does not seem to have an impact, as families which maintained or improved their income from before displacement are as likely to consider returning as those whose income is significantly lower.⁸

Our in-depth interviews with ten IDP households, of which four received free housing in the Villas de San Pablo project (Figure 1)⁹ in Barranquilla, another four in the Nueva Esperanza project (Figure 2)¹⁰ in the neighboring city of Soledad and two who are still on the waiting list, confirm that return to the place of origin is not the preferred alternative. All of the beneficiaries expressed their satisfaction of having received a house or apartment for free and declared their willingness to stay there permanently. Only two of the interviewed households are in process of Land Restitution, although they have no intention to return and they indicate they will sell the restituted property as soon as possible. In other cases, the interviewed IDPs are either not entitled for restitution, because their areas of origin are not yet eligible for restitution, or they do not bother to apply as they do not believe the process truly works in a transparent and timely efficient manner. Still, all the interviewees indicated that they miss some aspects of living in the rural areas, such as the ability to produce their own food. For this reason, two respondents said they would consider moving into the countryside, although not to the same area where they came from, but somewhere else.

Figure 1. Villas de San Pablo housing project

Figure 2. Nueva Esperanza housing project

All ten households report that at least one member receives regular income through employment or pension. Those who worked usually kept the same occupation they had before moving into the Free Housing project. The majority were self-employed, either in formal or informal businesses, such as food vending and workshops. They operated either from the previous houses in the city, or (illegally) from the new houses or apartments in their respective Free Housing projects.

Our interviewees agreed that the opportunities for employment and education for them and their kids are by far greater in urban areas than in the countryside and this is perhaps the main reason why they want to stay close to the city. We came across a number of IDPs, particularly woman who, out of their own initiative, signed up for professional training programs and academic courses. Most households sent their children to local schools or even universities. They have furthermore no intention of passing their farming skills and traditions on to their descendants.

Other most common reasons for not returning were: the perceived insecurity in the place of origin, and bad memories from violence and displacement. The Free Housing projects, on the other hand, are seen as relatively secure places which offer “calmness” and “dignified” living conditions. One person claimed that her previous neighborhood in Barranquilla, where she settled after the displacement, was “too dangerous” and the Free Housing program offered her a way out.

It is also evident that the new social networks that developed after displacement are currently stronger than the pre-conflict networks in rural areas. Several of our respondents believe that the old communities in the villages where they come from no longer exist, and eventual return would imply starting everything from scratch, a perception that is aggravated as time goes on. The relatively slow progress of Land Restitution and the inability to open claim processing in many of the affected areas that have not yet been selected may further discourage the IDP population from returning.

Key informant and household interviews conducted in the primarily rural municipality of El Carmen de Bolívar, which was severely affected by the conflict, indicate that in the rather small group of the displaced persons who decided to return, most were already old, and did so regardless of the Land Restitution initiative. They might have bought another plot in the area or managed to recover their old property if it was still left abandoned. The returned households we spoke to were families, who settled in the main town, as opposed to the farm itself like before the displacement. In a few cases, the returnees engaged in typical urban occupations and their farms served them as a weekend house. Any kind of cultivation or animal breeding was not in form of a large-scale agriculture, but rather a leisure and family gardening activity.

Figure 3. Vacant farm in El Carmen de Bolívar. It was restituted to the original owner, but he did not want to return there and reengage in agriculture.

The conclusion from our interviews is that the Free Housing program has been more popular, as it allows the IDPs to sustain the means of livelihood and social networks they developed in towns and cities where they settled after the displacement. Land Restitution, on the other hand, fails to preserve or improve the current livelihood situation of the IDPs, as the return to the often depopulated rural areas and the reestablishment of agricultural production is generally not seen as an attractive and economically viable alternative.

The advantages in the offer of Free Housing are reflected in the number of IDPs who signed up for the program. It is estimated that up to 900,000 households are on the waiting lists for Free Housing across the country (Minvivienda, 2014b), compared with only around 73,000 claims for Land Restitution that were filed by June 2015 (Valencia, 2015). To date around 100,000 households benefited from the housing program, compared to only 1,368 restitution sentences (Valencia, 2015) for around 4,000 households were given, which is well below expectations and original estimates of the URT, whose plan was to settle 360,000 cases by 2021 (Sabogal Urrego, 2013, Semana, 2015).¹¹ From our interviews and observations it is evident that the number of beneficiaries of Land Restitution who returned and live on their land is relatively low, although the exact figure is unknown.

Discussion

The data presented in the previous section leaves no doubt that the majority of IDPs does not want to return to the places of origin and prefers to stay in receptor cities. This applies not only to those who received housing for free from the government, but to the entire victimized group in general. Therefore, it can be argued that those IDP households would have stayed in the cities anyway, regardless of whether they benefit from the Free Housing program or not.

Following this thought, another question may be asked. Would the Land Restitution program tempt the IDPs from the Free Housing projects to return, if they did not benefit from this initiative? The interview and survey data suggest that Land Restitution would probably not have caused a massive return to the countryside, as the IDPs prefer the employment and education opportunities in the city. The free house or apartment can, therefore, barely be an improvement in housing conditions, particularly for those who lived in precarious dwellings in under-serviced informal settlements.

It is important though to observe that the new housing provided by the government may for many of the IDPs be the first formally owned property that could be revoked if the family does not move into the housing unit within a specific period of time. Coping with this new, formal housing arrangement may require financial stability, which may be easier achieved by remaining in the city and preserving the current source of income.

The 10-year limitation on selling and renting out the new housing unit may further reduce the mobility of the beneficiary IDP households, which would also discourage return. At the same time, the 2-years period that the landowner needs to wait before being able to sell or rent out the restituted rural property combined with a commonly accepted practice of not returning to these lands leaves those who benefit from both programs literary without a choice. For them, staying at the subsidized housing and waiting to sell, rent out, or just keeping the restituted property vacant is the only feasible option. Therefore, it can be argued that although the Free Housing program does not make a significant change to the number of IDPs who do not return, it 'cements' their decision to stay in the city and makes it much less likely and more complicated to return in the future.

The advantages of the Free Housing programs over Land Restitution and return incentives are clear. Not only is the housing program the preferred choice of the IDPs, as it was explained before, but it also is in line with the general migration trend in Colombia from rural to urban areas and the preference for city living. Furthermore, the estimated government spending per beneficiary is just one third in the Free Housing program, compared to Land Restitution (Sliwa, 2015).

However, while the Colombian government takes credit for the intermediate success of the Free Housing program, there are no guarantees that the housing projects will make a lasting change in the quality of life of the IDP population. Some academics questioned the basic idea of providing dwellings for free, even if it was meant as a compensation measure for the victims. They suggest that this kind of welfare leads to lack of sense of ownership of the dwellings, which may result in poor maintenance and deterioration in the future, as it happened in many similar public housing projects in the past (Correra et al., 2014, Gilbert, 2013, Hamdi, 2010). The interviewed new residents themselves, although very happy for having received free housing from the government, reported some shortcomings, including small size of the units and lack of trees and green spaces.

We also learned that for many of the residents, it is the first time they need to pay bills for public services. However, similarly to South Africa, some of the respondents who live in the Free Housing projects report that they are afraid of not being able to afford the bills and maintenance. A couple of them were prohibited from using some parts of their new dwellings for economic uses which, as they say, limits their livelihood and income-generation opportunities.

Other serious complains relate to the poor location (often outside of the built area of the city), overcrowding, use of cheap and prefabricated materials, lack of quality public spaces and commercial uses, as well as inadequate provision of health centers, and police stations (Correra et al., 2014).

Figure 4. Siete de Abril is one of many informal settlements in Barranquilla largely inhabited by the IDPs.

Figure 5. Las Gardenias Free Housing project in Barranquilla.

Insecurity might be a growing problem in the new Free Housing projects in the future, as an increasing number of crime, activity of local street gangs, acts of vandalism, stealing and consumption of drugs in common spaces are being reported (El Heraldó, 2015). Lack of ownership and insufficient funds for housing improvement led to a surprisingly rapid deterioration of private and common areas, which could easily be observed during our field visits. Many of the projects are quickly turning into 'ghettos' and isolated pockets of poverty.

Some of those issues can be mitigated through a number of interventions. First of all, the new housing projects should be better integrated with the city, which can be achieved by creating socially mixed and inclusive communities in better locations close to employment centers, and by improving public transportation accessibility. Introducing flexible, mixed land-use development and providing affordable spaces for commercial and small-scale industrial activities within the social housing projects that may be rented out to residents will also likely widen the livelihood opportunities of the IDP population and contribute to their reintegration in the society.

Is the Free Housing program necessary?

From the three potential types of interventions for the IDPs – facilitating return, providing new housing and improving existing housing – only two are tried in Colombia and none with a greater success. While the Land Restitution program fails to bring masses of IDPs back to rural areas, the Free Housing program resulted in the relocation of thousands of the displaced families within the same city and placing them in new housing projects, some of which may sooner or later become slums.

This discussion raises an important question: if so many of the IDPs choose the Free Housing program over return to the rural area, because they prefer to stay close the city, then why would the government not help them improve their current housing situation so that they would not have to move at all? Perhaps, as suggested by Gilbert (2013), the political payoffs and the popularity of the idea of building new housing for the victims and giving it for free was among the reasons why the Colombian government decided to choose this strategy, as opposed to, for example, a gradual improvement and regularization of the informal neighborhoods in which many of the IDP's live. If large-scale return is not the desired alternative by the IDPs, then perhaps the answer lays in the opposite – a solution that minimizes any relocation, even if it would be within the same city.

Taking the funding from the Free Housing program and using it for house improvement grants and subsidies for water bills, public transportation, education and health services for the poor or even food and paychecks of the low-income earners, as suggested by Gilbert (2013) seems especially valid in this context. Formalization and further investment in public infrastructure in informal and squatter settlements according to the principles described by Turner (1976) and Hamdi (1995) might not only be a less expensive, but probably also a more desired alternative, since it would allow the displaced

households to maintain their current livelihood situations without the necessity of relocation. This strategy will not only allow the IDPs to remain in their (relatively) better location, but also maintain the social network structures of neighbors, relatives and friends who live in the same areas, something that is crucial in their livelihood strategies.

Conclusion

This paper provides another case study that confirms the significance of urbanization as a process that irreversibly changes the way people live. Broadly, the results of this research shows that the success of large-scale land reforms and housing programs depends on whether the principles of these schemes work with or against the general rural-urban migration trends and livelihood choices of the target population. The dynamics of the Colombian situation is somehow different than in other countries in similar situation (Sri Lanka, Bosnia and South Africa), which means that good post-conflict housing and return policies for the victim population need to consider the local context and (as much as possible) the individual preferences and needs of the IDP households.

In the discussed case, the urban IDPs in Colombia are generally unwilling to return to rural areas and would rather take advantage of housing subsidies that allow them to stay in their receptor city, as opposed to applying for initiatives which facilitate land restitution and return to the old property. Our study shows that the livelihoods of the IDPs in Colombia depend on the access to employment centers and income they can produce from home. However, these needs have been poorly addressed by planners and policymakers responsible for the new housing projects. These concerns need to be urgently addressed in order to develop successful initiatives that can truly reintegrate the IDPs with the rest of the society. In addition, there needs to be more coordination between the different reparation programs to ensure that the benefits are delivered fairly, in an efficient and organized way.

The changes we propose to the reparation programs in Colombia imply the improvement or reconsideration of the massive, 100% subsidized housing as a solution to the challenges of urban IDPs. These social housing projects need to be better incorporated with the social and physical fabric of the city in order to combat the process of socio-spatial segregation and ghettoization, which starts to become evident in the Free Housing projects. Alternatively, the Colombian government should support the consolidation and physical upgrading of the peripheral informal settlements in which the majority of the IDP population lives.

Notes

¹ The currently ongoing armed conflict in Colombia began approximately in 1964. The three sides of the conflict are: the Colombian state forces, the left-wing guerrillas, including the Revolutionary Armed Forces of Colombia (FARC) and the right-wing paramilitary groups. Originally, the rebel groups were motivated by their ideological reasons, but eventually the conflict turned into a war on drugs and the control of land for narcotic production and trafficking (Serres, 2000).

² The federal government allocated \$29 million USD for operation of the Land Restitution program for the period between 2011 and 2021. On top of that, the URT received donations from various international organizations and foreign governments, whose estimated contribution may be up to \$200 million USD (El Nuevo Siglo, 2012, Unidad de Víctimas, 2014). The estimated total federal spending for the Free Housing program is around \$9.4 million USD (Sliwa, 2015). Land for construction of housing projects is usually provided by municipal and departmental governments (El Colombiano, 2014). Additional funding is provided as a subsidy from the National Savings Fund (Fonvivienda). The rest is covered by local donors and private enterprises involved in the construction of the Free Housing projects.

³ The thesis was delivered at the Norwegian University of Science and Technology, as part of the Urban Ecological Planning Master's programme. The investigation was conducted in collaboration with the Colombia Land and Gender Project at the Norwegian Institute for Urban and Regional Research and the Land Observatory project at the Universidad del Norte in Barranquilla, Colombia, both of which provided financial support for the research. The fieldwork was performed primarily in two chosen locations: the metropolitan region of Barranquilla and Soledad in Atlántico department and the municipality of El Carmen de Bolívar in Bolívar department.

⁴ *Conjunto Urbano Nonoalco Tlatelolco* built in 1960s in the center of Mexico City is perhaps the most famous example of such a large scale public housing renewal project in Latin America. It was built according to the modernist design principles and today houses close to 55,000 people.

⁵ Except of Colombia and South Africa, other countries which (with limited success) attempt to offer fully subsidized housing schemes are Venezuela, Chile, Brazil and Zimbabwe (Chiumia, 2014).

⁶ *Ley de Víctimas y Restitución de Tierras y sus Decretos Reglamentarios*, Law 1448 of 11. June 2011.

⁷ According to Par. 1 of Art. 66 of The Victims' Law, "*to guarantee effective and integral attention of the returned or relocated population, [the provision of] dignified housing is the responsibility of the Ministry of Environment, Housing and Territorial Development [today the Ministry of Housing, City and Territory] in case of urban housing, and the responsibility of the Ministry of Agriculture and Rural Development in case of rural housing*" (Ministerio de Justicia y del Derecho, 2011).

⁸ In our RDS survey, we asked the respondent households to estimate their monthly incomes before the displacement and last year (that is 2013). This data allowed us to calculate average values and compare the results between the different sub-groups of our respondents.

⁹ Villas de San Pablo is a Free Housing project located about 5 km outside of the built area of Barranquilla. The project was built and is still operated by the landowner, the Mario Santo Domingo Foundation. It consists of two parts: 1) 832 units in apartment blocks that are part of the 100,000 Free Housing project and 2) close to 2,000 single-family houses built as part of other subsidy programs. The planned capacity of the entire project after expansion in the next years is up to 20,000 dwellings.

¹⁰ Nueva Esperanza is located in the southwestern periphery of Soledad, next to a settlement that was established primarily by the IDPs. The project is composed of 1,561 single family, two-bedroom attached houses, each with a patio and a small garden.

¹¹ According to our informants in El Carmen de Bolívar, the local URT office is under pressure to "*prove results*" and in order to meet the quota set by the head office in Bogotá, they often call people who used to own land in the area to encourage them to apply for Land Restitution, even if there was no proven dispossession of the property.

Industrious Flanders and Brussels – the Northern Area case

Abstract

For almost two years, Flanders and Brussels are cautiously starting to cooperate on territorial challenges. The cross border northern area, with old industrial estates, the airport, new vacant offices and old villages, is the testing ground.

In the cooperation we will assemble a territorial development program. The first phase consisted of confronting local and regional stakeholders with different types of research by design and student work. This paper will focus on work done by students of CassCities (London Metropolitan University), 1010 architects + urbanists, Artgineering and Studio 014 associato Bernardo Secchi – Paola Viganò. Ideas and concepts can help convince stakeholders to embrace the wonderful life in the Brussels northern area, making sure that industrial and production activities can remain side by side with housing and leisure in mixed industrial estates, along highstreets, or in old villages.

The aim is to show how we can incorporate the urban fringe into the vibrant city of Brussels. This will not happen by demolishing and reconstructing large areas, but through accepting the value of what is there, by nurturing the possible and defining what is missing. Careful looking, embracing lucky finds and stimulating everyone to accept and promote urban production seem to be key to success.

'Industrial areas [...] are not well-understood. Most people have no idea what is made and assembled in their borough, because industrial areas are unwelcoming and do not have a public face. It is difficult to gain an appreciation of their scale and purpose without observing them first hand.'

Scott, Gort, *From Around Here: Tottenham Employment Study* (London: Haringey Council 2013), p. 4

1 a challenge for the Brussels Metropolitan area

“Brussels, like many large metropolises around the world has grown beyond the city’s administrative boundaries. Also like some other major cities, Brussels is a city region, surrounded by another region with different actors, plans, political and economic goals and histories. What makes the case of the Brussels city region special is the existence of different official languages and cultures on both sides of the city’s boundaries. Any attempt to propose a common urban and development plan for the metropolitan region that crosses Brussels’ borders will be challenged by a patchwork of histories, cultures, municipalities, regions, languages and identities. The current search for a vision for the Northern Area, a border-crossing area that includes the Zaventem airport and other national and international institutions and infrastructures therefore poses major challenges to architects, planners, and politicians. Any spatial solution expressed into a planning vision for this area will have to take into account the particular regional and local framework.” (Hein C., 2014)

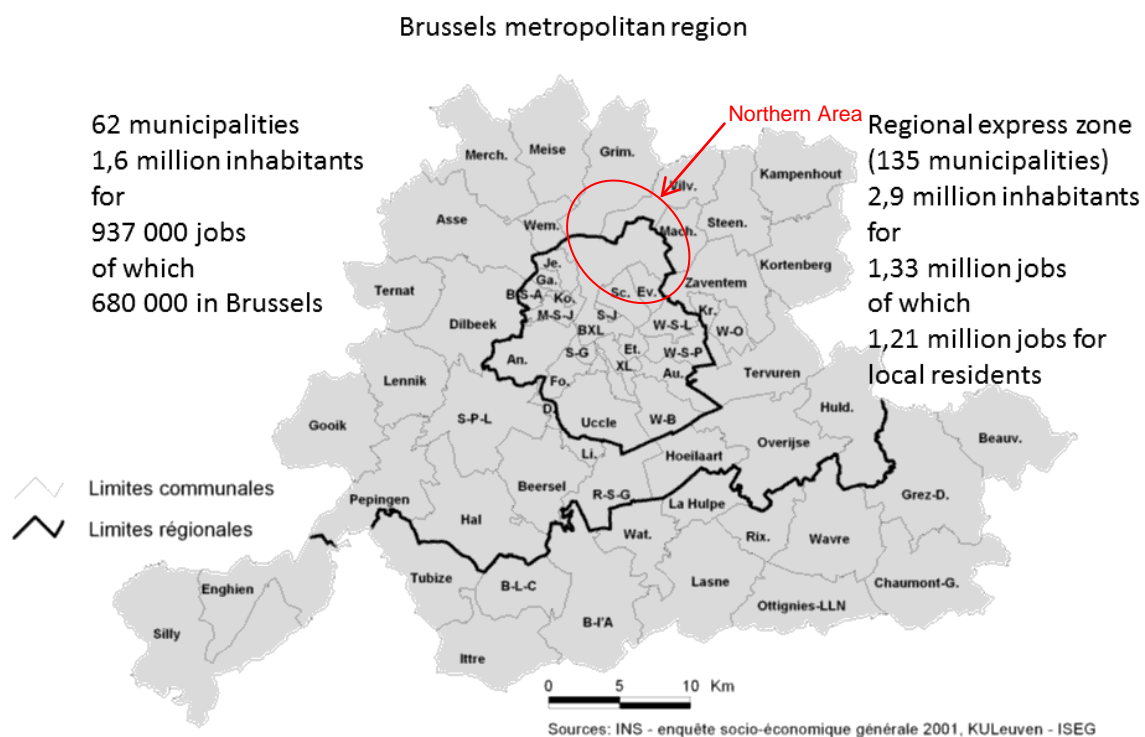

Figure 1: Brussels’ Northern Area situated within the metropolitan region

During the 2014 CassCities/RuimteVlaanderen summer school, Eric Corijn¹ formulated the major challenge for the Brussels metropolitan area as follows: *“to truly understand the*

dynamics of Brussels, one must acknowledge the extremely rapid growth of the population. The downward demographic trend which began from the historical population maximum in 1968 (1.079.181 inhabitants) is turned. ... On January 1, 2013 1,154,635 people were registered in the Brussels-Capital Region (19 municipalities). Between 2010 and 2020, a net growth of over 140,000 people is expected.” Specific for the Brussels situation is that the net growth of the population is associated with an ongoing suburbanisation. The Brussels-Capital Region keeps losing around 5,000 people annually to the other regions. Between 2005 and 2013, the Flemish suburbs gained 25,000 inhabitants to a total of 415,000 people.”

The industrial production based society evolved since the late 1950s to an advanced service economy, while Brussels slowly profiled itself as the capital of the European Union.ⁱⁱ

Unemployment in the industrial working class remains structural, especially among young people and workers with a migration background. One-third to over half of young people in some neighborhoods are unemployed. Nevertheless, the economy continued to grow in Brussels in the service and healthcare sectors and as a result there are more than 710,000 jobs, of which 365,000 are occupied by commuters. 54 percent of commuters living in Flemish or Walloon Brabant. According to Eric Corijn over 105,000 jobs are directly connected to international functions of Brussels. Corijn: "This internationalization of the Brussels economy is also present in the suburbs and the fringe, more specific in the logistics activities and the airport region." Lack of sufficient demand for low-skilled productive work in Brussels results in a strong dualisation of society and poverty. Social and economic integration of the periphery in the dynamic of Brussels-Capital Region will also be visible in the form of urbanization. The new residents of the fringe bring higher densities and social multi-culturalisation. Part of the population moving out to the fringe do so because of upward social mobility from the (impoverished) canal neighborhoods of Brussels. These social developments are at odds with the detached housing trend that dominates the Flemish periphery today. Densification is necessary to strengthen urban functions and services, especially in the existing smaller cities, like Vilvoorde and the old villages.

Production of goods remains a very important element of economy, not least for employment. New Industrial Policy in Flanders (Flanders in Action, Pact 2020) is mend for 'Maintaining prosperity and competitiveness in a changing world by transforming 'industrial activities'. Elements of the strategy are competition in a globalised world, prosperity and safeguarding our environment.

For spatial policy facilitating economy often means providing places, well-equipped locations, where (industrial) production happens. Spatial policy is interested in the concentration of activities and in reducing employee trips by car. We know that cities, towns and smaller settlements have the largest concentration of inhabitants and are therefore the main areas of recruitment for employees. In the structure plan of Flanders (1997), the vision on space, the goal is set that mixed use of space is to be improved. Nevertheless in the years since approval of the structure plan industry seems to get expelled from the settlements.

Traditional spatial policy seems to favour separation of the economic function, and especially production, from dwellings and away from the centres of cities, towns and other settlements.

Flanders has dedicated hundreds of hectares to large business parks in the process of demarcating urban areas. In doing so the space for production activities has been included in the urban area, more or less near the city but almost always on greenfield locations, mostly on land formerly used for agriculture. In strategic port zones, the same kind of development is being planned and equipped for future harbour and logistic activities. Provinces are responsible for the development of a vision on space of the smaller towns and economic nodes. They made the same choices, providing space on greenfield locations for middle-large business parks when demarcating town boundaries. Municipalities are providing space for small business parks next to their main village. Overall, there have been a significant amount of planning initiatives for the separation of production sites from settlements.

In the same period former industrial sites or harbour sites in or nearby city centres were abandoned, because of problems with congestion, size of infrastructure (or size of ships and trucks), delocalisation of activities or industry (Zajac 2015). This economic reality provided the opportunity to rethink the future of those former production sites, called brownfields. Most of those sites were not reconverted into production sites, or even into sites where production sites are mixed in. The redevelopment mainly concerns dwellings, with a rather limited addition with offices, hotels, restaurants, cafés, shops and services: e.g. The Old Dockyards Project in Ghent; The Islet Development in Antwerp etc.), but also inner-city production sites, the large old factories (eg. Vilvorde Renault-site; Mechelen, Lamot and Comet-sites), are locations to create new city neighbourhoods, but without integrating or incorporating production space. These are projects led by the government or institutions commissioned by the government.

It is not only the government which promotes reconversion of production sites into dwellings. Smaller industrial buildings in the urban fabric are often redeveloped into lofts or apartments. In two studies concerning the economic value of a parcel, the findings reveal relevant arguments. For private developers return on investment and profit is without any doubt an essential condition for considering a project.

From a developers' point of view, residential development is far more lucrative (Maring et al. 2015, Pisman et al., 2015, Dugernier 2014) than development of production sites. For an entrepreneur in search of space it is probably easier to buy a ready-to-build plot of land than an old building that needs to be demolished or at least adapted.

2 Planning with stakeholders, researchers, designers and students

The research for this case study is strongly embedded in the Brussels Northern Area project. For the first time since the establishment of the three Belgian regions in 1989, the Brussels Region and Flanders are collaborating on a 'territorial development program'. Previous regional plans hardly even mentioned the existence of other regions. Planning has therefore to be nimble, avoiding stubbornness and obstinacy, and aim for collaboration and consensus building. The Northern Area project explicitly want to leave the old functionalist planning paradigm (shown in chapter 1) behind, for two main reasons:

1. Old recipes that worked perfectly in one region, will only arouse suspicion within the Northern Area project. If Flanders would propose to proceed as they usually do, the Brussels' partners will almost naturally be opposed to the approach and the outcome. A fresh start is needed to emphasize the fact that this is a first attempt to do Belgian cross-border planning projects.
2. For more than 20 years, all spatial planning initiatives resulted in a further suburbanisation of the Brussels Metropolitan Fringe. Industry was pushed out and replaced by either Dutch style residential developments or office parks. Both types of development created build up areas that have no link with a real urban experience, and these monofunctional areas are struggling.

Gibbons' 'Making space for Dalston' project (Gibbons, 2010) could not give a better description of our ambitions with the Brussels Northern Area project: *"Making Space in Dalston is a design led example of deliberative planning; the process of constant feedback between thinking and doing, where partners prefer to get their hands dirty in collaboration with local people rather than spending money on reports or subscribing to conventional top-down approach typical of the masterplanning process. Having been conceived over three years ago the methodology of valuing what's there, nurturing the possible and defining what's missing, from grass roots up, [...] it offers an early insight into the practical and design implications of shifting the balance of power. By involving local people in decision-making, it allowed local partners to take ownership of the projects, discuss governance and evolve together the mechanisms for future sustainability. [...]"*

Figure 2: Making space in Dalston: the principles of the study (Gibbons 2010)

[...] The project has promoted the role of an open dialogue in delivering responsive and meaningful change. By building trust and enthusiasm about public space in Dalston, and with a modest spend matched with a significant quantum of sweat equity from stakeholders, the project provides a test case for how the idea of the Big Society will play out at the point of delivery of new urban plans. It demonstrates the possibilities of incremental regeneration in evolving fine-grained deliverable innovations, particularly given an area of natural cultural diversity, and the entrepreneurial approach of the designers. The process forged new alliances, formal and informal, delivering relevant projects within a tight timeframe to composite client groups and interested parties, under a strategic umbrella, with restricted means, not reliant on economic fortune.”(Gibbons, 2010)

Like Dalston, the Northern Area project was initiated as a bottom up process, with no official agenda nor goals. Local stakeholders were asked to join the discussion and to take part in the construction of a real common understanding and vision of the northern fringe of Brussels. As the northern area is significantly larger than Dalston, we chose a more structured approach, involving researchers and design teams to enable an open dialogue.

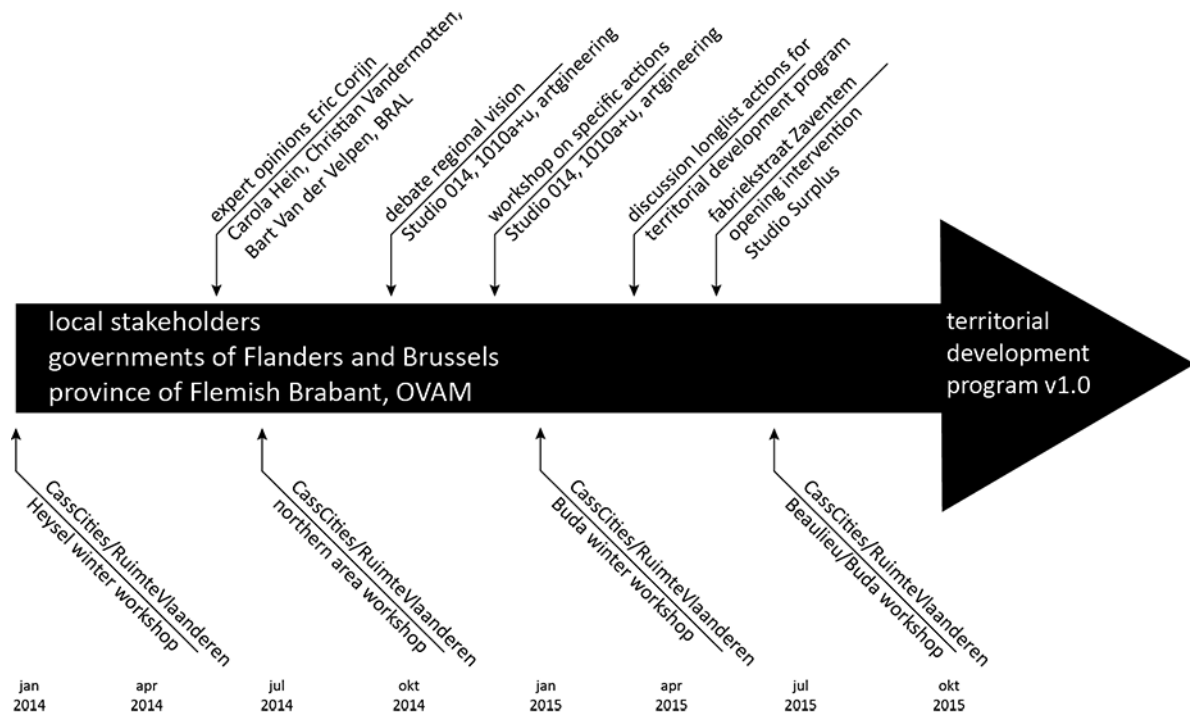

Figure 3: Brussels Northern Area Project scheme 2014-2015

Local stakeholders are at the center of the planning process, and, after some joined fact finding, did propose a first long list of what can become an action program called 'territorial development program'. To help discussion and promote debate, RuimteVlaanderen, the spatial development department Flanders, invested in research and design. Instead of commissioning one big comprehensive study, we asked for different research and design opinions. The divergent research or design statements were used as a starting point for stakeholder workshops and debate. Five well known Brussels' researchers or opinion makers (Eric Corijn, Christian Vandermotten, Bart Vander Velpen, Carola Hein, BRAL) presented their expert opinion on what to do with the Northern Area, and four design teams (Studio 014 associato Bernardo Secchi – Paola Viganò, 1010a+u, Artgineering, Studio Surplus) each focused on a specific area or topic. Both researchers and designers were chosen because their previous work showed that they have a sharp opinion on the development of the Brussels Metropolitan area.

The open planning process is driven by the input of designers and researchers, and continually adjusts the assignment of the design projects. Stakeholders were invited to discuss the research and design proposals and give guidelines to the teams for the next phase. The input (research and design) and the output (development program) are intertwined and cannot be seen separately.

To avoid self centeredness and to open our minds to fresh and different views, a collaboration with teachers and students from Cass Cities (London Metropolitan University) was initiated. Through two winter workshops with Cass Cities students, and two international summer workshops, a vast number of excellent and new ideas were produced and introduced in the planning process.

As the Northern Area project only finishes its first year at full speed, we have mainly been involved in valuing what is there, and started to nurture the possible. During the 2015 summer workshop, we engaged three owners/developpers of different sites to participate in the discussions and debate with students and other stakeholders.

3 Four CassCities/RuimteVlaanderen Workshops

In this paper will limit ourselves to the impact the four student workshops had on the project. The other research and design results will only be discussed if there is a clear link between the workshops and what the research or design teams proposed.

3.1 Heysel Winter Workshop 27-28 January 2014

The imminent debate on the construction of a new national football stadium pushed RuimteVlaanderen to propose Heysel as the site for the first workshop. Students from Cass Citiesⁱⁱⁱ were assigned to look for a good green link, some 20,000 new homes and a place for a new football stadium.

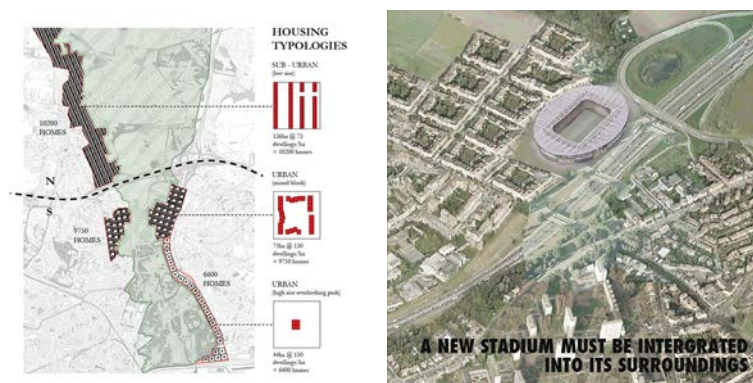

Figure 4: Heysel workshop proposed 26,000 new homes (left) and an urban football stadium (right)

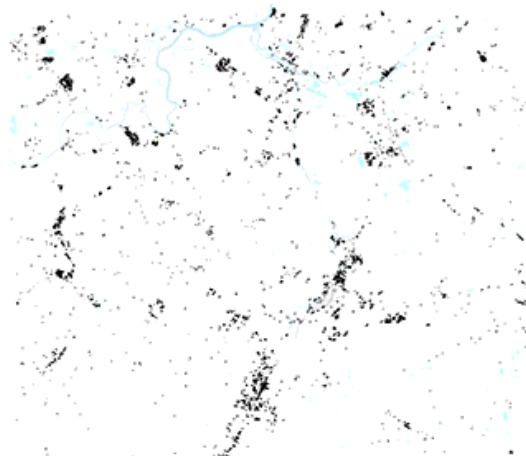

Students questioned territorial assets that everyone in the Belgian or Brussels context is so used to that no one even thinks of challenging it. Every national function, from the inaccessible royal park to the exhibition center was compared with good European examples. Originally conceived as a world expo, the Heysel area was supposed to be a large experience park, but is now taken over by cars and mediocrity. The workshop proposed not 20,000 but 26,000 homes, including building high rise housing on the royal Avenue de Meysse.

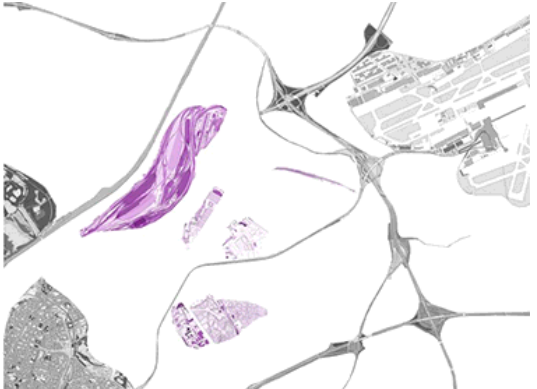

This first workshop was so successful that almost all the concepts and ideas still are part of the territorial development program. Meanwhile, a political decision has been made to construct a new stadium, but without the proposed urban environment. Extension of the public transport network will be part of the new development.

3.2 Northern Area Summer School 30 June – 6 July 2014

The second workshop was open to all international students interested in cities. 20 students^{iv} were accepted to join the complex discussion on the future of a vast part of the Northern area. As the assignment was to look for the future of this part of the metropolis in a context of demographic growth, students focused more on valuing the existing and looking for missed opportunities. Careful looking on a vast territory proved to be difficult, yet it revealed these 7 lucky finds (Fig 5.)

In the approach described by Gibbons (2010), the students and teachers valued what is there, and thus awarded some territorial assets with the 'lucky find' title. Lucky finds are the things everyone takes for granted, but that from a functionalist planning point of view should no longer exist. The lucky finds make the city liveable, vibrant and generally interesting. They make streets nice to walk along, and contribute to the urban look and feel of the place. Lucky finds are a crucial means to communicate to politicians (and other stakeholders) what is really valuable.

1	The galaxy comes to town	
---	--------------------------	--

2	A filigree economy	
3	A good and growable transport network	
4	An eccentricity of residual landscapes	
5	Compounds and blockages	

6	Very European	
7	Old streets	

Figure 5: 7 lucky finds, CassCities/RuimteVlaanderen 2014 Summer School

Though these lucky finds do not seem very spectacular, they helped focusing the process on the essential parts. All 7 lucky finds influenced the choice of main topics in the territorial development program. A good example is Bordet and the ‘Good and growable transport network’.

Figure 6-7: elaborating the Bordet public transport node: left: CassCities/RuimteVlaanderen 2014 Summer School, right: Artgineering 2015

Bordet is on the verge of four lucky finds (very European, transport network, old streets, the galaxy comes to town). One of the student’s proposals (Fig.6) evolved through the work of Artgineering to a full new intermobility hub (Fig. 7) and became a crucial part of the Framework action ‘international boulevard’ (Fig. 8).

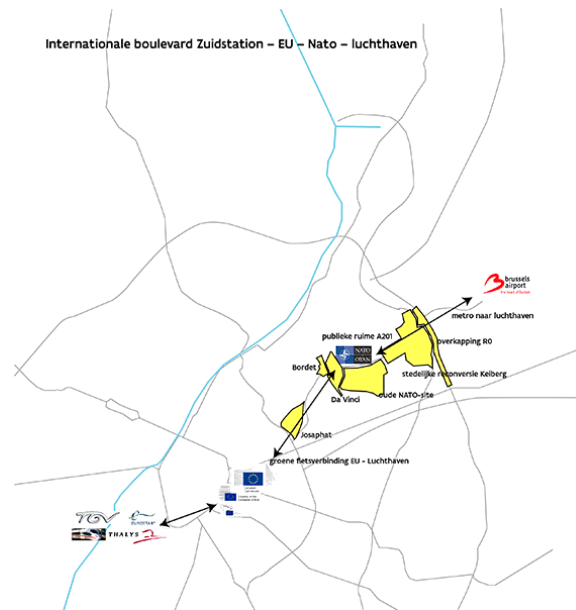

Figure 8: Northern area framework action 'International boulevard'

3.3 Buda Winter Workshop 22-24 January 2015

Both 2015 workshops focused on the area around the Buda train station. The winter workshop with CassCities students^v, mainly worked along the canal and proposed 20 ideas. Most of the work involved 'valuing what is there', showing 'Buda Lucky Finds' and even a postcard. (Fig. 9-10) Other students took it a step further to 'nurturing the possible', where they proposed interventions that could revitalise the area.

Figure 9-10: Buda Lucky Finds (left) and postcard from Buda (right) CassCities/RuimteVlaanderen 2015 Winter Workshop

Examples are the transporter bridge, an inventory of assets of Buda that need upgrading, or creating access to industrial processes and wholesale companies.

Figure 11-12: extrovert plastic flower wholesale (left) and transporter bridge (right)
CassCities/RuimteVlaanderen 2015 Winter Workshop

Figure 13: Nurture the possible at Buda Bridge CassCities/RuimteVlaanderen 2015 Winter Workshop

During this 3-day workshop, many great ideas were developed, that showed to RuimteVlaanderen and to other stakeholders the power of this positive approach. Showing the vast array of possibilities, and explaining how you can make them happen, was for most stakeholders the first time they heard someone talk this positive on the Buda Area. One local investor joined the discussions, and is one of the early adaptors. His company is now developing a bar and a shared workshop in a shed that was hardly used.

Thus, the third workshop proved that the valuing and nurturing approach could activate inspired action. This also convinced partners in the Northern Area project to get investors involved in the planning process and in the 2015 Summer School.

3.4 Beaulieu/Buda Summer School 6-10 July 2015

As we proposed to work on four smaller sites within the Buda area, the 27 international students^{vi} took the big step from *valuing* and *nurturing* to *'define what is missing'*. The owners/developpers of three sites were actively involved in the *'defining'* ideas and proposals during the workshop.

Figure 14: Four sites in Buda

Students started with careful looking to the assigned area, and did first steps to inventarisation (eg Fig 15: catalogue of vacant space), and truly understanding the place through interviewing residents, owners and workers. The focus on a smaller areas brought discussions closer to reality, and resulted in proposals that took advantage of dead end streets and remote or enclosed spaces. The Bruulstraat backyard roller coaster shows that you can do amazing, creative things in an invisible secluded space.

Figure 15-16: Catalogue of vacant buildings (left) and Backyard roller coaster (right)
CassCities/RuimteVlaanderen 2015 Summer School

One group worked on the area surrounding a new giant shopping mall. Not everyone is in favour of such a big building, focused on its interior space, but the group managed to show

how the surrounding areas could benefit from this multi million investment. They made two sets of postcards for Buda One set showed the existing assets, another the possibilities of the area. In one final proposal they wanted to show the investor what a real urban dialogue with the surrounding industrial area would mean, and even how he could make additional profit.

Figure 17: six postcards of the existing fabric CassCities/RuimteVlaanderen 2015 Summer School

Figure 18: Proposal for integrating the planned shopping mall in the industrial area CassCities/RuimteVlaanderen 2015 Summer School

On the adjacent IRET development site, others went as far as giving architectural proposals for the “Kerklaan” street. In collaboration with the developer, the proposed different versions for his site, and showed how he could incorporate contemporary industrial use into a housing project. The idea evolved into a promising final debate where the developer engaged himself to study the proposals. He then asked RuimteVlaanderen to support him in discussions with local and other administrations to bring good ideas and concepts in realization.

Figure 19-20: new development along Kerklaan (left, in blue and green) and proposed new street front Kerklaan (right) CassCities/RuimteVlaanderen 2015 Summer School

4 discussion

The Buda workshops show the importance and fragility of ‘old’ industrial areas. One important element is to make them visible and enjoyable as an urban experience. Celebrating industrial production by staging events, such as the Brussels’ Festival Canal seems a crucial step if we want to move away from functionalist planning methods.

Figure 21-22: Workers’ giants parade in Lokeren (left) and proposal for a Buda giants event (right) CassCities/RuimteVlaanderen 2015 Summer School

Organising a Buda-fest where local companies make giants, following an old tradition from medieval processions, and 19th century workers’ traditions (Fig 21). Creating urban legends, or even just recent traditions (eg Zinneke parade in Brussels) will prove necessary to regain an urban pride of old industrial areas. If we want to have a chance changing the urge to sweep everything away. We have to move from sweeping change and transform it into planting seeds for next generations.

For the Northern Area project, the challenge to come is to deliver real change on the field. To assure that the first attempts are reasonably successful, and that the enthuse other investors to start working on a larger scale.

However, the pragmatism of the ideas we are developing also needs some sort of economic or commercial dimension that begins to explore the feasibility of taking advantage of the developable areas the analysis is revealing. Some sort of research that begins to demonstrate the economic value that we are potentially unlocking for the city, for the community and other stakeholders could provide some very interesting headline figures and make people pay attention.

This would begin to demonstrate the financial value of the whole project and help spur the authorities' and the market's interest in the project.

It's real! It's worth a lot of money!

This work is very valuable to Brussels and to the regions, and could transform the economic future of Brussels. Ways of measuring this might include attaching a notional value based on current real estate values to the land uses contemplated. This could then be measured against costs of creating the opportunities.

“And here is my article (book introduction for a never published book) advocating an extrovert economy:

An extrovert economy.

A few months ago I visited a big Dutch new town. It's one that's doing reasonably well, and it's all very green and neat. But there's something odd about the place, in a way we've all seen before. Something seems to be missing, because it's hidden away. It's the economy that's tucked away beyond the trees, out of view. The office blocks and the industry are off on their own, landscaped and screened. The schools, colleges and the healthcare buildings are lurking around the back on quiet suburban roads. The shops and community centres, and the places to get a meal or a drink, are in little precincts that you go to when you need to, and only then. It feels like that town turned out the way it did because people had in mind an idea that the economy is something others do for you, or do to you, that it is okay for it to be over there, not here, that there is no need for it to be exposed.”

Comparative Analysis of Green Areas in Different Shiraz Residential to Define a New Criteria for Studying Urban Greening

Mahsa Chizfahm Daneshmandian, Shiraz University, Iran

(E-mail address: Mahsa_rezonans@yahoo.com)

Kaveh Fattahi, Shiraz University, Iran

1. Abstract

Since ancient times Shiraz is known for having beautiful gardens, worldwide famous as Persian Gardens. Its gardens mostly remain in two forms of large and small scale gardens. The large scale gardens are those typically known in the world as Persian Gardens, which are listed in UNESCO's world heritage sites. The small ones are those located within heart of small buildings, namely courtyard houses.

Today, public and private sectors and their strategic plans are mostly focused on large scale gardens. However in this paper we would like to change the focus from large-scale to small-scale Gardens. This is mostly done to retain and increase green space area not only in the form of large Garden but also to distribute them within each private building. To do so we try to study and compare three areas of Shiraz with three different characters and different public green per capita (GPC). One is in Shiraz traditional texture famous for its small courtyard houses. The second is one in Grid-based detached houses and finally modern high-rise buildings.

Their attitudes toward urban vegetation have been studied via interference of two criteria of capitation and mental imagination of their resident. To do so we have applied two quantitative and qualitative methods, via Interpolation method using GIS and questioner.

Our result show that the Grid-based detached texture that are experiencing drastic shift in recent years, though having higher GPC compare with the traditional case, have drastically less satisfied its inhabitants. We suggest method as a useful tool to encompass both quantitative (GPC) and qualitative (inhabitation image) figures to save the new approaches in development of greening new areas of Shiraz.

Key words: small-scale gardens, private GPC, building density, residents' mental imagery

2. Introduction

During last century, world's population had a rapid growth. It has been 10 folded, from 1900 to 2000 and by the end of 2008 half of world's population live in urban areas (United Nations, 2008). This process is still on the run till the present day. According to a United Nations prediction, world population will reach 9.6 billion by 2050 and more than 60 per cent of the whole will live in cities. It highlights that growth will be mainly in developing countries (United Nations, 2008). Inevitably, this entails huge challenges especially in large cities, such as biodiversity loss, climate change, over development, urban population densification, public health and social inequality and the effects of economic recession.

Iran's cities aren't except. The destruction of natural ecosystems of Iran began from large resident of population in urban areas, in late of Qajar epoch (Bahram soltani, 2005: 3). Although most cities of Iran located in valuable environmental context, and gardens and trees played prominent role in urban residents, unfortunately in this century lots of green lands have been converted to industrial and residential zones so there is nothing left from their ecological richness (Movahed, 2005: 95). Green areas reduction is more visible in cities such as Kashan, Tehran, Kerman and Shiraz. (Bahram soltani, 2005: 4-5)

This trend has led to the emergence of many environmental movements in the world. That started from prominent figures of the planning world Geddes, Howard and his 'Garden City' Movement and Mumford with his analysis of the 'Rise and Fall of Megalopolis' (Moughtin and Shirley, 2005: 2-3). To that we can add 'Silent Spring' by Rachel Carson (1962), 'Design with Nature' by Ian McHarg (1969), 'Small is Beautiful' by Schumacher (1974) and 'The Tragedy of the Commons' by Hardin (1977) as studies and theories in the causes of current environmental problems which led to the theory of sustainability. Also new urban design movements such as traditional neighborhood development (TND), transit-oriented development (TOD), Urban Village, Regionalism, Environmentalism, and Smart Growth have been proposed to make balance in the built and natural environments.

In Iran some considerable strategies have been suggested or even executed too. "Cultivation in Vacation" is a strategy pominated in Shiraz to encourage mid class citizen to buy lands in Shiraz nearby areas to enjoy their leisure times by gardening, with the scope converting wastelands into gardens. In raising many debates among scholars regarding, its impacts ecological, social and economic issues specially that of reduction of water resources for their nearby agriculture farms. Some other new strategies remained on the table; such as proposing a mandatory rule, to supply at least one tree per residential units in each apartment of Shiraz.

Shiraz with 1.460.000 inhabitants, is the most populous city in the south of Iran (Bazregar, 2012). This city considered by many Iranians to be the city of gardens. It's mainly because of its fertile plains, enclosing between mountains, and it specific weather conditions (Arian pour, 1986: 108). However nowadays, due to urban area expansion, most of gardens and green lands of this city have been disappeared. According to current statistics, area of the urban districts has changed, from about 900 ha, in 1956 to 24000 ha, in 2015, which means it multiples by 27 times. In the meantime this gardens area has been increased from 1565 ha in 1956 to 5962 ha in 1985 but in recent years it lost 3623 ha (Barzegar, 2012).

Table 1: Changing land use of Shiraz districts

Source: (Barzegar, 2012) and (Shiraz Municipality's Department of Parks and Green Spaces, 2015)

Figure 1: Shiraz land use changes in time

As figure 2 shows Shiraz green spaces per capita is 20.4. Though it is more than the world standard of 20 square meters per capita but considering its history of being a Garden city and vegetation reduction (figure1), Shiraz green areas should be considered seriously.

Figure 2: Green Space per capita in cities of the world (Source: Ziari et al, 2009: 302; Majnunian, 1995; Vázquez, 2011; Shiraz Municipality's Department of Parks and Green Spaces, 2015)

Many scholar don't believe in method of assess cities vegetation. Due to standard green space per capita in various part of the world and even in various cities of a country is different, related to its spatial ecology, climate, social, cultural and technical factors. Bahram soltani believes that "each green element in urban environment should be evaluated according to its performance. For example, the green area of traffic network might be having environmental impacts, but its performance is for traffic flow. We couldn't mix various green elements with different performance just due to they are plant and eventually reach to false number called green space per capita" (Bahram Soltani, 2005: 192). As well, Glason believes that, standards are a general guide, not clear instruction (Ziari et al, 2009: 301).therefore it isn't fair to concentrate on quantities factors and put qualitative factors aside.

To calculate green area per capita statistics, parks and public gardens areas and main streets boulevards and crofts areas with width more than 24 meters are be considered. Without taking into account the various residential, educational, administrative and public bodies green areas (Shiraz Municipality's Department of Parks and Green Spaces, 2015). Residential green spaces areas, making large amount of urban vegetation, and they play critical role in people's life. Therefore, it seems that, it's essential to legalize private green space per capita in addition to public green space per capita, and improves urban vegetation through small scale gardens.

Recently many small-scale environmental projects have been considered in different part of the world. Most of them concentrate on leading and supporting project of energy and

environment to protect limited resources. Furthermore this view has been mentioned in some part of diverse urban plans. For example, "The new Vision for Sydney 2030" contains three main visions of a Green, Global and Connected City. In part of green city, planners considered large-scale plans such as integrated and connected network, distribution of public green space as well as small private space. In the vision report mention that "Sydney will be internationally recognized as an environmental leader with outstanding environmental performance and new 'green' industries driving economic growth. The City will reduce its greenhouse gas emissions, with a network of green infrastructure to reduce energy, water and waste demands, led by major renewal sites. The City will help contain the Sydney Region's urban footprint by planning for new housing opportunities integrated with vital transport, facilities, infrastructure and open space. The City will protect native flora, fauna and ecologies." (Bonakdar et al, 2010)

During 2012/13, the City of Sydney continued to work towards the targets outlined in Sustainable Sydney 2030 program. According to this, there are 51 green roofs and 26 green walls on buildings across the local government area. Totalling 89,287m², these installations deliver environmental and community benefits including improved air quality, biodiversity, insulation and visual amenity. (Sustainable Sydney 2030 Snapshot, 2013)

Therefore, in this study we want to compare three different cases in Shiraz with diverse green space per capita, first located in historic center of city (8th municipality) with 4.31 public square meter per capita green spaces. Second and third in new texture of city (6th municipality) with 28.7 public square meter per capita green spaces. this is interesting for us to know is quality of green spaces in new part of city, 7 times more than historic center? Therefore we seek to answer to two main questions:

1. How is the private green space capitation in these three different residential areas of Shiraz in comparison with public green space per capita?
2. How is the residents' mental imagery and performance of green spaces in these three different characters in compare with public and private green space per capita?

3. Research Method

To do so we limited our studies to a parcel of each selected residential areas that include more than 90% residential buildings coverage and approximately 6 hectares private or semi-private green area. Therefore the special parcels are:

1. Organic Historical Texture, located in historical center of city. The selected area is about 500m*400m, with approximately 4000 residents.
2. Grid base separated texture, located in new district. The selected area is about 500m*350m, with around 3000 residents.
3. High density islands, located in high-rise apartment complex in new district. The selected area is approximately 400m*300m, with about 5000 residents.

To acquire optimum results and provide an appropriate response to the questions, in this research process we have used combination of quantitative and qualitative methods. Evaluate quantitative data, contain green private space capitation and building density, mostly performed by GIS.

In order to attain integrate and comparable map from these three different texture, we used Spatial Analyst in Arc GIS. In this method a set of sample points representing changes in landscape, population, or environment can be used to visualize the continuity and variability of observed data across a surface through the use of interpolation tools. Interpolation is a procedure used to predict the values of cells at locations that lack sampled points. It is based on the principle of spatial autocorrelation or spatial dependence, which measures degree of relationship/dependence between near and distant objects (Childs, 2004: 32). There are two categories of interpolation techniques: deterministic and geostatistical. Deterministic interpolation techniques create surfaces based on measured points or mathematical formulas. Methods such as inverse distance weight (IDW) are based on the extent of similarity of cells. (Childs, 2004: 33) It seems essential to say that, in this study for calculating

private green spaces we consider courtyard areas of each parcel. For apartments it include area of all large enclosure garden areas for each block without including little green parts of paths and parking lots.

In the other hand, to assess qualitative data, we used questionnaire. Qualitative analyze in this study seek to understand the residents' mental imagery and performance of green spaces. The statistical population is inhabitants of these three cases. To achieve reliable result, 20 questionnaires randomly distributed between residents.

4. Case Studies

4.1 Shiraz and Its Gardens

Shiraz is center of Fars province and located in south east of Iran. Basically Shiraz soil has great talent for cultivation and growing garden and tree, hence it simply possible to establish garden in the city. It has also countless Kariz (canals) that provide required water (Aryanpour, 1986: 108). In the Achaemenid era, Pars district gardens were worldwide famous, known as the Persian Gardens. Motifs cypress trees carved on the steps of Persepolis represents the gardens and green land of this district in that time (Aryanpour, 1986: 110).

Historians and tourists, who have seen Shiraz in the previous century, quote that, The Shiraz city has always formed by continuous gardens and most of the people lived in these gardens. Chardin, a French traveler, in his travelogue mention that, "What is most remarkable in Shiraz is its Gardens which twenty of them is really unique and has beautiful trees that you never find anything like them. Shiraz at that time surrounded by walls. Beyond these walls gardens were continuing (Figure 3). Tavernier in his travelogue wrote, vast lands of north and west of Shiraz, from hillside to cities walls, covered by gardens and green areas (Aryanpour, 1986: 119-112).

Figure 3: View of Shiraz from the north (Source: travelogue Chardin)

In recent decades, due to the city populating growth, development limits, lack of suitable land for construction, economic issues, the new trends of high-rise buildings, land speculation and particularly reducing, a large number of gardens in and around the city have been deliberately destroyed. Remained gardens mostly are in tow forms of large and small scale Gardens. The large scale gardens are those typically known in the world as Persian Gardens, which are listed and nominated in UNECO's world heritage sites. In addition small part of the Ghasroddasht gardens and wide parks recently constructed. The small ones are those located within heart of small buildings, known as courtyard houses. Herbert and Barabrt Shirley said: "In Shiraz few house didn't have a garden and the garden is liked the forest of tall sycamore and cypress (Aryanpour, 1986: 112).

Figure 4: From left, Tomb of Hafez (Zolfaghari, 2008); Naranjestan_e Qavam Yard; view of ghasroddasht gardens (Farrokhmanesh, 2011)

4.2 Three Residential Areas

In this study we want to analysis three different residential green areas with three different characters (Figure 5 and 6). First is in historical center of Shiraz city, with congested and organic urban texture. Areas of public green space in this texture possess a low footprint. green per capita of public space have been reported 4.3 square meter, however, Within these organic textures, exist courtyards, which can be considered as an urban green texture. Courtyard is the main principle and hart of ancient Shiraz residence (Memarian, 1994: 159). The courtyard houses have a very old history; many cities in the Middle East used this type of housing. Durability of these houses till present represents their functional desirability. These courtyards mostly contain elements such as basins and gardens with trees of sour orange, orange and tangerine. Form of these courtyards provides suitable light and air for residents (Memarian, 1994: 161).

Second case located in northwest of Shiraz in modern and new texture of Maaliabad, with grid base separated texture. These regular houses have independent private yards; contain 40 percent of each parcel areas in one side. Due to elevation policy proposed by the municipal authorities, house of this regen evolving from 1 and 2 stories to apartments with 4 and 5 floors.

Third case is a high rise apartment complex with semi-private green areas. Located also in northwest of Shiraz in modern and new texture of Maaliabad, with equal green public space precipitation as second case.

Figure 5: From left; 1) courtyard houses in historical center; 2) houses with private yard in grid base separated texture; 3) semi-private green areas in high rise apartment complex

Figure 6: From left; 1) courtyard houses in historical texture; 3) semi-private green areas in new texture

5. Result and Discussion

At this stage, we try to analyze private per capita green space, building density and mental imagery of residents about their environments in three samples based on the methodology described above.

To analyze the private per capita green space and building density, we use a system of mapping called Interpolate Map system, using Arc Map software. To do so we need to convert each plot's data including- parcels areas, building areas, yard areas, number of floors, parcels population, private green space per capita and building density- to a specific point within the plot. Then through Spatial Analyst and via IDW method, from various models of interpolation, set private green space per capita as input variables and create green private capitation map (Figure 7). A similar approach applied to calculate the building density (Figure 8). The resulting maps provide set of contour lines that illustrate integrated analysis of the private green spaces per capita and building density distribution in each sample.

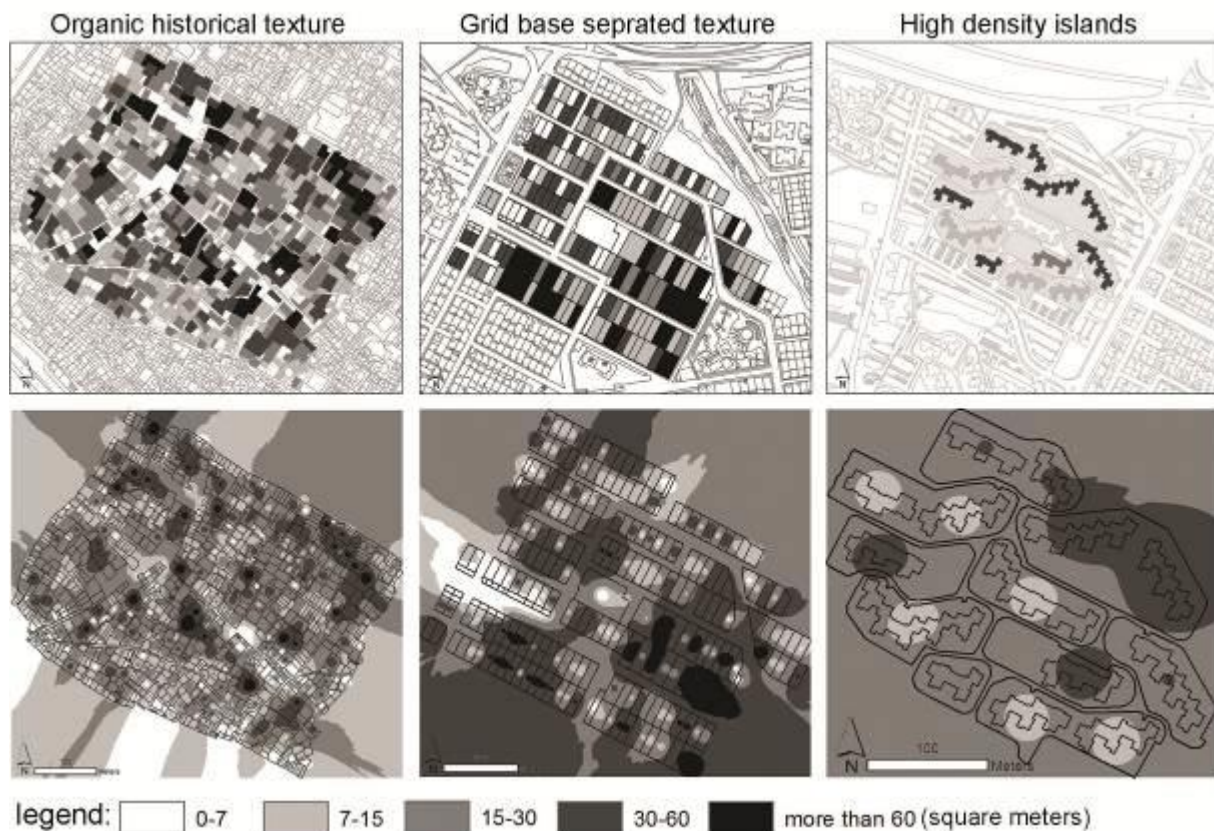

Figure 7: green private and semi-private capitation in three different samples

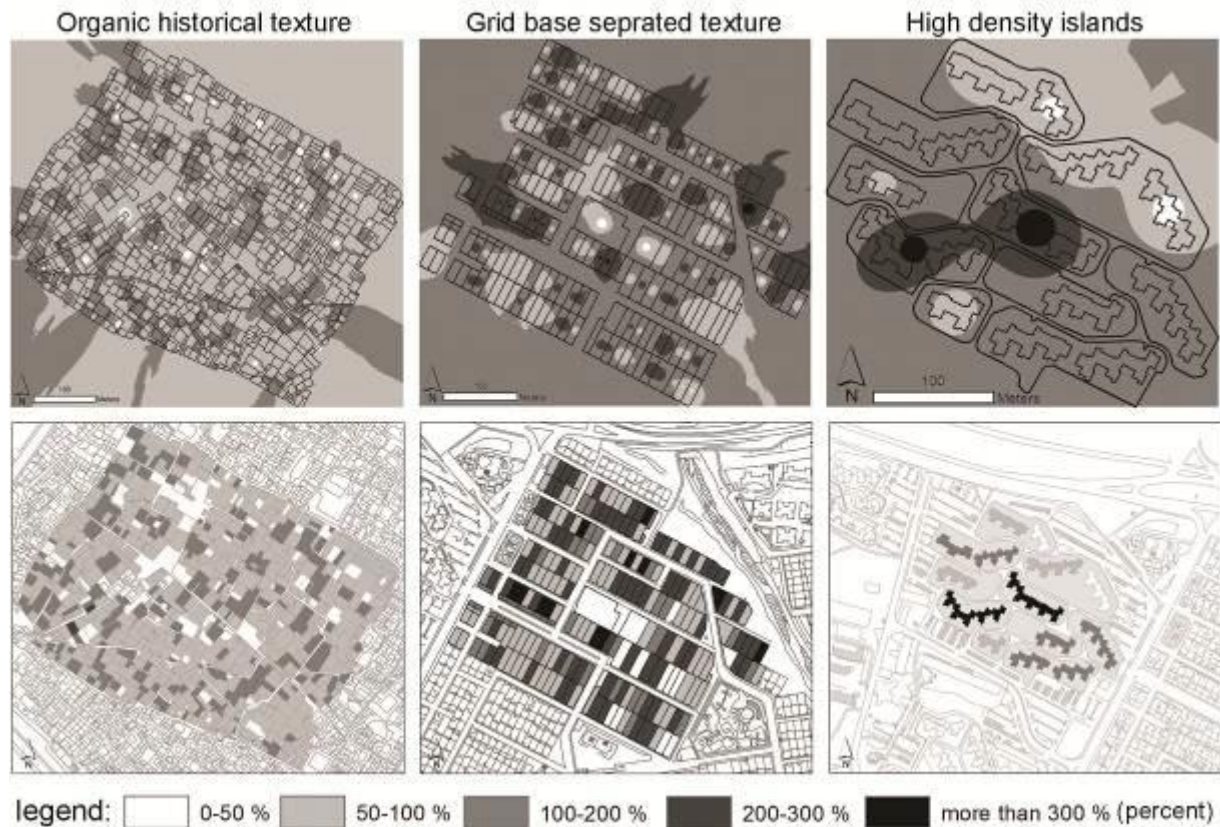

Figure 8: building density in three different samples

Public green space and private gardens capitation show an opposing pattern of occurrence in different cases. Capitation of private gardens in three characters shows that, generally it has highest amount in grid base separated texture, about 20.6 square meters. Historical texture with 15.4 square meters per capita is more than apartments with 11.8 square meters. In general comparing, public green space per capita of new district, obtained by official calculations, is 7 times more than historical district; While private gardens capitation in these two cases is almost equal, and approximately it's higher in historical texture. (Private gardens capitation historical district=15.4 Private gardens capitation new district = 14.8)

Distribution of private gardens capitation in modern district confirms that, it contains concentrate and large zones of the same capitation which irregular pattern. Although in historic district, it contains small zones which change in more harmonious.

The interesting item in comparing building density and green private space capitation is that, building density of modern district has direct impact on private green space per capita. There is approximately an overall reduction in building density while moving from low gardens precipitation to high. However, the building density in the historical district doesn't have specific relationship with private garden per capita. This comparison indicates that in new district by increasing building density and the ratio of growth in population, providing private green space for residents have been neglected (Figure 9 and 10).

In addition, this issue is obvious in compare distribution of building density and green private space capitation in figure 7 and 8.

Figure 9: private green space capitation and building density in modern and new texture

Figure 10: private green space capitation and building density in historical texture

To analyze residents’ mental imagery and performance of green space usage, from these three cases, we discuss about two main questions. The first question is about the amount of private and public green spaces usage, and second is about satisfaction rate allocated to private gardens. Due to, grid base separated texture is in the middle of huge change, from single-unit to apartment type, for better analyze, we have separated the questionnaire results in two individual parts. (Table 2)

Questionnaire results indicate that, the use of private gardens in single-units houses are more than apartments. As well this amount in traditional houses is more than new homes and in the apartment complexes is more than separated apartment. It determined that, although private green space per capita in grid base separated texture have maximum range, form the view of residents private garden performance in the apartment form of this texture is minimum. Due to the specific condition and character of the historical district, there are few public green spaces in that district, so usage of public green space in the modern texture is more and the apartment’s type is further.

While historical district and apartment complexes have near statistical rate of private green space capitation, residents’ satisfaction in historical houses are approximately 2 times more than apartment complexes. Generally the residents of new region often believe that traditional courtyard houses have superior performance than their private and semi-private gardens.

Table 2: result of questionnaire

	public usage		private usage		Rate of satisfaction
	score	percent	score	percent	
historical texture	40	32.26	84	67.74	60
New texture (single-unit)	58	43.94	74	56.06	68
new texture (apartment)	74	71.15	30	28.85	44
Apartment complex	70	62.50	42	37.50	32

6. Conclusion and Recommendation

Issue of green space development considered as an important in sustaining cities. Shiraz green spaces, in addition to enhancing the quality of residents' life by environmental, psychological and aesthetic benefits play an identification role for citizens.

Due to our analysis and assessments carried out and regarding to our research questions finds out that:

GPC of public spaces within new district is about 7 times more than this variable in historical texture, while GPC of private spaces in these two districts are almost equal. Therefore, considering private GPC in addition public capitation, bring more acceptable condition from urban vegetation. We believe to have a better image of GPC in a district we should get credit to private green area, too and current system of calculations GPC dose not reflect the real condition.

Private green space Distribution in new district has a significant relation with building density, while in historical texture, there is not such correlation between these two variables. This proves that, in recent constructions of new district, providing private green spaces has been neglected. While the green areas spaces should be adopted with the area's inhabitants. Our results show that despite increasing in number of building floors, green spaces area has not increased.

Although private GPC in new district and historical district is almost equal, satisfaction rate and performance of gardens in historical district is substantially higher than new district, spatially in compare with high-rise buildings.

In addition, grid base separated texture is in the middle of huge change, from single-unit to apartment type. Satisfaction rate and performance of green private space, in these two types are completely different. While this case has the highest per capita of private and public green space, satisfaction rate of these apartment type is less than half of single-units. In addition to the prior explanations performance of single-units' garden, in this new type has been reduced to parking spaces and skylights. So apartment type of separated texture has the least satisfaction rate and performance of green private space. It seems that by continuing this trend, the quality of this residential environment will be deteriorate substantially.

Residential zones encompass main parts of cites' area and they are growing continuously. Our studies show that crediting private green spaces could have significant impacts on distribution of urban vegetation and hence increasing inhabitants' image of greening.

Finally as grid base separated texture have much more problems comparing with the other two cases to improve the situation we recommend to reduce the buildings occupation ratio to provide following sufficient green space for residents.

Are Cities in Nigeria Keeping up with Challenges for Global Competition?

Precious N. Ede and Opuenebo B. Owei
Institute of Geosciences and Space Technology
Rivers State University of Science and Technology
Npkolu-Oroworukwo, Port Harcourt.

Abstract

Cities all over are regarded as beacons of development due to their immense contributions to national economies. Cities in Nigeria have been growing very rapidly with no commensurate improvements in the rate at which social services and infrastructure are provided; the result is a gradual decline in the quality of life and of the environment. In view of the poor performance of Nigeria and its cities it is pertinent to inquire if cities in the country are keeping up with or are capable of changes that can make them compete globally. It is also germane to explore what role planning can play in the development of cities with authentic Nigerian identity given their peculiar business environment and challenges. This study uses published data to examine impediments to city performance in Nigeria. Where applicable, Nigeria's cities were compared to that elsewhere as to shed light on future opportunities for improvement. Additional insight on the character of urbanization and important militating factors were gathered through interviews with city and local government officials in the country. The top cities where it is most conducive to do business and the least business friendly cities in Nigeria were highlighted. Other findings show 34 improvements when compared to previous surveys of which 13 focused on starting a business, 8 on dealing with construction permits, 10 on registering property, and 3 on enforcing contracts. The major factors militating against competitiveness in Nigeria were listed as infrastructure deficit, corruption, access to finance, policy inconsistency and red tape. Nigeria as Africa's largest market and economy should lead by making its cities more competitive to put the country on a sustainable path to long-run growth. It is advised that institutions, infrastructure, health and primary education need to be prioritised and the predominantly young population's productive capacity leveraged with the necessary skills to engage in higher value-added employment. Cities in Nigeria should imbibe economic strategies in all their activities to foster investment, and city managers should begin to think in global perspective, even where their statutory duties are local.

Key words: Nigerian cities, city investment plan, role of planning.

1.0 Introduction

The litany of issues dogging Nigerian cities presented in Onibokun and Faniran (1995) has hardly changed 20 years on. These are general human and environmental poverty, declining quality of life and the underutilised and absence of some quality of human resources. Housing and associated facilities (such as water, electricity and waste disposal) are grossly inadequate. Millions live in substandard environments such as slums, plagued by squalor and grossly inadequate social services; as a consequence, shortage of schools, poor health facilities and lack of opportunities for recreation among others is experienced. Delinquency and crime thrive due to the gradual decline of traditional social values and the breakdown of family cohesiveness and community spirit. Moreover, the capacity of law enforcement institutions to prevent crime is

increasingly hampered by technological and resource limitations. In many Nigerian cities, the city centres are decaying without programmes of rehabilitation while new urban peripheries develop without planning or the necessary infrastructure. Intra-city mobility is greatly hampered by poor planning and inefficient land use. The urban economy is characterized by low and marginal productivity and high rates of unemployment and underemployment. The low capacity utilization in the industrial sector also continuously worsens the employment-generating capacity of the urban economy. For the small firms it was worse; about 25 per cent of their total value was committed to electricity generation at several times the cost in developed countries. The Manufacturers Association of Nigeria (MAN) in a 2014 study estimated energy cost of manufacturing production as 40 per cent (Adekoya, 2015). The high cost of producing power individually and other infrastructural services are passed on to the consumers in the form of higher prices.

Nigeria is a large and diverse country with contrasts in physical, ethnic and social mix. These complexities are challenges to investment decisions as sub-national differences in business environment, income, education and culture must be considered. As a result of globalisation however cities tend to resemble or imitate one another across regional lines as much as within national milieus. The benefit of this assumption is that cities can be compared with one another without much regard to regional nuances; after all, urbanization flourishes because people seek the security, opportunities and wider economic prospects that cities provide. Lagos is ranked as one of the largest cities in the world and along with Kano is ranked by KPMG (2012) among the 10 largest in Africa. In addition to the two cities, Abuja, Ibadan, Kaduna and Port Harcourt are listed by Hedrick-Wong and Angelopulo (2014) as cities in Nigeria with a population of over 1 million. In contemporary perception of a city's worth, large population alone is inadequate; nevertheless, in most analysis only Lagos among Nigeria's cities features in the international platform. The 2013 Economist magazine ranking included Alexandria, Cairo, Cape Town, Durban, Johannesburg Lagos and Nairobi in its Hot Spots 2025: benchmarking the future competitiveness of cities in Africa. According to The Economist Intelligence Unit (2013), the 120 cities world-wide included in the study were selected based on regional diversity, economic importance and size of population, and Lagos was placed 119 just above the least ranked city. This raises a question on whether Lagos and other cities in Nigeria have any prospects to keep up with challenges for global competition.

Presently there is an academic resurgence in cities because leading cities in the world outperform the country in which they are situated in most economic indices; as a consequence, they play important role in driving regional and national growth. The observations imply that cities need to optimize their resources as they grow. A world in which half of human population live in cities, over 70 per cent of economic outputs and 80 per cent of energy consumption are attributed to cities has prompted ARCADIS (2015) to describe the 21st century as the 'age of the city'. In view of the dismal image of Nigeria and its cities it is pertinent to ask if cities in Nigeria are keeping up with or are capable of changes that can make them compete globally. It is also appropriate to explore the development of cities with authentic Nigerian identity given the peculiar business environment and challenges. What this study espouses is the experience of urbanization in Nigeria in an increasingly global context and the role planning can play to raise its cities profile.

1.1 Study Objectives

Urban hierarchy theories attribute cities with primacy, industry, services and innovation. According to these theories, city size and designation are concomitant to comparative standing within urban hierarchies. The reality is that people are pulled to cities because of the greater

chances cities afford them to fulfil life's dreams. Naturally, those cities that confer better economic and general wellbeing will as well attract the best migrants, be they investors, innovators, leisure seekers or other reasons from within and outside the region. Africa is predicted to claim seven of the world's 10 fastest growing economies by 2015, yet cities in Africa and indeed Nigeria perform poorly in most rankings of world cities. The goal of this study is to review published rankings of Nigeria's city with a view to appraise their performance and outline how planning can be applied to attract investment to them.

The specific objectives of the study are:

- a) To determine the status of Nigerian cities and adduce explanation for their present state as well as what can be implemented to change their fortunes.
- b) Explore outside of city rankings the arguments and perceptions that may impinge on their global reach.
- c) Outline what role planning can play in the development of cities with authentic Nigerian identity given their peculiar business environment and challenges.

2.0 Methodology

This study relies on published information on cities in Nigeria, supplemented with interviews with city and local government officials. The broad data provided by various surveys on cities in Nigeria were used to characterize their prospects. Ultimately, the purpose is to compare Nigerian cities across indices in order to determine their national and regional rankings as well as what they are doing to improve themselves. The World Bank's (2014) publication by far presents the most extensive sub-national data as it covers major business cities in 35 of the 36 states in Nigeria and the Federal Capital Territory (FCT) of Abuja. The data from this document form the principal source relied on to examine cities in Nigeria as to their preparedness not only to do business, but what improvements they are embracing when compared to previous publications on the subject and rankings by other organizations that may be applicable. The 2014 version of the document compares federal and state business regulations that affect four stages in the life of a small to medium-size domestic firm: starting a business, dealing with construction permits, registering property, and enforcing contracts. The report also compares gender-specific employment data from the main public agencies in charge of administering the benchmarked areas: land registries, building authorities and Corporate Affairs Commission branches in each state. The purpose of the World Bank (2014) study was not to literally rank Nigeria's cities but compare them among themselves and with other leading cities across the world. In this study the World Bank scores have been aggregated for each of the territories of Nigeria; samples from each of the leading commercial city of the state was used to produce a grading of business friendly order.

3.0 Results and Discussion

The top ten cities where it is most conducive to do business in Nigeria were Aba, Owerri, Onitsha, Abakaliki, Uyo, Lagos, Enugu, Port-Harcourt, Yola and Warri. The scores for each of these cities ranged between the highest – Aba (127) to Warri (93). Ten least business friendly cities in Nigeria from bottom are Katsina, Bauchi, Dutse, Gusau, Birnin Kebbi, Minna, Gombe, Damaturu, Lokoja and Ilorin (see Figure 1). Politically, Nigeria is divided into six geo-political zones or region and a region may comprise between five to seven states (Figure 2). Every state in the South-east of Nigeria had a city among the top ten places and the best four cities in which

to do business in the country were in the zone. The next region with the most cities in the top ten was the South-south with 3 cities. The South-west and the entire north (of 3 geo-political zones) had only one city each in the top ten. The key findings of World Bank (2014) report recorded 34 improvements, of which 13 focused on starting a business, 8 on dealing with construction permits, 10 on registering property, and 3 on enforcing contracts. The cities of Calabar, Ado Ekiti, Minna, Abeokuta, and Port Harcourt made the biggest strides towards the national frontier of good practices since 2010 (Capaul and Papahagi, 2014). While most reform efforts focused on reducing the complexity and cost of regulatory processes, several cities also focused on longer-term judicial reforms to strengthen the legal institutions for contract enforcement.

Figure 1: City Ranking on Ease of Doing Business (Data: World Bank, 2014)

Despite improvements, the World Bank (2014) notes that challenges persist: no single state or city ranks at the top in all the areas monitored. Sharing local best practices and coordinating better between federal and state governments are critical to improving the business environment for all Nigerians. The 2014 Doing Business in Nigeria compared to four years earlier recorded reforms that make it easier to start a business: 13 states introduced reforms improving the internal processes of federal or state agencies, such as the Corporate Affairs Commission and state ministries of commerce. Less burdensome requirements and faster approvals of construction permits, as in Yola and Dutse, would make Nigeria one of the best performers in this area, which is more efficient than the OECD average of 13 procedures and 147 days. Uneven implementation of federal legislation and differences in state fees drive the large variation in the cost to register property from 7 per cent of the property value in Damaturu to 26.4 per cent in Benin City. Katsina remains the easiest place to enforce a contract within Nigeria: resolving a standardised commercial dispute takes 314 days and 41 procedures and costs 26 per cent of the claim value. Overall, it is easier to deal with construction permits in Jigawa and Sokoto; register property in Zamfara and Gombe; enforce a contract in Katsina and Kaduna and start a business in Abuja, FCT and Zamfara.

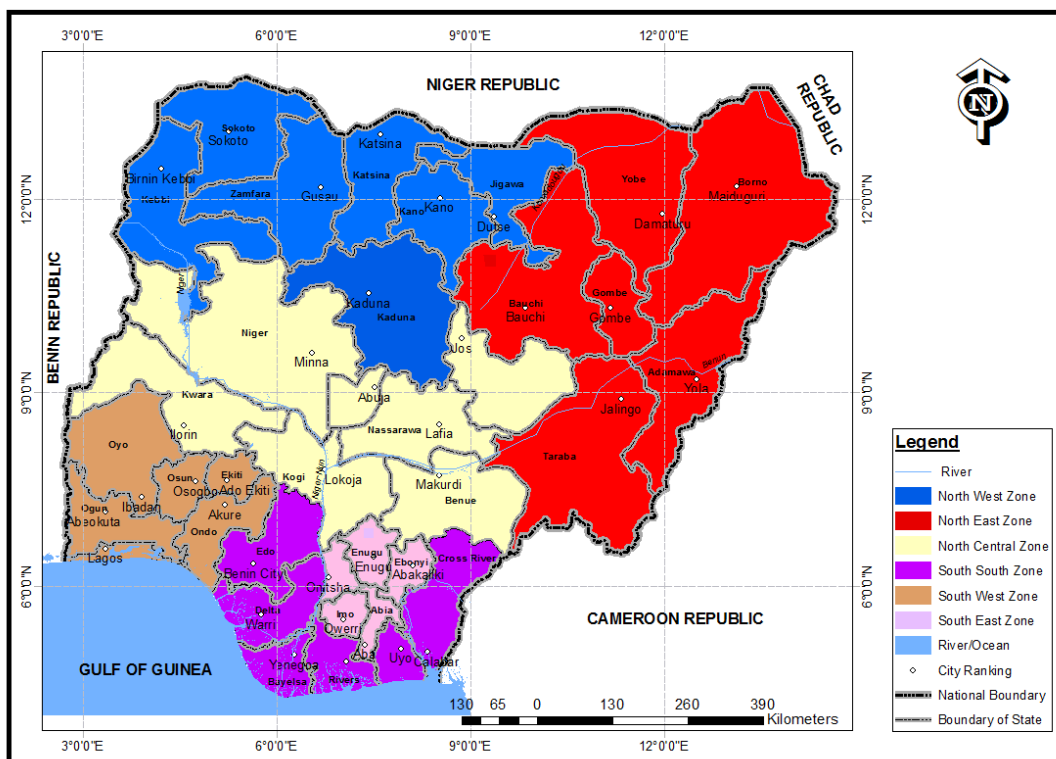

Figure 2: Nigeria's Geo-political Zones and Cities in the Study

4.0 Cities' Ranking and the Implications

In the last ten years many organizations have ranked cities and national economies according to an assortment of criteria like GDP per capita, infrastructure and productivity. Florida (2015) synthesised five of these rankings to collate a table of 25 most economically powerful cities in the world, but no African city made the list. Florida's list was dominated by cities in North America, Europe, East Asia and Australia. While regions like Latin America, Africa, Middle East

and South Asia were conspicuously absent. The outcome of Florida's synthesis of the world's most economically powerful cities raises some questions because cities in those economies that did not make the list, such as, Mexico City, Sao Paulo, Buenos Aries, Lagos, Cairo, Johannesburg, Dubai, Mumbai and Delhi have clear visibility. Some of these cities are ostensibly destinations of foreign direct investment (FDI) (see World Bank (2014a) and therefore difficult to ignore as economic powerhouses among cities of the world. In spite of these reservations, there is a lure to narrow Florida's approach to Africa and Nigeria, because available data affords us the opportunity to do so. Nigerian cities featured in other city rankings such as those by MasterCard and AT Kearney (2014) for Africa includes Lagos, Abuja, Port Harcourt, Kaduna, Kano and Ibadan. Only Lagos (6) and Port Harcourt (8) are among the top ten; the position of the others were: Kano (11), Ibadan (13), Kaduna (21) and Abuja (26). Nigerian cities' relative position in the Africa City Growth Index (ACGI) published by MasterCard (Hedrick-Wong and Angelopulo, 2014) is presented in Table 1.

Table 1: Ranking of Nigeria's Cities in MasterCard's ACGI

<i>City</i>	<i>Rank in Africa</i>	<i>Category</i>
Lagos	6	Medium high growth
Abuja	9	Medium low growth
Port Harcourt	16	"
Ibadan	25	"
Kaduna	26	"
Kano	31	"

Source: Hedrick-Wong Angelopulo (2014).

The ACGI assesses the growth potential of Africa's most important cities. It provides internal and external perspective of current and future growth. This is indicative of potential profitability of investment for African cities.

Although in one of the variables used by FDI (2015) Nigeria ranked 10th under mega cities cost effectiveness due largely to low wage bill, taxation and energy cost; Nigerian cities rank among the most expensive in the world, and in Africa Abuja ranks second and Lagos 4th (The Economist Intelligent Unit, 2013). One of the reasons for the situation is infrastructure deficit, particularly power supply. Assuaging the power supply needs of Nigeria alone can improve economic output and livelihood in the short-term. At the present, power supply from the national grid last for only a few hours daily in all cities, and even this epileptic rate is not guaranteed. Despite these drawbacks, Nigerian cities especially Lagos and Abuja according to the Economist are among African cities with the best opportunities for growth in the near future. In recent years, annual economic growth for the country hovered around 7 per cent, although low crude oil prices is expected to ditch growth to 5 per cent in 2015. If this GDP scorecard was achieved under deplorable infrastructure, improvements will portend even better growth. In this scenario, two factors will help in revitalising Nigerian cities: rising income per capita and lower cost of doing business.

Urban ranking processes do not pretend to practice urban economics, therefore only a deliberate infusion of physical planning can leverage the process to grow a city. Urban master plans in Nigeria do not emphasize significant economic variables; for instance, the four volumes that comprise the Greater Port Harcourt Master Plan, 2008 have titles on transportation, water management, social infrastructure and energy, but nothing on economic plan. No city among

those surveyed in this study has an economic unit and none too regularly stages tradeshows. Cities like Lagos, Abuja, Port Harcourt and Kaduna host annual trade fairs, but these are at the discretion of firms, jointly under the various chambers of commerce and industry. No city consciously participates in the fairs with the intension of promoting itself among participating businesses. City administrations ought to take advantage of these expos to lure investors by initially establishing commercial desks within the proposed economic units linked to investment agencies and firms. Unequivocal assurances should be given to institutional investors for both green-field and brown-field developments – long-term infrastructure for sectors such as transportation and water supply. Through appropriate pricing of land and land rights, consolidation of revenue channels to eliminate multiple taxation and outright tax breaks in the early years of a business are perfect economic incentives that cities in Nigeria can use to attract investment. If city planners realise this and incorporate incentives for investors, potentially such a city will be positioned to reap bountifully. It is therefore in the interest of urban and regional planning process to set the stage and mobilise innate endowments for business growth. This can be achieved by concurrently adapting national policies on FDI at the city level. Exploiting this same window, cities enhance their special attributes based on the specific needs of prospective investors and by identifying local assets that promote investment, the process is brought within the ambit of city planning. City investment plans and portfolios should be a prerequisite of urban master plans in Nigeria if it has to attain positive city ratings.

There are no overt FDI plans in most of the leading cities identified by 2014 Doing Business in Nigeria. In this study we argue that firms and cities in Nigeria should begin to develop frameworks for external exposure, which is the best way to achieve long-time survival and global competitiveness. Physical planning in Nigeria has to include the needs of industrial parks, agglomeration economic principles, and specific comparative and locational advantages into the various plan categories. The instrumentality of planning can also be used to galvanize assets and local capacities to showcase on a common platform provided by city plans. For the benefit of the firm, a copious strategy should be devised in city plans to foster investment. When cities package their viability through planning; investors will take notice and do business in them. Cost of doing business, such as wages, taxes, industrial relations and security though not easy to incorporate into physical planning can become legislative agenda for municipal authorities. Notwithstanding, some studies found no correlation between cost of doing business and FDI (PSRC, 2009). City plans with existing clusters of services and industrial parks, such as Port Harcourt (Trans Amadi), Lagos (Oshodi), Enugu (Emene), Calabar (Tinapa) and Agbara in Ogun are examples in Nigeria where FDI can latch onto should they be upgraded. In one of the critical areas, The Economist Intelligence Unit (2015) cited how Lagos State has established a security trust fund thereby shifting the focus from policing to a broader community response. In addition, a public-private partnership is being used to mobilize resources to fund and manage urban infrastructure in Lagos.

So what makes business tick in Aba more than other cities in Nigeria and what factors besides ease of starting business, getting permits, property registration and enforcing contract are culpable? The common denominator in the responses was that there is minimal government intervention in the affairs of small and medium enterprises in that city. Regulations and renewal of relevant and operational permits and taxes are not rigorously enforced as a result revenues accruing to government from the city do not match expectations. In a rather malicious twist, urban infrastructure is neglected by government, even though everywhere, businesses seek perpetual tax break. In very large cities like Lagos what is observed in Aba is seen in sectors of the city where informal businesses subsist – those areas of the city lack basic amenities compared to the main business districts for many reasons; in addition, such areas lack critical

political and economic muscle to effect change. On the positive side, apprenticeship, mentorship and improvisation are very strong in Nigerian cities ranked highly and that reduces business mortality. Aba which was ranked 1st by the World Bank (2014) has a very good business reputation, but it lags in many other indices like crime, infrastructure, environment and liveability. Even the businesses carried on in Aba are predominantly informal, micro-scale and are difficult to monitor and measure. Aba does not merely suffer from poor infrastructure, but also from long neglect of whatever little infrastructure that existed and failure by successive state and local governments to initiate new ones. This description though applicable to some other cities in Nigeria, irrespective of ranking is stark for Aba, hence, the disengagement between published rankings and reality.

4.1 Urban Governance Issues

Urban management in Nigeria is conducted under the local government system and the governance issues inherent are rooted in statutes that impede business development. The earliest urban planning law in Nigeria was the 1917 Township Ordinance. The objective of the law was to classify Nigeria's cities into first, second and third class order based mainly on their national, regional and district administrative roles. The 1917 law distorted the pre-colonial hierarchy because it contrasted with other attributes such as prior commercial status, cultural and traditional standing among existing cities. In 1946 the Town and Country Planning Ordinance was promulgated, but it only emphasised development control and sanitation. These colonial laws were superseded in 1992 by the Urban and Regional Planning Act repudiated by the courts because by the structure of the Nigerian state; the federal cannot constitutionally legislate on residual matters. The 1946 law with all its shortcomings is the basis of city planning in the country. The superimposition of the local government administration on Nigeria's urban centres created a multiplicity of jurisdictions within large urban areas, especially those with over one million people. The only city in the country that is spared of this debilitating structure is the Federal Capital territory of Abuja, whose special municipal status was guaranteed in the constitution. Lacking in single municipal system of government, large cities in Nigeria are weakened and cannot galvanise citywide effort for resource mobilisation and planning. The jurisdictional gap has prompted state governments to intervene in the provision of critical infrastructure and services, such as roads and sanitation.

Issues of fragmented administrative units within municipalities can be tackled with the example of Greater Port Harcourt. Port Harcourt's municipal plan of 2008 span eight local government areas and is being implemented by a Greater Port Harcourt City Development Authority, under the auspices of the Rivers State government. In the absence of adequate legal structure for urban governance, the example of Port Harcourt is advisable as a model to other cities in Nigeria. With some framework in place, cities should begin to promote local economic plans at the level of municipal administration. It is however observed that if the leading business city in a state is not the state capital, as in the case of Onitsha (Anambra State) and Aba (Abia State), they suffer neglect due to resource constraints of the state or distance from the capital.

4.2 Authentic Nigerian Cities

Historically, urbanization in Nigeria predates the advent of Europeans, equated with colonial periods because cities like Bonny, Benin City, Ibadan, Kano and Zaria had prior international exposure across the Atlantic and the Sahara, which colonialism from the 19th century did much to curtail. These pre-colonial cities grew on trade and commerce and their spatial layout had rudiments of planning with measures for development control (Metz, 1991; NITP, 2014). Principles such as "competiveness" and "doing business", contained in recent city rankings are

therefore not alien to the character of cities in Nigeria. In fact, cities like Aba, Onitsha and Lagos that are currently ranked highly within Nigeria have visible competitive spirit among businesses.

In this study, we have identified how cities in Nigeria can attract FDI, but the process may increase inequality. Watson (2014) warns that African cities that concertedly promote business risk unduly imitating cities elsewhere, while ignoring the overwhelming poverty of majority of its population. An authentic Nigerian city should look beyond improving investment climate by addressing the needs of the residents, especially those likely to be side-lined by the influx of FDI because of their lack of skills and expropriation of existing jobs through mechanization and digitization. All over Africa there are proposals for tech savvy neighbourhood developments called smart cities, but such developments will further alienate the urban poor, isolate traditional sectors of the city and engender polarisation instead of inclusiveness. According to (Adepetun, 2015) such smart cities have been proposed for Lagos and Abuja, ostensibly to anchor local technology firms to smartly invest and position for global competition. The UN-HABITAT (2012) advises that it is proper to organise a city in such a way that economic growth benefits a greater number of people; else those deprived become a nuisance. The case for social progress measurement has already been made by Porter *et al.* (2014) as a way for countries to assess the proportion of their population that benefit from changes in economic fortunes, such as gross domestic product (GDP). Nigerian cities focusing on attracting FDI as an option for growth should include social and environmentally desirable goals at local levels in their framework as well. Urban growth in Nigeria leap-frog while planners dare to catch-up, a process well exemplified in the study by Owei *et al.* (2008) for Abuja and Port Harcourt in what was termed "Scatterization". Nigeria's city planners will have to be proactive in order to make their input in a rapidly evolving cityscape meaningful.

6.0 Conclusions

The major factors militating against competitiveness in Nigeria were listed by Schwab (2014) as infrastructure deficit, corruption, access to finance, policy instability and red tape. Nollen (2011) outlines the most frequently occurring features of the most competitive cities as good human capital, well-functioning markets and institutions, good infrastructure, and good government. Nigeria as Africa's largest market and economy should lead by making its cities more competitive to place the country on a sustainable path to long-run growth and competitiveness. The predominantly young population's productive capacity must be harnessed with necessary skills to engage in higher value-added employment. Until amicable resolution is found for issues of fragmented administrative units within municipalities, the example of Greater Port Harcourt may serve other cities in Nigeria. A firm scanning for a city in which to locate has to examine the positive features of a city in relation to the firm's goal, brand disposition and costs. In this sense a city's relationship with the firms it host and the potential to attract more businesses is synergistic and amenable to planning. Just as firms nurture values, cities should cultivate brands around themselves and plan to grow their brand values as well; that way cities create niches that stand them out. It is in the interest of urban and regional planning process to set the stage and mobilise innate endowments for business growth. This can be achieved by concurrently adapting national policies on FDI at the city level. Exploiting this same window, cities enhance their special attributes based on the specific needs of prospective investors and by identifying local assets that promote investment, the process is brought within the ambit of city planning. City investment plans and portfolios should be a prerequisite of urban master plans in Nigeria if it has to attain positive city ratings.

Dimensions of urban waterfront regeneration: Case study of Halic / The Golden Horn

- an assessment of obstacles and opportunities for inclusiveness

Serin GEAMBAZU, Ion Mincu University of Architecture and Urban Planning, Bucharest,
Romania

1. Introduction: a concern about heterodox socio-spatial configurations in global cities

The spread of neo-liberal political and economic ideology and the proliferation of global capital have created new opportunities and challenges for cities everywhere, especially in the so called "global cities". Over the last decades, many cities worldwide have promoted urban waterfront regeneration for a variety of reasons building on the particular scenery of these sites. The success of the first well known urban waterfront regeneration project, Baltimore Inner Harbor regeneration (1960), has served as a prototype for cities around the world with the desire to position themselves in the race to become Global Cities (Harvey 1989) by providing strategically located high-quality investment opportunities to attract global capital, or by constructing attractive spaces to promote tourism and leisure. Nowadays, almost every city at water's edge is engaged in regeneration projects with strong political impetuses and interest from various parties: authorities, developers and neighboring communities (Hoyle 2001). These developments have been critically examined by many scholars, many of which share the belief that urban waterfront regeneration is often not addressing the underlying, deep-rooted problems of the cities and furthermore, ignoring the socially and economically unstable landscapes in which they often occur, veritably contributing to the escalation of inequality, polarization and deprivation in the city (Harvey 1989; 2005; Brownill 1990; Gordon 1997b; Hoyle 2000; Saarinen and Kumpulainen 2005; Butler 2007; Healey 1997; Gordon 1997a, 1997b; Feldman 1999; Fainstein 2001; Granath 2005; Butler 2007).

It is generally assumed that globalization leads to the same type of transformations and urban development trends everywhere in the world. However, it cannot create a certain prototype for spatial development or a new spatial order for cities. Rather, it gives a variety of spatial patterns, also called "global urban forms". This standardization (or 'nothingization', as Ritzer calls it) takes place in many aspects of urban life of global cities everywhere and destroys what is there most alive, the identity and socio-economical constructions of the place. Furthermore, what Relph (1976) and Augé (1995) advice within the popular terminologies of non-places and settings of placelessness is about the construction of spaces which are produced and have their identity extremely embedded in the market dynamics. Places on where the lack of authenticity with community non-involvement in the construction of the setting has become a normal issue.

The article is studying urban waterfront regeneration as a complex urban intervention, specifically its special governance, resistance and impacts on the neighboring tissue, which could be considered a prism through which broader societal transformation processes and related planning challenges can be understood. The case brought forward is the recent

urban waterfront regeneration along Halic/ The Golden Horn, in Istanbul, Turkey. For the scope of this study, the empirical research gathered both primary and secondary data through: literature review, review of laws, review of official documents and land-use plans, articles from media, 31 interviews with stakeholders, 91 questionnaires (with the community and planning practitioners), participatory- observation, workshops, observation and photographs and an internship made by the author at Istanbul Metropolitan Planning office during the field-research in Istanbul.

2. Urban waterfront regeneration in Istanbul: Halic/ The Golden Horn

2.1 Context: planning in global Istanbul and dynamics of urban regeneration

Since the 1980s in Turkey's milieu, national policy intended to make Istanbul the focal point of a neo-liberal strategy approach to integrate the Turkish economy with global markets. This was visible also in the accelerating transformation of urban space, making it the showcase of the country's new era of internationalism (Enlil 2011; Uzun 2010, Çınar, C et al, 2006; İnalÇekiç and Gezici, 2005; Keyder, 2005; Karadag, 2010).

Under this context, during the last thirty five years, investments have been located within the city in order to change the local landscape pushing it towards the global city image. Therefore, the city has been expanding with multiple mega-projects and naturally, a strong representative symbol of the global, emerged: *waterfront regenerations* in the valuable "soft" space of inner city usually modifying natural coast profiles.

These territorial changes have been not only modifying natural structures, they have generated such a special urban form by the transformation or even replacement of the original communities and their identities. Behind the consolidation of new waterfronts, local populations are experiencing struggles and contradictory emigrational patterns in the inner city; dynamics that have been usually explained by secondary data, statics and within many articles uniquely pointing on the production of *geçekondus*. However, it is still not evaluated what happened in those spaces where is a coexistence of new migrants moving to the developments and local populations that are being affected by market dynamics.

In order to understand the planning processes of the regeneration of Halic's waterfront, a reflection is done upon the peculiarities of Istanbul's urban regeneration policies and the institutional framework at city and national level that have facilitated it. Urban regeneration is steered as a tool for development within a special legal framework (Law of Conservation-Law No. 2863) and while the purpose of the projects seem to be in the name of upgrading the built environment and improving the living conditions of the poor, the top-down approach, reduce the projects to just transformation of physical space and neglecting the social, economic and environmental dimensions, which along with the unwillingness of government to allow grassroots participation in the planning process become the focus of discontent and protest.

2.2 Halic/ The Golden Horn: a fragmented waterfront

Halic, a 7,5 km bay of the Bosphorus strait and the cradle of settlement since the birth of the city, is heavily industrialized and contaminated in the 1970s and since then experiences a long process of transformation along its waterfront.

In line with popular North- Western examples of urban waterfront regeneration at that time, this process is triggered by Mayor Dalan in 1983, who famously stated his mission: „*The water of the Halic will be as blue as my eyes*” (*Radikal Newspaper*). The project is sponsored by World Bank and the industrial waterfront is transformed into a huge vacant land which becomes large green park areas (Enlil 2011). Behind the environmental concerns, there was also an economic motivation to bring Istanbul between the competitive global cities with a vision of a "Cultural Valley". The following forced de-industrialization process of the 1980s is impressive and did indeed improve Halic from an environmental perspective, but the clearing process was pursued with a heavy-handed, top-down governmental approach to planning and the legacy of mayor Dalan is contested among academia, civil society, non-governmental organization and experts in planning: The project created an approximately 50m wide strip of vacant land– a great opportunity in terms of offering open green spaces for the city- but destroyed 100 Ottoman-era buildings and an additional 30,000 structures, displaced neighborhoods within 50-100 m along the shoreline (Köksal 1996, 2005; Yerliyurt 2008; Bezmez 2008) and most importantly brought mass unemployment and poverty in the backstage neighborhoods populated by former dock and shipyard workers (Köksal 2005; Bezmez 2008; Yeliyurt 2008; Enlil 2011).

The following initiatives to regenerate Halic's waterfront showed no intention of resolving the social and economic burning issues of the neighboring communities. Within the same top-down planning approach, as in the 80's clearance intervention, urban waterfront regeneration projects are ad-hoc initiative of different bodies of the government depending on ownership and planning rights over the land. Therefore within privileged legal means facilitated by different governmental bodies and by a national policy on urban, developments for middle-high income citizens are created: "*With empty convention centers in the middle of poor neighborhoods, a few art galleries right beside demolished historic buildings, and newly built museums next to squatter housing*". (Bezmez 2008 pp. 817).

Although the attempts to transform Halic with the vision of a "Cultural Valley Project" are not different from other urban waterfront regeneration projects around the world, in terms of process, they can't be explained through just one clear framework of public-private partnerships, intense processes of urban entrepreneurialism or gentrification as other classical North-Western examples. As a response to this regime of urban regeneration (Dincer 2011a; Dincer 2011b) urban social movements are formalized in Neighbourhood Associations or non-governmental organization taking an active role in the planning process.(Kerimoglu and Gezici 2010; Dincer- 2011b;Bezmez 2008)

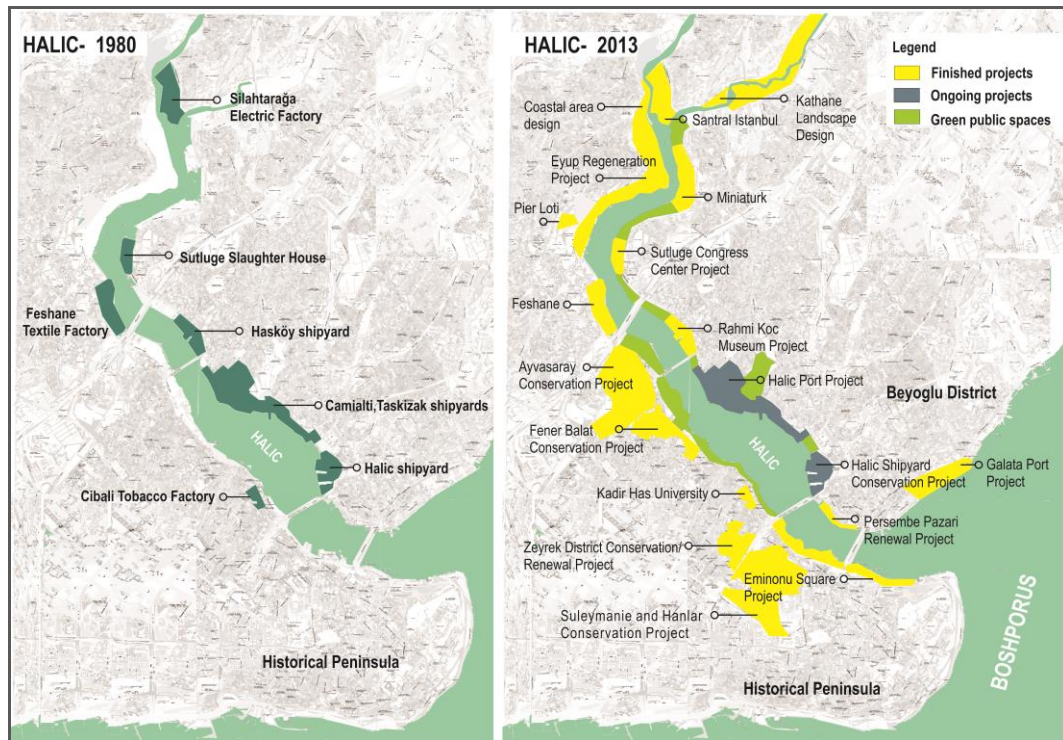

Figure 1: Change of Halic's waterfront from 1980s until 2013

2.3 Decision making process: latest urban waterfront development along Halic/ The Golden Horn

Social justice has the dimension of a process rather than an outcome and therefore the planning process is of a particular importance to portray "governance of place" (Healey 2003). "The extent to which opportunities for participation are picked up in reality is an important indicator of balancing interests, even though is primarily the privileged, most articulate and directly concerned elements of society that attempt to participate in public decision-making processes". (Heinrich and Nuisl 2011)

This sub-chapter is an overview on the decision-making process for the urban waterfront regeneration of Halic Shipyards (Tersane-i Amire Arsenal), the latest urban waterfront regeneration development along Halic.: a first attempt in regenerating Halic Shipyards is presented, followed by the current state, two urban waterfront regeneration projects in on-going process of transformation. These urban waterfront regeneration projects are: Halic Shipyard Conservation Project (Haliç Tersanesi Rölöve, Restitüsyon, Restorasyon, Yeni Kullanım ve Peyzaj Projesi) in the area of Halic shipyard and Halic Port Project (Halic Yat Limani Projesi) in the area of Camialti and Taskizak shipyards.

The first attempt to officially create a plan to regenerate the area of Halic, Camialti and Taskizak shipyards is in 2011, when all three shipyards come under the authority of Istanbul Metropolitan Municipality (IMM). The final goal is to create a comprehensive urban regeneration project and reconnect Beyoglu district with its waterfront along the Halic.

Being declared as a Conservation Area, the development is managed by the Department of Historic Environment Protection (DHEP, in Turkish Tarihi Çevre Koruma Mudurlugu is the representative body of Istanbul Metropolitan Municipality in the areas declared for conservation. It is empowered by the Decision No. 313 in 04/06/1999 and has a management

role within the project, making sure that the project it is accomplished in line with the requirements of the Law of Conservation), which focuses on the restoration of the historical buildings on the site and change of the current functions in new ones according to the needs of the citizens. DHEP designates through a bid the task of making and designing the plans to Istanbul Metropolitan Planning (IMP- Bimtas S.A., is a semi-private company and also a research center for Istanbul Metropolitan Municipality. It has long lasting collaborations with academia, neighborhood associations and wide experience in planning in Istanbul, being also it is the company that made the last Master plan of Istanbul 2009 and many other important development projects).

In line with the requirements of the Law of Conservation, the Conservation Board No. II is added to the decision-making process. This Board is linked directly and represents the interest of the Ministry of Culture and Tourism, has great power on the project's outcomes, evaluating the plans and being able to cancel them.

The plans done for a preliminary project (in Turkish "avan proje") start on January 2011 and finish in June 2011, but without any request for participation from the citizens side and no reflection on the surrounding neighborhoods. The proposed functions for the area are: cultural, recreational, social services and commerce functions and are approved by the Conservation Board No. II in July 2012. The next step in planning process after the preliminary project, according to Main Law of Construction (Law No.3194), is the implementation project (in Turkish: "uygulama projesi") which did not continue with all three shipyards. Here a shift in the governance forms of the project changes the planning process along with rising concern on the project's future outcomes: just one of the shipyards went further to the implementation phase under the name of Halic Shipyard Conservation Project, when the area of the other two shipyards is being privatized. Holding the ownership of the land of Camialti and Taskizak shipyards, the Ministry of Transport Maritime Affairs and Communications (MTMAC) decides to withdraw the project from the authority of IMM.

In 2013, a new urban waterfront regeneration project is declared for privatization and classified by the Prime-minister Tayyip Erdoğan as: "*miraculous project*" ("muhteşem proje") which appears with the name: Halic Port Project. The urban waterfront regeneration project is initiated by the MTMAC, under the Law of Privatization, known as Built Operate and Transfer (Yap Islet Devret- Law. No. 3996) and is approved by Higher Council of Privatization (HCP); this also being possible because, according to the Law of Privatization, since 1994, the authority to make and approve plans concerning estates included in the privatization program was transferred from local authorities to the HCP.

The area is given to auction and is announced in the Official Paper (Resmi Gazete, page 28646) on 13 May 2013. The tender is taken on 2 July 2013 by "Sembol International Investment", "Ekopark Tourism" and "Fine Otelcilik Girişim Group"(Sembol Uluslararası Yatırım-Ekopark Turizm-Fine Otelcilik Girişim Grubu) for 49 years: 4 years for building and 45 years for usage. The requirements of the project are given beforehand to the investors, being decided by the MTMAC and approved by the HPC. These are: "*two yacht ports, two five stars hotels, small shops, offices, museums, culture and a congress center*" Taking into account these foreseen outcomes of the project, it can be argued that this development is not designed for the interest of all citizens of Istanbul or the neighboring community, but rather for tourists and high-middle income class. The promised outcomes of the project are presented in the media through the political discourse as the only information channel for citizens and therefore raised a big wave of criticism from academia and other expert's side, questioning the way decision is being taken.

Therefore, the planning process is lacking transparency and the Privatization Law gives central government power to privatize public land without any consideration of the civil society. Also local municipality has been taken out from the planning process and also the

1/1.000 plans that should be done for the Camialti and Taskizak shipyards are developed by the private investor, this raising questions concerning the conservation of the shipyards.: The only actor from the government side having decision power over the outcomes of this project remains the Conservation Board No.II.

In contrast, the area of Halic shipyard is developed further by IMM within the Halic Shipyard Conservation Project. Major actors in the planning process here are: IMM, the initiator of the project, owner of the land and also the provider of the finance in realizing it; the DHEP managing the project, having mainly the responsibility to assure the conservation and restoration of the historical monuments in the area; the Conservation Board No. II, representative of Ministry of Culture and Tourism, having also the main responsibility to assure the conservation and restoration of the monuments; IMP in charge of the plans and design of the project and also IDO (Sehir Hatlari) - a private company of public transport on water, having currently the tender over the area of Halic shipyard.

In the interviews with representatives from the planning department of IMP, the team planning Halic Shipyard Conservation Project, it is revealed that the outcomes of the project will take into consideration the previous suggestions and that the project will respect the 1/1000 Plans of Beyoglu in terms of conservation of the shipyards, along with the recommendations of implementing cultural and recreational activities. Moreover creation of green spaces is emphasized, the vision being to open the waterfront for the broad public, the citizens of Istanbul. Proposed strategies concerning the development are: *"conservation of the buildings, enhancing the transportation in the area, introduction of recreational and exposition areas, bringing the city to the waterfront, protection of green spaces and ensure the participation of the local people of the area."*

However, the project contains no analysis of impact assessment such as: environmental, economic or social, this showing the physical focus of urban waterfront regeneration in planning, putting in doubt the success and purpose of this project. There is also no information provided for the broader public about the project or the request for any collaboration from the citizen's side. The chance to challenge decision making is possible at the end of the project. As all projects made by municipality, also this one is presented to the community at the end of the planning process, plans are hanged in the Istanbul Metropolitan Municipality building and within 30 days the interested parties have the right to contest the project through court. This leads to questioning the outcomes of the project because of this type of non-transparent planning process that leaves no input from the citizen's perspective.

Therefore, as seen and criticized in other examples of projects along the Halic, the project could also potentially enhance existing socio-economic problems, a matter that will be presented in the following part of the article, by analyzing the neighboring community in rapport to the project.

Looking at the current state of the transformation of the three shipyards, there are two urban waterfront regeneration projects with different governance forms. The area of Camialti and Taskizak shipyards is under the authority of a private investor and it can be argued if the project will benefit the broader public of Istanbul. The area of Halic shipyard remained under the authority of the government, but the planning process is un-transparent and the project is not shared or questioned within the interested public. In an attempt to compare the projects from the perspective of the information available, paradoxically, the Halic Port Project is much more known by the public than the project made by the municipality because of the exposure in the media. However there is a major gap of good quality information for citizens regarding both projects.

This was reflected in the questioners conducted with the neighboring community, academia, planners from Istanbul Metropolitan Planning and citizens participating to forums organized

by the representatives of the resistance to the regeneration of the shipyards. An urban social movement appeared on 23 August 2013 under the name of Halic Resistance (Halic Dayansimasi). Other opposing parties are: Bedrettin Neighborhood Association, Chamber of Architects, Chamber of Urban Planners, Assembly of Architects and Engineers, Chamber of Shipbuilding Engineers, Academia and other urban social movements.

2.4 The struggle of the neighboring community: Bedrettin Neighborhood

This part presents the evaluation of the urban waterfront regeneration projects, considering the impact on the neighboring community. Bedrettin Neighborhood is chosen for analysis because it is one of the closest communities next to the shipyards, also being the first group of actors impacted or that could benefit from the transformation.

Bedrettin Neighborhood is a low income neighborhood (according to median monthly household income 2010) at the shores of Halic, in Beyoglu District. It was strongly connected to Halic, Camialti and Taskizak shipyards, being occupied by blue collar workers. Therefore, the neighborhood was much affected by the clearance process done by mayor Dalan in 1983, the first regeneration along Halic, its current problematic economic condition being outcome of the forced deindustrialization process of that time. Today, approximately 1500 people live in Bedrettin Neighborhood and are mostly divided as retired workers from the shipyards, people coming from Anatolian side of Turkey during the industrialization period and a considerable group of roma minorities.

Based on the interviews with the "muhtar" (mayor of neighborhood) of Bedrettin Neighborhood, the questioners realized with the community and the personal observations on site, is found that the neighborhood is in on-going transformation due to several reasons. First, Bedrettin Neighborhood was declared as Renewal Area in 2005 and, according to Law of Renewal, the neighborhood will go under a process of regeneration which will put in danger of displacement the poor citizens. Although 80% of the citizens living there, own their land, the houses built are not in good condition, being classified as "gecekonu", squatter housing, and have to be renewed and improved for their safety, this being a hard task for the majority of the community which is poor. Second, the increasing prices of land in the area are the proof of the process of gentrification remarked also along the whole waterfront of Halic.

These changes bring a strong opposition from the community, who is against this renewal project and in fear of deposition. Together with their muhtar, the community found a neighborhood association named Bedrettin Neighborhood Association. This type of associations provide information and support to the community by organizing meetings, being in touch with other Neighborhood Associations concerning collective interest and fight in legal means against urban regeneration projects, which were clearly understood by the Istanbulites as equal to a degree of displacement for them: "*We want to defend the place where we live, the place where we worked so much for. We took our water from the polluted Halic and we survived Dalan's demolitions. We don't want to go from here and we will fight against this neoliberal agenda.*" says Suleyman Songur, representative of Bedrettin Neighborhood. The association has the purpose to fight in court, as the only way of challenging decision-making, against the regeneration of their neighborhood and all other regeneration projects that could affect them. This is also the reason why Bedrettin Neighborhood is engaging in opposition towards Halic Shipyard Conservation Project. All citizens of Bedrettin Neighborhood signed a list opposing this intervention and the municipality's project was given to court. However, the results were not positive ones and this created mistrust between the community of Bedrettin Neighborhood and municipality along with loss of hope towards the actions of the government. In this context, although the purpose of the urban renewal project seems to be in the name of upgrading the built environment and improving the living conditions of this poor community, the top-down

approach along with the unwillingness of government to allow any participation from the citizen's side can be questioned.

The reason for opposition, from the citizen's perspective was not only the fear of displacement, but also the difference between the new proposed plans and their actual needs. As reason for this are the un-transparent processes of planning with no collaboration or participation from the community's side. Public planning policy in Turkey gives rights of involvement in planning process just to the owners of the land and welcomes participation from the citizen's perspective at the end of the planning process. Therefore, the lack of information regarding the project makes the community come closer to Chamber of Architects, Neighborhood Associations and Halic Resistance urban social movement, the actors currently engaged in a fight against the waterfront regeneration of the shipyards. In the questioners conducted during the meetings of Halic Resistance, besides the fear of displacement answers also as: "to learn the truth", "because this project is being used strategically against us" were given.

Looking to Bedrettin Neighborhood, one could see a condensed living environment, trapped between wide boulevards and with a great view towards the shore of Halic. Analyzing the built environment, it can be seen through the narrow streets and lack of public spaces, that it evolved organically and unplanned. The lack of public space and also green areas is a main loss for this neighborhood, but also one of the main aspects that Halic Shipyard Conservation Project could improve.

Although, as previously mentioned, the citizens of Bedrettin Neighborhood are against the Halic Shipyard Conservation Project, outcomes of the questioners regarding what they would need in the future development were: green spaces, culture and education facilities, keeping the working shipyards, health facilities. In the discussions with the community, especially with the group of mothers, mostly staying home and taking care of their children, the need of closer public space and green areas was emphasized. It was found that families go to other parks along the Halic and make barbeques or just bring their children to play, this being the only recreational activity for these families. An intriguing vision of the children is the one of the "fisherman", a symbol of the waterfront of Istanbul which should not be blurred in the landscape of waterfront development for global economic gain given by projects in name of tourism and consumption.

Taking into account the vulnerable position of the neighborhood in terms of economic situation, the on-going gentrification process at Halic's waterfront and the renewal project in the agenda of the government, it can be argued that Halic Shipyard Conservation Project will contribute to this picture considerably, creating social and economic impacts on the community.

The community of Bedrettin Neighborhood is an important actor being the most affected by the project, but also by its potential to give inputs to the project. Due to the lack of consideration of this neighborhood in the planning process the true benefiting outcomes of the project will not be achieved. Opportunities for more inclusive and transparent processes in planning can be found after analyzing the neighboring community as the openness and interest of the community in participatory planning methods and in expressing their need. The community is not only in need of public green space which can be created with the Halic Shipyard Conservation Project, but also in need of programs and solutions for its vulnerable economical condition. Halic Shipyard Conservation Project, if planned carefully, might satisfy and resolve some of the problems faced by the community, but this is possible only if the community is involved in the planning process.

2.5 Governance dynamics

With the new more entrepreneurial forms of governance, also new arrangements articulating state - civil society relationship come forward (Swyngedow 2005). In urban waterfront regeneration, urban social movements formalized as community groups or non-governmental organizations, coming often from the neighboring communities and other interested or affected parties become a source of ideas and influence the pace and pattern of development. They encourage, restrain, warn and provide qualitative overviews. (Krausse 1995; Cau 1996).

These new actors engaged in opposition, observed and identified within the period of this research, are social movements representing partly defined groups of civil society, chambers of experts in field of planning and community organizations: Halic Resistance, Academia, Bedrettin Neighborhood Association, Chamber of Architects, Chamber of Urban Planners, Chambers of Mechanical Engineers, The Lawyers Association, Union of Chambers of Turkish Engineers and Architects, Neighborhood Associations and also political parties, such as CHP. However, three main groups of actors in this opposition are chosen to present their interests and roles as they have been most active since the beginning of the planning process: Chamber of Architects, Bedrettin Neighborhood Associations and the platform where all and others meet, the social movement- Halic Resistance.

Chamber of Architects is the first actor which opposed to the regeneration of the shipyards and gave support to others that came along during the planning process. According to the 6235 Act of Union of Chambers of Turkish Engineers and Architects, the Chamber has the right to sue development projects which are not benefiting the rights of the society. The main reason to be against this regeneration, from their perspective, is that it will create displacement in the neighboring community, the shipyards will not be conserved and moreover the project will not benefit the needs of the citizens. Although the Chamber of Architects is practicing advocacy planning, it is still a centralized institution that evaluates projects from its expert perspective and has a focus on the concern of conservation of heritage, the monuments existing on the site of the shipyards. The Chamber is also stigmatized as being against all development projects and not seeking solutions, being in conflict with the government, outcome of many law suits against this type of projects. It's the discourse tended to focus towards the cancelation of the projects, but not militating for inclusion, transparency and information, outcome of the mistrust towards " *the neo-liberal agenda of the government and all the mega-projects triggered by it.*"

So non-governmental organizations funded in 2005 in order to fight with legal means against urban regeneration project for the community of Bedrettin Neighborhood, is Bedrettin Neighborhood Association. As Mr. Cem Tuzun, the representative of Beyoglu Neighborhood Associations, explains: " *to defend the rights of the citizens against a neoliberal agenda of the government*" ; " *to keep surviving in our neighborhoods*". The aim is to fight in court against any regeneration project that could put in danger of displacement the community. " *We want to defend the place where we live, the place where we worked so much for. We took our water from the polluted Halic and we survived Dalan's demolitions. We don't want to go from here and we will fight against this neoliberal agenda.*" says Suleyman Songur, representative of Bedrettin Neighborhood.

Halic Resistance urban social movement is the platform where all interested parties meet and militate against the regeneration of the shipyards. This social movement militates for: *the importance of the shipyards from the conservation point of view* and also its *production potential*. Moreover it is against the " *clear neo-liberal transformation of the shipyards*". One of the initiators of the movement, Dr. Arh. Gul Koksall calls these urban regeneration projects as: " *the hegemony of the government*". As a core, a board was created from representatives of: academia, Chamber of Architects, Chambers of Mechanical Engineers, Bedrettin

Neighborhood Association and former workers at the shipyards. Decisions are taken during meetings or in innovative ways through social media and mail groups. On 19.11.2013 a petition to Conservation Board regarding the clearance of Taskizak and Camialti shipyards was given as a violation of the Law of Conservation. This event builds on the efficiency of the movement in monitoring the development of the shipyards, report any violation of the law and call responsible bodies to action. However it also depends on the Chamber of Architects for its legal fight, being the institution with the right to sue the urban regeneration projects. In addition to the aforementioned, because of the informal means in which the resistance is reaching the information, false beliefs can be spread to wide public, fact revealed also in the interviews with the participants at the meeting of the movement. Also 45% of the participants come to the meetings not only to support the resistance, but also to inform themselves about the regeneration projects. Therefore, the need of information is underlined regarding these projects and here is the point where this kind of movements gain popularity for being open to participation and sharing knowledge.

The new actors engaging in resistance have no power in decision making over the projects, but they have influence on the planning process due to their actions. The collaborative networks and their innovative ways of decision taking makes them strong actors that have to be taken into account. These collaborations can challenge or conceivably stop the project. Opposition can be seen as an opportunity in increasing democracy, challenging the projects by creating debate and trying to reach a broader public, being always in contact with the media. Still, their demands in the project cannot be taken as indicator for the needs of the all citizens of Istanbul, rather they can be used as an indicator to the need of change in the planning process towards more transparent and inclusive one and can be used to improve the project.

2.6 Relationships and positions of the actors

Relationships of the actors are "*crucial in understanding the direction of the planning processes.*" (Nuisl and Heinrichs 2010). The relationships were established as outcome of the interviews conducted by the researcher and through participatory observation. When mapping the relationships, there are two clusters of actors that do not come together, this situations are reflected on the clash of interests and gap between civil society representatives and the government. One group represents the actors involved directly in the planning process and the other represents the strong opposition. The first ones has hierarchical vertical relationships by territorial responsibility of different governmental bodies and market based relationships by contractual agreements. The other group in opposition to the project is represented by collaborative and horizontal relationships of the non-governmental organizations, social movements and other civil society representatives.

Analyzing the actors in opposition and the horizontal network-like relations, overlapping interconnections among them can be observed. The boundaries between these actors are hard to be defined as they cooperate and interconnect with each other rapidly, using innovative means of communication in exchanging of opinions and in deciding common action. When the main actors from opposition, and ones involved in the planning process are considered for their relationship, there is a long lasting conflict between them which resulted from the interviews conducted with representatives of both sides, this making also harder for the two groups to come together. It can be argued that even though the resistance is engaging with the community into a fight against the urban regeneration agenda of the government, undertaking an advocacy planning role, it is also creating a barrier between state and citizens.

A stakeholder analysis has been developed as an outcome of the questionnaires and interviews realized with representative of the institutions involved in the planning process, but

also with the representatives of the social movements, civil society, neighboring community, non-governmental organizations, planning experts and academia- mostly all 91 total participants to the interviews and questionnaires in this research. The methodology was taken from the study: Governance and Multi stakeholder Processes by Nancy Vallejo and Pierre Hauselmann (2004)- a product of the Sustainable Commodity Initiative, a joint venture of the United Nations Conference on Trade and Development and IISD. The purpose was to find first the most interested and most powerful actors in the planning process. Than recommendations are given according to the methodology and the results from the questioners are represented in the matrix below.

RELATIONSHIPS OF ACTORS IN HALIC SHIPYARD CONSERVATION PROJECT

3. Conclusions

3.1 Evaluating the planning process:

Halic Shipyard Conservation project is initiated and subsidized by IMM, but the central government has regulatory power over the project outcomes, due to the special national laws designated for urban regeneration. Private sector is added to the decision-making process by IMM, but local government, Beyoğlu Municipality, the district in which the project is done, is missing from the planning process. Although the project is made for the public interest, it was found that there is no consideration of giving information or chance for participation to the most interested parties: the neighboring communities or the citizens of Istanbul. Looking at the decision-making process, the first attempt to officially create a plan for regenerating the area of Halic shipyard was together with Camialti and Taskizak shipyards, but as a result of the deficiencies in legal framework giving total rights to owners of land and central government, the latter ones were privatized.

The lack of information and broadly-based rights of influence are manifested by this opposition that is part of a broader fight against the "neo-liberal agenda of the government". The neighboring community's need of information and the lack of trust towards projects initiated by the government brings it closer to the actors in resistance. The collaborative networks and their innovative ways of decision taking can challenge and even conceivably hazard the project.

The planning process of this particular urban waterfront regeneration was found therefore as not inclusive, not transparent and not giving opportunity to challenge decision-making in the planning process. Therefore, it can be argued that what could be a good project creating public space and reconnecting the urban tissue of Beyoglu district with its waterfront, will fail to reach its true potential in benefiting the neighboring community and also the broad public of Istanbul. This due to its exclusive governance, the top down approach to planning and the legal framework given by the national policy on urban regeneration.

At the first glance, urban waterfront regeneration in the context of Istanbul reveals the same features of the popular contested cases of North and Western examples .The privileged governance structures identified in the literature review of urban waterfront regeneration projects aiming economical gain over the conception of a new city image and planning focusing on mostly physical transformation, ignoring the social problems of the neighboring sites and not taking the opportunity to resolve them can be seen also in the case study.

However, the form in which these outcomes reveal themselves, are different. Much of the literature on urban waterfront regeneration warns about the entrepreneurial governance forms, the private-public partnerships and the active role of private sector in the development of the projects, which lead to displacement of the communities, gentrification and other negative impacts. In the context of Istanbul, the leading factors are an entrepreneurial government and also a national policy on urban regeneration designated by the central government. In contrast with other urban waterfront regeneration projects around the world, which reveal citizens struggle with displacement, job opportunities, social housing opportunities and public space at waterfront as reasons for opposition, the case study presents also other encompassing motivations. The strong and constantly growing opposition is also part of a leading strategy of the citizens of Istanbul to get back the rights to the city. This is owed to long term accumulation of tensions facing the current urban planning practices in Istanbul, Turkey. The resistance, therefore, is not outcome of the particular regeneration of Halic shipyard or the privatization of the other two shipyards, Camialti and Taskizak shipyards (part of Halic Shipyards- Tersane-i Amire Arsenal), but rather of a bigger picture of urban regeneration projects done in Istanbul.

Hence, there is a waterfront regeneration project made for public interest, but the rights of the future users of the space, of the neighboring community and mostly of the citizens of Istanbul are in this way lost behind a neo-liberal agenda of the central and local government, un-transparent planning processes and the fight of the strong opposition parties gaining ground of governance landscape.

3.2 Recommendations

In term of urban waterfront regeneration there is a clear need for success not only by those at the top. Levine suggests equity in planning and democratized redevelopment agenda process that target residents in greatest need and policies that better link this regeneration to neighborhood's economic needs. (Levine 1987b) Unfortunately there is no necessary linkage between economic growth and social equity.

One may argue that only through a change towards a more inclusive planning approach, along with clear targets for the improvement of the quality of life for the neighboring community, the studied urban waterfront regeneration projects will be able to escape the current deadlocks and collisions between government, investors, resistance and local community and might have a chance to actually set an urgently needed precedent of a new planning culture in Istanbul.

The top down-governance forms have to combine with the bottom-up governance forms in order to achieve a physically and socially successful development. The citizens of Istanbul must be informed and included in the decision-making process in the planning process. The Municipality of Beyoglu has to be incorporated into the planning process, defining the link with the citizens from the district in which the project is done.

Taking into account the importance of the area by its location and accessibility, but also its cultural and historical value at local, national and international level there is a need in having a broader voice of influence and expertise into decision-making from various planning experts and academia. The management bodies in urban waterfront regeneration were found of great importance, scholars designating them as the reason for success of these interventions. The narrow approach to urban regeneration focusing on physical transformation given by the national policy, verified by Conservation Boar No.II and managed by the DHEP has to be enlarged and has to take into consideration more factors through impact assessment studies of social and environmental aspects.

Lastly, the project has to include the neighboring community in the planning process and its needs considered. By including the community in the planning process, the project can also resolve old social and economic problems left heritage since the forced deindustrialization of the area, thus, creating more heterogeneous environments in the city. The project can help to improve the quality of life for the neighboring community with creation of: public green spaces, culture and education facilities, health facilities and also playgrounds for children. Also job creation is proposed, but this only by keeping production going at the shipyard. It has been proved in other waterfront regeneration projects around the world that the jobs from cultural, tourism and other retail activities were absorbed by middle income population. All these points can be achieved only by involving directly the community in the planning process and in the implementation phase. It was found that the neighboring community is open to communication, and is willing to give input that will enrich the projects outcomes and therefore it can be engaged into participatory planning methods in the further planning process.

Considering the bigger picture of urban regeneration; will the citizenship struggle of Istanbulities will overcome and change the current approach to planning of an entrepreneurial government and the market forces is a question that we should pursue. However, what we are facing in the case of Istanbul can be resolved just by democratic mechanisms within the planning process, by understanding the territory as political and social construction. We have to focus on change and how to make it happen because as one of the respondents explained, we want to "keep *surviving in our neighborhoods*".

Under current conditions, urban waterfront regeneration in the context of Istanbul presents a different picture from a number of similar interventions of this type studied in the existing literature. In order to come with a comprehensive theoretical framework that explains present-day urban waterfront regeneration and how these kinds of mega-projects shape urban spaces, it necessitates the analysis of different localities in distinct geographical settings.

Abstract

Canal construction in China has a long history. The Beijing-Hangzhou Grand Canal is longest canal in the world. The Canal landscape shares large scale and continuous viewing features. After the Grand Canal has been placed in the World Heritage List, the governments and citizens started to focus more on its landscape function. The vision is the main way for people to perceive and experience landscape. But one viewer would get different experience from the same landscape when he was set in different viewing system. During the process of city renewal along the canal, how to propose effective landscape improvement strategy based on the landscape visual evaluation from tourists and citizens in different viewing systems are an actual question. Based on our former research, which has already established a subjective quantitative visual evaluation system under the influence of multi-factor interactive model, in this paper, we deepen the research and analysis at the characteristics of the canal landscape visual in different viewing systems. Then, we constructed and optimized dynamic viewing system for the Grand Canal Hangzhou section and overlook system. In addition, we also made the landscape control guideline for establishing area and landscape improvement method for built-up area. Finally, we proposed promotion strategy on urban spatial form, landscape improving and tour routes optimization, thus improving the canal landscape visual perception and image entirely. The proposed methods have good operability and universality, we believe that they will contribute to the scientific and more precise research of the future canal landscape.

Keywords: visual evaluation; the Grand Canal; landscape improvement strategy; viewing system

1. Introduction

The Grand Canal is one of the most ancient canals, which has the longest mileage and largest engineering quantity of the world. It is also a symbol of Chinese culture and has still been used till now. The Grand Canal is 1797 km in length which flows from Beijing in north to Hangzhou in south, passes through four provinces and two municipalities and connects five major river systems. It is also an important ancient transport routes that plays great role in the development and exchanges of economy and culture between south and north region of China, especially the development of industrial and agricultural economy in the area along the canal. After the Grand Canal was made World Heritage in 2014, its function as landscape has attracted more and more attention from both government and citizens. As a large scale, continuous linear urban open public space, landscape along the canal is closely linked with people's life and tour experience. The Grand Canal landscape, *i.e.*, the city space landscape of its two sides and surrounding, has

the characteristics of both historicity and sightseeing. It is the center of the future city life, urban tourism and urban industrial development. Therefore, the improvement of landscape along the canal is an important part of the city renewal and promotes mutually with urban space development.

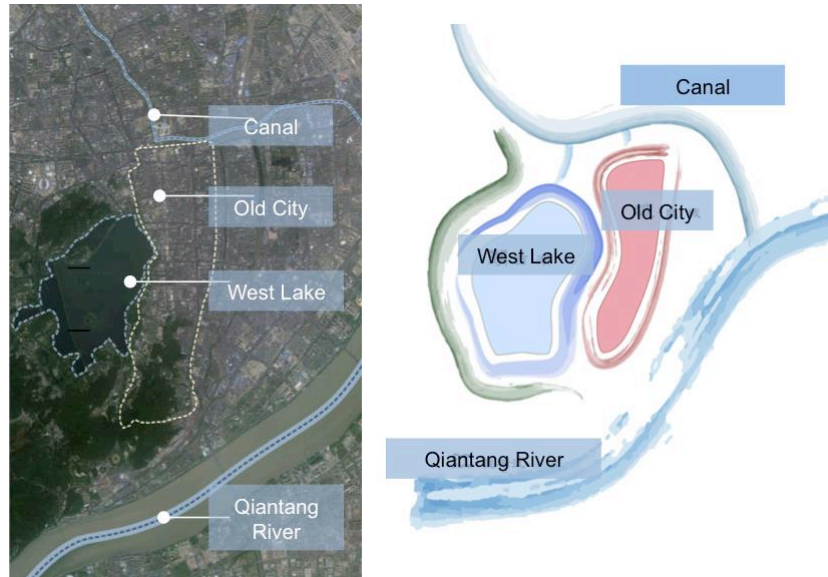

Figure 1: The Grand Canal location map.

The vision is the main way for people to perceive and experience landscape. But one viewer would get different experience from the same landscape when he was set in different viewing system. Landscape visual evaluation is quantized evaluation of landscape visual perception. In the case of canal landscape, in the same physical space of the city environment and viewing viewers in different viewing systems may get different landscape visual evaluation even in the same city space environment. Our research focus on the question “During the process of city renewal along the canal, how to propose effective landscape improvement strategy based on the actual landscape visual evaluation from tourists and citizens in different viewing system”.

The research scope of this paper is the Grand Canal Hangzhou section as shown in Fig. 1, which traverses the main urban area of Hangzhou city. It is 54 km long and about 45 to 150 meters wide. The region we studied in this paper is 500-1000 meters wide on both sides of the Grand Canal which covers about 94 square kilometers. Hangzhou, as the south end and east end of the Great Canal, plays an important role in the cities along the canal. It is also the confluence of the Grand Canal and other 5 main horizontal river systems. In addition, Hangzhou is the only city, which is both ancient “canal four big city” and provincial capital now. It ranks third in the cities along the canal both in GDP and the amount of heritage places, outstands in both city development and historical remains. It seems like the epitome of the Grand Canal with similar complexity and diversity as the characteristic of sections. Therefore, the research of landscape improvement strategy on this section will inspire the landscape improvement of the whole Grand Canal.

The Grand Canal is not only the main body of the Hangzhou water network system, but also closely linked with historic context, future development, citizens' life and city image of Hangzhou. It passes through different boroughs, connects urban and rural areas. The riverside areas have composite city functions that are complex and diverse. Also, it has plentiful coastal landscape elements which present evolution tendency from outskirts landscape to metropolis landscape. Based on the field study, we found that the viewing system is consisted of static part, including bank, boat, bridge and building, and dynamic part which includes pedestrian system, slow-bicycle system and sightseeing boat system. The visual perception and landscape visual evaluation of the viewers in the viewing system are decisive to both city image and citizens' living quality. However, the current status cannot satisfy these functional requirements fully. Therefore, the research on the dynamic viewing system of the Grand Canal has important practical value.

Based on our former research (Jin and Wang, 2013), which has already established a subjective quantitative visual evaluation system under the influence of multi-factor interactive model, in this paper, we deepen the research and analyze at the characteristics of the canal landscape visual in different viewing system. Then, we constructed and optimized dynamic viewing system for the Grand Canal Hangzhou section and overlook system. We also made the landscape control guideline for new urban area and landscape improvement method for old urban area. Finally, we proposed upgrade strategy on city spatial form layer, landscape improvement layer and tour routes optimization layer, thus improving the canal landscape visual perception and image entirely. The proposed methods have good operability and universality; we believe that they will contribute to the scientific and more precise research of the future canal landscape.

2. Methods

2.1 The analysis, composition and visual characteristics of viewing system

As one way of interaction between people and landscape, viewing is to perceive the existence of landscape using the vision as the medium. People can conduct the quantized evaluation of 'landscape visual perception', the substance of which is to evaluate the value of the city physical environment based on vision layer. Viewing system is the chosen tour manner of the viewer during the tour, which is usually be divided into dynamic and static viewing system. The static viewing system means viewer get the landscape visual perception from a fixed stationary point, where the physical relationship of viewer and landscape system is relative stable and the obtained landscape visual evaluation is interrupted punctate distribution. Besides landscape system itself, the main factor which affects the visual evaluation result of the viewer in static viewing system is relevant with stadia and visual angle between the stationary point and landscape. With the change of the stationary point, the stadia and visual angle also changes accordingly. Among the space of cities along the canal, the main places that can be served as stationary point of static viewing are urban gateway, urban dominating points, urban open space and Visual corridor. In our research, the static viewing system is consisted of bank, boat, bridge and building.

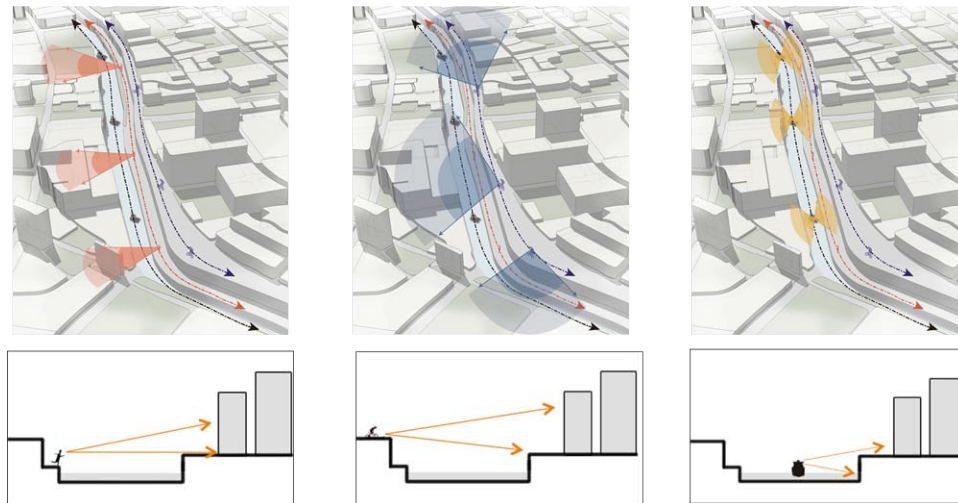

Figure 2: Illustration of vision characters in different motion systems.

In dynamic viewing system, which is different from the static viewing system, people obtain the landscape visual reception in different motion states, and then form the visual evaluation on the city landscape within one scope so that to accumulate the evaluation on all parts to form the landscape visual evaluation distribution. Therefore, the landscape visual evaluation obtained by viewers in dynamic system can be seen as the collection of evaluation result of countless stationary points, which presents linear distribution. Besides landscape system itself and motion speed, the main factor which affects the visual evaluation result of the viewer in dynamic viewing system is relevant with stadia and visual angle between its tour route and landscape. In different motion systems, with the change of the tour route and motion state, the viewer may obtain different visual evaluation on same landscape. In the same dynamic viewing system, viewer and the landscape system keep relative stable physical relationship in the basic viewing unit(1-2kms), whose speed, stadia and visual angle remain unchanged. The dynamic viewing system of landscape along the canal is mainly the slow-traffic system. Based on the field study, the dynamic viewing system of the Grand Canal is consisted of pedestrian system, slow-bicycle system and sightseeing boat system as shown in Fig. 2.

2.2 Construction of the landscape evaluation system based on vision reception

In our former research, according to the landscape composite characteristics of canal landscape, as well as considering the basic idea of visual aesthetics and ecological aesthetics, we established evaluation elements for evaluating the landscape system itself, which was divided into three category layer elements and nine system layer elements which includes contour rhythm, contour recognition, contour fluctuations, building façade, building materials, building roof, visual plaque, visual hierarchy and visual color (Celio, Ott, Sirén, and Grêt-Regamey, 2015). In the meanwhile, we embody the landscape visual evaluation on canal landscape into the evaluation of its two-side urban façade and establish corresponding quantized evaluation criteria. After that, we rate every element involved to get the visual evaluation score T of corresponding layer. Therefore, the score of urban outline, architectural form and visual perception are denoted

by T_{UO} , T_{AF} and T_{VP} , respectively. Notation S_{UO}^n is used to denote the score of evaluation elements in urban outline, where $n=1,2,3$ represents the contour rhythm, contour recognition and contour fluctuations, respectively. Similarly, S_{AF}^n and S_{VP}^n are defined as the score of each element in architectural form and visual perception. The highest score of each element is 10, which means no modification is needed, and the lowest score is 0, which means the modification is inevitable. The T_{UO} , T_{AF} and T_{VP} could be calculated by summing up the score of all elements as $T_{UO} = \sum_{n=1}^3 S_{UO}^n$, $T_{AF} = \sum_{n=1}^3 S_{AF}^n$, $T_{VP} = \sum_{n=1}^3 S_{VP}^n$.

On the other hand, we introduce the concept of landscape visual attention-degree, *i.e.*, the degree of visual attention paid to different landscape elements. As the connections between visual perception and quantified visual evaluation, the landscape visual attention-degree is one major parameter that describes different Ferris system viewing them for the important parameters of the difference between the same landscape system in different categories of factor of landscape visual attention. The main influencing factors is viewing in different motion system speed, distance and angle, static system of stopping point can be considered for speed is zero, the motion of the system. Based on the factors analysis in decision-making, we carry out pairwise comparisons of relative importance to build the judgment matrix. The eigenvector calculated represents the relative weight of these visual elements in different environments and motion systems, and could be assigned as the value of corresponding landscape visual attention-degree.

We introduce notion E_{m-c} to denote landscape visual attention-degree in both viewing systems (static and dynamic), *i.e.*, the weight of each element for landscape visual evaluation in different motion system, where m stands for the motion patterns and c for different category layer elements. For example, E_{bi-uo} denotes the landscape visual attention-degree of urban outline in slow-bicycle system and E_{ug-vp} represents the landscape visual attention-degree of visual perception when viewer stands at the urban gateway (stationary point). We can easily get the relation that

$$E_{p-uo} + E_{p-af} + E_{p-vp} = E_{bi-uo} + E_{bi-af} + E_{bi-vp} = E_{bo-uo} + E_{bo-af} + E_{bo-vp} = 1.$$

$$E_{ug-uo} + E_{ug-af} + E_{ug-vp} = E_{dp-uo} + E_{dp-af} + E_{dp-vp} = E_{os-uo} + E_{os-af} + E_{os-vp} = E_{vc-uo} + E_{vc-af} + E_{vc-vp} = 1.$$

Therefore, the visual evaluation of one landscape subsection or stationary point X in different motion systems are defined as following equations, respectively is defined in the similar way

$$X_{Pedestrian} = E_{p-uo} \times T_{UO} + E_{p-af} \times T_{AF} + E_{p-vp} \times T_{VP}.$$

$$X_{Slow-bicycle} = E_{bi-uo} \times T_{UO} + E_{bi-af} \times T_{AF} + E_{bi-vp} \times T_{VP}.$$

$$X_{Sightseeing-boat} = E_{bo-uo} \times T_{UO} + E_{bo-af} \times T_{AF} + E_{bo-vp} \times T_{VP}.$$

$$X_{Urban-gateway} = E_{ug-uo} \times T_{UO} + E_{ug-af} \times T_{AF} + E_{ug-vp} \times T_{VP}.$$

$$X_{Dominating-point} = E_{dp-uo} \times T_{UO} + E_{dp-af} \times T_{AF} + E_{dp-vp} \times T_{VP}.$$

$$X_{Open-space} = E_{os-uo} \times T_{UO} + E_{os-af} \times T_{AF} + E_{os-vp} \times T_{VP}.$$

$$X_{Visual-corridor} = E_{vc-uo} \times T_{UO} + E_{vc-af} \times T_{AF} + E_{vc-vp} \times T_{VP}.$$

In conclusion, landscape visual evaluation in different motion systems is related with not only objective landscape quality but also landscape visual attention-degree. By building a quantitative visual evaluation system under the influence of the objective multi-factor interactive model, we quantize the result of landscape visual evaluation obtained from viewers in different viewing systems, and then provide the technical support and basis for the subsequent research on landscape improvement strategy.

3. Results

3.1 Data Analysis

According to the distribution of heritage points, landmarks and open space along the canal, also considering the urban gateway and existing visual corridor, as well as the surrounding urban dominating point, we set 23 stationary points in the middle of the canal, 7 of which are on the bridges, the other are on the boat. In addition, we set other dominating stationary points and 6 points on the bank. We analyze stadia and view angle from stationary points firstly, and then rate all the elements to get the distribution of the landscape visual evaluation of these stationary points. Therefore, we can understand the visual evaluation status of the Grand Canal's static viewing system. The darker color and wider radiation range would indicate this stationary point has better landscape visual evaluation as shown in Fig.3.

Besides, we divide this section of the Grand Canal into landscape subsection every 1000-2000 meters, resulting in 38 landscape subsections in total. We utilize the mathematical model proposed in to calculate corresponding score and summed up unweightedly for these landscape subsections. After that we input the data of every district into GIS. Using surface analysis tool, we obtain the 3D landscape visual evaluation model. Similarly, the area with better the current landscape visual evaluation would display darker color (Svatonova and Rybansky, 2014).

The dynamic tour system of the Grand Canal includes pedestrian system, slow-bicycle system and sightseeing boat system. Pedestrianism is the main dynamic visiting way, which has the convenience and flexibility that no other transport tool equips. The active crowds are mainly nearby residents supplemented by tourists with relaxation and taking a walk as their main objectives. Slow-bicycle system is an important part of the Grand Canal motion system due to its

Figure 3: Analysis of static viewing system and landscape visual evaluation model.

wide popularity and great participation. The main participation crowd of slow-bicycle system is nearby residents. The sightseeing boat system plays the role of connecting the visual relationship between landscape point and green corridor of the Grand Canal. Also, it establishes the relationship between heritage itself and the tourist interpretation system. The streamline of sightseeing boat system is more successive and complete in longer absolute length when compared with that of general urban recreation zone. The participation crowd is mainly tourists.

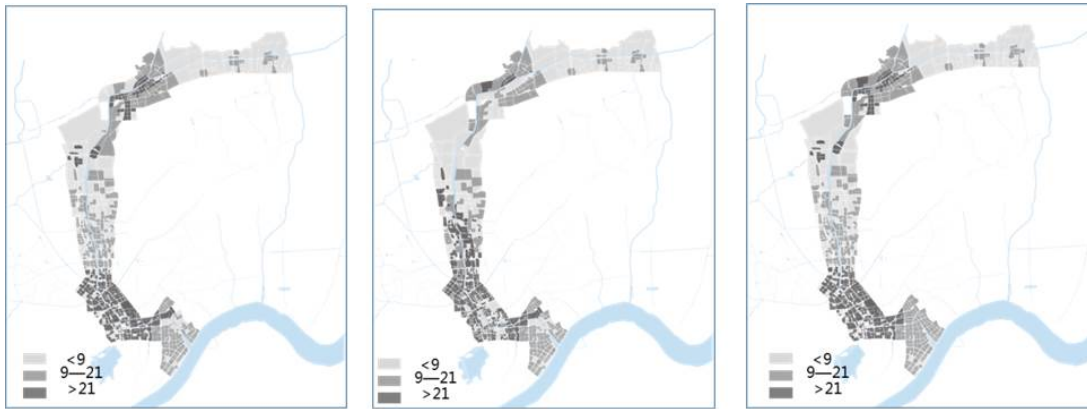

Figure 4: Illustration of vision characters in different motion systems.

Given the differences of landscape status and environment of surrounding cities among different landscape subsections, we utilize the mathematical model proposed calculate corresponding score get the distribution of the Grand Canal landscape visual evaluation score and the evaluation result in different dynamic tour system. Similarly, the darker the color of the area is, the better the visual evaluation of the landscape status in this viewing system is as shown in Fig 4.

3.2 Promotion strategy on viewing system

Through the analysis and calculation of visual evaluation results of the landscape itself and that in different viewing system, we divide the Grand Canal landscape promotion strategy into two parts. One is the promotion of landscape itself, the other is optimization of viewing system. When we optimize the viewing system, we don't change the landscape itself but to optimize the tour route to improve the overall landscape visual perception and image. It mainly includes the integration of dynamic viewing system and organization of static viewing system, namely tour routes optimization and overlook system construction as shown in Fig.5.

3.2.1 Dynamic viewing system optimization

We established quantitative multi-factor visual evaluation system and assigned the parameters and weighted value to obtain the distribution of the landscape visual evaluation value in different dynamic viewing systems. The area with score above 21 is considered as first-class area where people are encouraged to pass. When the score of the area is between 9 and 21, we define it as the second-class area, where we recommend planning appropriate tour route there only after improving landscape quality. When the score is below 9, the subsection needs special landscape renovation, and is not suitable to tourist for the moment. We pay more attention to connect the first-class areas. Considering the public traffic transfer point, landscape resources, basic visiting unit and existing tourist routes, we constructed landscape dynamic viewing system of the Grand Canal Hangzhou section, optimized existing tour routes and planned some new tour routes.

This dynamic viewing system can establish the relationship between the landscape visual evaluation elements and urban motion systems. The differences of landscape visual attention-degree on elements of different layers and its accompanying diversity in visual evaluation are adequately considered in different motion system via scientific and effective operation. Therefore, we can enhance advantage and avoid disadvantage of landscape to improve the overall landscape visual perception and landscape image of the Grand Canal. In addition, it enjoys good adaptability in city function because it fully takes into account of environmental influence of the urban space around the Grand Canal.

3.2.2 Overlook system construction

The ideal city overlook system should be consisted of numbers of overlook points and circle-layers and cover existing overlook landscape resource along the canal (Wang, Yang, Chen and Xu, 2013). In the above research, we chose the stationary point through spatial analysis, constructed quantitative multi-factor visual evaluation system, calculated the parameters and weighted value, and determined the distribution of landscape visual evaluation score in different static viewing system. Besides these, through delimiting the landscape circle-layer, *i.e.*, analyzing the stadia and view angle of the stationary points, and integrating the visual corridor, we established overlook system to control 3 main overlook factors: landscape target, viewing point and corridor axes.

Figure 5: Overlook system construction.

In our research, the overlook targets of stationary points are banks, boats, bridges and buildings. Canal, historical relics along, revetment, open space, kinds of buildings, bridges and the space under bridges are all viewing targets of stationary points on boats, whose stadia is short and view angle is small. The targets of the stationary points on bridges include bridges themselves, landscape revetment near the bridge, canal landscape corridor, symbol landscape and skyline. Its stadia is short and view angle is large. The revetment along the pavement, buildings on the other side and the skyline are viewing target of the points on banks whose stadia is far and view angle is small. The surrounding urban viewing, overlooked viewing are the target of the points on buildings, *i.e.*, dominating points. Its stadia is far and view angle is large. According to the obtained landscape visual evaluation score distribution in different static viewing system, we chose 80 stationary viewing points (includes 14 points on bridges, 20 points on boat, 26 points on banks and other 20 dominating points) and 12 overlook corridors (includes 5 visual corridors and planned 7 canal viewing axes).

This static viewing system is based on scientific and effective operation on quantitative multi-factor visual evaluation system. We analyzed the stadia and view angle of different stationary points and obtained the distribution of the landscape visual evaluation score in different viewing system. Considering the spatial characteristics of overlook system, such as continuity and interactivity, we sorted out existing static viewing system, and then constructed new overlook system to promote the overall landscape image of canal.

3.3 Promotion strategy on landscape optimization

The research object of the Grand Canal landscape promotion includes built-up area and establishing area these two parts, corresponds to applications of landscape optimization and city spatial form promotion, respectively. Among them, the existing zone along the Grand Canal involves multiple center districts of Hangzhou and protected historic zones. In this region, we

chose the key lots to transform and controlled the landscape system elements pointedly to improve the visual evaluation of landscape along the canal.

The key transformation lots are the points at key locations in the viewing system but with low landscape visual evaluation score. For example, the stationary points obtained after spatial analysis, including urban gateway, urban dominating point, open space and end point of visual corridor, but landscape quality status of which are below the first-class standard (the landscape visual evaluation score is below 21). Or the added important sections for connecting tour routes in dynamic viewing system, but landscape quality status of which are below first-class standard).

In static viewing system, we focus on modifying the dominant elements in different viewing system. For example, the stationary point on boat located at Genshanmen Park. Its stadia is near and view angle is small but the visual perception is valued. Therefore, we made corresponding regulation according to the quantified evaluation criterion. In dynamic viewing system, we analyzed landscape visual attention-degree distribution in the zone where added routes and focused on controlling and transforming corresponding elements. Qiaoxi historic cultural block is such an example. We added cycling tour routes there to connect nearby two slow-bicycle transition points. Other corresponding regulations are made according to the criterion because people in this zone value the urban outline more as shown in Fig. 6.

Figure 6: Optimization of Qiaoxi block.

Although we can improve the landscape visual reception and image through only optimizing the tour routes, some problems exist. The landscape visual evaluation score of the extra section for connecting tour routes and the stationary points that are important to urban spatial form may below first-class standard. The promotion strategy of landscape optimization will consider landscape status and visual attention-degree distribution to make the specific regulation according to the evaluation criterion so that we can solve the problem of low visual evaluation on part of new tour routes, which is brought by the viewing system optimization

3.4 Promotion strategy on urban spatial form

In the case of establishing areas (which are mainly located at west part of the canal), we formulated landscape control guidelines on urban spatial form to hierarchically control the set of height, volume and visual corridor. This can be seen as the long-dated way to control and promote the landscape along the canal, also the target of the future deepened research.

Based on the spatial pattern prediction model of GIS (Aklıbaşında and Bulut, 2014), we made comprehensive analysis on all elements that affect the city development so that we can get the judgement on development intensity of future city and formulate control guidelines on the height as shown in Fig. 7. There are 6 types in all. Height zone 1 includes mainly super high-rise

buildings that above 100m. The height of buildings in zone 2-6 are basically 80-100m, 50-80m, 24-50m, 12-24m and below 12m, respectively.

Figure 7: Spatial pattern prediction model of GIS.

The height zone 1 includes the core area of municipal center and sub-center where have been highly developed; height zone 2 includes highly developed residential area adjacent to the central area; height zone 3 mainly refers to the residential and comprehensive development area located at the outer circle of the center and sub-center; height zone 4 is the residential and comprehensive development area close to the height zone 3; height zone 5 includes general areas of low intensity residential and comprehensive development area; height zone 6 includes industrial and logistic area, surrounding ecological conservation areas and sensitive area where control requirements are high. Through the analysis and research, a little part of establishing areas along the canal is height zone 2 and 3, but most of the which belong to height zone 4-6.

Figure 8: Hierarchical control from the refinery to canal new town.

Zone 2, 3, 4 and 5 are mainly located near the industrial relic area which are the key future development areas. The differences of the development intensity and the height enhanced the layering of urban landscape. However, too messy building height may cause mutual occlusion. Therefore, we set hierarchical control guidelines for the important landscape corridor along the canal. Take the visual corridor from the refinery to canal new town as an example, whose length is about 3000 meters. We see viewpoint of visual corridor as the datum and set one control unit along the Grand Canal every 1000 meters. The buildings in these control units should be limited to the corresponding height according to specific standard as shown in Fig. 8.

Through making hierarchical regulation on the set of height, volume and visual corridor of future urban spatial form in establishing area, we formulated the landscape control optimization mode whose main part is spatial form control guidelines. Then, we can control and promote the landscape visual evaluation of the establishing area along the canal on urban spatial form.

4. Conclusions

Based on our former research, we take the Grand Canal as an example to study and analyze the viewers' characteristics of landscape visual evaluation on canal landscape in different viewing system. Then, we established a quantitative visual evaluation system under the influence of the objective multi-factor interactive model. This method uses intuitive and clear data to illustrate the complex city relationship, and provides technical support and guidelines for subsequent optimization design. Based on these, we constructed and optimized viewing system and overlook system of the Grand Canal Hangzhou section, formulated the landscape control guidelines for new urban areas and landscape optimization methods for existing areas. Finally, we proposed promotion strategies on urban spatial form, landscape optimization and tour routes, trying to find the balance point between preservation and development to seek reasonable and scientific landscape promotion strategy.

In addition, the method of visual evaluation and the canal landscape promotion strategy are scientific and general applicable. They can be easily applied to large scale, continuous linear urban open public space. We can adjust the corresponding factors in the landscape visual evaluation, viewing systems and urban spatial form according to the specific situation and requirements.

New Mahalle

(New Mahalle – a more urban, green, inclusive neighbourhood.)

Eirini OIKONOMOPOULOU, MSc in Sustainable Urban Design, Sweden

1. Introduction

Nowadays, almost half of world's population lives in urban areas and these amount are constantly growing. Urbanization has reached high levels and, especially in developing countries, cities with a population greater than 10 million have become extremely common. (Morano E, 2003) These led to a huge social inequality within city's neighborhoods. When poor population comes to survive in the urbanized world, they have to face a variety of problems conserving different aspect of living, for example access to qualitative housing and public spaces. Uncontrolled urban environments are appearing in big cities to cover the extreme demand of housing and they are constantly expanding. Such environments are called *slums*. (UN-HABITAT, 2003)

Istanbul has 14.4 million people living in its metropolitan area and it is the biggest city of Turkey and one of the most populated metropolitan areas in the world. After its recent fast growth, as in other megacities in the world, Istanbul faces density and urbanization problems. The combination of build environment from different periods is very interesting and challenging for architects and urban planners. Especially when it comes to bad quality historic neighborhoods the difficulties and challenges are much more.

2. Theoretical Background

2.1 Urbanization

From industrial revolution till today, developing world has been trying to enforce its economy by enlarging industrial and services sectors. Obviously, the majority of these economic activities are taking place in cities. Employment opportunities are constantly increasing in urban areas, causing people move from rural to urban areas in an extreme rate. Urbanization is so fast that urban areas are extending from district cities to metropolitan areas in less than a decade. (UN-HABITAT, 2007)

These rapid "domestic" migration is happening because of economic and business reasons. People in developing countries in order to have a sufficient income, are forced to search for better job opportunities in big cities, where the majority of economic and developing activities are taking place. Big industrial complexes are being built in order to find cheaper (than in developed world) workers. One more reason for urbanization is political situation and warfare which could cause whole population from an areas (or country) move in order to survive. (UN-HABITAT, 2007)

As cities are considered economic wealthy centres, people moving to them are expecting better income and working conditions. As more people are moving there the need of work placements are growing in a rate that could not be covered by the rate economic activity are growing. As a result, instead of finding a better financial state immigrants are still trapped in poverty. Urbanization of population leads to urbanization of poverty and unemployment. In this case, urban poverty is expected to be between 45 – 50% by 2020. (Moreno E., 2003)

2.2 Megacities

At 19th century, even if there was not an official definition of what is a *megacity*, cities with more than 1 million population was considered as one of those. As situation worldwide changed, such a definition would have given us too many megacities today. Since 1970, United Nations have officially defined megacity as a city with more than 10 million population. (Morano E, 2003)

Today, there are 28 megacities around the world. Tokyo is the most populated city in the world with a population around 38 million. It is followed by Delhi with 25 million, Shanghai with 23 million, Mexico City, Mumbai and Sao Paolo with 21 million inhabitants each. By 2030, it is expected to have 41 megacities with Tokyo still the biggest with 37 million followed by Delhi with 36 million. It is also interesting to say that except from the number of megacities

which almost tripled in 24 years, similar growing pattern follow urban areas in various levels. Most megacities today are located in the developing world. More than one third of them are in Asia, six of them in China, four in India and it is expected to have seven more by 2030. (United Nations, 2014)

2.3 Informal Settlement Area (Slum)

Apart from the need of workplaces, there is also a huge demand for cheap housing, but city's development speed is lower than the demand, so municipalities cannot offer enough housing options. As the demand for cheap housing raises, informal residential areas emerge as an immediate and cheap solution, because people do not have to pay for the land and they constructed (or renovated) their houses as cheaply as they can. (UN-HABITAT, 2003)

The word *slum* appeared by the end of 18th century in everyday language in Great Britain. The term was used to describe the informal activities which low income social groups was doing. It was meaning places or areas where informal activities was happening. (Davis M., 2007)

By the middle of 19th century, the term appeared in text and defined in dictionaries. *Oxford English Dictionary* defined slum as "A squalid and overcrowded urban street or district inhabited by very poor people". At the same period slum areas found in French, USA and India. As a result phenomenon recognized worldwide and started researching common characteristics the world round. (Morano E, 2003)

Until the begging of 21st century there was no official definition of the term slum, so in each country there were different definitions and often translations of the term, like favela or barrio in Latin America, gecekondu in Turkey. In 2002 UN-HABITAT held in Nairobi, Kenya, a worldwide conference where an official definition of the term *slum* was defined. According to this "an area is considered as slum if it has at least one of the following characteristics:

- a) Poor accessibility to clear water.
- b) Poor accessibility in sanitation facilities (private or public).
- c) Poor construction quality of houses.
- d) It is highly dense area.
- e) It is unsafe area. Illegal activities are held and inhabitants have no guarantee for their stay there." (UN-HABITAT, 2003)

2.4 The Islamic City

Trying to define what is a livable qualitative urban space for a contemporary city like Istanbul, the Islamic character of it should be considered as well. So, I search the principles of the traditional Islamic city, try to identify them into the existing form of urban space and city fabric and wonder how public space could be changed to become more livable and at the same time still acceptable by resident's mentality.

Traditional Islamic city

The basic neighborhood building guidelines in the traditional Islamic city are determined by principles and guidelines started by the time the Prophet Mohammed settled in Medina. Core in urban design is the house and the access to it as it described socially and physically by the essence and spirit of Islam and their development and evolution of Islamic law through the time as the religion spread. Very important is the influence of scholars. Some of them created schools of law and they strongly influence lifestyle and design guidelines. (Hakim B. S., 1988)

The decision-making process of physical formation of the city is based on the interaction of rulers (people with governmental and/or religious power) and citizens although they act in different scales. Rulers decide on the macro scale of the city and they create a first scale urban fabric of governance, religious and economic centers (or buildings) and major infrastructure. On the other hand, citizens' decision are on the micro scale of a neighborhood. They create a second scale urban fabric of private houses, streets and open spaces. Although rulers influence the urban fabric by creating a planned structure, citizens' influence is spread in greater area and affect the lives of most people. (Hakim B.S., 1988)

The guidelines followed by rulers and citizens in the traditional Islamic city are the behavioral guidelines stated in Islamic law. Harm is the basic guideline, everyone should exercise their right without harming others. Second important policy which regulates Islamic behavior is privacy. In physical terms it has to do with the private domain of the house. In this case visual corridors into private areas should be avoided to secure personal privacy. Other behavioral principles are interdependence, right of original usage, respect for others' property, pre-emption and right of access to water. (Hakim B.S., 1988)

Figure 1: Height of the windows to secure privacy. Source: Hakim B.S., 1988

On the city level, Islamic city is defined mainly by rulers or designers. Mosque is the core of the Islamic city, the same importance it has in the society. It is the main public space in the city, where people meet, socialize and interact. It combines religious services, open/ green space, educational services and governing facilities. Next to it there is usually a bazaar or a weekly street market (for smaller mosques). (Abu-Lughod J. L., 1987) It is obvious that the mosque is a physical center for the city and the neighborhood and at the same time a spiritual center.

Residents of each neighborhood have similar religious, ethical or socio-economical characteristics. (Abu-Lughod J. L., 1987) Social, cultural and political structure is different between Islamic and non-Islamic cities. Cities which adopted Islam later on usually follow the previous urban structure with limited changes in religious centers and social structure. The implemented principles from Islam was aiming to serve personal privacy. (Karimian H.)

A neighborhood in the Islamic city is cluster of houses usually organized according to religion, ethnicity or language. It is quite autonomous as it has its own mosque which is religious, governmental and economical center. Multiculturalism in the whole Islamic city is represented as combination of different social groups in neighborhoods. Social structure is defined by the people's relation and interaction within the neighborhood and it is the main factor shaping urban form of neighborhood. (Karimian H.) Mixture of social groups in the same neighborhood exists in the cotemporary Islamic city and especially in the international western influenced ones, like Istanbul. (Saoud R., 2002)

The financial and trade activity of the neighborhood is served by small local shops, but the major needs of residents are covered by market streets or indoor market next to the mosque. In some cases when the mosque and the neighborhood are not so important, the market is a street market in a weekly basis in order to cover residents basic needs, but in other cases the market is so famous for its size or its focus on specific products that it attracts costumers from other neighborhoods. (Behar C., 2003)

Roads and streets are connecting neighborhood with the close ones and having as a goal to serve mobility between houses and center of the neighborhood. Street network inside the neighborhood is a combination of main, usually busy roads and narrower streets. Both are used as public life spaces. (Behar C., 2003) Houses are the actual private space for each family and it has a garden or yard for outdoor activities Houses are usually inner oriented in order to give residents the necessary privacy. (Hakim B. S., 1988)

3. The city of Istanbul

3.1 Turkey and Istanbul

Turkey is a transcontinental country, between Europe and Asia, with an important geostrategic location. It works as a strategic location between Asia, Africa and Europe and through the time, as the crossroad of civilizations and cultures. It has Mediterranean Sea on its south, Aegean Sea on its west and Black Sea on its north. Bosphorus, Sea of Marmara and Dardanelles are all together formulate the Turkish Straits, which connects Aegean Sea with Black Sea and demarcates the boundary between Europe and Asia.

Turkey is a republic since 1923 (29/10). Its area is 783.562 km² and it had 76.667.864 population on 2013. Turkey's capital city is Ankara and other big cities are Istanbul, Izmir, Bursa, and Adana. Istanbul is the most populated city of Turkey and on the country level, Istanbul is the main air hub for domestic travels and the second main train hub. It consists of two parts, the European and the Asian part divided by Bosphorus Sea. One third of its population lives in the Asian part. Through the times, Istanbul (Constantinople as known before 19th century) was capital city of Roman, Byzantine and Ottoman Empire.

Since 2004, province and city of Istanbul have the same boundaries. The city of Istanbul covers an area of 5.461 km², it had 14.107.954 inhabitants on 2013 (it is expected to reach 15 million inhabitants by 2015) and an average density of 2.725 people/km². (Turkish Statistical Institution) For administration purposes, province is divided in 39 districts and each of them in neighborhoods (*mahalle*).

3.2 Today and Tomorrow

From socio-economic aspect, the city of Istanbul today combines upper, medium and lower income classes. Especially in the central - historic areas, all different socio-economic level are found, but the majority of population especially close to the touristic zone and the waterfront belongs to the upper class. If we compare European side with Asian one, in the first we found lower socio-economic neighborhoods in greater extend as in the Asian side. (Derviş P., Öner M., 2009) Fener and Balat are such neighborhoods, characterized as centrally located, historical and low income.

As the city expanded through the time and different civilization were building one after the other, the actual core of the city is very densely built. Green areas are limited in the central areas of Istanbul, they are usually across the waterfront and the main attractions.

On transportation level, today Istanbul has an extensive bus network with local and express bus lines. Some of them are connecting both sides and the majority of them connect central locations. (Derviş P., Öner M., 2009) Finally, a very important and popular way of commuting in that city is by ferry.

In the future, it is expected that urban fabric will reach the Black Sea coast till 2030 and population will be more than 18 million. A third bridge (Yavuz Sultan Selim Bridge) is already being constructed and it is expected to finish by the end of 2015. By the next two years, three metro lines are going to be constructed and one is being planned in order to make transportations more effective in both sides. It is also planned to add an extra tram line to connect north suburbs.

Figure 4: Green and slum areas, today.

4. The Focus Area: Fener and Balat

4.1 Fatih: The Historic District

Fatih is the historical peninsula of the city of Istanbul and a district and a municipality by itself since 2009. It covers an area of 13 km² with a population of 428.857 people (2012). Its density reaches 33.000 people per km² which makes it one of the denser districts. (Turkish Statistical Institution) Fatih's borders are mainly defined by the topography as it has Golden Horn to the North and Sea of Marmara to the South. To the North, Theodosian wall is remarking the Western borders.

Fatih is was the first core of the city and its history starts from ancient times. During the Byzantine period Fatih was the actual city of Constantinople with a lot of governmental and religious buildings spread all over the district. Today, it is a crowded working class district, as after 1960s large amounts of middle class immigrants moved in. It has a unique character as it combines areas with strong cosmopolitan atmosphere, historic and touristic neighborhoods as well as extreme conservative communities.

4.2 Fener and Balat

Fener and Balat are two neighborhood in Fatih district which are located by the Golden Horn. Their history starts already from the Byzantine period as they were wealthy and important areas of the city of Constantinople. Today, they are one of the poorest areas of Istanbul and populated by immigrants from Eastern Turkey or Syria but with the unique colorful atmosphere and the long history make them one of UNESCO's World Cultural and Natural Heritage areas (as part of the Historic Areas of Istanbul), however less than 1% of tourists visits it.

Fener

Fener is a neighborhood by the Golden Horn close to the Theodosian wall which is known as the Greek neighborhood. Its streets are full of old wooden mansions and churches with picturesque facades dating from the Byzantine and Ottoman period. After the conquest of Constantinople, Fener was mostly populated by Greeks,

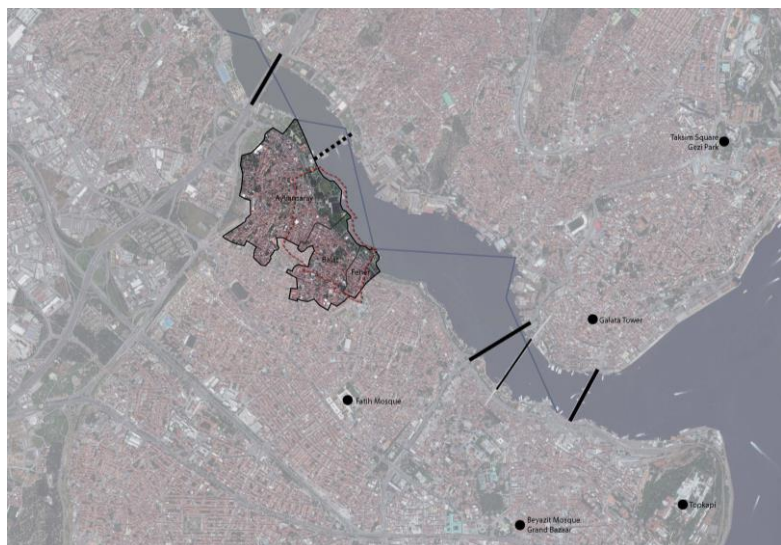

Figure 5: Focus area. Base source: google maps

especial some important and wealthy families The Patriarchate of Constantinople moved also to that area and made it even more important. From that time till today, Fener has very important role in Christianity as the center of Christian Orthodoxy. All over the area, there are a lot of old Greek Orthodox churches, the Phanar Roman Orthodox Lyceum and an important Bulgarian church by the shore of Golden Horn.

Even from the last period of the Ottoman Empire, Fener had already started losing parts of the Greek wealthy population, as they moved to other district of Istanbul. Especially after the Istanbul pogrom (6-7 September 1955), the area declined and was left almost abandoned. After that, immigrants from inner Turkey, Anatolia, and Syria moved into the area and occupied the run down, empty buildings.

Balat

Balat is the neighborhood right next to Fener, by the Golden Horn, towards the Theodosian wall. From the Byzantine period, it was a Jewish district, when a Jewish community settled here. Ahrida (Ohrid) Synagogue is one of the oldest synagogues in the city and it is located in Balat.

But after an earthquake (1894) and some fires in the area, the majority of Jewish people moved to Galata area, and they gradually were replaced by immigrants from Black Sea region. By the establishment of Turkish Republic, warehouses, factories and workshops appeared in the area because of the close proximity to the waterfront. Later on, they were left empty because of location change of port activities.

Ayvansaray

Ayvansaray is a neighborhood between the Theodosian Wall and Balat by the Golden Horn. During Byzantine Period, Palace of Blachernae, an imperial residence in suburbs, was located there. Today, it is a picturesque quiet residential neighborhood, with a number of historic monuments though. Parts of the neighborhood, especially close to historical monuments, are also protected as UNESCO's World Cultural and Natural Heritage Convention.

4.3 Historic Areas of Istanbul

The Outstanding Universal Value of Istanbul (speaking about the Historical Peninsula) resides in its unique integration of architectural masterpieces that reflect the meeting of Europe and Asia over many centuries, and in its skyline formed by the creative genius of Byzantine and Ottoman architects.

The four areas of the site are the Archaeological Park, at the tip of the Historic peninsula; the Suleymaniye quarter with Suleymaniye Mosque complex, bazaars and vernacular settlement around it; the Zeyrek area of settlement around the Zeyrek Mosque (the former church of the Pantocrator), and the area along both sides of the Theodosian land walls including remains of the former Blachernae Palace. The site was scripted in on 1985 and it fulfills the 4 first criteria from the criteria list, all of the cultural ones. (UNESCO World Heritage Center)

Finding a balance between change and preservation is a delicate issue in the Historic Areas. The Management Plan, which is currently being prepared in collaboration with all stakeholders in conformity with the related legislation, will address this issue. It will address the traffic and transport plan for the city, the urban regeneration strategy and tourism management, and will provide a proper framework to ensure that construction and infrastructure projects respect the Outstanding Universal Value of the property. It will also include policies for conservation, standards for restoration and rehabilitation, management responsibilities, accessibility, visitor management, policies for increasing the perception of the site, increasing the quality of daily life, risk management, awareness raising and training. (UNESCO World Heritage Center)

Rehabilitation of Fener and Balat Districts Programme

Rehabilitation of Fener and Balat Districts Programme is a joint programme of the European Union and Fatih Municipality. The Programme is being implemented by Fatih Municipality, supported by a Technical Assistance Team and it started in January 2003. It works under four concepts: restoration of houses, social rehabilitation, renovation of the historical Balat Market and establishment of a waste management strategy and it aims for the active

participation of the district inhabitants through regular feedback on implementation and decision-making. (Rehabilitation of Fener and Balat Programme)

4.4 Design Area

As the 3 neighborhoods are huge, for that specific project it is selected the area between Yıldırım Street and Çiğirli Çeşme Street by the Golden Horn, which includes parts of all of them.

Urban fabric is dense with narrow streets. As it was an area with former important churches and schools, there are still big open spaces around them which are fences or unused. In the dense area, there is a variety of public building, some of them built on Byzantine and Ottoman period. The most interesting of the area is that a core of old dense wooden buildings already exists close to the waterfront, but on the top of the hill there are newly constructed concrete apartment buildings. Between the new and the old urban fabric, there is an area where new meets old constructions, and as there are some empty plots, this is an opportunity to create an interesting combination of historic and contemporary built environment.

As the area is an old neighborhood of the city which became abandoned after the majority of its residents moved to other parts of the city or in other countries, the quality of some buildings are poor or bad. Some need minor reparation to maintain their situation and some need extend reparations to reinforce their construction in order to be safe for their residents. Few of the buildings though are half demolished and they need a reconstruction to reach their original situation. The majority of poor quality buildings are in the area of Fener.

The area has a unique topography which influence the built environment. It is built between the waterfront and a hill, so the northwest part is on the top of the hill (approximately 30 m above sea level) and it goes all the way down till Golden Horn (in around 500 m). As a result, main streets are following the topography and there is one highway street close to the waterfront, and one narrower on the top of the hill. Bus lines are passing by these two main streets and there is no connection between the waterfront and the hill. Secondary streets are connecting the two main streets.

As the topography is so strong, there are two major cores. One on the top of the hill, which is the conservative neighborhood of Çarşamba with a strong commercial center. Close to the waterfront, there is the commercial center of Balat, with restaurants and cafes, small shops and workshops. Between the two centers, residents use to walk.

In such a dense urban fabric, there are not so many green/public spaces. There is a big linear park by the waterfront, but it is separated from the actual city by the busy highway. Smaller green/public spaces are located close to main public buildings and they are as their outdoors space.

So, streets and pavements are where the actual public life is found. There are also two big empty spaces which are fenced and inaccessible because they belong to the Ecumenical Patriarchate.

Figure 6: Built environment and public buildings (black).

Figure 7: Bad quality buildings.

Figure 8: Topography.

Figure 9: Green and public spaces vs empty spaces.

5. Design Toolbox

5.1 Design Principles

According to a research project made by Gehl Architects and EMBARQ Turkey, the historic peninsula of Istanbul is an area of a great importance, various qualities and potentials to become a livable and sustainable part of the city. Their analysis and strategies are referring to the actual historical core up to the first city wall on three different layers: City Qualities, Walkability and Recreation.

My focus area is outside of the research area of that project, but I think that it has a huge importance for city's history and should be treated as the rest of the historic areas, so it would become a part of them and a node between the actual historic core and the Theodosian walls historic area

5.2 City and District Level

Urban Structure

First layer of design principles is the urban structure. As the area is quite old, its structure is defined through the time and it should be protected and preserve as a quality, a memory of the past.

Inclination in some streets are so high, so steep grades are necessary. This challenging pedestrian landscape is difficult for people with disabilities, people with prams or the elderly and bikers.

The presence of monuments sometimes works as barriers in terms of integration with the rest of the city and the waterfront, especially in the areas close to the walls. By the time some monuments have been ignored (maintenance and proper utilization of area around them) which affect their quality today.

Due to the messy street network, the city is complex to comprehend, access and orientate in it. Because of the lack of planning, there is no clear pedestrian network, there are only few walking routes which are difficult to be followed due to poor connections between them. The lack of proper and clear pedestrian crossings, bridges or subways add more difficulties in pedestrian network.

Public transportation is usually crowded, especially the lines serving the inner city and the Asian side. Also, there is poor connection between the different means of transportation and pedestrian network lacks of bike infrastructure.

Strategy

A pedestrian oriented neighborhood which promotes walking, cycling, and public transportation and makes it easy for users to change among them. Effective connectivity with the rest of the city will enable residents to commute easier and tourists to reach the area.

Urban Space

Second layer of design principles is the urban space. Access to adequate and qualitative urban space is based on planning and maintenance in the space especially in historic areas like these.

Footways are frequently used for parking and that way pedestrians are forced onto the road. Lack of maintenance of the pavements, pedestrian streets and public lights create poor walking conditions and unsafety in the public space. Street network is car oriented and as a result there is not enough safe pedestrian crossing.

Tourists tend to visit monuments in the very central areas and forget to enjoy the actual city life and "secret" monuments. Many of them have poor surroundings and improper maintenance.

Figure 10: Steps and steep streets.

Figure 11: Historic wall as a barrier.

Figure 12: Promote walking, cycling, and public transportation.

Figure 13: Isolated green and public spaces (urban leftovers).

Public squares are not part of the usual vocabulary of that city (as it has an Islamic character) and there are leftover pieces with no particular character or identity.

Strategy

Attractive public spaces and historic sites integrated with the rest of the city. It is important for the sustainable development of the neighborhood and the health of their residents to provide qualitative urban space, adequate access to public and green spaces for everyone.

Figure 14: Neighborhood integrated with the city.

Social Life

Third layer of design principles is the public life. Social life in the public space has to do with the balance between private and public space, sense of belonging and safety.

During the night, some areas are empty as they lack of night activities as well as accommodation. Except from busy street, passing by in the rest of the area gives a feeling of unsafety, especially for women.

The streets experience a severe lack of resting facilities, they are mostly for walking. The only place that public benches could be found is in mosque yards. Many children are playing in the street because of the lack of facilities for them within urban open spaces.

Strategy

Greater variety of activities around the clock in a multifunctional city will make livable neighborhoods and activate financially the area. By creating commercial and leisure activities, neighborhood will become more popular and economical sustainable.

Figure 15: Traffic, noise and fumes.

Figure 16: Variety of activities.

5.3 Street Function

In order to upgrade the quality of urban environment, reduce the use of the car, promote walking and create a financially and socially active neighborhood all day round, street function will change and a new network will be proposed. The new network aims to give more space to pedestrians and bikers and discourage the car use inside the area. Following it is shown different kind streets functions in the area today and the changes are proposed to them.

To make the street more pedestrian friendly and enable connection with the waterfront, road width will decrease and bike lanes will be implemented. As the bus lines connecting the area with the rest of the city are passing on that street, bus lane (for all the different bus and taxi providers) in both directions is proposed. Also, both pavements are becoming slightly wider to be used by more pedestrians and staircases/ steps are implemented by the waterfront to allow people reach the water.

Figure 17: Section transformation of highway and park.

5.4 Focus Area

Aim for the focus area is to create an alternative urban structure which will be example for the rest of the city and gradually will spread its qualities. To encourage the bike travel across the waterfront, a bike way will be implemented and structure the linear park connecting the central areas and with Eyüp. Fener and Balat will be a stop along the bike way towards Eyüp for visiting historical buildings, have a rest in the park, eat lunch or dinner or enjoy the unique urban environment of the historic neighborhood.

The new street network is pedestrian and bike oriented, so a new block division has been implemented using the existing urban fabric by changing the street function. The linear park is connected with the urban fabric and green/open spaces are introduced where it is possible so the green starts integrating into the built environment and gives everyone the possibility to access it. At the same time, new construction will fill the empty plot to make a continuous city environment, structure the open spaces and provide residential and commercial facilities.

In order to minimize the urban gaps and give the filling of a continuous dense urban neighborhood, new construction are added where it is necessary. A new pedestrian network

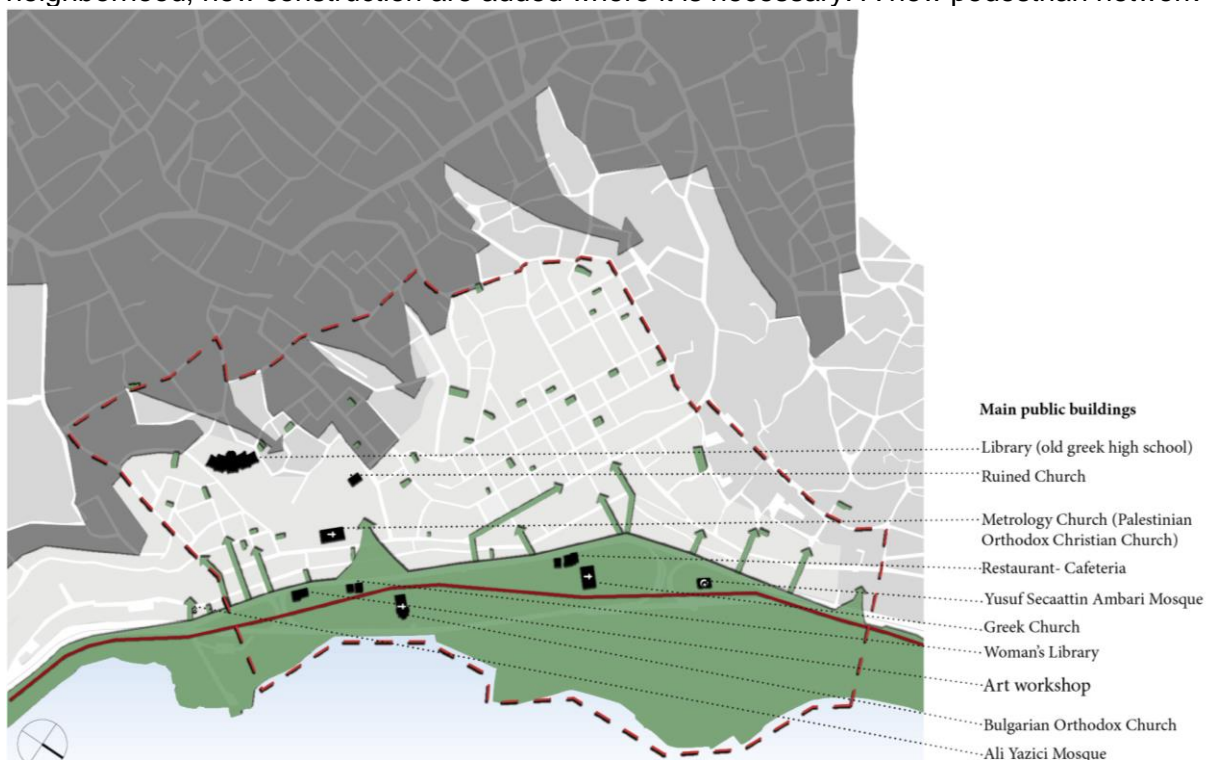

Figure 18: Strategy: Highlight public buildings, expand green areas and densify.

aims to connect all public buildings in the area and combined with new green areas will create a safe and pleasant urban environment. As it goes up to the hill, it becomes more urban and green and open spaces are smaller with little more private character.

5.5 Reparation and Climate Strategies

According to the proposed strategy for reparation, buildings are categorized according to their structural condition. The ones with no or limited structural reparation will be totally restored and maintained from times to times to act as reminders of the history of the neighborhood. The ones that need sever construction reparation will be kept as ruins and they will act as memory open spaces. On that way, the neighborhood will have enough open and green spaces with an alternative historically loaded character to their residents.

Water management in the area is another important issue, as today there is no proper drainage system on the streets. To improve the water management, drainage is combined with a water collection system. Every tree which will be planted in the pedestrian streets and public spaces, will be combined with an underground water storage and perforated pavement, so the rain water will be collected and stored to be reused in the neighborhood.

6. Proposal

Project proposal is developed in 3 levels: the neighborhood level, the new core which is created and the street and public space level. In all level, they are used the strategies above to upgrade the urban quality and provide and create an example area for the city.

6.1 Masterplan – Neighborhood level

Figure 19: Masterplan.

A new street hierarchy is implemented based on the existing street pattern, so new blocks are formulated in order to encourage safe pedestrian and bike movements. The linear park which was located between the two lanes of Ayvansaray Street, is now connected with the city fabric and green is gradually flowing inside the urban. The linear park works as a buffer zone between the city and the busy street, and as the most public space of the area. Cultural functions are spread all over it, from museums and libraries till religious buildings, the majority of them already existing.

As we walk up to the hill, public and green spaces become smaller, in order to provide both privacy and public life. The new core of the neighborhood is the market square, by Vodina Street. Its new functions as an open green space, is to host the weekly street market of the neighborhood and combine the new with the old buildings. The Ruin square, located northern of the Market square, is the upper corner of the former church yard, which contains the ruins of a mall church. Formulated as a small urban open space, with the ruins in the center offers a reminder of the past with an interaction with the modern city life. New street hierarchy offers a pedestrian network with focus on offering both busy commercial and private neighborhood-feeling streets. Public spaces and street functions are design so the more up to the hill, the more focused on privacy, so they are becoming smaller and less commercial.

Figure 20: Zoom in plan and section.

7. Conclusion: Qualities for a livable district

I number the urban qualities which are considered necessary and important in order to achieve sustainability in public life in modern Islamic cities which are result of the research above.

1. *Public spaces and urban green.* Spaces like mosques, squares and parks where people could meet and socialize. Also, green spaces are important for a better environment, atmosphere and mental health for people living in urban areas.
2. *Financial activity in urban environment.* Market or street market is an important event for a district, a generator for future development and could enforce street life. Especially in Islamic cities, market is close to the mosque (center of neighborhood) and it is an important event for the neighborhood.
3. *Street network- Connectivity.* Roads and streets to facilitate commute in the district and to other districts and provide the necessary space for pedestrians, bikes and cars.
4. *Building quality.* Adequate quality of construction, access to water, electricity and sanitation for all the houses
5. *Mixed uses.* Mixed uses in the area in order to have a livable and financially active neighborhood all day.
6. *Social sustainability.* Mix of different culture, income and age group. Balance between public and private areas to ensure people's interaction and safety feeling for women and children. (Gehl, 2008)

The Test Planning Process and the case of Patras

Theodora PAPAMICHAIL, Institute for Spatial and Landscape Development (IRL)
ETH Zurich, Switzerland

Abstract

Infrastructure development is traditionally related to top-down strategies. Nevertheless, in last decades the urban redevelopment of cities requires top-down policies complemented with bottom-up approaches. This is true specifically in complex institutional frameworks which need the enforcement of the interested public. Regarding the socio-economic crisis in Greece, infrastructure networks have already been dramatically influenced mainly by the fragmented decision-making between the different planning levels and actors. The territorial scope focuses at the west part of Greece in the city of Patras. Thus, the case study of the railway development in Patras will represent an informal procedure, called Test Planning. In one word Test planning is a collaboration process among numerous stakeholders. The idea to use such a procedure in Patras emerged due to the different interests of various actors concerning the railway integration in the urban fabric the last two decades. This allows to examine the Test Planning Procedure in a situation of crisis. It was initiated in 2014 and it is expected to be completed in September of 2015, involving the important actors of the city, regional development agencies and independent experts of various disciplines. Regarding the research methodology it will be developed in several steps. Firstly since the paper is a part of an extensive and progressive project, the broader problematics and potential of the specific rail section will be introduced. Secondly relating to the Test Planning Process the different phases will be presented. In the end, the outcomes of that process may contribute both in other cases of railway redevelopment and in spatial planning issues forming new guidelines for a long-term self-governance model and an alternative conceptual basis in Greece.

Introduction

Railway had a significant role in industrial, economical and urban growth of the cities since the very early years. Nowadays, there is a big debate on railway infrastructure related to the spatial and urban planning context as well as to the institutional context regarding the development of new approaches and methods. More specifically, in Patras case, the impact of railway networks is examined on macro and micro level, focusing on EU Transport Corridors, the national and regional network system and on local level just as the fragmentation of urban grid or the reactivation of surrounded brownfields or inactive sections. Furthermore, beyond the physical planning, new approaches on decision-making are developed in order to face long-term problems unsolved by traditional planning practices.

As a representative example of the above statements, the project of the Test Planning in Patras is selected as a case study. In 19th and early 20th century, the city was a main trading and cultural hub and the role of the railway was remarkably decisive. Nowadays a reliable and direct connection between Athens- Patras is a strategic project of high priority due to the fact that it contributes to reduce the East-West division of high-performance transport infrastructure that exists in Greece for a longer period and connects Patras port (western gate) with its hinterland. Since the last two decades, an endless discussion and unsustainable studies about a fast connection between Athens-Patras and simultaneously urban integration of the rail tracks have been developed without concrete results. At the same time the city seeks of further urban development and economic growth. Thus the problematic focuses on the implementation of an ad hoc method that gathers together various stakeholders and actors and it will provide alternative and feasible solutions.

The paper is structured as follows: After a brief introduction about the role of railway infrastructure and the main problematic, the procedure of Test Planning is represented focusing on the specific principles. Afterwards, a further analysis on the potential of Patras case follows. This examines Patras position on international, national, regional and local level. Then, the organization and participants, as well as an overview of the Test Planning process in Patras are illustrated. In the end, the paper concludes with the impact of this procedure regarding the operational, regional, urban and institutional context.

1. Test Planning Process: Definition

Test Planning Process is an informal method for achieving concrete and feasible proposals in challenging tasks in spatial planning. It stimulates a critical discourse on implementation solutions regarding long-term problems. (ETH et al.,2013) Instead of traditional and formal spatial planning methods, Test Planning is a collaboration process among numerous stakeholders of different interests, which combines top-down policies with bottom-up approaches. More than a common competition, Test planning is gathering competitive ideas from different planning teams who are working together in a cooperative process with an interdisciplinary steering committee. The resulted contributions are presented and discussed and after a close evaluation are promoted to the correspondent executive committee for further elaboration and implementation.

1.1 Development and establishment of the method

The method was developed through the so-called Vienna Model in 1970s after the massive flooding of Donau River that caused considerable damages. Due to the huge size of the disaster and the big number interested groups of the city, the planners realized that the traditional planning methods were insufficient. A new plan, called the Vienna Model, was intended to organize all the interested groups in a three-year planning process in order to find sufficient solutions. Despite the satisfactory solutions of that process the time period of the process was needed to be shortened when this was applied to other tasks. As a result a Test Planning process today lasts for one year, with an eventual second year as a concentration phase. Conducting a Test Planning Process in Greece allows to this cooperative method, which has proven itself in difficult and complex projects in Switzerland, Germany and Austria, to be tested in an especially challenging environment and further developed. This explains the special interest of the ETH Zurich Chair, who designed the Test Planning procedure in 2001 and has had successful experiences with it since then. (ETH et al.,2013)

1.2 The principles

Briefly, some basic key-principles are referred below:

1. Concurrence of ideas!

The core of Test Planning is the competition of various ideas. As a result the most efficient solution is given to the contractor against the frame of given conditions.

2. Rhythm!

Ideas and solutions become mature through the regular meetings due to a repetitive discussion and continuous testing.

3. No winner!

Unlike a traditional competition, there are no unique winning proposals. This method examines the different ideas of the teams since in complex tasks since there is no often an ideal solution.

4. Ad hoc organization!

Test Planning is an independent procedure and the roles even of local and regional officials attribute according this fact. As a result, alternative, impartial solutions can emerge.

5. Communication!

Test Planning sites are about areas whose future is strongly of high public interest. Towards a public support of the results and the attraction of different actors, communicating and marketing the different steps and solutions is necessary since the beginning.

6. Problem & Solution Finding!

Apart from the final solutions, a redefinition or identifying new problems against the given ones take place. This turns Test Planning to a dynamic procedure.

7. “Protected Process”!

Ideas and solutions are firstly discussed and tested in close meetings between the teams and Steering Committee before any publication in order to develop a strong argumentation. Thus, a fruitful and discourse dialogue with different actors and the public can follow afterwards.

The Test Planning process belongs at the collaboration procedures and combines top-down policies with bottom-up approaches. The main concept of the method is to discuss the ideas through the planning process and highlight the advantages and disadvantages of each proposal. Through dialogue and criticism teams can build concrete results focusing on the existing and most important problems of the task. In general Test-Planning procedures provide a framework of a continuous organization and learning while it is a flexible and open process.

Complex spatial problems with several actors are characterized by the presence of “seams” (spatial, functional organizational), that complicate the implementation of traditional planning tools and methods. Along with a fragmented and unilateral decision-making and the scarcity of strategic planning, a new methodological and customized model is required based on coordination, cooperation and communication against the conflict of interests. Test Planning Process can turn to a new methodological model in order to influence the spatial practices in such complicating contexts as in Greece. The constructive dialogue during the procedure is a basic element both among the teams and the interdisciplinary experts and also benefits the final recommendations Steering Committee. Thus a common ground of trust and openness is formulated among various stakeholders.

The Test Planning Process ensures efficient results in complex and challenging tasks due to critical discourse. The different approaches of each team in combination with the final recommendations of the Steering Committee give an overall view both at the real problematics and a variant of solutions to the Executive Committee. Furthermore, the substantiated arguments and results prior based on constructive criticism favor and support a probable second concentration phase in future. Since the most serious mistakes happen in the beginning of each planning process, the gained information from various experts and the planning teams ensure a progressive process.

2. Test Planning Process in practice

After the Vienna experience and the development of the Vienna Model other practices were mostly promoted by the Chair for Spatial development of the ETH Zurich as a form of collaboration between the academia and planning practice in order to create the opportunity to achieving two mutual goals; on one hand, engaging the research in the solution of complex planning situations, on the other, experimenting the feasibility and effectiveness of the methods and instruments developed by the so-called Action Planning school in over 30 years in different cases and different contexts. (Tosoni, 2014)

Focusing at the Trans-European corridor Rotterdam- Genoa, several projects took place. The case of Europa Viertel in Frankfurt am Mein (1996-today) related to the revitalization of the shunting yard in the North West part of the city, offered the opportunity to deal with a complex spatial problem with various involved actors. Thus, new hints regarding the so called Test Planning Process were developed for the analysis of the process design method. Furthermore, Bovisa Gasometri brownfield area in Milano was another case that was

embedded at the daily routine of the involved Institution (Chair for Spatial Planning and development, ETH). Later on the process was also implemented in Switzerland such as in the largest industrial wasteland in Solothurn area (2011-12) a complex case study regarding the different interests of various actors, airport or the cooperation project regarding Pfaffikon city where traffic reorganization and urban areas restructuring around the railway station area were urgent. Regarding the above case studies a systematic research has already been established and developed. This allows both to enrich and improve these ad hoc procedures and to reach concrete results.

3. Patras as a potential hub

Patras illustrates high potential on a further transport infrastructure development, especially that of rail. It is rather important to remark that since the modern establishment of the city, both its economic and cultural profile have been closely related to its transportation importance, being largely oriented to European destinations. The specific role of the city on international, national/regional and local level is represented below.

3.1 International Level

Greece is being situated at the crossroads of three continents and the intersection of Asian and European trade routes. It is at the same time a Southeastern European gate for Asia and Africa as well as a gate to the Middle East for Europe. In addition to this, the country is currently in the middle of a geopolitical transformation due to the shifting of the global trade routes to Asia. For instance, this is greatly illustrated in the hub deal between Hewlett-Packard, Cosco and Trainose, increasing the geopolitical importance of the Piraeus port, thus strengthening its position among the top European ports. Thus, Greece from a peripheral position is transferred to the heart of the Trans-European transportation networks and creates the potentials for economic development. Meanwhile, the European Commission is interested to develop a unified cross-border traffic management system including roads and railways for both transport and traffic management (TEN-T projects: corridor Orient/East-Med). Therefore, an improvement in railway network in Greece is expected in Hamburg-Athens- and further to Patras- corridor. This corridor is one of the most strategic EC projects, since it connects the central Europe to the maritime interfaces to the North, Black, Baltic and Mediterranean seas. In a more global context Patras may be described as part of a major worldwide economic and political 'puzzle' that has to be resolved as soon as possible. In an explicit way this international character that could be directed forward, towards the expected future of Patras, seems analogous in many ways to the character of its historical neoclassical past of 19th and early 20th century.

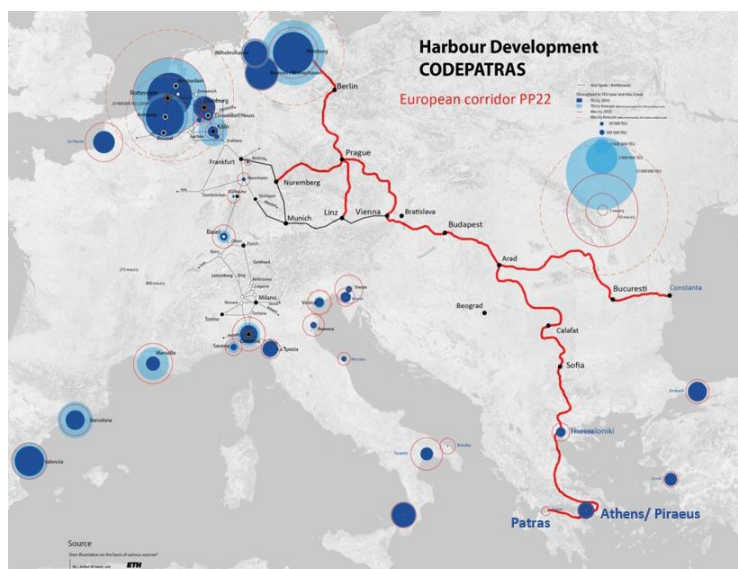

Figure 1: Europe Orient/ East-Med corridor, ETH, IRL, Zurich

3.2 National and Regional Level

Considering the national transport networks, Patras as one of the most important urban centers and portal zones, is part of the main transport corridors in Greece, such as PATHE (a road corridor connecting Patras-Athens- Thessaloniki- Euzonoi). Simultaneously with the development of the road, the air and maritime transport, the railway network will complete a future integrated transportation system both on national and regional level.

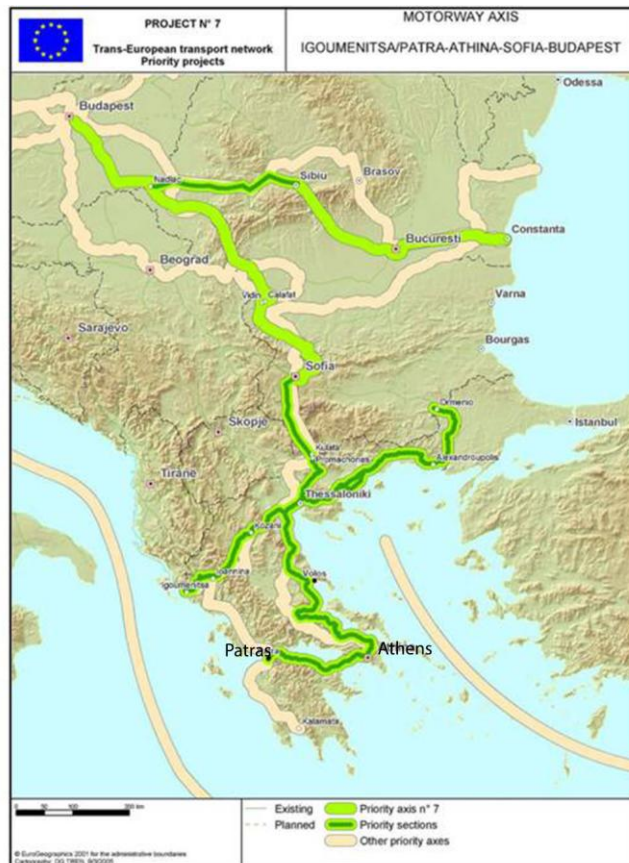

Figure 2: Greece PATHE, road and rail network, “City- Port Eco Logistics CIELO”, European Territorial Cooperation Program, Greece- Italy 2007-2013

In addition to this, Patras is part of Peloponnese region that is characterized by a unique natural and cultural landscape as well as a significant primary production. Both the present and the future potential contribution of the region in Greek economy are remarkable. Regarding the existing Spatial Planning Framework (GG, 2003) on regional level, an integrated transportation system in Peloponnese should be strengthened. Since small-scale airports, bus connections and ports (most of them orientated as cruise ship ports), the reactivation of the existing rail network could be decisive, for tourism as well as promoting local agricultural and art craft activities.

However in a more generalized sense the presented proposals refer to a condition of a much broader, economic and political significance. It is within this general context that the particular importance of the city of Patras has to be evaluated; not as an isolated urban territory ‘enclosed’ in the interior of contemporary Greek economic reality, but more likely as a part of an extended international, national and regional network of transportation relations.

3.3 Local level

Regarding the given reality of Patras, there are numerous hidden potential related to the natural landscape, the historical and cultural context as well as the existing transport facilities. Firstly, Patras is shaped as an urban stripe along the coastal front and is bounded by Panachaikon Mountain in the east. Moreover water axis perpendicular to the existing rail tracks as well as open and green spaces can be included to a general strategic plan and be correlated in an extended and peri-urban green network. Secondly the history of the city and the cultural background have left an obvious imprint through important architectural spots and elements or the ancient remains. In addition to this Patras is significant educational and research center due to the University, the Technical Institute, the Science Park etc. concentrating ca.30000 students and scientific staff. Furthermore, concerning the existing transport infrastructure, three important systems are identified; the public transportation system (intercity and local bus, the suburban railway), the port system (domestic and international ship routes to Italy and Ionian Islands) and the road system (the new by-pass and mini by-pass road) that intend to decrease the inner traffic. However, the above systems and potential features do not respond to an integrated strategic approach for the city.

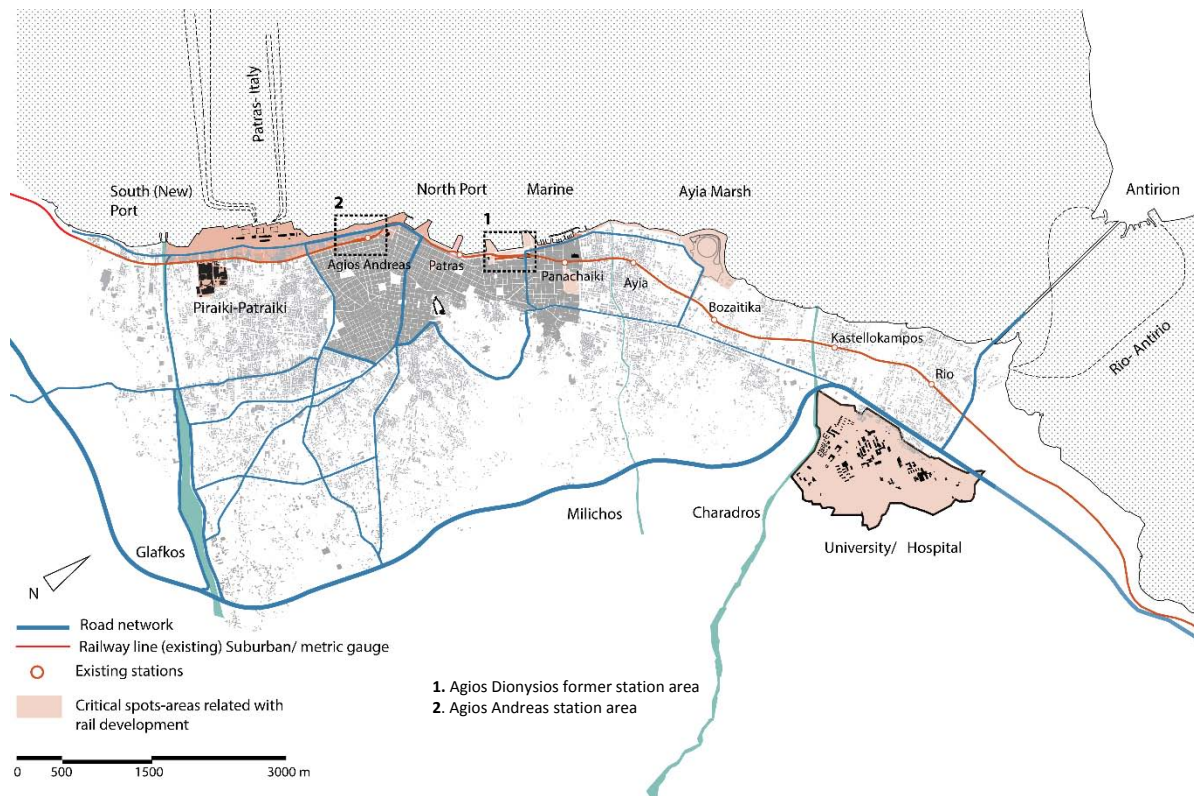

Figure 3: Patras map illustrating the most important features related to the existing rail alignment, Theodora Papamichail, IRL, ETH

4. Test Planning and the case of Patras

In Greece, Test Planning Process is a pioneer method since it was firstly implemented in the case of Patras. It was an initiative of the ETH in Zurich under the supervision of Prof. Scholl in close collaboration with the University of Patras and the National Technical University of Athens. The key question for this Test Planning procedure is the railway connection between Athens and Patras and more specifically the section between the north region of Rio and the south region of the New Port. Beyond the rail connection, there are other tasks closely related to the reactivation of the rail line. In order to test the forthcoming results in Patras, the idea of a Test Planning process emerged. One such process involves the important actors of the city and regional development, independent experts of various disciplines, as well as

several planning teams that would develop innovative solutions based on a mutually set goals and tasks. The contributions of the teams would be deliver the foundation for informing the executive representatives of the city and region and the population, outlining their involvement in further steps.

4.1 Problematics and the task

The problematics are referred to the existing and future operation of railway system as well as to further urban development in Patras. Considering the operational context, on the one hand the suburban train stops at Kiato while the construction works continue along the corridor Patras-Athens. The expropriation section reaches the suburban areas of Patras city where a temporary rail station is planned since the rail alignment across the city center is not yet defined. On the other hand, the local suburban train operates from Agios Vasiliios to Agios Andreas station serving approximately 8000 pass/day and reducing by 70,000 cars in daily traffic and tends to be extended to the south and north.¹ Given the above circumstance, the meeting node of the metric gauge and the new standard gauge is Mpozaitika location. Moreover the rail tracks should be integrated in the urban fabric with a perspective that the new port (South Port) is connected by train since it is a precondition of the EU funds that have been invested on the construction of the New Port. The methodological framework includes the below statements:

- The standard gauge will reach Mpozaitika area and is a given circumstance.
- The current operation of the local suburban train should continue despite any future construction works.
- The operation of Proastiakos should continue at the South Peloponnese (Kato Achaia, Pyrgos) in normal or metric gauge. Moreover it should run at a minimum twice/hour.
- Considering Intermodal operation for rail, intercity/local bus.
- The new port should be part of the standard gauge, meanwhile accessible by metric gauge. Cargo trains should be able to run on the standard gauge to/from the South Port where full length train yard operations should be available (or divided in two half trains in an area outside the city).
- For future development, Ro-Ro (piggy-backs and trailers) connections to Italy, a train berth is necessary. A container handling infrastructure can also be considered in the port. (Frezadou, Papamichail, Signer, 2015)

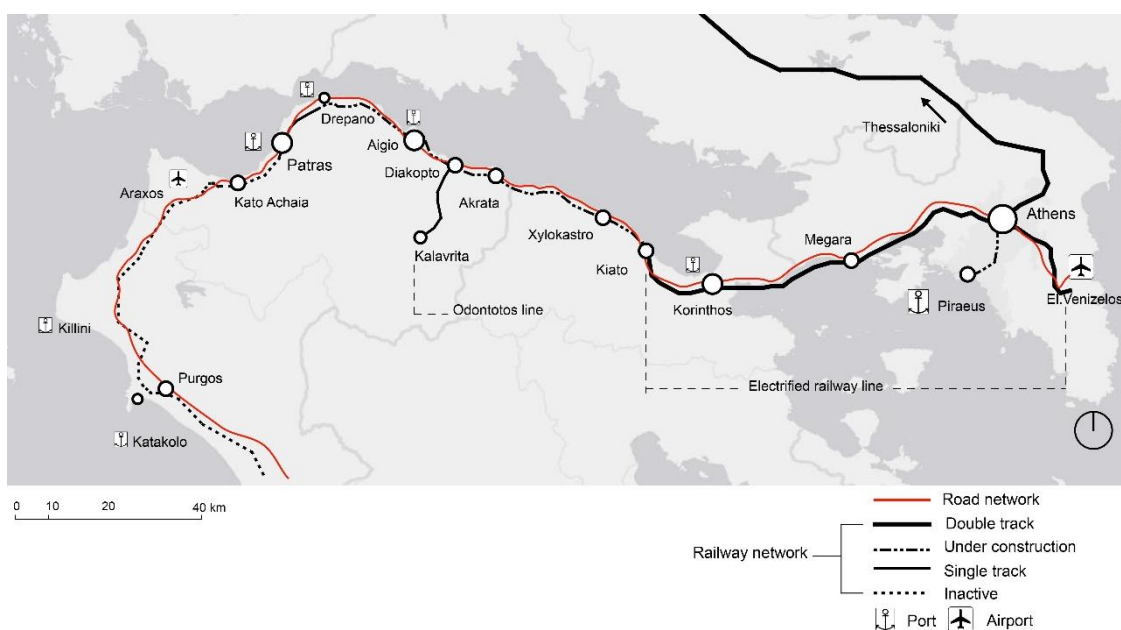

Figure 4: Rail and road networks, Patras-Athens, IRL, ETH

Regarding the urban development of the city, it is closely related to the natural landscape, potential brownfields along the existing rail alignment and the economical rehabilitation. Thus the perimeter is defined with a minimum 250 m, i.e. 125 m each side of the existing metric gauge including important areas of the city that seek for revitalization. The above mentioned perimeter will be adjusted in the following cases (critical spots):

- Sections between the three rivers and the rail line.
- Sections with important facilities (sports, education, historic and cultural heritage)
- Sections with brownfields along the rail tracks.
- Sections between the existing road networks, close to the given perimeter.

The relevant proposals should provide a stepwise development that will present a short-term a medium term and a long-term solutions. As a result the development perspective should both include the above mentioned and a wider observation perimeter such as the broader Patras region or Peloponnese.

5. Organization of Test Planning procedure

Regarding the organization of the process, people from interdisciplinary fields are grouped together according to the following team structure:

5.1 Executive Committee

Usually two to nine persons, representatives of the decision-making authorities of the contracting political authorities and companies. It is regularly informed by the work of Steering Committee and approves the recommendations that result by the Test Planning Process. (ETH et al.,2013) The immediate related stakeholders of the rail operation and integration are OSE², ERGOSE³, the Municipality of Patras, the Ministry of Transportation and Networks. Further stakeholders may be interested regarding urban planning and economic development such as OLPA⁴. However, in the case of Patras the constitution of the Executive Committee was not clearly defined since the different interests prevent the representatives from a common dialogue. This non-collaboration spirit and the negative competition is one of the main reasons that the rail integration in Patras is a long-term problem counting almost two decades of negotiations and insufficient solutions. The process and the publication of the results is a common effort to reunite the various interests.

5.2 Steering Committee

It is consisted often by seven to eleven interdisciplinary experts chosen by the commissioner as well as independent experts (ETH et al.,2013); leads the Test Planning Process, examines carefully the content and is responsible for the final recommendations and the attention of the Executive Committee. In this case, academics from ETH, University of Patras and University of Athens as well as international and local experts from planning, architecture and transportation fields composed the team.

5.3 Teams

In the current project, four teams participated. The different background and experiences of each team offered various insights on the task on both macro-scale and in-depth studies. Moreover they strengthened their knowledge with more experts on economics, transport and landscape architecture. The number of the teams is wisely selected since with a smaller number of teams there is a danger that a weak team stays out of discussion and only the contributions of two teams are included. The following four teams participated in the process:

- ASTOC, Architects & Planners, Germany
- Feddersen, Feddersen & Klostermann, Switzerland
- Carydi office, Greece
- International University Team (ETH Zurich, University of Patras, University of Athens)

5.4 Planning Team

Usually three to four people, responsible for the preparation and the fundamentals of the test planning, pretesting the project and taking the operative leadership of the process. The preparation of the task mission lasted approximately six months. (ETH et al., 2013) Further meetings and workshops before were supported by the Chair of Spatial Development in Zurich in collaboration with the University of Patras and the University of Athens. In Test-Planning Process, time-consuming coordination with high level positions is avoided. A diagrammatic and embedded at Patras case the organization of the process is represented below.

Figure 5: Organizational Structure of Test Planning Process, ETH, IRL Institute, 2015

6. An overview of the Process

In general, Test Planning Process follows different stages. Beyond the typical one year period of the procedure, several steps precede and ensue, inextricably linked with Test Planning Process:

6.1 Preceding steps

- In 2012 in Zurich, a Preparatory meeting took place where the first problematics and the relevant information were presented regarding the railway and spatial development of Greece and the region of Patras. Experts with a different background from the academic and professional field participated providing their experiences on international and local level. A first idea regarding the task definition started to emerge.
- Later on, a Joint Seminar Week followed in the city of Patras in June 2013 between the ETH in Zurich, University of Patras and the National Technical University of Athens with 35 participants. Swiss and Greek students worked in mixed groups coordinated by interdisciplinary experts. The future railway corridor between Kiato and Patras and the integration of the rail line to the urban grid was taken as a case study. The results were promising since alternative ideas were proposed that could be implemented gradually with manageable costs.

- In February 2014, a Swiss-Greek Mobile Seminar was held in Zurich. This seminar offered the opportunity to discuss all the relevant tasks regarding an integrated infrastructure and urban approach in Patras. Through travelling at the eastern part of Switzerland the participants faced different examples of rail development. Two visits were carried out; one in Chur, at the node of the normal width track with the Rhaetian Railway and the other in Domat Ems at the industrial mixed gauge track. In Ardez/Lower Engadine a possible Test Planning process for Patras was discussed.

6.2 Test Planning Process (TPP)

This phase lasted 6 months according the following stages:

- **12.12.2014:** Constitution of Steering Committee. First discussion and improvement of the task mission
- **6.2.2015:** the kick-off event took place in Patras where the task was presented and the teams together with the steering committee and experts visited the most critical spots along the existing railway line.
- **27.2.2015:** a workshop discussion took place between the steering committee and each team separately. The idea of the enclosed meetings was that each time had to keep its own direction in order to achieve various final solutions in the end even with some common points. The teams have the opportunity to visit again the critical sites related to the task mission.
- **27.3.2015:** a common interim presentation held where the Steering Committee as well as the members of the teams had the chance to discuss each solution and highlight the main points.
- **29.5.2015:** the final presentation took place with remarkable results. Each team presented its complete proposal and a constructive criticism followed.
- **5.6.2015:** the final reports and the posters were submitted. The Steering Committee will compile them in the form of an overview for a comprehensive presentation. It should be highlighted hereby that the purpose is not to select one of the four solutions but combine them in the most appropriate way. For this reason the final session of the Steering Committee aims to develop further recommendations to gain the attention of the Executive Committee.
- **29/30.6.2015:** the Steering Committee met and discussed on the final proposals of the teams and on the follow-up recommendations. Afterwards these would be transferred to the Executive Committee for further discussion and implementation.

During the above six-month procedure the role of the Steering Committee was determinant since they were providing the correspondent feedback after each meeting and supporting any idea and solution.

6.3 Simultaneous and following steps

The communication with the public is a crucial and usually parallel procedure in order to motivate and communicate the results to all target groups information activities since the beginning of the process. Apart from related articles at the local press and online information during the procedure, an exhibition that takes place in September of 2015 will present officially the final results. Such an effort will exert to attract more actors and citizens, especially the interest of the Executive Committee that its constitution and position until the final results remained neutral. In the current case, Test Planning Process, after its completion, consists a foundation firstly regarding the value of a constructive dialogue and the meeting of the stakeholders who already have submitted contradictory proposals based on different interests, such as OSE, ERGOSE and the Municipality of Patras. Additionally, as a future perspective an interactive interface is about to be established among other interested and significant stakeholder groups (citizens, NGOs, technical chambers and

associations, environmentalists etc.) regarding the implementation of TPP results. This can be achieved through workshops that would bring the above mentioned groups on a common ground. Regarding the socioeconomic crisis, new models of action planning should emerge. Thus, Test Planning as a representative of merging bottom-up and top-down policies can activate alternative procedures minimizing any risks and delays. At the graphic below the process is represented in steps:

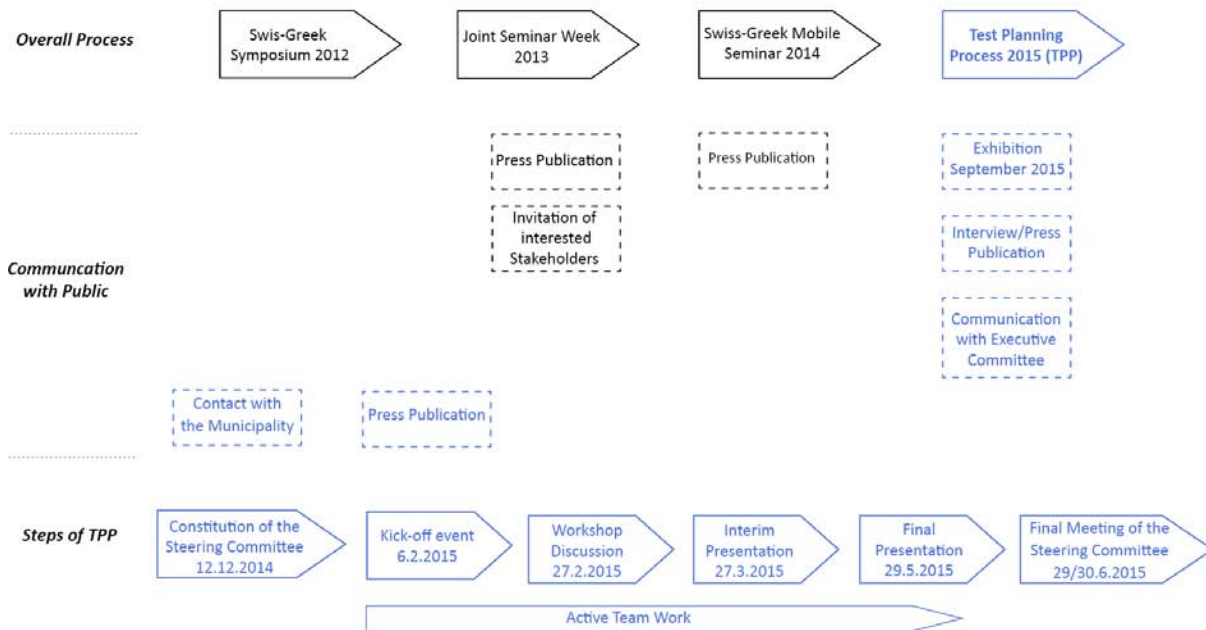

Figure 6: Overall Procedure of Patras project, Theodora Papamichail, IRL, ETH.

7. Concluding remarks: Future expectations

Regarding the above mentioned process, the outcome⁵ of this project is articulated on operational, urban and institutional context. Each team provided a different oriented solution focused on different scale levels (local, regional, national). Through a continuous feedback the arguments were crystallized and the ideas matured, while reports on the disregarded options were submitted too.

Firstly on operational level, the main points are represented below:

- Reliable and fast connection to Athens, with three types of connections (Intercity, Interegio, Suburban trains) achieving different transport needs on regional and local level.
- According to above, the suburban train in Patras is still in operation despite any future infrastructure works.
- Alternative solutions for cargo trains and freight facilities.
- Additional means of transportation supporting the railroad, such as tram connections, towards an integrated transport system.
- The costs of the construction and operation are feasible and compatible with the Greek context.

On urban and regional context,

- Ideas to support and reactivate Peloponnese network to support primary, secondary and tertiary economic sectors (i.e. agriculture, tourism)
- Strengthen a future decentralized model of living between Patras and Athens, and further in Peloponnese region.

- Revitalization of brownfields in vicinity, such as Agios Dionysios former station.
- Improving the current situation of public and green spaces.
- New economic hubs and revitalization of critical spots, such as city's waterfront, Piraiki Patraiki former industrial area etc.

Both on operational and urban context, the proposals were placed on a short-term (next 5-7 years), mid-term (up to 15 years) and long-term (in 30 years) development periods providing a strategic planning through time.

On institutional context, comparing to the formal Planning System, Test Planning Process as an ad hoc organization limits bureaucratic processes and gathers more interested stakeholders together. It can also cooperate with the Spatial Laws and promote new urban policies related to the revitalization of critical spots. Moreover, it can control the privatization policies and the discrimination of the railway system. This may consist an opportunity for further research and documentation.

To conclude with, new hints about the Test Planning resulted also through this project. Regarding the nature of the Greek Planning context important actors, such as the Municipality were approached later, after the results of the submission of the proposals. This proves that Test Planning is an open, independent and flexible process. In addition, a constitution of an International University team was created for the first time and it competed successfully with the other three, professional ones. This team was formed by six experts from the three Universities (ETH, Zurich, Universities of Patras and Athens) that completed the project with creativity, perseverance and enthusiasm. Furthermore, the problem of the railway development was redefined, a procedure that led to concrete and feasible solutions. As a result, Test Planning process is proved itself in complex tasks, combining different fields and experts and offering great opportunities of future development and collaboration in the Greek context.

¹ The reactivation of the metric line in Patras (Agios Vasilios-->Agios Andreas, diesel line, one train/hour) is the more profitable since it operated again with almost zero costs and it services 1.6 Mio pass/year than the section Kiato-->Airport (double gauge, electrified, one train/hour) that costed 200 Mio Euros and it services 4 Mio pass/year.

² OSE, Hellenic Railway Organization: responsible to maintain and operating rail infrastructure.

³ ERGOSE, subsidiary company of Ose, responsible of the management of OSE's investment program projects

⁴ OLPA, Organization of Patras Port

⁵ The results will be announced in September 2015. Thus the proposals of the teams, the review and the recommendations of the Steering Committee are confidential until then, and only general remarks are referred above. The overall documentation will be represented at the Brussels workshop.

A place-based spatial policy in Flanders – a quest for success and realizations, partners and instruments.

Ann PISMAN, Spatial Development Department Flanders & Ghent University, Belgium

1 KEYWORDS

Area development, Flanders, spatial planning, a place-based approach

2 Abstract

Spatial planning in Europe and in Flanders is tackling internal and external problems. The region is still recovering from a deep financial crisis and is struggling with social and climatological changes. Traditional spatial planning has not always been able to deal with these new challenges and actors that are coming forward. In the Europe 2020 strategy (2010-2020) Europe introduced the idea of a '*place-based approach*' as an alternative or addition to traditional spatial planning, referring to the context-dependent nature of efficiency and equity problems that the policy deals with, and to the fact that design of integrated interventions must be tailored to places, since it largely depends on the knowledge and preferences of people living in it. Nevertheless, little research has examined the use of the place-based approach in Flanders.

In this paper the place-based approach, also called area development, is referred to as a tool to deal with the complexity of spatial development, more specifically a proactive planning approach, characterized by an intensive coordination of initiators, plans and projects in one specific area, in order to implement the plans and projects on the field. A place-based environmental policy was already introduced in Flanders in the Flemish Mina-2 plan 1997-2001 and has been more recently developed within the context of spatial planning. At this moment, different actors are testing area-development in Flanders.

This paper reports results from different studies examining two cases in Flanders: area development in the Valley of the Lys by the Province of West-Flanders together with other regional actors, and the Flemish process for the demarcation of the urban growth boundary of Aalst. The paper unravels similarities and specific aspects of the two cases and describes the degree of implementations of plan intentions.

We found that authorities are experimenting with place-based planning in Flanders for several years, but that results, actors and instruments differ. These results can be used to develop future place-based planning, programs and projects in Flanders.

3 Introduction

Spatial planning in Europe and in Flanders is tackling internal and external problems. The region is still recovering from a deep financial crisis and is struggling with social and climatological changes. The traditional land use planning – being a more passive planning approach aimed at controlling land use through a zoning system and regulations - has not always been able to deal with these new items and with the new actors that come forward (Albrechts, 2006). Planning authorities are struggling with the growing importance of citizens, and more general with the broad range of actors involved in a planning process. There is a need for cross-fertilization between the model-based and top-down planning views, with the bottom-up experiences, to construct an integrated approach. In current policy settings, spatial planning tends to emphasise the achievement of policy intentions through realisation of actual spatial interventions and growing importance of citizens as spatial actors (Sager, 2011).

Meanwhile Europe introduced the so-called '*place-based approach*'. Nevertheless, little research has examined the use of the place-based approach in Flanders. In section 4 the context and use of place-based planning in Europe and Flanders is described.

The purpose of this paper is to show what happens in practice; that is how the regional government of Flanders, together with other actors, are experimenting with new planning instruments in order to get the plans implemented on the field. We will illustrate these experiments with two cases, the urban region of Aalst and the area development in the Valley of the Lys. We hypothesize, in part 5 of this paper, that place-based planning processes are very time-demanding, but at the end some of them are really contributing to the implementation of the spatial visions in these areas.

The paper ends with general and specific conclusions on place-based planning in Flanders and in the two cases, and recommendations for further research.

4 The context and use of place-based planning in Europe and Flanders

In the Europe 2020 strategy (2010-2020) Europe has introduced the idea of a place-based approach as an alternative or addition to traditional spatial planning, referring to the context-dependent nature of efficiency and equity problems that the policy deals with, and to the fact that design of integrated interventions must be tailored to places, since it largely depends on knowledge and preferences of people living in it (ESPON and Politecnico di Torino, 2014). Place-based development policy can be defined as '*a long-term development strategy whose objective is to reduce persistent inefficiency and inequality in specific places, through the production of bundles of integrated, place-tailored public goods and services, designed and implemented by eliciting and aggregating local preferences and knowledge through participatory political institutions, and by establishing linkages with other places; and promoted from outside the place by a system of multilevel governance where grants subject to conditionalities on both objectives and institutions are transferred from higher to lower levels of government.*' (Barca, 2009, pag. 5). Place policy making is embedded in multiple institutional domains and arenas, which challenge the hierarchical setting of planning levels and the traditional administrative boundaries. All relevant actors (public and private) need to be involved in new planning processes, for different reasons: procedural competences, acceptance and legitimacy, substantive contributions, etc.

This place-based planning approach is related to a more general approach of strategic planning. In the nineties, in many countries a different type of planning was needed, moving away from regulatory policy and instruments to a more development-led approach that aims to intervene more directly, more coherently and more selectively in social reality and development (Albrechts, 2006).

A place-based environmental policy was already introduced in Flanders in the Flemish Milieu 2 plan 1997-2001 and has been more recently developed within the context of spatial

planning. Albrechts et al.(1999). It can be considered as a specific form of strategic planning, with special attention for the organization of planning processes, and dynamic networks of various actors from different policy domains interacting in arenas and fora (Van den Broeck, 2001). Since that moment, different experiments with this planning methodology have started, but the regional authorities have decided not to formalize this planning method in the legacy system. Recently, several Flemish authors have described actual trends in the planning system, using keywords related to the place-based planning such as strategic planning, project-planning, transitions, governance and coproduction (Van den Broeck, 2008, Boussauw and Boelens, 2013, Coppens et al., 2014).

Within this paper the place-based approach, also called area development, is referred to as a tool to deal with the complexity of spatial development, more specifically a proactive planning approach, characterized by an intensive coordination of initiators, plans and projects in one specific area, in order to implement the plans and projects on the field.

Within Flanders, different planning initiatives and partners can be found, linked with area development on a regional scale. Over the past few years, due to the Flemish decree concerning the inter-municipal or intercommunal cooperation of July the 6th 2001, (Vlaamse Regering, 2001) a large number of regional initiatives were established (Pisman et al., 2013).

First of all, planning processes for the demarcation of urban growth areas can be distinguished. In 1997, Flanders adopted the Spatial Structure Plan for Flanders, a spatial policy plan (Ministerie van de Vlaamse Gemeenschap, 2011). One of the leading ideas of the Structure Plan has been to (re)develop and enforce the urban areas, characterized by intense spatial, cultural and socio-economic interactions and by higher building densities. The authorities want to create extra houses and industrial zones within the urban areas, and to stimulate more sustainable mobility. Shortly after the adoption of the plan, Flemish authorities started planning processes in each of the urban areas, to discuss about future development with key actors in the region, in order to agree on a program and on different zoning plans mainly for extra housing and economic activities. In fact these planning processes have a lot of characteristics of place-based planning.

Next, the subsidizing of strategic projects by the Flemish authorities, is been given attention in this paper. *“A strategic project is a project with an integral and spatial character which contributes to the spatial quality of an area. The project is place-based and is related with different policy domains and different policy levels. It must be able to realize the strategic project within a short or medium time period.”* (Departement Ruimte Vlaanderen, 2012, pag. 7). The Flemish authorities started subsidizing project managers for strategic projects since 2004.

Finally the specific programs for area development by the provinces, are noteworthy. In practice, the provinces have been taken many initiatives for area development on a regional level. Often, those initiatives are financed by European funds and situated within the place-based approach. Due to the closer contact with both the local and the Flemish level, the provinces are in the ideal position to deal with conflicting or competing objectives at different planning levels.

5 Hypothesis and methodology

This paper wants to contribute to the growing awareness that producing plans may not be considered as the main purpose of planning. Planning without implementation on the field is futile. Accordingly Europe has introduced the idea of a place-based approach. The present study seeks to elaborate the implementation of two place-based planning processes in Flanders. The hypothesis is that place based planning processes are very time-demanding, but at the end they are really contributing to the implementation of the spatial visions in these areas.

In order to test this hypothesis two planning processes are analyzed. At first a general description of the different steps in the planning processes is given, focusing on the actors involved and the main visions developed. This analysis is based on literature study of policy documents and selective bilateral contacts with key-actors. At second, focusing on the realizations anno 2015, the data of the building and allocation permits are explored, more specifically the number of permits is taken into account. The registers of building and allocation permits are developed by the local communities, and can be considered as indicators for the dynamics within a specific area. In Flanders an allocation permit is obligatory to divide a plot in multiple, smaller plots in order to sell at least one of those plots as building land. A building permit is necessary to build, rebuild, demolish a built structure, fell a tree, etc. Further research is however necessary since for example not all activities need a building or allocation permit, not everything is registered correctly, the impact of permits is differently, a permit doesn't necessarily lead to a realization on the field.

6 Case demarcation of urban growth boundaries – case urban region Aalst

The first case is situated within the central part of Flanders, between Brussels and Ghent. The center of the area is the urban region of Aalst, but also parts of local communities of Denderleeuw, Liedekerke, Haaltert, Erpe-Mere and Affligem are included. The urban region has approximately 80.000 inhabitants. The analysis refers to the time period 2003-2015.

Figure 1 case 1

6.1 Demarcation of the urban growth boundary of Aalst by the Flemish Authorities (2003)

In Aalst the planning process for the demarcation of the urban growth boundary was organized between 1998 and 2000. The process was supervised by communication experts (CIBE) and by spatial planning experts (studiebureau Omgeving). Local authorities, as well as representatives of the provincial and regional level (different domains) and local inhabitants, were invited to participate. The result was a shared vision on the urban area, and a limited set of actions.

Unfortunately, it took three years for the Flemish authorities to develop and approve the regional zoning plan for the urban area of Aalst. The main reason for this delay is the experimental phase of urban planning in this stage. The planning process in Aalst was the first experiment with this type of planning together with local key-holders. The zoning plan itself, was also one of the first experiments with the new planning codex. Finally the Flemish government approved the regional zoning plan in 2003 (Vlaamse regering, 2003). In the table and map below, changes in zoning are displayed. The zoning plan creates many new opportunities for housing and economic activities. At the same time natural areas within the urban tissue are safeguarded and neighborhoods close to railway stations received

opportunities to redevelop these areas with higher building densities and with a mixture of activities.

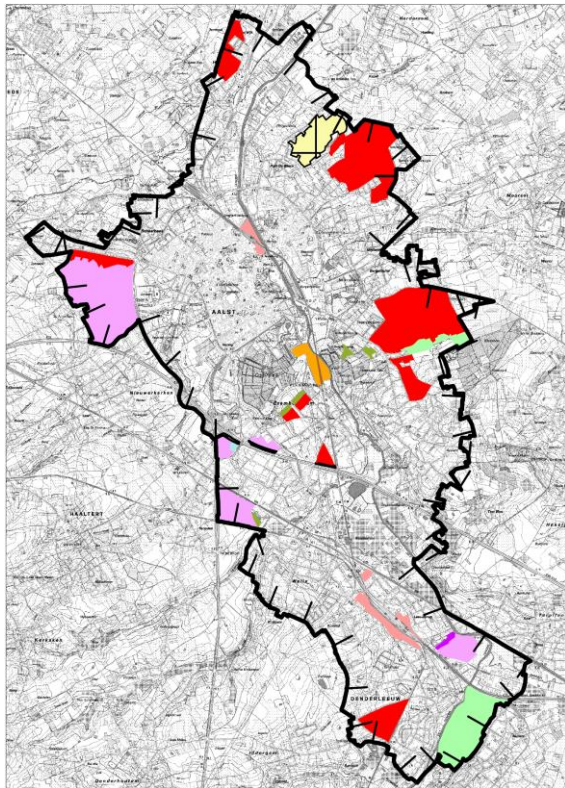

Figure 2 Map regional zoning plan, case 1

Categories zoning plan	Area
Residential areas	-12 ha
Industry / offices	124 ha
Agricultural areas	-180 ha
Recreational areas	11 ha
Nature	7 ha
Other green	56 ha
Railway areas / mixed use	21 ha

Table 1: Areas included in the regional zoning plan, case 1

6.2 Strategic project Siezegemkouter (2007-2011)

In 2006, the strategic project Siezegemkouter was initialized by a provincial development organization (development of industrial areas), and funded by the Flemish authorities as a strategic project. Initially, the aim was to coordinate the realization of a qualitative, sustainable industrial zone at the western border of the urban area. The strategic project was not related to the general residential program included within the zoning plan, but only referred to one of the industrial zones included in the general plan.

After a short period, political questions arose about the zoning plan, and new research, a masterplan and finally a new zoning plan, were necessary in order to find a consensus about the development of the area (Vlaamse Regering, 2013). The funding of the strategic project was used to re-do the planning process of the specific area, and for the moment the area is not yet realized.

6.3 General observations of the planning process and analysis of the building permits within case area 1

The planning process for the urban region of Aalst, finished 15 years ago, was one of the pioneer projects of Flemish spatial planning and place-based planning. The consensus and dynamic at that moment, did not result in many urban projects or long lasting planning initiatives. The ideas to create a project group for the acquisition and development of regional industrial zones and a consultation platform to discuss cross-border and common problems and opportunities were not realized. The action plan mentioned two other strategic projects:

Waterfront Dender and Station Denderleeuw, but no local actors were found to initiate and coordinate these projects.

Based on the data in the registers with building and allocation permits in the period 2004-2015 (table 2) and on bilateral contacts with local actors, it was found that in all areas of the zoning plan, initiatives were taken. In the residential areas allocation permits were given to divide the land. At the moment, the residential areas are partly realized, mostly by private actors. Furthermore the urban agricultural area, the peri-urban green and natural areas are preserved. For the two neighborhoods around the railway stations masterplans were developed and the areas are currently under construction. Because of the complexity, the implementation is spread over several years. The realization of the industrial areas seems to be the most difficult part. Siezegemkouter is not yet realized. Further research is necessary to give a correct overview.

On the map below (figure 3) the different areas of the zoning plan are situated on a heatmap, giving information about the building and allocation permits for the complete urban area and the local communities (partly) situated within the urban area (Aalst, Denderleeuw, Liedekerke, Haaltert, Erpe-Mere and Affligem). The darker zones on the map are referring to neighborhoods with a higher concentration of permits. The map indicates that the central zones of the urban area (Aalst, Denderleeuw) have the highest number of permits, but also some of the residential areas, rezoned within the zoning plan for demarcation of the urban growth boundary of Aalst are lighted on the map.

Referring to the concept of place-based planning within the case of Aalst we noticed, during the planning process of the demarcation of the urban growth area of Aalst, an intention to start a regional coordination of plans and projects. This intention however, did not result into other coordinating initiatives or actors within the region. Finally, most of the initial zoning plans are realized by private actors. To realize industrial zones within this complex planning context without a regional coordination seems to be more difficult.

Figure 3: Heat map building permits, case 1

Area zoning plan	Building permits	Allocation permits
Residential areas	271	40
Industry / offices	59	4
Agricultural areas	13	4
Recreational areas	7	0
Nature and other green	20	3
Railway stations	25	0
complete map	12.808	1.210

Table 2: Number of building / allocation permits per area, case 1

7 Case 2 area development by different regional actors– The Valley of the Lys between Wervik and Kortrijk in West-Flanders

The second case is situated within the Western part of Flanders, along the valley of the Lys, which is currently part of an important ecological corridor and open area within the urban tissue of the region Kortrijk-Roeselare-Lille. The valley is surrounded by historical villages, cities and industrial areas. The historical presence of industrial activities, mainly textile industries, determines the actual view. The originally meandering River Lys is replaced by a wide channel with a water regime adapted to shipping. Only fragments of the original landscape, like some relicts of old Lys arms, are remaining.

The second case is much more complicated than the first one, since more actors and more planning instruments are involved. The analysis refers to the situation in the time period 2006-2015. We distinguished four successive planning instruments or processes.

Figure 4: case 2

7.1 Demarcation of the urban growth boundary of Kortrijk by Flemish Authorities (2006)

In 2006, the Flemish government approved the regional zoning plan for the demarcation of the urban area of Kortrijk (Vlaamse Regering, 2006). Thus, the first step of the planning process seems very similar to the first case for the urban area of Aalst. The planning process (2001-2004) was an intensive exercise in strategic planning together with the most important local and regional actors. Finally, Flemish authorities decided not to include the rezoning of the Lys valley in the zoning plan, notwithstanding the shared planning concept that the valley could function as a central green area within the urban region. They argued that it was too early to rezone the area, since the vision needed to be completed with shared actions.

7.2 Area development within the valley of the Lys by Province of West-Flanders

Medio 2003 the province of West-Flanders, intercommunal partner Leiedal and four local authorities (Wervik, Menen, Wevelgem and Kortrijk) decided to develop a shared vision for the Valley of the Lys. This resulted in a report (Provincie West-Vlaanderen and Intercommunale Leiedal, 2005) with a general vision describing the area within a time period of 15 years, and a list of 107 actions with an indication of actors involved and a distinction between short-term, mid-term or long-term actions. Yearly, the action program is followed up by a steering group (Pisman et al., 2011a, Pisman et al., 2011b).

7.3 Regional zoning plan for the valley of the Lys (2008)

The regional zoning plan for the Lys Valley and Open Areas in the region of Kortrijk was adopted by the Flemish Government in 2008, two years after the adoption of the demarcation of the urban area (Vlaamse Regering, 2008). The vision of the Province, Leiedal and four local communities was inspiring for the zoning plan. The plan aims to keep the valley as open and natural as possible in the future. In the table and map below, changes in zoning

are displayed. The zoning plan changes originally residential, industrial and agricultural areas into natural zones.

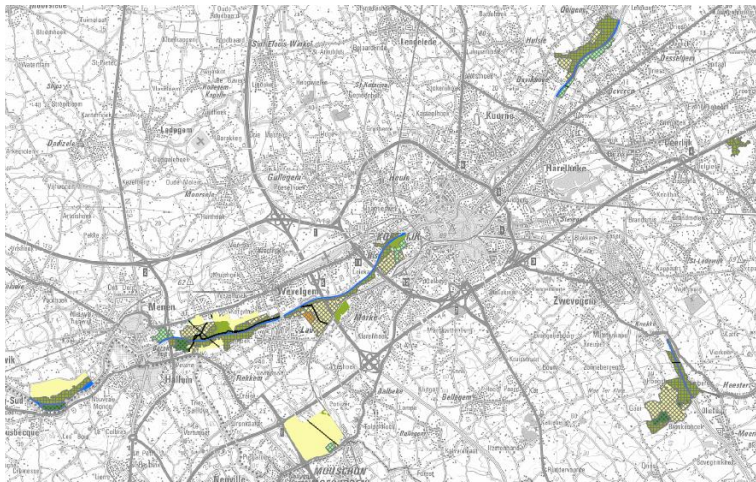

Figure 5: Map regional zoning plan, case 2

Categories zoning plan	Area
Residential areas	-9 ha
Woodland	-30 ha
Agricultural areas	-171 ha
Industry	-2 ha
Recreation	+8 ha
Nature	+202 ha
Other green	+31 ha

Table 3: Areas included in the regional zoning plan, case 2

7.4 Strategic project ‘Green Trails’(2010-2013, 2014-2017)

In 2010 Flemish authorities started to subsidize strategic project ‘Green Trails’ (‘Groene Sporen’). This project includes a wider area than Valley of the Lys, since also three other green trails: valley of the Scheldt, Heulebeek and channel between Bossuit and Kortrijk are analyzed. The strategic project aims to use green infrastructure to develop the regional identity and landscape quality.

A charter was adopted between two main partners: province of West-Flanders and intercommunal actor Leiedal. For every trail a steering group has been installed and a list of actions has been described (Departement Ruimte Vlaanderen, 2012).

Recently the project has started up for a second period (2014-2017). The global aim of the strategic project is unchanged, but more partners are included since the province of East-Flanders has become an official partner. Secondly the strategic project is now more explicitly situated in an international or interregional context of Euro-metropolis of Lille-Kortrijk-Tournai. Finally the project will pay more attention to creating a local agenda together with local authorities.

7.5 General observations of the planning process and analysis of the building permits within case area 2

Generally, the region around Kortrijk is known as an area with a very active planning scene on a regional scale. The analysis shows that over the past 10 years, many planning processes have been organized successfully. The central and driving actors are province of West-Flanders and intercommunal organization Leiedal. Flemish authorities for spatial development and for other policy domains are often involved, as well as local authorities. Recently, planning processes become more international or interregional orientated, introducing new actors as the province of East-Flanders, Wallonia or France.

In 2010, five years after the consensus on the general vision and according actions, the area-development in the Valley of the Lys was evaluated by University of Ghent. They confirmed the intensive planning processes and planning activities in the area, but were more critical about the results of those planning processes in the field. Many actions were not

yet realized because of the continuing planning phase and the complexity of planning actors and planning responsibilities.

For this paper we decided to analyze the register of building and allocation permits in the area (2006-2015), in order to have an overview of actions that led to an actual change in the field.

The heatmap (figure 6) shows that the areas included in the zoning plan for valley of the Lys are not the areas within the urban area (Harelbeke, Kortrijk, Menen, Waregem, Wervik, Zwevegem, Wevelgem, Wielsbeke) that have many applications for building or allocation permits. The darker zones on the map, showing the areas with the most applications, are situated in the built-up-zones of the urban area, and not in the open core of the valley.

Table 4 gives a more detailed overview of the number of building permits or allocation permits (dividing of a larger plot into smaller building plots). The number of building and allocation permits is rather limited in all areas. This is a first indication that the actual changes on the field are restricted. Further research, however, is necessary since the main option of the zoning plan was to keep the areas open in the future. The preservation of the open areas, such as the transformation of an agricultural zone into a more natural use, does not always demand building or allocation permits.

Figure 6: Heat map building permits, case 2

8 Conclusion and discussion

In general, this paper addresses that place-based environmental policy has recently been developed within the context of spatial planning in Flanders. The place-based approach, also called area development, is referred to as a tool to deal with the complexity of spatial development, more specifically a proactive planning approach, characterized by an intensive coordination of initiators, plans and projects in one specific area, in order to implement the plans and projects on the field. Flemish, as well as provincial and intercommunal initiators for this planning approach were identified.

In case studies it was found that the planning processes for the demarcation of urban growth areas can be founders for place-based planning. Furthermore, in the case of Kortrijk, the subsidizing of strategic projects by the Flemish authorities was useful because a process manager was financed. However, referring to the case of Aalst, if there is no initiator in the region to submit a strategic project, this opportunity is missed.

In the second case of Kortrijk, multiple place-based planning initiatives have been detected, leading to diverse and intensive planning processes and activities. The initiators for these planning activities range from Flemish authorities, intercommunal actors, to the province of West-Flanders. This has not lead to discussions about the global vision on the future of the area. This paper does not focus on multi-level governance or cooperation, but both cases deliver interesting insights. Regional and multi-level cooperation is becoming more and more an essential part of Flemish planning activities (Saris et al., 2011, Boucké, 2015, Instituut van de overheid- KU Leuven et al., 2012).

Focusing on the implementation of the planning projects, in the first case of Aalst, 15 years after the adoption of the zoning plan for the demarcation of the urban growth area, most of the initial plans are realized by private actors. To realize industrial zones within this complex planning context without a regional coordination seems to be more difficult. The most important industrial zone, Siezegemkouter, is not yet realized. For the second case of Kortrijk, more research is necessary to evaluate the results of the numerous planning processes in the field.

To conclude, we found that authorities are experimenting with place-based planning in Flanders for several years, but that results, actors and instruments differ. These results can be used to develop future place-based planning programs and projects in Flanders.

In this paper only two cases are analyzed. It can be interesting to elaborate this research with more cases in the future. The selection of the cases can be discussed. The cases are selected because of the involvement of the author in parts of the planning processes in the past and because of previous research within these areas. In addition, the zoning plan for the demarcation of the urban growth boundary for Aalst was the first zoning plan adopted, which makes it an interesting case because of the longer time period. Furthermore, the region around Kortrijk is well-known for its regional planning activities (Pisman et al., 2013), and the combination of two zoning plans within a recent time frame together with a sequence of strategic projects, justify the selection of Kortrijk as case.

The quantitative analysis of building and allocation permits is useful because it gives a general view of the dynamics on the field in the areas. However the quantitative analysis can be discussed and further research is recommended for different reasons, such as: not all activities need a building or allocation permit, not everything is registered correctly, the impact of permits is differently, a permit doesn't necessarily lead to a realization on the field. More interviews with local actors and an analysis of recent evolutions and changes on maps or on the field can be added in the future.

Open City: Smart managing the city

Jelle Rijpma; Eva van Bolderen

On behalf of Jelle Rijpma Advies [consultancy firm] and Brabant Academy; The Netherlands

INTRODUCTION and summary

We are facing a paradigm shift in our society. You can feel it everywhere; incubators, creative people and innovators are uprooting the old systems. Conflicts are occurring between old and new institutions, undermining foundations that have provided years of service. Rotmans argues that at this moment we are at a tipping point; we are developing into a more sustainable society: from linear to cyclical thinking, from vertical to horizontal organizing and from top-down to bottom-up management (Rotmans, 2012, 2013).

All these transitions in the world affect the cities we live in, and thereby, the way in which we should be practicing city planning. We see that city planning no longer uses pre-set designs: it has become a matter of smart management. We are moving towards a city planning with new partnerships, with new forms of interaction between unequal parties and that stimulates self-organization.

Three to four years ago, Jelle Rijpma Advies and the open innovation platform Brabant Academy started looking for new forms of cooperation and innovation within cities in a continuous project called Open City. In this project, new tools for urban development are developed and applied, using the city as a laboratory (Brabant Academy, 2014). Through pilot projects and practical examples, a conceptual framework of the Open City is being developed. This framework is not fixed because it must continue to reflect the changes and dynamics of society. This conceptual framework is based on a set of different examples that show that smart management is the new way of practicing city planning. Smart management consists of three cornerstones.

Firstly, the integration of technological, social and environmental values of a city: These values are all of interest for current cities, but you should not see them separately from each other; they complement each other, together adding value to the culture and economy of the city. Technological innovations will not be successful without social innovations. Additionally, technological and social innovations have a huge impact on the environment. New city planning initiatives should take these relationships into account.

Secondly, new partnerships: New forms of partnerships allow decisions to be made on an equal basis, with unequal parties. Different parties should be seen more as partners instead of parties *to deal with*: citizens become partners; in real estate, tenants do not have to be just tenants but become partners; farmers become energy suppliers et cetera. These new

partnerships and roles are driven by openness, honesty and transparency. A wide range of examples derived from pilot projects demonstrates that new partnerships can be successful in city development without the need of big plans or large efforts in time, money or resources.

Finally, a clear vision and strategy: A couple of examples are given in the paper to make clear that a pre-set design is not necessary. A clear vision of and strategy for city planning—what should the city look like in the future and what is needed to make it a reality—will help you achieve your goals.

At the end we, the authors, ask you for commitment and contribution for realizing Open City and to formulate and construct a renewed body of knowledge which deals with the fascinating changes in our society worldwide.

1. Open City

The societal changes we are recognizing worldwide more and more started 15 to 20 years ago. National policymakers started to discuss items like the network-economy and the 24/7 economy all around the world. In the Netherlands, it has been translated to concepts of network cities and regions. We notice that political changes have been taking place at the same time. People are becoming more critical of the politicians as well as of big companies who have to supply health services, energy, water and so on. People argue that “they are not listening” and “that there is no freedom of choice in” the services; this while prices keep going up. The financial crisis that started about ten years ago has speed up the process of change. Citizens did not want others to provide solutions but started to organize themselves more and more. It does not matter whether they buy their energy or their care services collectively or even if they make their own energy; all the signs are pointing in the same direction: *self-organizing together* within society and especially within the city.

Rotmans specifically articulates how this applies to the Netherlands. He states that we are facing a paradigm shift in our society. You can feel it everywhere; incubators, creative people and innovators are uprooting the old systems. Conflicts are occurring between old and new institutions, undermining foundations that have provided years of service. Rotmans argues that at this moment we are at a tipping point; we are developing into a more sustainable society: from linear to cyclical thinking, from vertical to horizontal organizing and from top-down to bottom-up management (Rotmans, 2012, 2013).

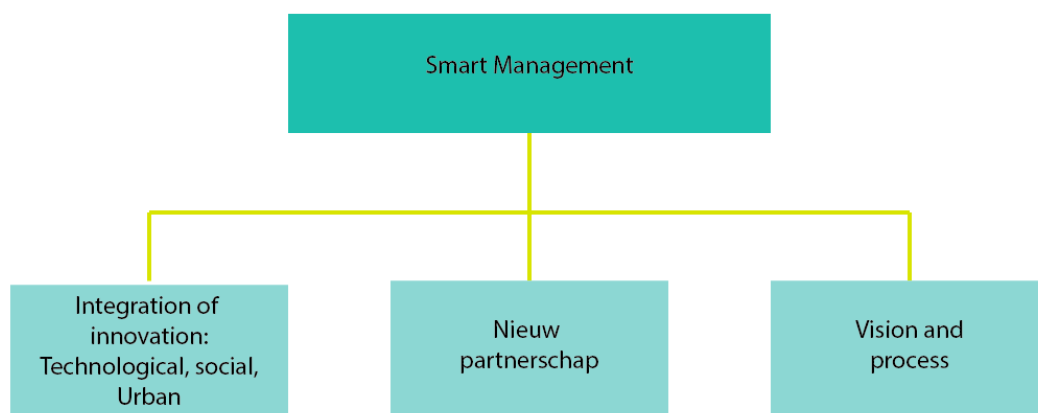

All these transitions in the world affect the cities we live in and thereby the way in which we should approach city planning. We see that city planning no longer uses pre-set designs: it has become a matter of smart management. We are moving towards a city planning with new partnerships, with new forms of interaction between unequal parties and that stimulates self-organization. We have been participating in

this process of change and transition for more than fifteen years, and we gradually are recognizing what the puzzle pieces are. Recently, we have contributed by putting some of the pieces into place, putting what we have learned into practice. Four years ago, we also started to create a new body of knowledge that will fit the paradigm of change. We call the transition Open City because we believe that the new city planning has to be open, transparent and fair for anyone. We aren't there yet! In the next few years, we have to make it work. Open City needs a body of knowledge for the future! We contribute to this body of knowledge and try to achieve the Open City with we do today

Four years ago, Jelle Rijpma Advies and the open innovation platform Brabant Academy started looking for new forms of cooperation and innovation within cities in a continuous project called Open City. In this project, new tools for urban development are developed and applied, using the city as a laboratory (Brabant Academy, 2014). Through pilot projects and practical examples, a conceptual framework for the Open City is being developed. This framework is not fixed because it must continue to reflect the changes and dynamics of society.

2. Smart Governance

The conceptual framework is the outcome of a set of different examples showing smart management as the new way to practice city planning. Smart management consists of three cornerstones.

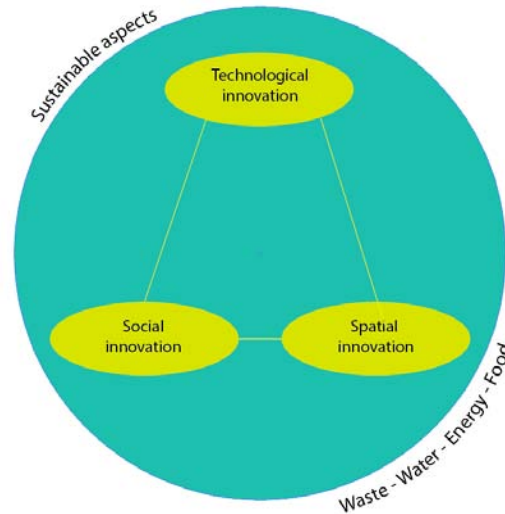

We will explain the meaning of the cornerstones in the following chapters.

3. Integration of innovations

In our society, we have a tremendous interest in the innovation of technology. When you think of our phones, our computers, our cars, our houses, etc., you will encounter technological innovations. But at the same time, technological innovation cannot take place without the adaptation of people. Even more important is that new technology is often adapted due to social innovation. For example, our urban space frequently asks for another use and can be the start of innovation.

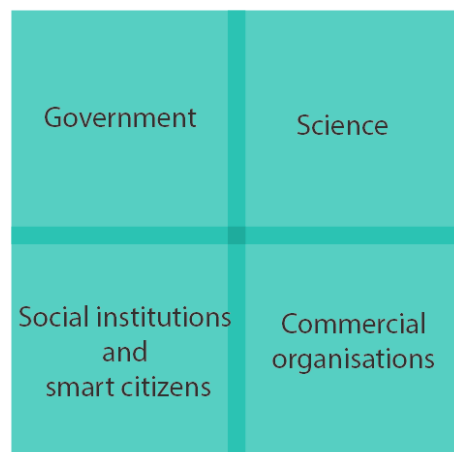

Sometimes we reinvent our space by growing vegetables on empty roofs or wasteland. When considering the question of the city growing its own food, we will have to consider producing food in a very different way, possibly with the use of new technologies and in other spaces. Social innovation and adaptation must take place simultaneously.

Worldwide we have to search for the connections between these three fields of innovation: technological, social and spatial. The approach to innovation is dependent on the economical state and the cultural values that the society concerned are based on. The issues presented by each city are different and will thus produce a different outcome despite their differences, every city has to value the chains of *waste*, *water*, *energy* and *food*. Those that do not will collapse sooner or later. It is better to start now rather than postponing this search until it is necessitated by something that happens in the future.

4. New Partnership and the smart citizen

Governments in many parts of the world have a democratic basis. We have elections and then we regulate money and power according to a voting majority. In some other parts of the world one is ruled by imposed laws. Nonetheless, people are connected worldwide and are able to communicate, gather knowledge and work together to start their own new businesses. People organize themselves. We then have a smart citizen! How will the government work together with the smart citizen? The democratic aspects will still be there, but we need another way of producing

knowledge or business, another way of solving particular problems, other ways of participation and so on.

There will be new partnerships. Most of them will contain several unequal members. So, one of the most intriguing questions is: how will they make decisions on an equal basis?

We started a project in the small village of Vught recently. In Vught, there are plans for big infrastructure projects. The biggest one concerns an existing railway. The railway has to be reconstructed because of the goal of diminishing transportation of goods by rail transport through a number of big cities elsewhere. The new route will be guided through Vught. The second big reason is that by reconstructing of the existing railroad, more speed train connection can realized between the growing Economy and region of Eindhoven and the existing economy in Amsterdam and the Hague. All from a international perspective of regional growth in the Netherlands and diminish the environmental burden for the big cities.

The first options for construction through Vught where too simple. A very good and normal way of top-down-thinking. And of course those solutions were not excepted by Vught. The community organized itself not on a base of Not In MY Backyard but on the base of going along with the national goals. And at the same stating the point that if the national government and regional government want a solution for their problem, it better be a good solution for all. The inhabitants organized themselves pretty good and formed a well educated power towards the national government. The local Government did the same as the local Government in Zeewolde which will be explained in the next chapter *Vision and Process*. They also made a strategic urban vision. The very strong organization of the inhabitants itself and the positive way of thinking along with the goals of the national and regional governments was very powerful and probably decisive action and attitude.

The conclusion at the end after just a few years(!) of planning and discussion, is that the railway will be reconstructed and brought below ground over a length of 1.5 kilometres through the village centre to the outskirts of the village. The national, regional and local governments agreed on the plans. It will be good for the governments but not for the inhabitants who live along the railway. It will directly influence those living in the 350 to 1500 houses directly along the railway and in the close vicinity thereof. The compensation for these people is governed by law but not sufficient, thus it arouses strong emotions. So, in 2014, after a an experiment in one of the streets involved, we at Jelle Rijpma Advies suggested to implement an independent platform for businesses, housing corporations, real estate developers, investors, banks, the local government and inhabitants with interests along the railway. Through this independent platform, Vught is trying to resolve the individual problems of the inhabitants along the railway. The basic question to solve for the inhabitants and others involved in platform will be "will I be okay" and secondly "how can I regain control of my situation". The platform does not create regulations or a fund for financial losses or damage. Thus, an inhabitant will not have rights provided through this platform, but he will be given assistance in getting his life back under his

own control. We spoke to a lot of inhabitants, and after a while they were smiling again.

By challenging them, they themselves came with their own, feasible ideas. The participants of the platform, or potential participants, were also cooperative because it was in their interest as well, and it is only in collaboration that they are capable of solving the problems of the inhabitants as well as their own. There are a few inhabitants going to build new homes elsewhere in Vught. The local government is providing the land, the estate agents will sell their current houses and some other parties will advise them how to build their new homes. Those inhabitants who cannot afford new build houses because of mortgage problems will be offered a loan on the land by the local government. The owners of an apartment building suggested that they could renovate a school nearby. Therefore, the local government initiated a first meeting to discuss this in July 2015. Others have suggested that they wanted support for their elderly parents who need to go to a service apartment. No financial claims are made; it is more like a trade with closed wallets, budget-neutral. Nevertheless, the result has to be, "I have control over my situation again". In September 2015, there will be individual interviews with all the inhabitants directly involved so that everybody knows the variety of individual problems and individual and collective wishes and solutions. The platform will deal with the problem of how to make decisions while there are so many unequal participants involved.

For this, we will use the existing but not very practiced method of consent. A decision will be based on if someone has *strong objections* and not by voting. Furthermore, there are strict rules for debate. We call the independent platform, including the method and the goal Dynamic Government. The process of the platform will be hosted by an independent host. The local government will be one of the partners in the platform and there is no partner who will rule. There is equal partnership. A few years ago, we at Jelle Rijpma Advies called this principle *New Partnership*. A new form, existing next to the democratic organization we know in the Netherlands. We are already experimenting with different situations. Vught's case forms a substantial project. The expectations are high, and the first steps are very promising. The way of approaching the inhabitants is conflicting with the normal way of behaviour by the Government. Mainly because the attitude has to be open for the real questions of the inhabitants but also it isn't about regulations and rights but it is about the answer to the question "can I get control on my live again". We hope that the method of the independent platform will help the inhabitants. And in the case of developing new attitudes and methods for reaching the Open City, we hope strongly that this Smart Management will be a example to learn from an behave the making of Open City.

5. Vision: strategy and process

If you accept the idea, the foresight, that citizens will be smart and will undertake more and more to fulfil their wishes and to solve their problems, then the existing government has to change its attitude. The government, including the local government, has to solve the question of what the government will do itself and what

it leaves to society. In urban planning we are used to the government making and executing plans. In this case, the government has full responsibility and control, which is a so called "top-down" method. If you do not agree with the plans you, then you have to protest and so on. The attitude is reactive and judicial and often with financial claims. This makes no one truly happy. At the same time, it is not wise for a government to let everyone free to build and plan as they choose (although that is an interesting hypothesis). Their might always be a collective interest, concerning all inhabitants. Nevertheless, it is certainly not wise to make big plans over a long period of time. Moreover, we do not need to. We can restrict ourselves to making a vision of the potential development and forming a strategy for the process that will lead to a good result. From the long career of Jelle Rijpma, we have selected examples that will guide us towards a or renewed urban planning.

One interesting case was realized in Zeewolde in 2009. In six months an urban vision was formulated for the urban development. This in order to combine the development of Zeewolde with the big proposed development in Almere for almost 60.000 new houses, according business locations and also the realization of 2000 hectares of new ecological structure. The plans should make the international position of the Region of Amsterdam stronger. It meant big plans and impact for Zeewolde. First attitude of Zeewolde was Not In My Backyard, which attitude was not very successfully. Therefore Zeewolde turned her attitude towards cooperation bases on a own urban vision. The local Government wanted a strong participation of the inhabitants of Zeewolde in formulating the urban vision. They also had little time because the plans of Almere were speeding up and were heading for agreement in the urgency program for the region of Amsterdam which needed commitment and decisions of the National Government.

De local government started with a discussion with six themes that were extremely important for Zeewolde. Then they started a process in which the inhabitants and participants in Zeewolde discussed the six themes and there potential solutions. The politicians stepped aside and were not involved during this process. The solutions were brought to the city council, and they made the decision about the urban development. No big plans were made, but a variety of chances were designated to be realized when the opportunity arose. In fact during the process there were several stakeholders who wanted to work together and also self-organizing goals of development en sustainability were introduced. Par example, Zeewolde produces wind energy for 135.000 households. The urban vision still is still implemented today, and the community's building and developing activity never had to stop because the solution was flexible. So the case of Zeewolde is a successful example of a strategy, which is based on a strategic and flexible urban vision executed by a following process in which there is made a successful connection between big plans of other governments and commitment of the local inhabitants.

We can find many examples of strategic urban vision followed by process in the region and in the city of Eindhoven. Jelle Rijpma was involved directly in some of them when representing the national government. The government of Eindhoven has been developing a range of new urban planning methods. One of which to be very proud of and is still existent and developing is the Key-Project West-Corridor. Key-

projects meant to be building projects related to urban transport. The national government would contribute with money for the expected losses. The key-projects should strongly contribute to the international economic development of the big cities in the Netherlands. Actually, the key project West Corridor Eindhoven is not and has never been a project. It is a strategic urban vision of the probable development for a part of the region and was followed by a process of development when the opportunity was there. It started as a line drawn by a civil servant from the city centre to the airport with the idea to incorporate public transport in the future. That line was integrated in the Fourth Nota of Urban and Regional Planning from the national government but was very different in comparison to the other Key-projects in the Netherlands. No one knew what the meaning of the line was, and working for the national government at that time Jelle Rijpma was sent out to find its meaning. It meant a corridor development over 7 to 8 kilometres and the ideas turned out to become a vision for the urban development and a strategy for the process of realizing its development. The first investment in infrastructure, now twenty years ago, was approximately 150 million euros and it was made to realize a continuous unobstructed bus lane. Twenty years and two billion euros later, the development of buildings and reconstructions of locations of the former Philips factories, is still going on. New Buildings, new development and so on.

The next example is the small river the Dommel in Eindhoven. In the time of industrialization, it became a polluted and forgotten river. The curves had disappeared because the water moved through the river quickly. It was used more like a drain than respected as a river. The local government asked for money from the national government, but the national government did not want to invest and contribute. Therefore, the local government copied the method of the West-Corridor: they made an urban vision for the potential development, and also made a strategy for the process. After ten years, the Dommel River has been almost fully restored. The strategy was very successful. Every time when the government or some other party was planning a building of renewal activity near the river, they were asked to do a little part of the reconstruction of the Dommel. Thus, over a time of ten years, the Dommel river was restored with no extra financial contributions. Part of the strategy was organizing a bike tour along the river for the inhabitants with the question, "how far can we follow the river this year?" This strategic action made the public involved and today it is an once every two year event. It has become an inspiration, motivating the organisation of musical events along the Dommel. The river is part of Eindhoven again!

There are more examples to tell about, such as the development of a continuous band of greenery from the city centre to the forest on the outskirts of the city. It has the same characteristics of vision, strategy and process, but also has a new element: a cooperation of landowners, users and consultants. Profits go to the participants only if the cooperation makes profit. This is a new aspect, especially for the consultants, who have to work according to a cost-covering agreement instead of hours and bills.

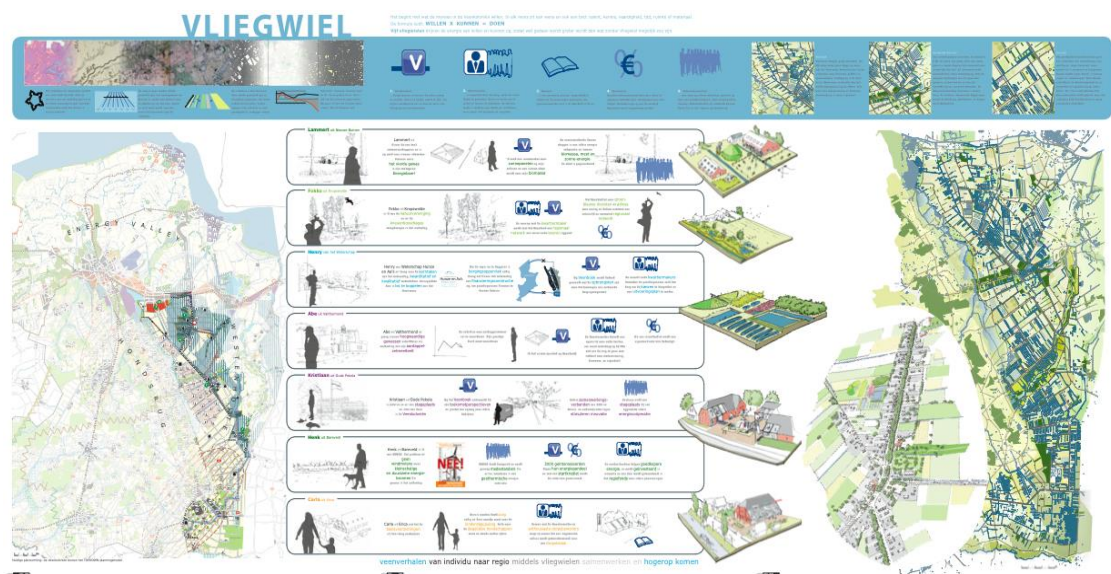

6. Challenge: Open City

Realizing the Open City concept and supporting it by providing a new body of knowledge for urban and regional planning is a worldwide challenge. It is a tremendous challenge. On the one hand, the local and regional government should change their traditional habitats. On the other hand, the other stakeholders and citizens have the same challenge of changing habits and attitudes.

What do we know of the mechanisms of the new multi-stakeholder collaborations, new partnerships and worldwide exchange of knowledge? Do we realize what open, transparent and honest is? And how do we make that work every time? How do we work together in order to make improvements for society, commercial and non-commercial. We, the authors, the members of the board of Brabant Academy and their supporters in Eindhoven, would like to invite everyone to contribute to the Open City. With Jelle Rijpma Advies and with Brabant Academy we will contribute as much as we can. It would be a wonderful idea to collaborate with ISOCARP on this subject. Maybe the idea can also influence ISOCARP Academy and involve ISOCARP Academy in the idea.

The plans of Jelle Rijpma Advies and Brabant Academy, involve the development of the next step in the world of Smart City, Smart Governance and Smart Citizens: We will make a pilot study of a location or zone in a city. The first steps have been taken herein by making a “city laboratory” in Eindhoven that focuses on energy and smart mobility. This will lead us to a clear urban vision that is flexible so that it can continuously adapt to the changing environment.

The second focus will be on the collaborations between and initiatives of citizens working together. We will continue with the ideas we presented in a challenge for the northeast part of the region Groningen. In that study we based the urban and regional development fully on the cooperation and actions that came from the citizens and on very finely differentiated prospective scenarios based on a rich variety in land use. In fact, this forms our basic view of how to approach sustainability. The image below, the plan pictured on the left demonstrates the top-down outcome and the plan picture on the right demonstrates the bottom-up outcome. In the middle the mechanisms and processes of self-organizing citizens are presented. Inspiration for new strategies is connected to open city processes.

The third focus should be sustainability. There will strong sustainability if the urban development is bases on the resulting contributions of the citizens themselves.

Of course, we take the lessons learned into account and we try to take the following step. We can learn lessons from elsewhere in the world and so on. Open City is a big idea! Join in! Contribute!

We, the authors, are very curious and are looking forward to a wonderful discussion and collaboration in realizing Open City.

The cooling effect of urban green infrastructure: does greenspace size and shape matter? (Taipei, Taiwan)

Wanyu SHIH, Department of Urban Planning and Disaster Management, Ming-Chuan University, Taiwan

Wanyu Shih

1. Introduction

Green Infrastructure (GI) plays a critical role in providing multiple ecosystem services in urban areas and their cooling effect is considered as a mitigation strategy for urban heat island effect (Gill et al., 2006). The temperature of urban GI and their immediate surroundings is found to be lower than that in built-up areas (e.g. Bowler et al., 2010; Tan and Li, 2013). Such a mechanism providing better thermal comfort in cities is important to improve human well-beings (Gill et al., 2006) and might have potential to reduce greenhouse gas emission by lower the need of using air-conditioners (Ca et al., 1998). Substantial studies have proved the cooling effect of GI and described the cause of its variation (e.g. Chang et al., 2007). However, less is known regarding the scale of the influence beyond the boundary of greenspaces; as a result, specific planning recommendations of greenspace distribution and design have been not able to be made (Bowler et al., 2010).

A number of studies has evaluated the effect of environmental factors to temperature contrast between greenspaces/parks and non-greenspaces/parks areas (cooling intensity), such as land cover (e.g. Tan & Li, 2013), greenspace configuration (Li, Zhou, Ouyang, Xu, & Zheng, 2012), and vegetation composition (e.g. Feyisa et al., 2014). Amongst various environmental factors, greenspace size and shape were commonly regarded as important characteristics determining greenspace cooling effect. It is generally agreed that larger greenspaces have better cooling effect (e.g. Chang et al., 2007; Tan & Li, 2013; Shashua-Bar & Hoffman, 2000) and there might be a threshold size for delivering more constant cooling benefits (Chang et al., 2007). However, the area-temperature relationship have not yet been fully understood. Greenspace shape changing the length of greenspace edge and so as to energy exchange is considered as one of the variances to this relationship, as there can be a trade-off between size and shape/edge effect. Studies so far analysing greenspace shape however have resulted in inconsistent findings and lacked agreed conclusions. For example, Chen et al. (2012) suggested an edge effect that parks with irregular shape have stronger cooling performance in terms of intensity and effect distance to adjacent areas; whereas Feyisa et al. (2014) found that greenspaces with irregular shape have greater cooling distance but less cooling intensity. Our knowledge regarding how greenspace size and shape might influence greenspace cooling effect on surrounding built environments has still been in a primary stage and generalisable results to give a more specific planning recommendation for greenspace modification is insufficient.

In order to shorten this knowledge gap, this study aims to explore area effect and shape effect on greenspace cooling performance. The interrelation between greenspace size and shape will be also discussed. In order to gain a larger size of case study areas, this study applied remote sensed data to extract land surface temperature (LST) and greenspace characteristics.

2. Study Area

This study used the urbanised area in Taipei Basin (25°N, 121°E) as the case study area, which includes parts of Taipei City and New Taipei City. The area covers approximately 2,726 km² and has population estimated to 6.67 million by 2014. The climate in this region is humid subtropical. According to the Central Weather Bureau (CWB) of Taiwan, the annual average temperature from 1981 to 2010 in Taipei is 23°C. The warmest month is July (29.6°C) and the coolest month is January (16.1°C). Due to global warming and rapid urbanisation (Bai et al., 2011), Taipei have showed a rapid warming trend. In the past 30 years, the increase rate of the annual temperature in Taipei has strikingly reached 0.27°C per year, which is faster than that of the global record of 0.16°C per year (CWB, 2014). Both the minimum temperature in summer and extreme hot days (4 days per decade in the last 30 years) have significantly increased in recent years (Bai et al., 2011; Hsu, Chou, Wu, Lu, Chen, & Chen, 2011). Thermal comfort for human well-beings, particularly in the summertime, has become an imperative issue.

3. Methods

The Landsat 8 satellite images took on 9 June, 2015 at 10:20 local time (summer morning) was gained from the United States Geological Survey (USGS). The first 9 bands of Landsat 8 are multispectral data from the Operational Land Imager (OLI). Except for Band 8 providing panchromatic data with a spatial resolution of 15m, the other OLI bands have a spatial resolution of 30m. Thermal data are provided by bands 10 and 11 with 100m resolution taken by the Thermal Infrared Sensor (TIRS). To facilitate spatial analysis with multispectral data, the thermal data was resampled to 30m by the USGS. This study utilized Band 2 to Band 7 for land classification and Band 10 for retrieving land surface temperature.

Quantum GIS (QGIS) Desktop 2.8.1 was applied to prepare satellite images and to perform spatial analyses. The Land Surface Temperature (LST) was retrieved from the thermal image of Band 10. Based on the procedure described by Congedo and Munafò (2014), the DN values of Band 10 were converted into TOA reflectance and corrected by DOS. This resulted in LST in degrees Kelvin and was further converted into degrees Celsius by the Semi-automatic Classification plugin (figure 1). With Zonal Statistic method in QGIS, this study calculated minimum, maximum, mode and mean LSTs of each case study greenspace and its surrounding buffer. Greenspace cooling effect (GCE) was observed by measuring temperature contrast between the immediate surroundings of greenspaces and the hottest spot of the basin.

Normalised Difference Vegetation Index (NDVI) with threshold values larger than 0.5 was applied to identify green infrastructure in the basin area. Greenspaces smaller than 2,700 m² and those located along river corridors, in the mountain regions, and under clouds were excluded from analyses. As a result, 1,168 greenspaces were selected for further analyses (figure 1). Figure 2 showed the size of case study greenspaces. Among them, 82.8% were below 2 hectare. The smallest and the largest greenspaces in the sample were respectively 2,700m² and 686,700m². A buffer with 50 meter width from the edge of the studied greenspaces was created around each studied greenspace in order to observe LST variations in its immediate surrounding areas. By means of the Polygon Shape Indices in QGIS, greenspace area in meter square and the value of shape index were calculated.

Figure 1: LST Distribution and Case Study Greenspaces

Figure 2: The Area (in meter square) of Case Study Greenspaces

Descriptive statistics was used to describe the minimum, maximum, and mean LST of greenspaces, buffer areas, and GCE. Pearson Rho Correlation Coefficient (two-tailed) and linear regression were firstly conducted between dependent variables of greenspace temperature, buffer temperature, and GCE and independent variables of greenspace size and shape in order to explore their relationship. Further, for examining non-linear relationship between greenspace size and dependent variables, the function of curve estimation, including logarithmic, quadratic, and cubic models, in the regression were performed. A one-way ANOVA was conducted to compare effect of greenspace area on dependent variables. All the statistical analyses were conducted with the software of IBM SPSS Statistics 22.

4. Results

In the study area, the LST ranged from 13.60°C to 34.14°C and the average temperature was 22.93°C. Within the case study greenspaces, the minimum, maximum and mean LST was measured at 19.84°C, 32.75°C and 27.29°C respectively, which was on average 6.85°C cooler than the hottest area of the basin. Comparing to the immediate surroundings outside

greenspaces (the 50m buffer areas), the greatest temperature contrast between inside and outside greenspaces was 6.22°C. Greenspaces were on average 0.12°C cooler. The coolest area at greenspaces were constantly cooler than the hottest area of the buffers, but the mean LST of 29.37% of greenspaces were higher than that of their immediate surroundings. According to the mode value, most of the areas within the buffer were 6.90°C below the hottest spot of the basin. The maximum LST contrast between the buffers and the hottest area of the basin was strikingly reached 15.31°C. The mean temperature of greenspaces significantly influenced the mean and the mode values of the LST at surrounding buffers ($r=0.993$, $P<0.001$; $r=0.963$, $P<0.001$). A strong linear relationship was found between the mean LST of greenspaces and that of buffers ($F(1,1166)=88750.99$, $p<0.001$) with an R^2 of 0.987. $P<0.001$). In other words, built-up areas tend to be cooler when they adjacent to a cooler greenspaces. According to this linear model, every degree in Celsius increased in greenspaces can lead to temperature rise in the immediate surroundings of greenspaces by 0.997°C.

The results of Pearson rho correlation coefficient showed that greenspace area was negatively related to the minimum greenspace LST ($r=-0.227$, $P<0.001$), the mean greenspace LST ($r=-0.106$, $P<0.001$), the minimum buffer LST ($r=-0.180$, $P<0.001$), the mean buffer LST ($r=-0.068$, $P<0.001$), and the mode buffer LST ($r=-0.113$, $P<0.001$) at a significant level, whilst their relationship were very weak. The regression analyses demonstrated similar results. Because some studies suggested that the relationship between greenspace size and greenspace temperature and/or cooling effect is not linear, this studies estimated their relationship with not only linear models, but also logarithmic, quadratic, and cubic models. Yet, as table 1 displayed, the goodness-of-fit (R^2) were very low in all models, indicating greenspace size is not likely a good predictor for the mean LST of greenspaces and that of buffers. The ANOVA T-test further confirmed this finding. The mean LST of either greenspaces or their buffers was not significantly different between different greenspace area (figure 3).

Table 1: Regression analyses of greenspace area to mean LST of greenspaces and buffers

Models	Mean LST of greenspaces					Mean LST of buffers				
	R ²	F	df1	df2	Sig.	R ²	F	df1	df2	Sig.
Linear	.011	13.267	1	1166	.000	.005	5.441	1	1166	.020
Logarithmic	.010	12.131	1	1166	.001	.002	2.405	1	1166	.121
Quadratic	.013	7.791	2	1165	.000	.005	2.809	2	1165	.061

Figure 3: The Distribution of the Mean LST of Buffer Areas by Greenspace Area (m²)

The size effect tends to be stronger on the minimum LST of greenspaces and that of buffers. As figure 4 demonstrated, there was a steady decreasing trend of minimum LST for both greenspace and buffers with the increase of greenspace size, which was reclassified by hectare. This was particularly obvious for greenspaces below 5 hectare that more samples were available (all more than 15) and therefore the result was statistically more valid. Also, the mean and maximum temperature contrast between greenspaces and their surroundings were more significantly varied by greenspace area. The one-way ANOVA demonstrated significant size effect on temperature contrast, which was respectively measured by average contrast (F(109,1058)=4.948; p<0.001) and maximum contrast (F(109,1058)=18.004; p<0.001) (figure 5a; figure 5b). The temperature contrast tends to increase with the size of greenspaces. As table 2 demonstrated, the logarithmic curve can better describe the relationship between greenspace area and temperature contrast. The description capability was particularly good for the maximum contrast, which the R² was 0.568 (P<0.001).

Figure 4: The Distribution of the Mean LST of Buffer Areas by Greenspace Area (m²)

Figure 5: The Distribution of the Mean LST of Buffer Areas by Greenspace Area (m²)

Table 2: Regression analyses of greenspace area to mean and maximum temperature contrast between greenspaces and buffers

Models	Mean Temperature Contrast					Maximum Temperature Contrast				
	R ²	F	df1	df2	Sig.	R ²	F	df1	df2	Sig.
Linear	.112	147.380	1	1166	.000	.399	772.709	1	1166	.000
Logarithmic	.244	376.355	1	1166	.000	.568	1532.548	1	1166	.000
Quadratic	.190	136.491	2	1165	.000	.512	611.166	2	1165	.000
Cubic	.230	116.019	3	1164	.000	.566	505.809	3	1164	.000

Within 343 greenspaces that were averagely hotter than their surroundings, 86.0% were below 10000 m² (1ha) and 96.2% were below 20000 m² (2ha). Yet, no significant relationship was found between these cases and greenspace area (figure 6).

Figure 6: Temperature Contrast of Hotter Greenspaces by Area (m²)

Similarly, the Pearson Rho Correlation showed greenspace shape was weakly and negatively related to the mean LST of greenspaces ($r=-0.083$, $p<0.005$) and was insignificantly related to the mean LST of buffers. The regression analyses also confirmed that greenspace shape was not a good predictor to these dependent variables. As table 3 demonstrated, the R^2 of the mean greenspace LST, mean buffer LST were negligible in all regression equations (table 3). When greenspace size was controlled, the effect of greenspace shape showed no improvement. On the contrary, the shape effect was a relatively good predictor for both the mean and the maximum temperature contrast, which the cubic equation was able to describe 10% and 40% of the cases respectively (table 3b). Increasing shape complexity tends to enlarge temperature contrast between a greenspace and its surroundings.

5. Discussions and Conclusions

This study examined the cooling effect of urban greenspaces focusing on the effect of greenspace size and shape. The results manifested distinct cooling function of urban greenspaces. Comparing to the hottest spot of the basin, greenspaces were on average 6.85°C cooler and most of the areas within the distance of 50m from greenspaces were 6.90°C cooler. The strong positive linear relationship revealed between the mean LST of greenspaces and that of buffers confirmed the findings of previous studies that greenspaces can reduce temperature of their surrounding built environments (e.g. Oliveira et al., 2011; Feyisa et al., 2014). The coolest spots of greenspaces were constantly cooler than the hottest areas of the 50m buffer. However, it is noteworthy that not all greenspaces were cooler than their surroundings when compared the mean temperature contrast between inside and outside greenspaces. The average LST of 29.37% of studied greenspaces were warmer than that of their buffers. Similar results were reported by the study of Chang, et al (2007) based on air-temperature in Taipei City, which indicated that many parks below 3 hectare were warmer than their surroundings.

Larger parks/greenspaces were generally reported to be either more likely to be cooler (e.g. Li et al., 2012; Xu and Yu, 2008) or that the cooling intensity was greater (e.g. Cao et al., 2010; Feyisa et al., 2014). The analyses of the size effect of greenspaces on the cooling performance was to some extent consistent with this argument. The minimum and the mean LST of greenspaces and that of adjacent areas tend to be lower in larger greenspaces, but the relationship/effect was very weak. The weak effect might be caused by greater range and variation of temperature inside larger greenspaces. According to the result, the minimum temperature of larger greenspaces tends to be lower, since they possess greater distance to the edge so as to prevent outside heat intrusion. Yet, increasing surface area also results in a longer interface with surrounding built environments, which subsequently increases the chance of thermal exchange with warmer built-up areas (Li et al., 2012). In this regard, the mean cooling magnitude of greenspaces and their cooling effect on surroundings were likely to be offset. This also explained why a more significant size effect was observed on the

maximum temperature contrast between the minimum LST of greenspaces and the maximum LST of buffers.

Some researchers asserted that the relationship between the cooling effect and the size of greenspace may not be linear (e.g. Cao et al., 2010, Chang et al., 2007) and there might be a minimum threshold size for delivering more constant cooling effect (Chang et al., 2007). In this study, 96.2% of warmer greenspaces were below 2 hectare. It is possible that small greenspaces were more likely to be influenced by the heat intrusion from surrounding built environments and therefore have higher temperature fluctuation as Chang et al. (2007) suggested. Yet, this assumption cannot be proved by this study, because the greenspaces in Taipei Basin is highly fragmented and there were more small greenspaces than medium- to large-sized greenspaces. As a result, the sampling size of greenspaces particularly above 5 hectares have been too small to make a statistically valid comparison in this study. More studies with more equal and large sampling size of different size of greenspaces will be necessary to observe a threshold size.

In addition, this study applied several models in the regression analyses to estimate possible curve for describing area-temperature relationship. The result showed a very low goodness-of-fit in all models either for the mean LST of greenspaces (the best R² was 0.014 in cubic equation) and or for that of buffers (the best R² was 0.05 in linear equation). Although logarithmic linear equations presented a greater R² to explain temperature contrast between greenspaces and surrounding built environments, it is inappropriate to apply this model for assessing cooling benefits from greenspace, because the model describes temperature difference caused by greenspace size rather than cooling benefits delivering from greenspaces to built-up environments.

Several studies pointed out greenspace shape as one of the important factors to cooling effect, whereas there is a lack of consistency among research findings. This study found that temperature contrast between inside and outside greenspaces tended to increase with shape complexity. Yet, the direct influence of greenspace shape on temperature reduction of greenspaces per se was less significant and it showed no statistical significant relationship with the mean temperature of buffers. It seems that the mean temperature outside greenspaces was not affected by greenspace shape. This is inconsistent with the study of Feyisa et al. (2014), which found cooler built-up areas around irregular greenspaces. As many researchers pointed out, greenspaces with irregular shape have greater interface with built environments that increases the chance of energy exchange (e.g. Chen et al., 2012; Feyisa et al., 2014; Zhou, Huang, & Cadenasso, 2011). In this sense, the lack of consistency of shape effect in the previous studies is understandable. Since the temperature in one area is the result of temperature exchange, the intensity of heat from either greenspaces or built environments can determine the final result and it is not necessarily to be consistent.

In summary, this study found that increasing greenspace size and shape complexity can generate lower minimum temperature both inside and outside greenspaces, but their influence tends to be small. Besides, both greenspace size and shape exert relatively minor or insignificant influence on reducing mean temperature outside greenspaces. Simply increasing large greenspaces or changing shape of greenspaces in cities might not lead to significant cooling contributions to built environments. For delivering more effective cooling benefits, more factors will have to be considered.

Introduction

The paper aims to present studies carried out for future sustainable redevelopment of underutilized areas in Bonsucesso district - Rio de Janeiro - Brazil, as one of the ways to reduce urban sprawl in environmentally protected areas or those lacking planning. The region studied has one of the largest subnormal occupancy rates in the city of Rio de Janeiro, especially the type known as favelas. On the other hand the region has favourable public transport network, available urban infrastructure and central location in relation to other areas of the city¹.

1. Characterization of The Study Area

Rio de Janeiro city is divided into five Planning Areas (AP): AP1, AP2, AP3, AP4 and AP5. Planning area 3 (AP3) comprehends 80 districts in 13 administrative regions (PCRJ, 2015), accounting for 16.6% of the municipal territory – 203.47km² – and 37.9% of the population residing in Rio de Janeiro, that is, 2,398,572 inhabitants according to CENSO 2010. Its demographic density is 11.788 inhabitants/km².

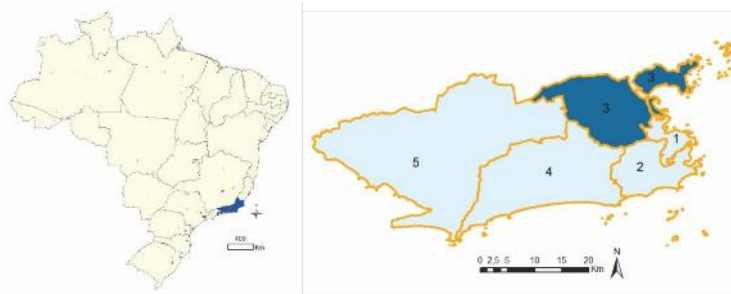

Figure 1: Brazils’ map with study area AP3 location

From its origin AP3 is divided into 3 parts:

AP3.1 – It grew from the Leopoldina Railway consisting of 6 administrative regions (RA): Ramos, Penha, Vigário Geral, Ilha do Governador, Complexo do Alemão and Complexo da Maré.

AP3.2 – The train service, in this case, Central do Brasil Railway, was the link both internally and with the downtown area. The following RAs belong to this region: Méier, Inhaúma and Jacarezinho.

Planning Areas	Area (m ²)		
	2008	2009	2010
Rio de Janeiro city	46 829 483	46 807 142	46 420 263
Planning Area 2	2 415 049	2 419 397	2 374 541
	4 180 960	4 186 523	4 110 146
	18 444 155	18 362 309	18 174 178
Planning Area 5	6 995 321	7 021 126	6 981 298
	14 793 998	14 817 787	14 780 100

Table 1: Slums by planning area

AP3.3 – In this case two railways made the link both internally and with downtown area: Central do Brasil Railway and its auxiliary line. The following RAs belong to this region: Irajá, Madureira, Anchieta and Pavuna.

About two in five cariocas (Rio de Janeiro inhabitants) live in AP3 – the highest population in the city (37.9%), and 1 in 2 slum dwellers lives in AP3, equivalent to 45.4% of the city population. Besides, it must be highlighted that 39.2% of slum areas in Rio de Janeiro are in AP3 representing 18,174,178m², however only 22.8% of the population living in AP3, 149,014 people, is in urbanized communities.

Rio de Janeiro population had a 1.4% growth between 1991/2000. On the other hand, in the period between 2000/2010 the population growth rate was 7.9%, and in AP3 it was 1.98%. The highest ones were Complexo do Alemão and Complexo da Maré accounting for more than 20% growth.

For a long time, the big possibilities of horizontal expansion were the norm in AP3 occupation, generating an area with little identity. In the last decade the AP3 urban structure has been going through changes. The opening of Linha Amarela (express highway) in 1997 made it possible to have new connections and access in all districts of the region. Along with the BRT Transcarioca (Bus Rapid Transit) linking Barra da Tijuca and Galeão it provided better connection between AP3 and AP4.

Among the 13 administrative regions that comprise the AP3, 8 are among the regions considered to be highly developed according to the HDI (Human Development Index), including Bonsucesso district, 0.861, considered to be an average development level. In contrast, the three worst rates of the city are in the same area as Bonsucesso: Jacarezinho (0.731), Complexo da Maré (0.719) and Complexo do Alemão (0.719), all of which are slum areas (figure 2).

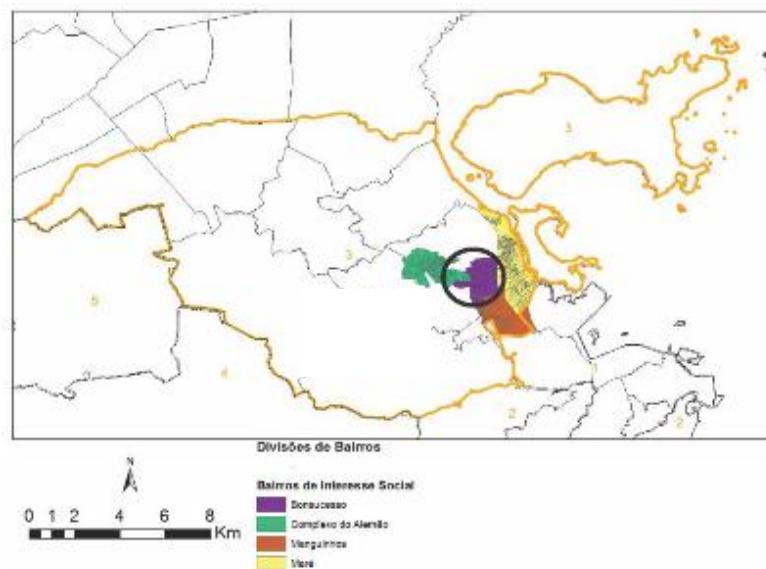

Figure 2: Bonsucesso district, Complexo da Maré, Complexo do Alemão and Jacarezinho

Concerning longevity, the area is above municipal average: 70.82 years old. However, in slum areas, longevity level is low: Complexo do Alemão (64.38), Complexo da Maré (66.03) and Jacarezinho (66.30).

With regard to Social Development Index (SDI) in 2000 AP3.1 scored 0.59 in SDI, well below the rate observed in Lagoa (0.81) district located in AP2. By the year 2010 the rate remained the same in AP3, i.e. improvement was not observed in the region in the decade analysed.

In 2010 the per capita income in AP3 was R\$794.37 (about 1.56 minimum wages), less than the city average R\$1,420.89 (1.79 minimum wages), and the slum areas had the lowest figures: Complexo do Alemão (R\$390.00), Jacarezinho (R\$405.56) and Complexo da Maré (R\$456.71), i.e. the favelas receive 1/3 of the average city wage.

In relation to schooling years Complexo do Alemão, Complexo da Maré and Jacarezinho present the worst city average with 4.2 years, 4.3 years and 4.7 years respectively.

As regards vegetation, according to Pereira Passos Institute (IPP, 2012), Rio de Janeiro city has a per capita rate of 55 m²/inhabit, while in AP3 it is only 3.5 m²/inhabit. The minimum recommended by Brazilian Society of Urban Vegetation (SBAU, 1996), is 15m² / inhabit. The AP3 presents one of highest preservation areas in Rio de Janeiro, Serra da Misericórdia, which has many degraded areas. The main aspects highlighted by Carvalho (2011) about Serra da Misericórdia environmental impacts are: Stress deriving from fringes of subnormal occupations, unplanned use of trails, trash accumulation and incineration, and ore extraction for cement industry. All those aspects were vectors for deforestation and degradation observed in Serra da Misericórdia.

Table 2: Income indicators - Inequality / population, 1991, 2000 and 2010.

Areas of Complexo do Alemão, Complexo da Maré and Jacarezinho (including Manguinhos) were occupied by the poorest segment of the population, who was neglected by public housing policies for decades. Thus, the morphological characteristics of the urban environment in these areas favoured occupation by criminal groups and consequent insecurity.

In 2010 the region was occupied by police forces that have promoted an improvement in public safety in the last five years. However, it is urgently needed to have urban interventions allowing use of space by the population without mischaracterizing its local peculiarities.

With the review of the data we can see that the regions of the Complexo do Alemão, Complexo da Maré and Jacarezinho (including Manguinhos) belong to the group of lower quality of life, access to education and social development index. On the other hand, in these regions there is a strong population growth, especially in the areas of subnormal occupation - slums - located mostly in the vicinity of the railway axis of Leopoldina - AP3.1.

Accordingly, and in view of the necessary delimitation of the study, AP3.1 was selected for analysis, as it has the largest subnormal housing conglomerates in the region and a wide range of local unsustainable points with global repercussions. The areas studied are seen as transitional spaces between the formal areas of the city and the slums. The study aims to investigate what planning strategies and urban design can be adopted to promote the

upgrading of the urban environment and the development of the region on a sustainable basis.

As a case study we selected the Bonsucesso district and its immediate surroundings that have developed from the end of 19th century along the Leopoldina Railway. The choice was due to the historical specificities and representative morphological characteristics of the region.

Regional characteristics:

- a) From the beginning it received groups linked to the poorest sections of the population;
- (b) It underwent a period of industrialization from the 1930s, which in turn attracted a mass of residents motivated by the offer of these jobs, but at first it did not have the adequate provision of infrastructure such as sanitation or transport;
- (c) It has specific aspects and socio-spatial segregation characteristics closely linked to their being torn along by two major highways, namely the railway itself and Brasil Av., built in the 1940s;
- (d) There were expansions on both sides of the formal urban area - two of the largest groups of favelas of Rio de Janeiro, namely the Complexo da Maré, bordering the Bay of Guanabara, and the Complexo do Alemão, occupying the hills of Serra da Misericórdia;
- (e) It is characterized today by residential areas and small trade and services, with urban voids and remaining unused sheds from the industrialization period, which had a relative deflation as of the 1970s;
- (f) and finally, as we intended to demonstrate, it has not received sufficient attention by the government - not being expressively considered in practically any of the major projects into effect or being planned.

2. Mapping of Unsustainability

The unsustainable spots in the area have been mapped and analysed with a view to potentially reversing the situation through an urban regeneration process as set forth in item 2.

To better understand the area, it was divided into five sub-areas that will be presented on separate maps.

*Figure 3: Five sub areas in Bonsucesso study area.
Source: Own Elaboration based on image from Google earth*

The most important square in Bonsucesso is the Praça das Nações (spot 1), which is located in the commercial centre of the neighborhood. Anyway, that square is deteriorated and unused, occupied by young offenders, homeless people and drug addicts. It's at the second sub-area (figure 5), near the centre of the district and it has good public transport. It is also close to very important roads and highways that connect so many parts of the city.

2.1 Subarea 1

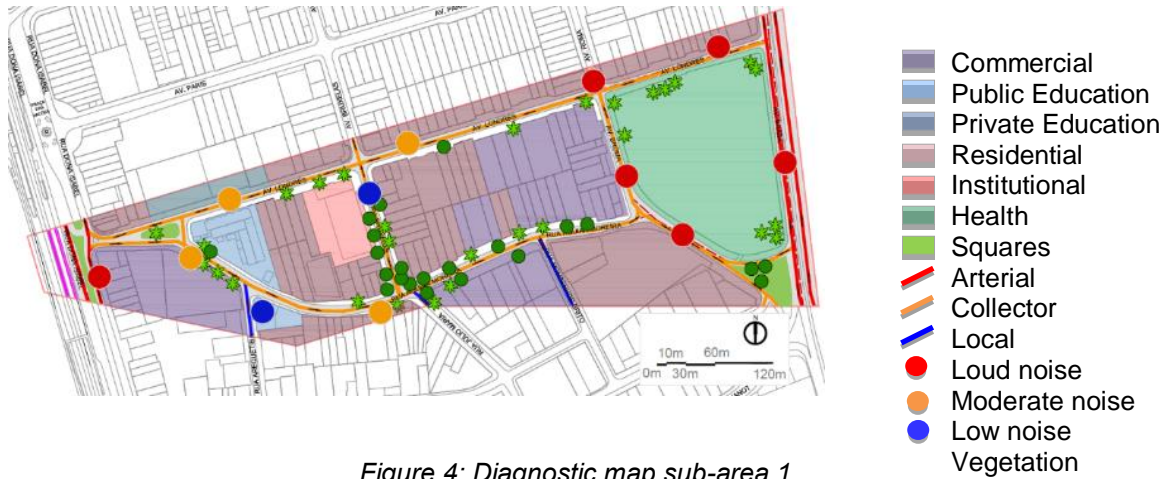

Figure 4: Diagnostic map sub-area 1

2.2 Subarea 2

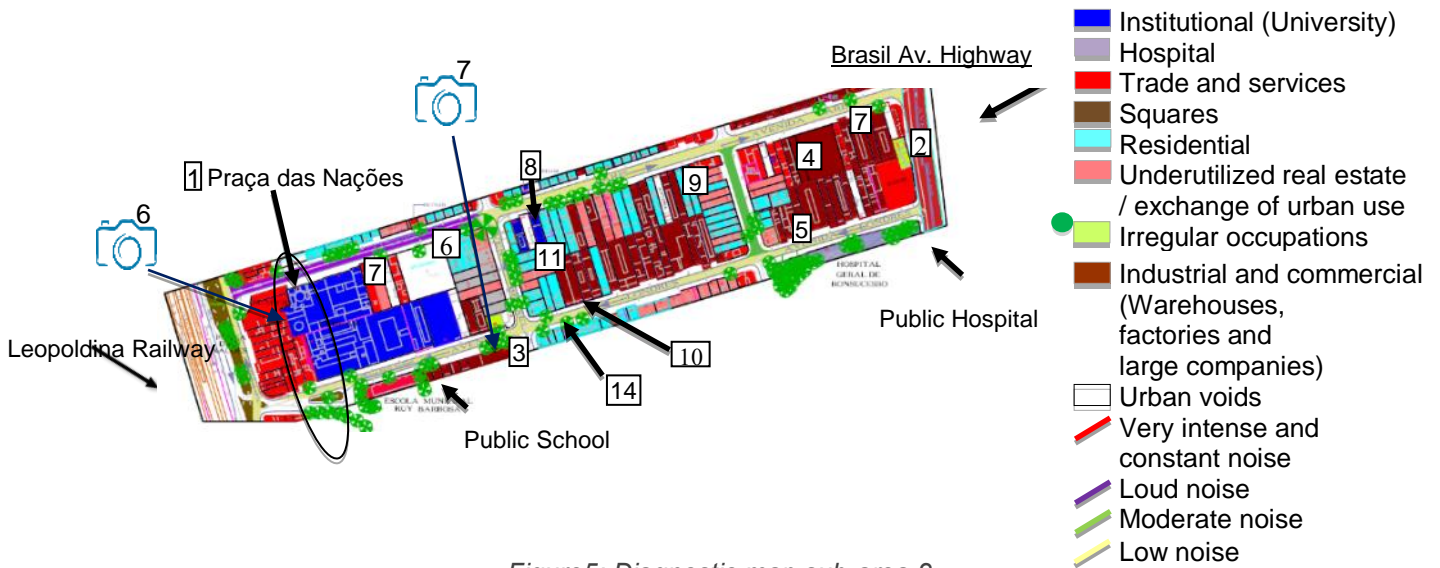

Figure 5: Diagnostic map sub-area 2
Source: Own Elaboration based on Alexandrino, 2015

Figure 6 and 7: Praça das Nações and parked cars on street.
Source: Aragão e Alexandrino, 2015.

The Praça da Nações was a redevelopment project – Rio Cidade - in 2008 with the replacement of paving for permeable blocks, installation of ramps for disabled people, widening sidewalks and installing new lampposts. On the other hand, living areas, equipment

for leisure and sports, or commercial areas were not included, hindering the use of space by residents living in the underutilized area.

The Bonsucesso district was one of the main industrial centres of the city, however with the migration of the industrial sector currently the region is marked by abandonment (spot 2), with the former under-utilized industrial buildings causing large urban voids.

In all the district we can see a large circulation of vehicles, including cargo vehicles. In the residential areas some streets are being used as parking (spot 3), and many gas stations located near schools and hospitals can cause explosions and contamination of groundwater and storm water (spot 4).

The terminus of the bus line occupying part of the road (spot 5) and the sidewalk hinder pedestrian movement, which is aggravated by the large concentration of informal street vendors.

Many urban problems could be observed, such as: irregular garbage dump (spot 6); drains get clogged by leaves and trash in the gutter preventing the correct flow of water into the culverts (spot 7), trees without pruning (spots 8 and 9) and residential areas with low pedestrian flow, favouring insecurity (spot 10).

2.3 Subarea 3

Figure 8: Diagnostic map sub-area 3
Source: Own Elaboration based on Nunes and Victório, 2015

2.4 Subarea 4

Figure 9: Diagnostic map sub-area 4
Source: Christino and Vieira, 2015

The fifth sub-area (figure 10) is the one that has greater amount of irregular occupations among the study areas; this is due to the occupation of the "Adeus and Piancó" hills and the bank of the Faria-Timbó river.

2.5 Subarea 5

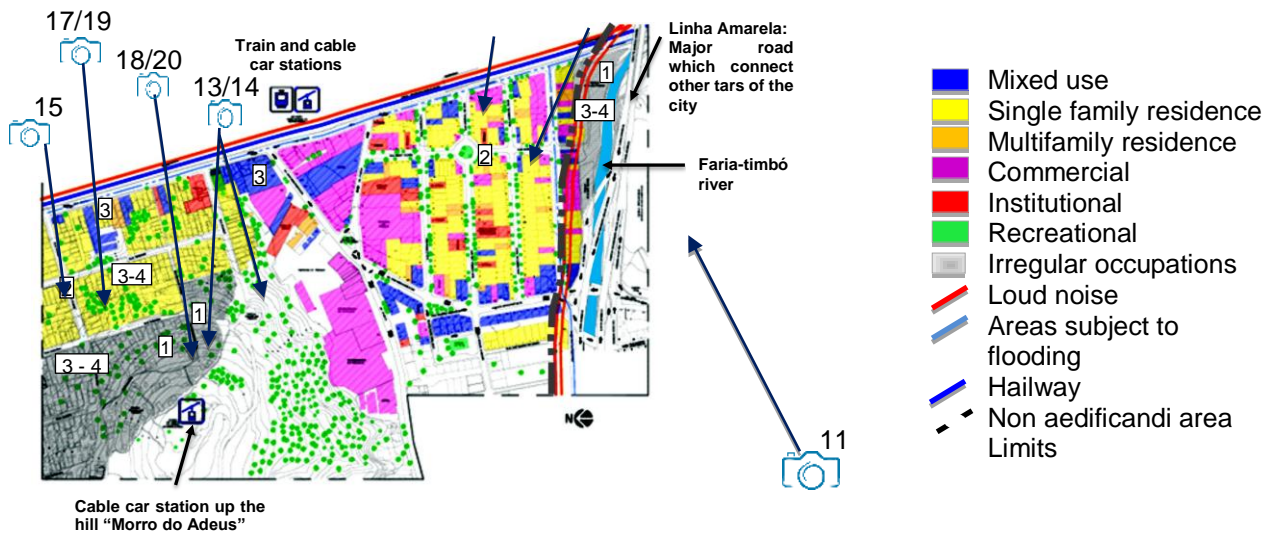

Figure 10: Diagnostic map sub-area 5
Source: Aragão and Sampaio, 2015

The study area has irregular occupation and environmental risks (Spot 1). The occupation of hillsides in Complexo do Alemão brings about soil fragmentation problems and sealing of the pathways. This problem makes the area very susceptible to landslides, offering direct risk to the community and potentially enhances areas of flooding at the lowest points due to the runoff of water that couldn't be absorbed by the soil.

The research identified other problems such as: the banks of Faria-Timbó river were taken by illegal occupations where 1003 people live (IBGE, 2010) in a community called “Vila São Pedro”. These people live under constant threat of flood.

Figure 11 and 12: Vila São Pedro and flooding area.
Source: Sampaio, 2014.

The region was largely deforested, and currently has a low level of afforestation on the slopes and in public streets (spot 2). This situation is directly linked to frequent flooding problems. Even on the sidewalks and streets with low traffic of light vehicles drainage material is not used, prevailing large-scale use of concrete and asphalt paving.

Figure 13 and 14: Slip risk areas.
Source: Google Earth, 2015

Figure 15 and 16: Absence of vegetation and impermeable flooring.
Source: Sampaio, 2014

The subnormal occupation area presents buildings at odds with urban standards (spot 3). In these areas buildings do not follow minimum standards for clearances and a lot of them do not offer good ventilation or natural lighting.

Figure 17 and 18: Typical Building
Source: Google Earth, 2015

Many problems were found with “theft” of energy and public lighting equipment degradation (spot 4), especially close to the poorest areas. The degraded power grid and the energy thefts offer health risks to inhabitants such as serious accidents with shocks and fires. It also has negative consequences both for economic aspects and for public safety since many streets have poor nighttime lighting.

All analyzed sub-areas do not have a significant number of trees or permeability paving. The public transport offer is good, including on the top of the hills because of Adeus cable car station and others, which meet the demand of the population farther from the centre of the district. However, the distance of the consolidated neighborhood and the lack of investment in urban infrastructure bring problems like poor lighting in public areas, which creates barren and unsafe areas.

Any areas studied, including urbanized areas, present uneven pavement and no maintenance hindering pedestrian circulation. These factors bring risk when walking. Furthermore, no facilities were found for the visually impaired, those with limited mobility and wheelchair users. This problem can be observed at *Praça das Nações* where there are trade areas and a large flow of people, however without appropriate care of pavement causing accident.

Figure 19 and 20: Power grid and sidewalks.
Source: Google Earth, 2015

The analysis concluded that Bonsucesso district has a proper infrastructure, but a low level of conservation. This factor, together with lack of urban planning, affects the development of the region.

Many factors must be reviewed, such as: better organization and distribution of commercial areas, use of urban voids, road traffic reorganization, adaptation of routes for pedestrians

and cyclists, replacement of air power grids with subterranean ones, afforestation of public roads, permeable floors, and awareness-raising and environmental education programs.

3. Data Analysis

With the analysis of unsustainability spots of the study area it was possible to develop strategies to enhance the urban development of an area in Rio de Janeiro city on a sustainable basis. Therefore, we selected strategic locations to implement local actions in order to integrate the sectorial procedures and promote "low-carbon planning" of the area through effective guidelines.

In this sense, the study can be considered a pilot for replication procedures in areas with great potential for development and that currently have a low urban, social, economic and environmental sustainability scenario. Both the city of Rio de Janeiro and other cities in emerging market countries that have regions with similar characteristics to the study area, and which suffer stress deriving from fringes of subnormal occupations, can benefit from the adaptation and implementation of strategies and recommendations suggested in the study.

The research conducted follows the guidelines formulated by ICLEI using low-emission strategies for urban planning, such as: high density, mixed use of the territory and the focus on green transport like walking, traveling by bicycle and public transport. Based on these principles we developed projects that include planned consolidation, taking advantage of underutilized areas, the requalification of spaces, using living spaces, creating bike lanes and pedestrian footpaths as vectors to leverage the economic and social growth on a sustainable basis.

As can be seen in the presentation area (item 1) AP3 is one of the regions with the highest population density of substandard housing in Rio de Janeiro city. These areas known as subnormal occupation fringes, or favelas, occupy much of the territory of AP3 and exert strong pressure on both formally urbanized areas and on the areas of environmental preservation.

On the other hand, the slums have their own dynamics of land use occupation and informal distribution of the occupied areas, which differ from the standards set for formal areas of the city. The fact that slums do not obey the rules of construction and land use established by the government makes the environment different from the rest of the city, but the high growth rate observed in these areas proves that although they are informal and are below the normal occupancy patterns, they are extremely bright areas with great potential connection in local and regional spheres.

In these regions the formal urban planning should be revised to meet the social dynamics of creation and multiplication of territory, without repeating the previously established model, but considering local peculiarities, such as: use of small fractions of the same piece of land for more than a building, use of tops of houses as free areas for construction, mixed use of buildings for housing and commerce, leisure facilities with multiple uses (sports, dances, parties, cultural events, religious services and other), operating 24 hours trade site, musical and cultural outdoor events among many other multiple uses that the environment of slum areas provides its dwellers.

Furthermore, planning should take into account the importance of preserving the environmental assets of the region to encourage the process of recovery of degraded areas by promoting reforestation programs in the areas of environmental protection, recycling and sustainable garbage disposal and reuse of rainwater, installation of organic pits, gardens and community orchards cultivation, ecological paving of roads, permeable paving, mapping and solution of the points of leakage and infiltration of water, protection and replanting of riparian vegetation, cleaning and protection of springs and streams.

Regarding creative economy planning should consider the potential in the region seeking to use and invigorate urban voids, encouraging local and international tourism activities with the installation of small connection cores and the training of local guides, fostering the opening and continuation of bars, restaurants and small hotels (hostels), sponsorship of cultural and sports events, economic incentives to micro and small entrepreneurs, subsidizing cultural, sporting and leisure activities.

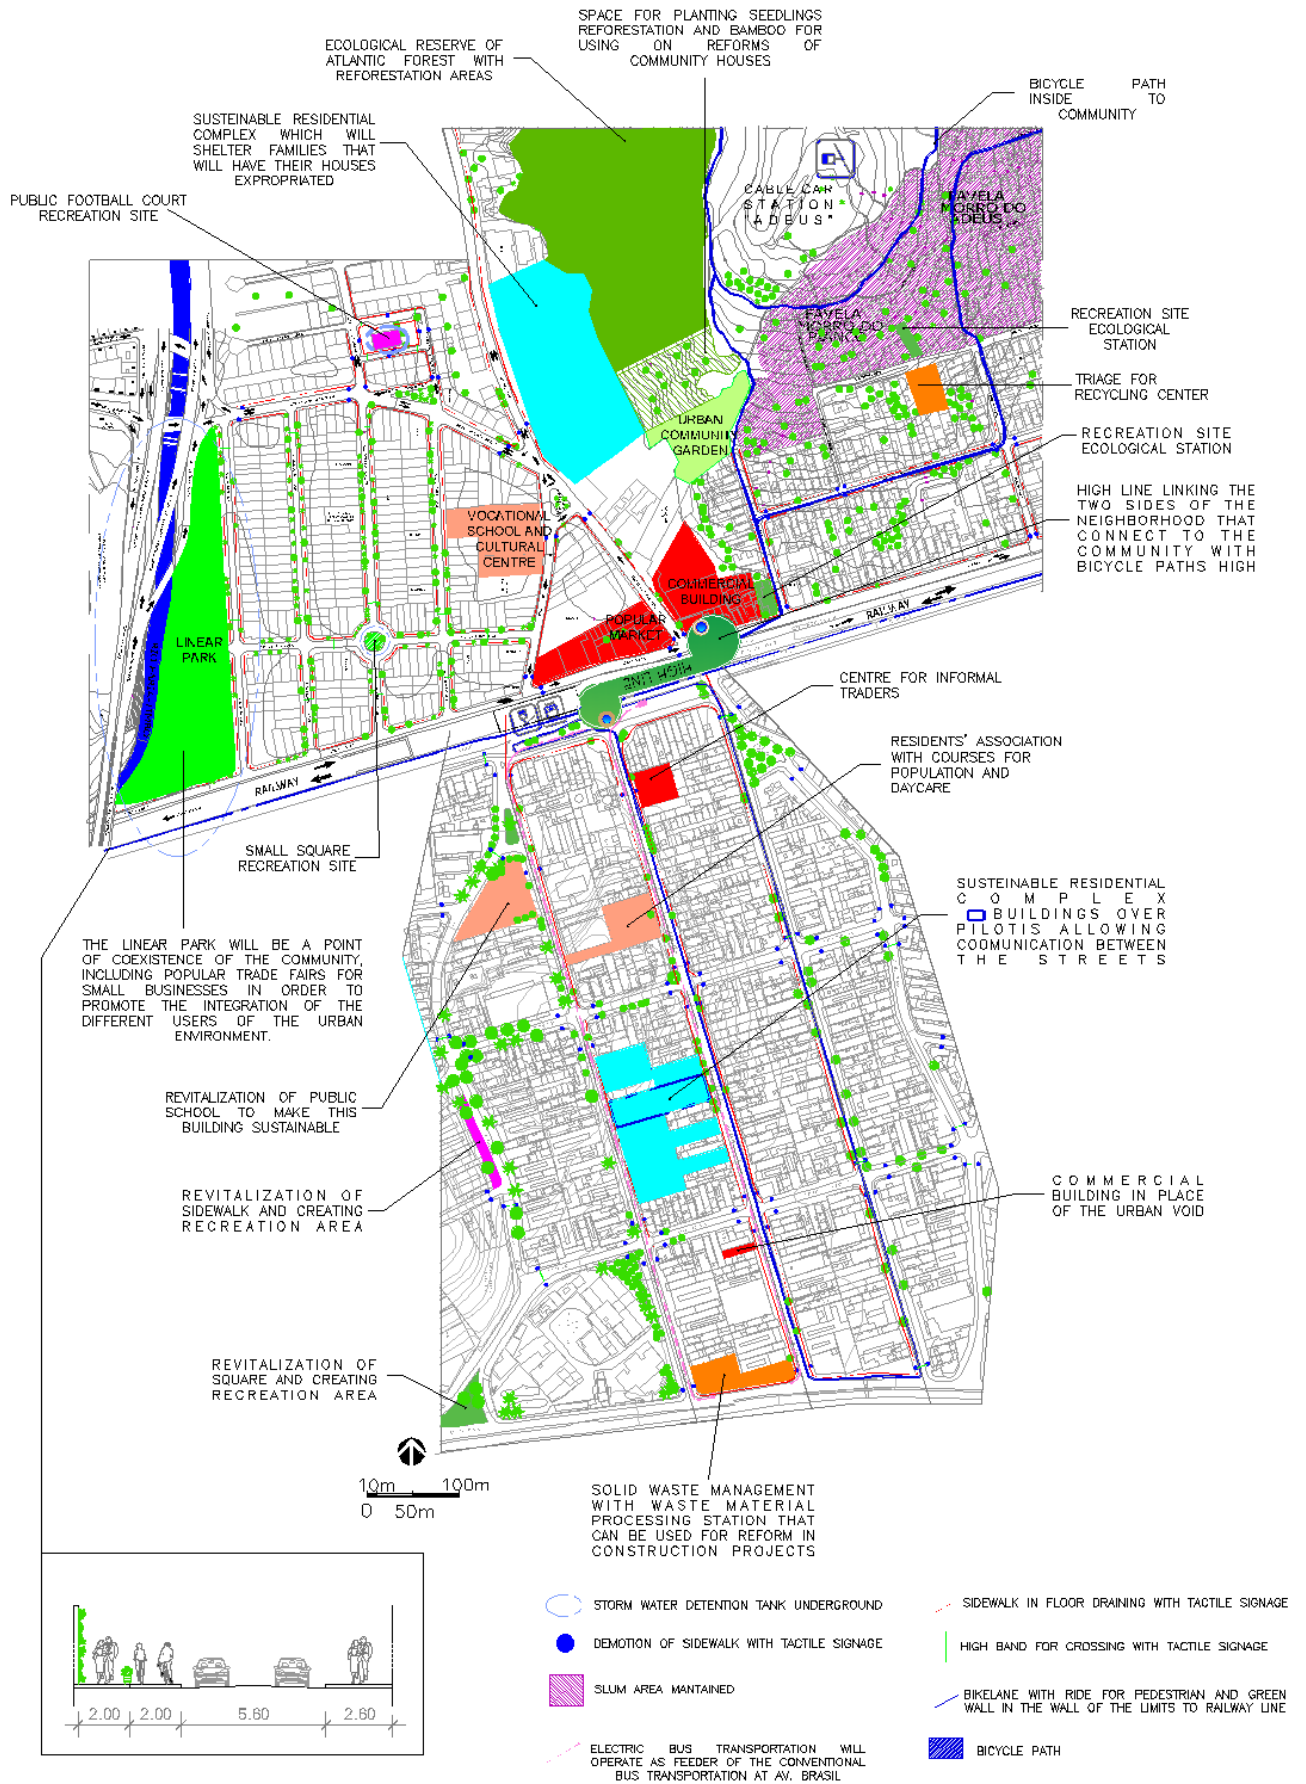

Figure 21: Map with new proposals seeking sustainability.
Source: Own Elaboration based on SMU, 2015

Even in the free carbon economy sector, we should encourage the use of passive energy programs and less energy-intensive building materials for the construction and renovation, reforested wood, laminated bamboo, recycled steel and glass and many others such as green bricks, low-emission cement, whose use in large scale could contribute to significant reductions in emissions of greenhouse gases (GHG).

Under the aspects mentioned urban densification would be appropriate to create conditions for the development of areas such as *Morro do Adeus*. It is usually developed in isolated and unrelated experiences with the neighbourhood itself and the city. Planning in this sense should be promoted "in cascade", i.e. it should be generated and expanded from the hills (where the slums and areas of environmental preservation are located) until you reach the formal district in the flat areas of the neighbourhood. With this movement, neighbourhoods could build dynamic exchanges with positive repercussions across existing regions now set apart from each other as a divided city and with no continuity.

The proposal comprises a plural, participative and connected planning, which seeks to contemplate the differences without imposing the rules "copied" from the formal planning, because these rules can hardly be replicated in areas of "free" occupation as the slums are configured. In this sense, sustainable planning for regions with strong urban and environmental conflict must obey local peculiarities adding the solutions adopted by the social experience to low carbon economy standards, strengthening innovation rules and concepts and integrating participatory planning to global chains of value.

As an example of the planned actions, some urban actions between the slums of Complexo do Alemão and the Bonsucesso neighbourhood are indicated in the intervention map (figure 21): High Line and Linear Park, small square recreation centre, urban community garden, ecological reserve with reforestation area, vocational school, solid waste management, and others.

Conclusion and Recommendations

The study found that while the region of AP3 in Rio de Janeiro city is provided with urban infrastructure in their formally established areas, there is a disconnection between the formal planning and actions developed in subnormal areas of the region. On the other hand, the lack of maintenance and the lack of social participation in the planning process contribute to the waste in the allocation of resources, with the consequent degradation of the urban environment.

In this regard, the present study was based on a thorough diagnosis of the unsustainability points that exist in each subarea of the neighbourhood, including the slum areas, seeking to establish a common line of action between the parties that today coexist separately.

Identifying the points of unsustainability, the urban planning scale was reduced to the level of city block. Thus, each section has been thought for the operation of the city block in the overall context, which approximates the project to the needs of local users without repeating intervention models dissociated from regional reality.

The first benefit suggested in the study was the variety of uses planned and its connection with the practices of green mobility as a way to streamline urban spaces using less fossil energy for displacements due to less dependence on motorized transport, resulting in the reduction of GHG emissions.

Another highlight in the proposed plan is the recovery of ecological reserve, which should act as a limiter and urban space controller promoting the improvement of environmental conditions in the region, which currently suffers from pollution and the absence of green areas. In this sense, the engagement of the local population is essential for the recovery of conservation areas and the proliferation of green areas in the city.

As an incentive to low-carbon economy the rational use of available environmental resources for the construction and renovation of buildings has been proposed. In this respect areas will be created for cultivation and production of bamboo and certified wood, low-emission cement production with the installation of waste recycling centres for civil construction, and installation of a ecological brickⁱⁱ production centre. All initiatives will be organized in

partnership with the private sector and may represent an equivalent economy of 0,03tEP / m² built or about 0.13 tons CO₂ eq / m² (CRUZ, 2015) to be built in AP3.

Ultimately, the creation of urban connection poles, which are currently installed where there are urban voids, aimed at strengthening the appreciation of the participatory planning and creating a permanent exchange between multiple experiences developed. All initiatives taken in subnormal areas could be replicated in formal areas of the neighbourhood, and vice versa. That is, the planning provides for the permanent connection between different areas of the neighbourhood, with multiplying actions that can be replicated in other districts of the city and other cities, leveraging local action to global levels.

The proposed actions, in general, require more social effort by inviting people to participate in the planning process, so that society can take ownership of the city.

The expected results are the spread of popular participation as driver of great changes in the urban environment, thereby contributing more effectively to preserve the environmental heritage and the development of the urban environment on a sustainable basis.

Toward the Urban Transition of Kragujevac: A New Life of Old Urban Generators

peer-reviewed paper

Aleksandra STUPAR, University of Belgrade - Faculty of Architecture, Serbia
Aleksandar GRUJIČIĆ, University of Belgrade - Faculty of Architecture, Serbia
Biljana GRUJIČIĆ, University of Belgrade - Faculty of Architecture, Serbia

After more than two turbulent decades of recent history, marked by the gradual break-up of Yugoslavia, international economic sanctions, internal political conflicts and a general social and economic crises, the cities in Serbia have been redefining their position and role in accordance to a new European development framework. Instigated on both institutional and non-institutional level, these changes have been visible in social, economic, environmental and spatial spheres, marking the beginning of the latest transition phase.

The focus of this paper is the city of Kragujevac, the fourth largest city in the Republic of Serbia, well-known as one of the most important industrial centers of Serbia after the WW II. The crises during the 1990s caused a significant economic decline, although after the 2000s and democratic changes, the general conditions were improved, attracting new investors and accelerating local economic development.

Considering the current situation and recently adopted "Integrated Urban Development Strategy for the Inner City of Kragujevac" (2012), this paper will elaborate two possible approaches toward the further transition, regeneration and development of selected urban spaces, based on the concept of temporary use and the increased interaction between the city and innovation processes. The presented proposals resulted from the work on master-theses, conducted under the supervision of professor Aleksandra Stupar at the Master course 'Integral Urbanism' at the University of Belgrade, Faculty of Architecture (2013/14).

1. Introduction

In spite of their growing importance in global networks of power, the contemporary cities have been facing numerous problems caused by a huge gap between their ambitions and real socio-economic conditions. The imposed development imperatives frequently collide, triggering a number of side effects – from illegal settlements, informal economy and urban disorder to social exclusion, conflicts, pressure and risk. Although recent strategies, plans and programs declaratively contain all necessary ingredients for democratic, technologically advanced and ecologically beneficent environment, the anticipated progress, social cohesion and flexibility frequently remain out of reach, challenging all spheres of governance, as well as the applied professional knowledge.

The methods of eradication, translocation, rehabilitation, adaptation or questionable 'beautification' of urban tissue represent typical answers to both growing social dissatisfaction and/or the pressure of global capital, while cities continue to be a testing ground for new approaches to environmentally advanced future. Focusing on neglected or devastated urban areas, such as outdated harbors, ex-industrial sites or former nodes of military or transportation infrastructure, urban interventions introduce modern generators of 'vibrancy', usually related to culture, business, technology, tourism and, most recently – environmental correctness, while the scale, objectives, methods and instruments could vary, depending on local circumstances.

Considering the complexity of almost endless list of variables which could direct urban development of every city, the case of Kragujevac (Serbia) represents an interesting example of fragile urban prosperity and shifting socio-economic conditions affecting current situation in this urban node. On its way toward a successful urban transition, the city adopted the "Integrated Urban Development Strategy for the Inner City of Kragujevac" (2012), a joint initiative/project conducted by the GIZ/AMBERO-ICON, the city of Kragujevac, local institutions and citizens. This Strategy represents a good platform for further development initiatives and interventions in/on urban tissue and it was, therefore, used as a realistic framework for the master projects/theses on the Master course 'Integral Urbanism' at the University of Belgrade, Faculty of Architecture (2013/14). Based upon program guidelines from the Strategy, the master projects used both academic/scientific approach and the knowledge from practice providing a new insight into development problems of the city and suggesting conceptual solutions to detected problems. The interaction between practice, research and education has produced interesting and up-to-date outcome and this paper presents proposals from two theses exploring the possibilities of the local economic development from the perspective of the temporary use of spaces and the multileveled relationship between city and innovation processes. The selected generators of further urban transition mutually upgrade the city image by using creative and knowledge economy, recreating and regenerating a productive and well-balanced city network able to merge global(ized) imperatives with local possibilities and expectations.

2. The theoretical background

Contemporary cities, described as postmodern, hybrid, intransitive and creative places, continuously upgrade their settings and activities. Efficiency, attractiveness and knowledge are recognized as mantras of every development document, while the flexibility of proposed solutions has to allow fast response to accumulated pressures, challenges and growing (re)fragmentation of urban environment. Therefore, every city traces its development upon an extensive list of regeneration and transformation programs which could be radical or moderate, driven by a selected 'theme' and focused on future or nostalgia. Being 'innovative' has also become a competitive advantage which could be recognized in different areas of urban life - from different phenomena, spatial typologies, various strategies, (in)formal processes, movements and activities, to the latest technologies and their amalgamation with urban hardware and software (Stupar, 2012). Considering the specificities of local context, this paper will focus on two spheres - culture and technological innovation, as possible generators of urban regeneration in Kragujevac.

2.1. The (con)temporary places of culture

Culture, as an important driver of urban regeneration, is essential to city attractiveness. Creative industries support economic strategies that allow the development and creation of new jobs, especially in times of economic crisis, but they also demand adequate places interesting to highly educated and creative people. The physical setting of cultural flows becomes, therefore, an indirect source of economic success and a catalyst of social development. Using culture as a tool for positioning and branding of a city has resulted in the creation of identity and social cohesion, encouraging community development and civic participation, as well as attracting various economic investments directed to both tangible and intangible resources (i.e. style, brand, design etc.).

Rapid changes in cities question traditional models of planning and architectural practice based on static models. Among the emerging types of urban spaces, there are those considered as temporary, provisional or ephemeral. Occupied in a certain period of time, often without a permanent character, they are mainly linked to informal processes. Arising from creative appropriation, these flexible spaces follow the changes of cities, easily adapting

to different scenarios of development. The conditions and causes for creating the temporary places could be very different. They could be the outcome of specific needs of a local community, emerging business/start-up companies or creative groups, resulting in improved quality of the city or a particular area which is currently not profitable. Consequently, the concept of temporary use refers to the temporary activation of free or unused land or buildings that do not require an emergency development plan. Creating a unique (but unstable) quality of temporality this concept actually prepares the selected site for some other activity which will last longer (Haydn and Temel, 2006). Although the concept of temporary use is generally not considered as a part of the natural cycle of urban development and is often associated with the crisis or the lack of development vision, there is an increasing number of successful cases all over the world. For example, the dynamic scene of Berlin's nomadic clubs and temporary events proves that the temporary use can represent an inclusive and innovative part of modern urban culture (Studio Urban Catalyst, 2003). Furthermore, the research conducted within the project Urban Catalyst (2001-2003) reveals potentials of applied mixed-use patterns consisting of arts, culture, education, leisure, sports, housing, manufacturing and trade. They attract heterogeneous groups of users, from start-up companies, migrants, refugees, to part-time activists and associations who are working in the same field or cooperate in a flexible way (Hentilä, 2003). Adaptive re-use of urban spaces (i.e. industrial heritage or other declining areas) also enables various, mostly vulnerable social groups to take action with a relatively modest investments. Creating a synergy they shape a new arena for collective learning (Hentilä and Lindborg, 2003). The existence of temporary use is directly related to the economic context of urban areas, acting as a catalyst for urban development. Berlin and London are among the best examples of cities that have taken advantage of temporary use for the development of small enterprises in order to regenerate economy. Berlin is currently experiencing an expansion of micro-entrepreneurship and 'culturepreneurs' (Lange, 2006), a specific type of entrepreneurship that experiments with new social, economic, and socio-spatial practices.

2.2. Setting the innovation nodes

The transformation of places which stimulate creativity and respond to future challenges has become an essential part of our urban reality. With increased economic and political power supported by local governments, cities have become incubators of innovation and change. Innovation also provides adequate means for positioning the city in contemporary global trends, using various forms of creation and networking to enable progress, stimulate economic development and prevent negative population migration.

According to Joseph Schumpeter (1934), innovation is the main driver of long-term economic growth and social change. He defined the concept of innovation broadly, claiming that it includes new products, production methods and sources of supply, as well as the exploitation of new markets and new ways of organizing companies. Most scientists and experts form definitions and arguments concerning innovation around these principles, emphasizing that innovation represents an essential element for the formation of values and the development of modern society (Solow, 1956; Mansfield, 1972; Romer, 1987; Nadiri, 1993; Edquist, 1997; Agarwal et al., 2003).

In a post-industrial knowledge economy growth depends not only on the chain of production and procurement, but also on other factors, such as human and intellectual capital. Scott and Storper (2003) state that "human capital is formed *in situ* on the basis of the education, training, learning through practice and a wider process of socialization" representing a dynamic combination of factors that often require a certain amount of spatially specific face-to-face interaction.

Despite the forecasts predicting the "death of the place and the distance" due to increased ICT networking, a local character still survives as an essential feature of economic and social life. The connection between locally-specific resources and regional level shows that capacity related to the character of a company and a learning processes can lead to regional (and global) competitive advantages if they are based on local capacities and capabilities

(Malmberg and Maskell, 2002; Wolfe, 2003). The continual existence of institutional support, built structure, knowledge and skills shapes a solid framework for innovative development. Cities contribute to economic development and prosperity supporting the creation of knowledge by linking entrepreneurship, people and institutions. Encouraging the exchange of ideas, they also facilitate localized knowledge spillovers and enable innovation.

There are two prevailing explanations of why cities are essential for innovation: the theory of agglomeration and specialization theory. The agglomeration provides a stimulating environment for entrepreneurship locating companies, providing access to a wide range of highly-trained and professional staff and allowing the exchange of ideas and information (Marshall, 1920). On the other hand, highly specialized economy provides comprehensive collaboration within the company, better matching of labor and labor mobility within companies, as well as the possibility of sharing supply chains. These two types of economies in the cities are not exclusive, and often coexist, especially in large urban areas. Innovation is successful due to the development of institutional cohesion and the creation of local, social and cultural conditions that lead to economic growth. Such institutions include local governments, scientific organizations and institutions, the representatives of business organizations, consulting firms for economic development and research centers.

Innovation district, used as a trigger of economic development, represents an area based on cooperation between higher education institutions, public sector and private industry, as well as science and technology. Ensuring the inflow of investments, it aims to support interdisciplinary partnerships/mutual benefits, which is the main characteristic of the knowledge economy. The research conducted by Michigan Municipal League in innovation districts in Pittsburgh, Boston, Portland and Toronto, 22@ Barcelona and smaller scale districts like Kendall Square and Cambridge, indicates common features (concepts), regardless of financial or thematic framework. Although some innovative districts are based on certain sectors, they all focus on individuals that create new opportunities, products and services. Consequently, the innovation district, according to studies above, should include:

- At least one university which is crucial for education and entrepreneurship networking;
- Programs for connecting business incubators with investment possibilities;
- Infrastructural investments;
- Public-private partnerships;
- Affordable housing;
- Mixed use;
- Open space accessibility and green infrastructure (Michigan's Urban and Metropolitan Strategy, 2012).

The emergence of innovative districts presents a new model based on the principle of cluster, including all the benefits of city locations. Since open, innovative economy requires closeness and integration, knowledge transfer takes place smoothly within and between clusters, companies, workers and institutions which support the knowledge economy. The growth of open innovation and networks enables the creation of ideas, as well as the collaboration and cooperation between various sectors (NESTA, 2009). These trends have influenced the change in urban planning and design of places which serve as catalysts of innovation. In general, innovation districts rely on redesign and conversion of buildings and business premises, supporting collaboration and open innovation. They also provide physical and social platform for the growth of entrepreneurship - incubation spaces, collaborative spaces, social networking, competitive products, technical support and supervising.

3. Kragujevac: generating the change

In this section the context of the city of Kragujevac will be presented, as well as two proposals which resulted from master-theses based on concepts and ideas elaborated in the previous part - the temporary use of derelict ex-industrial and ex-military spaces, and the

establishment of new, competitive innovation nodes/districts, generated from existing university and research nuclei. Due to its specific socio-economic background, identified problems and potentials, as well as the proposed official development strategy of the city, Kragujevac represents an excellent urban polygon for testing and applying locally adjusted variations of these concepts. The first project 'Regeneration of neglected spaces by applying the temporary use concept' (author Biljana Grujičić) - is focused on the improvement of the cultural and tourist offer. It is structured around the concept of temporary use which stimulates urban renewal and regeneration integrating art and cultural strategies into neglected urban spaces of abandoned industrial areas. The second project - 'Innovation district Kragujevac' (author Aleksandar Grujičić) - uses a link between cities and innovation, as a ground base for economic growth.

3.1. The context

The city of Kragujevac, as the administrative center of Šumadija County, is located in central Serbia, 140 km southeast from the Serbian capital Belgrade. Its historical importance could be traced back to 1818, when it became the capital of Serbia, liberated from Ottomans. During that period, the city experienced a rapid urban development, establishing first gymnasium in Serbia, as well as the first court, first theatre and other public facilities. The industrialization of the country also started in Kragujevac, with the first military cannon being made in the military factory "Topolivnica" (1853). The period between two World Wars was also intensive for the city, which became the most important military and industrial center in Yugoslavia.

Figure 1. The position of the city of Kragujevac
https://commons.wikimedia.org/wiki/File:Mapa_Srbije.svg

After the Second World War, the process of urban renewal was conducted following the economic development which positioned Kragujevac as the center of the Yugoslav car industry. During this period, large investments were directed to activities related to manufacture, housing, public and infrastructural facilities. In the mid 1970s the population has exceeded 100.000, but the crisis during the 1990s caused a significant economic decline, resulting in abandoned and devastated industrial areas in the city centre. The overall urban identity was changed leading to more spontaneous and uncontrolled urban development. After the 2000s general conditions of the city were improved, opening new possibilities and attracting investors (for ex. Fiat) which enabled acceleration of local economic growth.

Today, Kragujevac has almost 200.000 inhabitants and according to the official planning documents it is marked as an urban node of national interest. However, the latest phase of development, characterized by increased population and the higher concentration of facilities

and activities in inner-city areas, has caused numerous problems, especially in the outdated traffic infrastructure. Simultaneously, the attractiveness of the central city area is reduced due to the inadequate urban connectivity, poor and insufficient maintenance of public spaces and architectural heritage. Therefore, an urgent revitalization and modernization of devastated central and northern areas was needed in order to activate urban potentials and increase overall competitiveness of the urban space.

The "Integrated Urban Development Strategy for the Inner City of Kragujevac", adopted in 2012, represents an important document which aims to adjust and improve current infrastructure of the inner city zone by using local and other available potentials for the future development. Sector goals and guidelines were based on the analysis of the current situation which also determined the target zones and their anticipated (sustainable) improvements. The strategy is based on five key-issues:

- Urban structure and the city appearance (revitalization of abandoned facilities and public spaces in inner-city areas in order to reshape urban identity);
- Infrastructure and traffic (rehabilitation and regulation);
- Economy and tourism (reactivation of abandoned sites and upgrading of tourist supply);
- Education and social services (extension, interconnection of facilities);
- Culture, leisure and recreation (preservation of cultural heritage, new events and upgrading of sports facilities).

Following the main trends of contemporary urban development, the recommendations of the Strategy included imperatives of accessibility, environmental quality, sustainability and public participation.

Considering all these elements, as well as the characteristics of the identified target areas, the students were obliged to select and apply some of the up-to-date development/generative concepts which could be recognized in contemporary cities (especially those with similar background, size and problems), developing their own proposals/projects. Having in mind that the whole process was synchronized with the city authorities and planning institutions from Kragujevac, the main idea was to create a set of solutions to identified problems, which could be later used as an input for future activities - from short-term/immediate actions, to long-term programs of urban transformation.

3.2. Redefining the cultural landscape

The central area of Kragujevac is divided into several parts, which are morphologically and functionally diverse. The highest potential for the application of the concept of temporary use could be detected in abandoned industrial facilities and ex-military zones to the west and northwest of the city center. In close proximity, on the south bank of the river Lepenica, there is the site of the former complex of "Zastava" factory. The northern part of this zone is an integral part of central urban area and a part of it has been bought by the city of Kragujevac in order to be reused for cultural and educational purposes. These spatial segments have a low level of urbanity.

From 2001 to 2009 there was an increase in the number of unemployed in industrial sector, while the number of employees in commercial and service activities did not change. However, the absolute number of unemployed is quite high. After the breakup of Yugoslavia, Kragujevac detected a decreased number of tourist visits, while 2005 represented a turning point which marked an upward trend in the number of both domestic and foreign tourists. However, the network, capacity and the quality of facilities of existing cultural institutions is inadequate. Considering all these elements, the central zone of Kragujevac could be used as a polygon for the application of the concept of temporary use which would raise the attractiveness of the location via the reactivation of abandoned industrial complexes, temporary installations and cultural events.

Based on the criteria of proximity to industrial heritage, concentration of open public spaces and the scope of the inner-city area, three sites/generators have been recognized for positioning the projects of temporary use: A) Vojno-tehnički zavod (Military-Technical

Institute), B) Donji (Mali) park (Lower (Small) Park), and C) area 'Prodor'. The location of the Military-Technical Institute is the central place for five temporary initiatives: "Open Library", "Urban Gardens", "Movement" (open-air cinema), "Art Colony" and "Magic on Ice" (open-air skating rink). The area of Lower Park is used as an intersection of paths linking Military-Technical Institute with 'Prodor'. The aim of this project is to reactivate abandoned buildings and open spaces, to increase quality of cultural activities and regenerate the site while preparing it for long-term use.

Figure 2. The areas selected for the application of the concept of temporary use

The project for the Military-Technical Institute is named "Industrial resolution", metaphorically representing major activities, while the area of Lower park should serve as a display for the projects of visual arts guiding users/pedestrians toward the meeting point in the city centre, at the end of the area 'Prodor'. These projects include a so-called 'Reading room', 'Meeting point', 'Kinetic wall', 'Anti-selfie' and 'The house of tea'. The culmination point of this direction includes temporary pavilions which would change over the season, according to a design theme launched by the Military-Technical Institute.

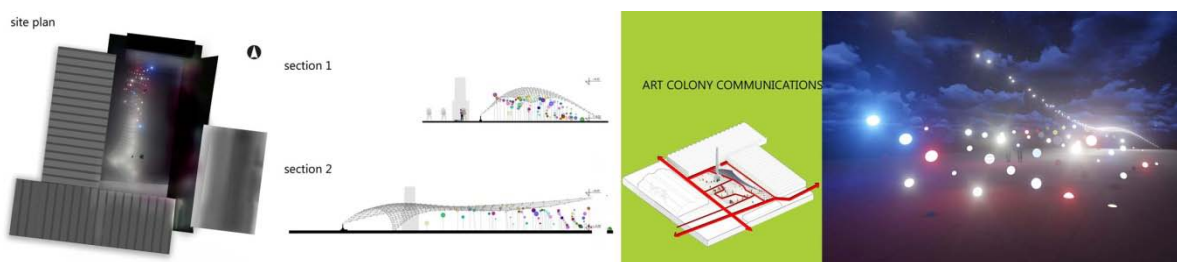

Figure 3. Temporary project "Art Colony", location A) the Military-Technical Institute

Establishing temporary spaces in Kragujevac would lead to a specific place making and the creation of a local identity rooted in the cultural heritage and modern tendencies. Temporary use tends to improve the general conditions of the surrounding, creating a positive influence on the anticipated permanent land use, its further development and future investments. It would create and upgrade new public spaces, stimulating collaborative practices.

3.3. Innovation District Kragujevac

Developing the innovation district in the central zone of Kragujevac requires an analysis based on the general concept of innovation district and the data about current land use, the existing housing stock, economic structure and the disposition of educational institutions. According to the "Integrated Urban Development Strategy for the Inner City of Kragujevac", housing occupies 40.2% of the central zone, while industry covers 20.3% and open green areas 3.8%. This structure is suitable for the development of an innovation district because industrial heritage could be transformed into new facilities for innovative industries. Existing residential buildings could also have a very important role in providing additional housing units or it could be upgraded to mixed use. Underutilized areas provide opportunities for complex activities and higher density. The anticipated positive trend in population growth by 2030 should provide the necessary human capacity for technological innovation. The strategy also states that the general development of abandoned industrial sites has a high potential (due to planned transformation of business and commercial activities). Thus, the regeneration of brownfields opens a possibility for introducing innovative content/facilities (offices, research institutions and laboratories) and combining it with residential and commercial buildings.

The structure of employment (49% in manufacturing and 50% in services and commercial activities) indicates a high importance of manufacturing sector, within which the process of innovation manifests the most. This arrangement naturally affects the innovation capacity of the city, while the dominance of small businesses represents a potential for connecting various activities able to form a network for the exchange of knowledge and innovation. However, the University of Kragujevac is seen as a key actor able to instigate networking with local entrepreneurs in order to create more defined research links, related to business activities. Furthermore, a large number of students within the region is considered to be an indicator of superior regional innovation potential and a guarantee of intensive interaction between young innovators and local or international companies.

The project of the Innovation District Kragujevac proposes a spatial concept based on a cross-linking of specific points around the central zone. This type of connection defines four categories of spaces:

- revitalized industry, as a larger zone which is a source of innovation and encouragement;
- educational institutions which provide human capital and are directly related to industry;
- system of interlinked educational and commercial facilities;
- green infrastructure, which supports user interaction, affects social capital and knowledge transfer.

The Innovation District represents a double node of the anticipated innovation network, which uses the advantages of high accessibility to all elements. Since the selected area currently mostly consists of single-family houses, the available free space has a sufficient capacity for future merging of educational/research/entrepreneurial activities.

Figure 4. The proposed innovation network

Zone A is dedicated to technological innovations (i.e. IT companies). The connectivity is established via overlapping activities - for example, academic/educational institutions and IT sector. Zone B hosts innovation companies focused on environmental issues. Green areas are dominant in this zone, promoting ecological imperatives. Eco-design companies are also positioned in this area, as well as experimental adaptation units and institutes and laboratory for research on climate changes.

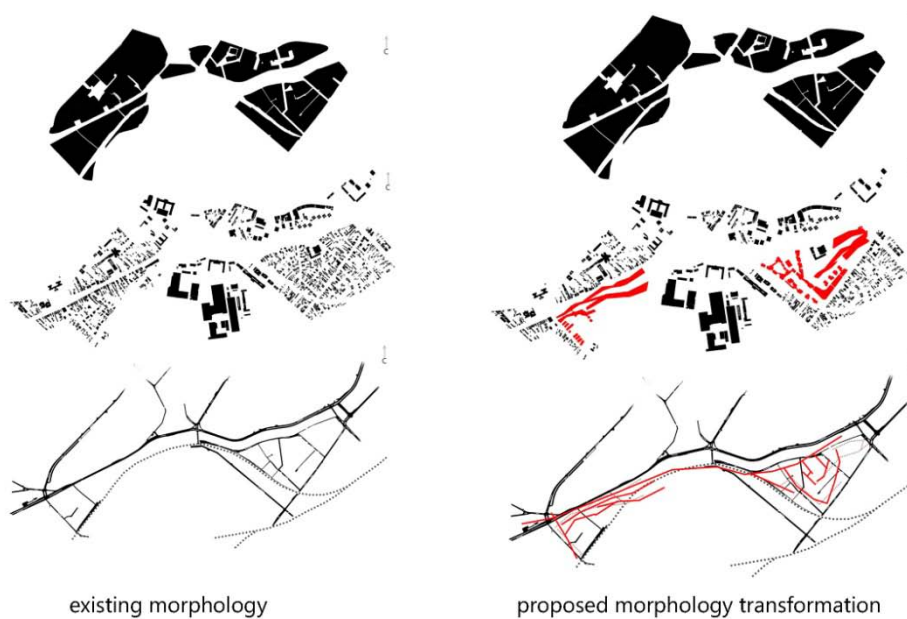

Figure 5. The morphology of the Innovation District

The project keeps existing block structure, while several places promote formation of macro-blocks in order to redefine inner communication. The buildings are transformed into longitudinal formations, while existing typology is preserved on the outer edges in order to maintain low density. Inner communications also allow integration with the river and the railway corridor.

Figure 6. Innovation District Kragujevac project- composition

This project recognizes and suggests the necessity of formulating a strategy on innovation, which would represent a framework for interdisciplinary collaboration. Creating a cluster of resources enables the city to face and keep up with global competition, where encouraging close connections between the industry, creative, education and public sector improves the Kragujevac micro activities, upgrades urban identity and promotes local economic development.

4. Conclusion

The process of continuous transition represents a necessity for every city eager to position itself in the global and regional hierarchy, but the boosting of competitive advantages usually demands enormous resources and skillfully implemented strategies. The frictions generated between ambitions and growing problems have generated several new or modified development concepts which could ease some tensions and bridge the gap between uncertain conditions, turbulent reality and anticipated visions. The application of the concept of temporary use and the activation of innovative district(s) are recognized as promising drivers of urban development and the city of Kragujevac could certainly benefit after considering some of the elements introduced by presented master-projects. Although currently in a domain of speculations and paper-architecture, these proposals are based on the officially adopted development strategy and their possible outcomes could contribute to a new urban identity. The ideas elaborated in these projects could also influence a higher attractiveness of space, providing future investments in the inner city region.

Obviously, the link between education and innovation could be established on many levels. Therefore, it is always interesting to have another perspective on emerging trends, allowing a flexible and inspiring knowledge exchange in which everyone gains - from students and professionals, to entrepreneurs and local community. However, the problem of implementation remains, reminding us that urban development represents just one of many indicators of social (dis)balance and its economic and technological premises.

Understanding neighbourhood with an activity-based approach to scientifically measure and evaluate its performance

Somayeh TAHERI MOOSAVI; University of Manchester; UK

1 Introduction

Regeneration practice in the UK has the history of about 30 years. Historically, practice has ranged from economic policies, through physical design and place making strategies to more complex initiative to shape and organise urban spaces as a social phenomenon in order to change life experience of the urban poor (CREW 2012). Since 2012 the National Planning Policy Framework (NPPF) in England emphasises on the local character of identified spatial locations to meet socio-economic and environmental requirements of sustainable development. The locations are neighbourhoods. More importantly, it is stated that planning decisions “address the connection between people and places and the integration of new development into the natural, built and historic environment” (Department for Communities and Local Government 2012, p.13). An appraisal of a decade regeneration practice in the UK shows that it has not delivered expected results and displaced problems elsewhere (Nisha and Nelson 2012). It, however, benefits the middle and higher income groups. The main identified reason is the incompatibility of the objectives of the regeneration schemes and the local social needs (Gosling 2008; Madanipour 2006; Nisha and Nelson 2012). Madanipour (2006) argues this issue makes some to think there is a dichotomy between any development and social factors. Regeneration has been “inconsistent in delivering effective, socially inclusive and equitable outcomes, raising concerns over its potential to cultivate life and character into declining urban spaces” (Nisha and Nelson 2012, p.14).

This paper is a part of the wider research about regeneration neighbourhoods with an activity-based approach. The research intends to inform designers, planners and policy makers about how to measure, evaluate and model the function of neighbourhood in the city, and how to maximise the certainty and reliability of urban policies, service programmes and regeneration proposals in neighbourhood. The main contribution of the research is its activity-based approach. This paper as a first of paper series introduces this approach, and focuses on the key concepts and the clustering method. The future publications by the author will bring more insights into the other aspect of the wider research. The case study is the Brunswick neighbourhood in Manchester, UK. The regeneration of this neighbourhood has started since January 2014. After this introduction, the case study and the aim of its regeneration are presented, followed by the data collection method in the third section. The fourth section has two sub-sections: first, the concepts of the activity-based approach for understanding neighbourhood, and second, the delineation of eight activity attributes to redefine activities with the K-means clustering technique. The paper concludes how the analyses with an activity-based approach contribute to various actions and decisions in the regeneration process of neighbourhood such as the Brunswick neighbourhood.

2 Brunswick neighbourhood

The Brunswick neighbourhood covers 29 hectares with the population of 3,540 in 2011 (HACT and OCSI 2013b; Solutions for Brunswick 2013). This gives a very high density of 122.1 people per hectare. It is located in the south of the city centre and is part of the Ardwick ward in the central Manchester (Figure 1). The Ardwick ward in general plays a reception role for the new migrants in Manchester (Manchester City Council 2006). In 2012, the population turnover rate per 1,000 people was +11, in a sense that 456 people moved into the neighbourhood and 445 people moved out (HACT and OCSI 2013a). Hence, the neighbourhood is a place for the black and minority groups by about half of the population.

The regeneration of the Brunswick neighbourhood has been an agenda for the Manchester City Council since 2007 (Manchester Partnership 2012; Manchester City Council 2007; Manchester City Council 2013). Before the regeneration starts, it was classified as one of the 5% most deprived neighbourhoods in England (Department for Communities and Local

Government 2011). In 2013, about half of the population claimed the Council Tax Benefit and 14.5% claimed income and/or employment support benefits (Valuation Office Agency (VOA) 2008; HACT and OCSI 2013a). At the same time, more than half of the population was economically inactive and about a third of the adults did not have the right level of qualification and skills to get a job. 12.6% of all residents had limiting long-term illness and only a third had healthy eating. Just under 60% of all houses are council homes, while only about 5% of all houses are worth more than £52,000. In average, there were 63.5 crime incidents per 1,000 people in Brunswick.

The vision to regenerate the Brunswick neighbourhood is: a transformed and successful neighbourhood with better linkages with the Oxford Road Corridor in the west, the city centre in the north and Ardwick Green in the east. Brunswick will be a neighbourhood of choice for existing and new residents with a wide range of high quality housing, shops and services within a safe and attractive environment (interview with the project manager in 2013). Neighbourhood of choice is a concept in the Manchester planning policies that seeks to transform neighbourhoods to “areas where people choose to live and work, which attract new higher earning residents while encouraging local people to stay in the area and benefit from this renaissance” (Manchester City Council 2007, p.8).

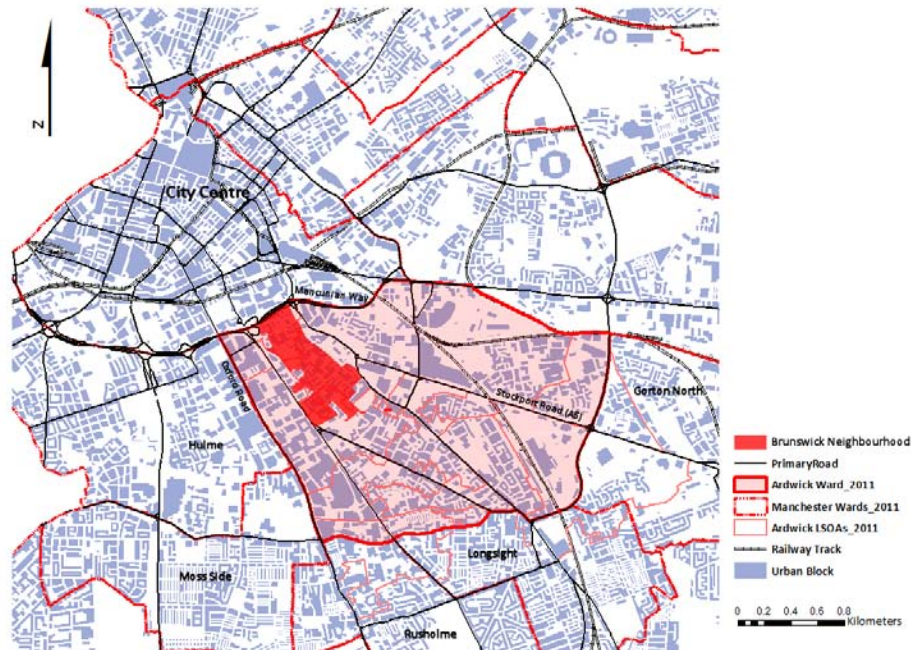

Figure 1: geographical location of Brunswick in the Ardwick ward

3 Diaries as a data collection method

Surveys are the common methods of collecting data of daily activities in literature (Jiang et al. 2012; Harvey and Taylor 2000). Participants are recruited as diarists to record their daily activities in diary booklets or via an online toolkit (Lee et al. 2000; McNally et al. 2003). The same method with a booklet was tested in the Brunswick neighbourhood. Three factors contributed to the failure of this attempt. First, low-skilled residents did not have competency to read maps. Second, every single activity from chatting to a neighbour to going to work was important for research at the neighbourhood scale. Many daily activities did not usually happen discretely. Hence, filling activity sheets was confusing and complicated for the residents. Third, the residents thought activity recording was a time consuming task and an extra pressure on their daily chores. Consequently, the researcher filled the diaries via structured interviews with the residents. The time target was a week period. Mostly, the residents were interviewed twice in a week to capture almost all daily activities from their short-time memories. The diaries comprised information about the social characteristics of

the interviewee and his/her household members, as well as about his/her house. The data of each activity comprised the information about time (the point at which activity was conducted including weekday/weekend and morning/afternoon, duration of activity, and position of activities in the daily schedules), about place (the geographical location of conducting activities and routes to destinations), and about actors (with whom activities were performed, whether there was any social interaction in destination, and who could conduct the activity instead of the interviewee). In the end, 18 residents were interviewed and 298 activities of 52 individuals (including the interviewees and their household members) were recorded. Table 1 shows the characteristics of the interviewees and the individuals. The residents aged below 16 years old and above 69 years old could not be interviewed because of the ethical regulations at the University of Manchester.

Table 1: age and gender distribution of the research sample

	Research Sample			Brunswick neighbourhood	
	Interviewee characteristics	Individual frequency	Individual percentage	Frequency	Percentage
Age					
under 16	N/A	21	40.4%	825	23.3%
16 ≤ age < 35	7	13	25.0%	1267	35.8%
35 ≤ age < 55	7	12	23.1%	981	27.7%
55 ≤ age < 70	4	6	11.5%	290	8.2%
70 and over	N/A	0	0.0%	177	5.0%
Gender					
Female	15	23	44.2%	1682	47.5%
Male	3	29	55.8%	1858	52.5%
Total	18	52	100.0%	3540	100.0%

4 Activity-based approach and neighbourhood research

4.1 Key concepts of the activity-based approach

Activity-based approach in general began from research on human behaviour and then it was particularly found in modelling travel behaviour (Chapin 1974; Hägerstrand 1970; Hägerstrand 1989; Jones 1983) and the cost analysis of economic activities (Scheinberg et al. 2010; Kurdve et al. 2015). By definition, *activity* is a physical and/or social interaction of an individual with environment (Rindt et al. 2002). People travel based on their demand to participate in a set of activities; participation in these activities comprises people's preferences and desires (Clarke 1986; Bowman and Ben-Akiva 2001; McNally and Rindt 2008). The activity set form *activity agenda* for an individual to participate, and the analysis of a particular activity and movement should be conducted in the context of the agenda. When the activity agenda is formed, the individual faces spatial-temporal constraints existed in different locations at different time, as well as personal constraints. Moreover, activities on the agenda have a series of attributes such as timing, duration, locations, frequency, transport and institutional considerations and inter-personal attentions. Based to the constraints, the person modifies the attributes of activities, and decides which ones to participate, where, with whom, at what time, for how long, in what priorities, with which mode of transport and from which route. The outcome of this decision is called *activity schedule* (Doherty and Miller 2000). *Activity pattern* refers to the collection of activities and trips actually performed by the participant during a day (Dong et al. 2006). Hence, activity patterns show the decision processes and the constraints, which influence the formation of the patterns, as well as the complex characteristics of the built environment. Finally, *activity episode* is a distinctive set of the continuous activities starting from home and ending at home during a day (Rindt et al. 2002).

A diary of a Brunswick resident whose workplace was in the Brunswick neighbourhood for a day was as follow: he went to his workplace at noon and used the minibus to pick up people for a class at 2 o'clock. These people lived in Grove Village and Victoria Park [two

neighbourhoods in the south of the Brunswick neighbourhood]. He brought people to the class, participated in the class for 2 hours with the others, dropped the participants off to their homes, returned the minibus, and finally went home. In the evening he shopped at the Tesco Local [local supermarket] on the corner of the Brunswick Street with his wife for about twenty minutes and went back home.

The activities of this resident were picking up and dropping off the people living in other neighbourhood, training at class and shopping. The resident had two activity episodes, as it is shown in Figure 2. The first episode contained three activities and the second one contains an activity of shopping. His daily activity pattern comprised both episodes. The constraint of his working environment was that the class happened at the fixed time, and also he needed to use the minibus at his workplace to pick up/drop off the other participants. This situation made him to decide to have training in the afternoon and then do shopping at night. He also needed to leave his home much earlier at noon, and to get back home not straight after the class. As the local supermarket was very close to their homes, he and his wife walked to Tesco. These descriptions shape the activity schedule of this resident. If this resident had a plan to do shopping in the morning instead of the evening in the first place, his activity agenda would be to do grocery shopping first and then to go to the work in the afternoon. He might have changed his agenda because of his wife not being able to make it in the morning, or the opening time of the supermarket that day.

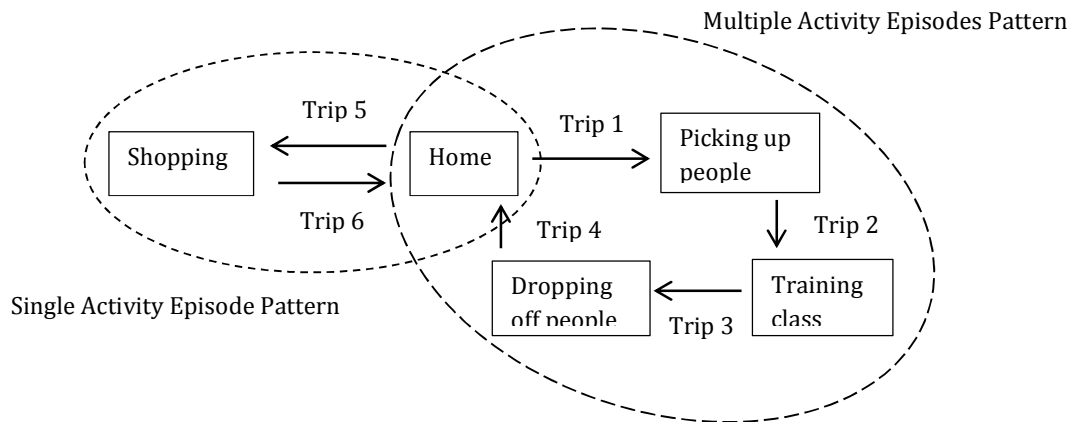

Figure 2: activity episode patterns of the daily activity schedule of a Brunswick resident

4.2 Clustering activities

In order to identify the activity pattern of the Brunswick residents and its links with the socio-demographics of residents, recent studies about grouping activities have two streams of research: first, grouping activities by type such as work, school, leisure and shopping (e.g. Davidson et al. 2007; Gan and Recker 2008; Beckx et al. 2009); second, grouping activities by their characteristics, which have effects on forming activity scheduling, such as frequency, duration, location and time (e.g. Delespaul et al. 2004; Doherty 2006; Mokhtarian et al. 2006; Akar et al. 2012). The former studies attempt to divide activity types into three categories (Doherty 2006; Mokhtarian et al. 2006): mandatory activities such as work and school that are fixed in time and space, maintenance activities such as shopping, banking, and medical appointments, and discretionary activities such as leisure, social events and family trips that are assumed to be more flexible. The latter stream of research argues that activity patterns are structured based on the activity attributes.

Regarding urban research, there are not distinctive boundaries between mandatory, maintenance and social activities in our environment due to the characteristics of activities. They occur in an interwoven pattern. For instance, a person who has a meeting with a

colleague in a park chooses to meet his colleague from the nearest bus stop. They talk to each other while walking to the park and then spend an hour outside a coffee shop in the park. In other words, they interchange the activities of walking, sitting and talking. Three aspects of activities contribute to this complex pattern (Mokhtarian et al. 2006).

First, the ability of *multitasking* shapes the daily life of people and their choice of activity. For instance, an employed mother in Brunswick prefers to work in the neighbourhood area although she can drive to the major employment hubs in Manchester. She is working part time in the local primary school. Her preference is due to the ability to be in the place where her sons are studying. She would like to know about new subjects that her children learn at school, to monitor her children's progress, and to get involved in the social activities at school while she works. By doing this, she is able to save time for her household obligations, and to be with the other members of her family.

Second, the activity patterns do not happen in a discrete set of activity episodes via an iterative process. They represent the *interaction trajectory* by breaking big chunks of obligatory and fun activities into smaller ones. For example, visiting the community, visiting a family member, shopping from a superstore, working for a couple of hours, shopping from the local stores, doing household chores for an hour, going back to work for another couple of hours, doing the rest of housekeeping, and going out for her children performance in the evening were the sequence of the daily activities of a Brunswick resident. In this pattern, shopping from the local store is interposed between two obligatory activities at work and at home because the store is located on the way to home. At the same time, the activity of shopping did not happen in one location.

Third, *people's perception* of different activities is varied. For some people's workspace is where they can interact with those who share the same values. Thus, it is not only an obligatory activity; it is a place to chat and socialise. In this sense, work has discretionary aspects. Therefore, *the multi-attribute nature of activities increases overlaps and multitasking*. Eight attributes of duration, spatial flexibility, temporal flexibility, personal flexibility (1-3), transport dependency and planning time were observable from the diaries of the Brunswick residents. They were defined and measured as follow:

Duration: measured as the duration of each activity in minutes, expressed as the difference between the start time and the end time of conducting an activity including travel time.

Temporal flexibility: measured as whether a certain activity has been recorded at different time of day. This type of flexibility was considered as a dummy variable. If the same person performed grocery shopping at different times, the temporal flexibility for this activity was valued 1. At the same time, if another interviewee performed this type of shopping at different times, the temporal flexibility for this activity was valued 1 for both residents.

Spatial flexibility: measured as different locations considered for a certain activity. Likewise to temporal flexibility, it was considered as a dummy variable. Value 1 showed the same activity recorded in different locations either performed by the same person or other residents.

Personal flexibility (1-3): measured as three means. Personal flexibility 1 was about whether another person either between family members, friends or community could take responsibility to do an activity for an individual. For example, a resident took care of her mother on weekends. In case she was busy that time, she would have asked her sister to do it. Personal flexibility 2 was about whether the activity conducted with other people, specifically family members and friends. Personal flexibility 3 was about whether an individual expected to socially interact with other people during his/her participation in an activity. All three means of this flexibility were similarly measured as dummy variables.

The first and second types of personal flexibility could be coded from the data in the diaries. The following analytical process measured personal flexibility 3. The activity participation of the Brunswick residents happens in different social contexts. By assuming how a resident communicates during his/her participation in an activity, six forms of social interactions can

be identified (Table 2). A participant in activities such as shopping and jogging might see many people and have very short casual conversation with these people. The participant does not necessarily know them and their communication is not the purpose of the participation. In this sense, it is assumed the individual is in the public context of city. If a resident is forcefully in a location because another person would like/need to participate in an activity and the resident's participation in that activity terminates as soon as the other person leaves, the resident will be in the public context of another person. Similarly, in this social context, communication with other people is not anticipated or certainly desired. The social interaction of the residents (personal flexibility 3) in the public context of city and in the public context of another person was valued 0.

Performing activities with family acquaintances and friends is the only private context, which a resident absolutely intends to communicate and socially interact. Likewise, participation in an activity within which other people who have a common vision and a sense of belonging – i.e. community – also contributes to social interaction. The former is called the private context and the latter is the context of community. Furthermore, the places like working and educational environments oblige their participants to communicate with their colleagues and peers. Equally, going to the public services such as health centre, bank and beauty centre results into the one-to-one social interaction between the participant and the service provider. Therefore, the social interaction of the Brunswick residents in these four contexts was valued 1. It is important to note that the participant could have family member(s) or friend(s) with himself/herself in any context. This information is measured in the attribute of personal flexibility 2 and did not have any effects on measuring personal flexibility 3.

Planning time: measured as whether a certain activity was routinized or pre-planned at least a week ago. As a dummy variable, value 0 was an indicator of spontaneous or less-than-a-week planned activity.

Transport dependency: measured as motorised modes of transport were used in conducting a certain activity. Walking and biking were valued 0 for this dummy variable.

Table 2: six social contexts in measuring the attribute of personal flexibility 3

Individual (+ family/friend) in the public context of city	
Jogging/walking/biking	Getting takeaways
Looking for jobs	Going to park/museum/library
Shopping	Swimming
Window shopping	Visit Christmas market for fun
Individual (+ family/friend) in the public context of another person	
Children performance	Children playing/Baby group classes
Take food for children	Dropping off/picking up children
Children swimming lessons	
Individual (+ family/friend) in the private context	
Visiting family, in-laws and friends	
Have a day out with family and friend	
Individual (+ family/friend) in the context of community	
Boxing/football	Coffee morning
Circuit training	Parents' reps meeting
Praying	Vocational classes and skills
Voluntary	Funeral
Individual (+ family/friend) with one-to-one interaction with another person	
Visit GP/dentist/midwife	Legal advice bureau
Banking	Administrative documents
Barbershop	Post
Individual (+ family/friend) in the context of obligation	
Work or College	After school clubs

Reclassification of the activities of the Brunswick residents was run with the K-means clustering technique. K-means is a partitional algorithm, which generally speaking clusters data points as a partition of the data. Here, if n is the number of activities (data points) with d -dimensional characteristics (eight attributes of activities), an $n \times d$ matrix is the input to K-means. The full description of the K-means algorithm and the configuration process can be found in Jain (2010) and Moore (2001). K-means clustering is a feature in many statistical applications including SPSS, STATA, R-statistics and MATLAB.

5 Discussion

Diaries counted in 298 daily activities. By eliminating the activities with the same attributes but performed on different days, the participants reported 203 one-off activities. These activities can be categorised by type in nine groups of shopping, leisure, services, social, work and/or school, just for kids and others (Table 3). In England, the scale of the wards in the cities is the focus of many local planning documents. Therefore, exploring how much the Ardwick ward attracts the daily activities of the Brunswick residents gives some insights into the performance of the facilities and services available at this scale. Figure 3 compares the proportions of 298 activities in each group inside and outside the Ardwick ward. One quarter of all activities is the participation of adults in the just-for-kids' activities in which they do not engage with the other people. Although the adults' engagement with the community through participatory just-for-kids' activities is much less in the ward, all of this type of activity are conducted inside the Ardwick boundary. Another type of activity, which only happens inside the Ardwick ward, is non-obligatory work/study. The sample presents the Brunswick residents mostly prefer to conduct two types of activity outside the ward, shopping and obligatory work/study. The residents' preference in shopping from outside the ward is only 1% higher than the shopping places available in Ardwick; however, the working and studying opportunities outside Ardwick are about 6% higher. Figure 4 displays the proportions of one-off activities inside and outside the Ardwick ward. The variation of shopping and obligatory work/study activities outside Ardwick is significantly higher than inside according to this figure. Above 15% of isolated shopping activities happen outside compare to above 11% inside. Isolated obligatory work/study activity type is about 6% more likely to happen outside. On the other hand, the ward accommodates more proportions of isolated leisure and social activity types. 6.4% of leisure activities and more than 11% of social activities happen inside compare to 3.4% and 9.4% respectively outside. Similar to the analysis of all activities, the majority of non-participatory just for kids happen inside Ardwick. However, the main activity type in this figure is shopping on contrary to the previous figure.

Five configurations of K-means clustering were run with SPSS to find the interactions between the attributes of the activities conducted inside and outside the Ardwick ward:

- I. Configuration of temporal, spatial, and personal (1-3) flexibilities
- II. Configuration of temporal, spatial, and personal (1-3) flexibilities and duration
- III. Configuration of temporal, spatial, and personal (1-3) flexibilities and transport dependency
- IV. Configuration of temporal, spatial, and personal (1-3) flexibilities and planned activities
- V. Configuration of temporal, spatial, and personal (1-3) flexibilities, duration and planned activities

In K-means clustering, the values of 3 and 4 as the numbers of clusters ($K = 3$ and $K = 4$) were valid for the configurations. The Mean Square Errors (*MSEs*), produced after each run, indicated how much each attribute had effects on forming the activity clusters. The lower *MSE* an attribute has, the highest effect it had on the differentiation of the clusters. To visually illustrate this effect, the radar graphs (Figure 5) are produced with the equation of $1 - MSEs$. Evidently, different configurations resulted in the similar activity clusters. Four activity clusters were identified in the Ardwick ward, and three clusters in the outside of the ward.

Table 3: activity groups based on their type

	Leisure	Services	Social
Shopping			
Grocery shopping	Boxing class	Visiting midwife	Visiting friends
Getting takeaways	Circuit training	Banking	Visiting own family
City centre shopping	Jogging	Visiting dentist	Attending the church for pray
Shopping from charity shops	Walking	Visiting GP	Visiting relatives
Shopping basic needs	Going to park	Getting prescriptions from GP	Visiting neighbours
Shopping from markets	Visiting museum	Going to barber shop	Going to coffee morning meetings at school
Buying petrol and gas	Swimming	Meeting with Legal advisor & solicitor	Participating in children performance
Having dinner in restaurants	Biking	Going to library	Meeting with parents' reps
Having coffee in coffee shops	Window shopping/visiting city centre market for fun	Printing and paper works	Chatting with other parents
			Going to funeral
Work/school			Other
Obligatory	Non-obligatory	Non-participatory	Participatory
Working	Going to parenting skills	Dropping off and picking up children	Going to children play classes
Going to college and studying	Volunteering at school	Bringing food for children at school	Looking for jobs
	Volunteering at church	Dropping off friends' children	Dropping off and picking up people for vocational classes
	Going to vocational classes		Participating in after school clubs
	Going to groups' meetings		Going to school shows

Figure 3: residents' participation in all activities inside and outside Ardwick (%)

Figure 4: residents' participation in one-off activities inside and outside Ardwick (%)

Inside-Ardwick activities

Configuration I

Configuration II

Configuration III

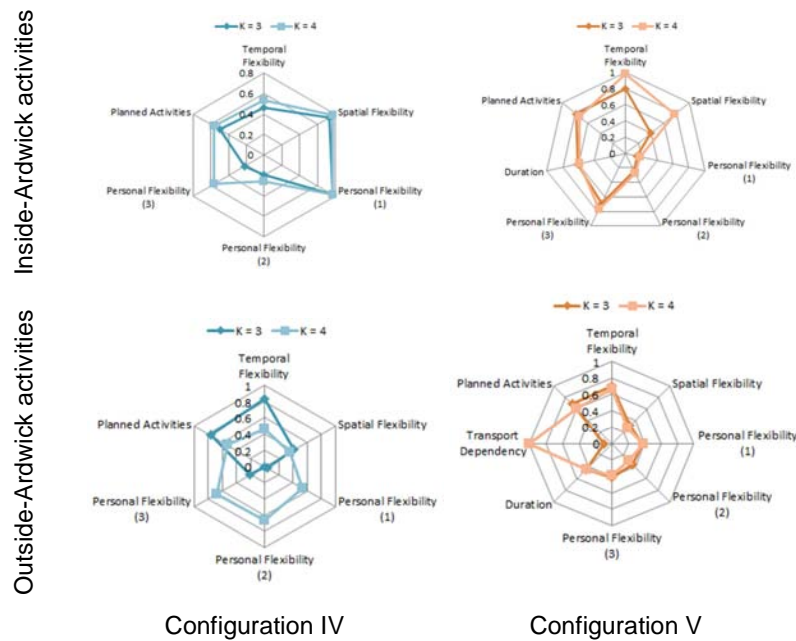

Figure 5: the effects of the activity attributes in forming the clusters

The activity clusters of inside Ardwick are:

Cluster 1: short activities which are completely planned/routinized; fixed in time and place, and being attended with family member(s)/friend(s); do not contribute to social interactions with people in the place

Cluster 2: long and planned activities which are fixed in time; contribute to social interactions with people in the place

Cluster 3: spontaneous activities which are fixed in place but flexible in time; encourage social interactions with people in the place

Cluster 4: spontaneous and individualised activities which are flexible in time and place; do not encourage social interactions with people in place

The activity clusters of outside Ardwick are:

Cluster 5: short and completely planned/routinized; fixed in time and place, and being attended with family member(s)/friend(s); motorized modes of transport are usually needed to get the destination; can be conducted by others and do not contribute to social interactions with people being in place

Cluster 6: very long, individualised, and almost planned/routinized; fixed in time but flexible in place; motorized modes of transport are needed to get the destination; contribute to social interactions with people being in place

Cluster 7: spontaneous, and flexible in time and in place; do not encourage social interactions with people in place.

Only one activity cluster in Ardwick (Cluster 2) and one activity cluster outside Ardwick (Cluster 6) accommodate the social interaction of the Brunswick residents. Cluster 3 partially encourages this interaction. Spatial flexibility contributes to social interaction according to the clusters. Transport is not necessary to conduct the activities inside the ward, while it is fundamental for the short and planned activities of Cluster 5 and very long and planned activities of Cluster 6. Similar short and planned activities happen inside and outside the ward and form Clusters 1 and 5. The spontaneous and flexible activities of Clusters 4 and 7

are also comparable. The spontaneous activities which are fixed in place only happen inside the Ardwick ward. The analysis of the activity types in relation to the activity clusters (Table 4) shows half of the shopping, social, leisure and service-related activities happen outside the Ardwick ward. Shopping happens at various places, while about 40% of leisure activities are spatially fixed. The leisure activities conducted by the Brunswick residents demonstrate various set of attributes. Some are spontaneous and either spatially fixed or flexible (Clusters 3 and 4), some last for a long period of time and planned in advance (Cluster 6), and some are spatially and temporally flexible outside the ward (Cluster 7). The non-obligatory work/study and participatory just-for-kids activities belong to long and planned activities which are fixed in time (Cluster 2). This means various places provide these activity types within Ardwick. More than three-fourth of the non-participatory just for kids activities happen inside the ward. The analysis of the activity clusters in relation to the activity types (Table 5) shows that the majority of short and routinised activities (Clusters 1 and 5) happen when the adults conduct the activities for their kids and do not participate themselves. Social interaction is limited to the obligatory and non-obligatory work/study, and the participatory just for kids activities. Surprisingly, some spontaneous activities are social and do not encourage social interaction (Cluster 7). The original data shows some visits to the neighbours or the family members were due to the sudden or obligation for care.

Table 4: percentage of the activity types in the activity clusters

	Clus. 1 N = 79	Clus. 2 N = 41	Clus. 3 N = 27	Clus. 4 N = 35	Clus. 5 N = 26	Clus. 6 N = 35	Clus. 7 N = 52
Obligatory work/study	-	24.2%	-	-	9.1%	66.7%	-
Non-obligatory work/study	-	100%	-	-	-	-	-
Shopping	-	-	-	47.5%	1.7%	1.7%	49.2%
Social	-	20.0%	37.5%	-	7.5%	10.0%	25.0%
Leisure	4.3%	4.3%	39.1%	13.0%	-	17.4%	21.7%
Service	-	-	23.1%	30.8%	7.7%	7.7%	30.8%
Non-participatory just for kids	78.7%	-	-	-	18.1%	3.2%	-
Participatory just for kids	-	100%	-	-	-	-	-
Other	44.4%	-	-	-	11.1%	-	44.4%

Table 5: percentage of the final activity clusters in the activity types

	Clus. 1 N = 79	Clus. 2 N = 41	Clus. 3 N = 27	Clus. 4 N = 35	Clus. 5 N = 26	Clus. 6 N = 35	Clus. 7 N = 52
Obligatory work/study	-	19.5%	-	-	11.5%	62.9%	-
Non-obligatory work/study	-	31.7%	-	-	-	-	-
Shopping	-	-	-	80.0%	3.8%	2.9%	55.8%
Social	-	19.5%	55.6%	-	11.5%	11.4%	19.2%
Leisure	1.3%	2.4%	33.3%	8.6%	-	11.4%	9.6%
Service	-	-	11.1%	11.4%	3.8%	2.9%	7.7%
Non-participatory just for kids	93.7%	-	-	-	65.4%	8.6%	-
Participatory just for kids	-	26.8%	-	-	-	-	-
Other	5.1%	-	-	-	3.8%	-	7.7%

6 Conclusion

This paper aimed to introduce the key concepts and a simple modelling technique of the activity-based approach for the purpose of neighbourhood studies. It is the first part of the publication series about regenerating neighbourhood with an activity-based approach. The key concepts of the activity-based approach provide the fundamental aspects of understanding the performance of neighbourhood spaces. It is assumed, activities are the outcome of the interaction between people and places. Exploring activities result into more comprehensive picture of neighbourhood as the patterns of activity participation shows the characteristics of actors, the constraints and the characteristics of environment. The arguments through the attributes of the activities offer the opportunity to quantify the performance of neighbourhood. Accordingly, it is possible to evaluate participations at various scales such as the ward and the city, to link the attribute-based definition of activities to different functions and assess the services provided, and to monitor the activities of the participants in order to identify their needs and the constraints of their participation in the other attribute-based activity clusters.

The Brunswick regeneration scheme aims to link Brunswick to the wider area and provide high quality housing and services for the current and future residents. The future publications will show how to link the activities of the Brunswick residents to their social profile, how to evaluate the service provision of a local agency, how to model and estimate the outcomes of the regeneration plans, and how to provide an evidence-based arguments to the issues mentioned in policy documents, community consultation reports and planning proposals of the neighbourhood regeneration projects.

Acknowledgement

The author would like to thank Dr Richard Kingston and Dr Stephen Hincks as PhD supervisors and Mr Nuno Pinto as a PhD advisor for their input during the development of the research.

Ecosystem service-based green space allocation planning: a new way to construct urban spaces

(ESP Method to Ensure Ecosystem Service Delivery in Urban Areas)

Fisqa TASYARA; Indonesia

Synopsis:

Many studies have shown that the amount of green open space has a positive correlation to the quality of the living environment and of urban population. Green open spaces can act as service providing units (SPU), providing ecosystem services to improve microclimates, absorb pollutants from the air, reduce noise levels, and reduce surface runoff volume. These contribute to sustainable environments. But is simply increasing the amount of green open space enough to increase urban living quality? Not necessarily so.

First: the production of ecosystem functions is different in each SPU due to the different physical characteristic, the temporal condition, and for certain services, to the distance between the green spaces and the source of the problem it regulates.

Second: ecosystem functions become ecosystem services when they are actually used by or provide a benefit to the human population. This implies a strong relation between demand and supply of ecosystem services (why?).

Third: delivery to beneficiaries has a very important role in ecosystem services. When the benefit of an ecosystem function cannot be delivered to the public it is not considered an ecosystem service. The benefit can only be delivered when there is a strong spatial relationship between the demand and supply of ecosystem services. This spatial relationship can happen when the supply and demand physically overlap, or because of an overlapping flow path. This flow path is heavily influenced by the distance between problem source, green space, population, meteorological condition and the urban structure and shapes.

Ecosystem service-based green space allocation planning is a method to construct urban spaces. They are allocated not only by the availability of land, but also on the physical characteristics of the location and spatial requirement for the green space to deliver the ecosystem services it supplies and demanded by the urban population. This approach takes into account the possible flow path of problems to be regulated by green space, the flow of ecosystem services, and the movement of the people to the ecosystem service locations.

Keywords: ecosystem services, urban planning; urban parks, park allocation planning

1. Introduction

1.1 Urban problems

Since the 1950s. the United Nations has detected an exponential increase of urban areas and urban populations. In 2014, 54% of the world's population lives in urban areas that only comprise less than 3% of the land surface of the earth. This proportion is projected to increase to 66% by 2050 (UN DESA, 2014). This population growth is commonly, if not automatically, followed by an increase of built-up areas and number of vehicles. These create problems such as an increase of temperature, air pollution, and noise disturbances which reduce the life quality of urban residence.

Urban problems are usually generated locally, therefore the most effective way to deal with them are commonly through local solutions (Bolund and Hunhammar, 1999). According to

Mas (as referred by Chiesura, 2004) the amount of green spaces, especially urban parks, has a positive correlation to the quality of living environment and health. Researchers found that urban parks can improve microclimate, absorb pollutants from the air, reduce noise levels, and contribute to sustainable environments (Honjo and Takakura, 1986; Givoni, 1991; Avissar, 1996; Jacobs, 1996; Huang and Chen, 2002; Yang, 2003; Chiesura, 2004; Lam, Ng, Hui and Chan, 2005; Neema and Ohgai, 2010; Cohen et al., 2014). Such benefits, and many more, are known as ecosystem services.

1.2 Ecosystem services in urban areas

Ecosystem services are the benefits people obtain from the ecosystems around them. They can either be tangible (such as food and fresh water) or intangible (such as air quality maintenance and water regulation) directly or indirectly from ecosystem functions (Constanza et al., 1997, Millennium Ecosystem Assessment, 2003). Ecosystem services are different from ecosystem functions. Ecosystem functions refer to the biological or system properties/processes of ecosystems. Ecosystem functions become ecosystem services only when it provides benefit to the population (Constanza et al., 1997; Serna-Chaveza, 2014). In other words, ecosystem functions become ecosystem services when they are actually used by populations. Figure 1 illustrates the connection between ecosystem, ecosystem functions, ecosystem service, and ecosystem service's demand.

Figure 1: Relation between supply and demand of ecosystem services (Tasyara, 2015)

Park's provisioned functions are ecosystem services only when they are utilized by and benefitted human population.

Constanza et al (1997), Bolund and Hunhammar (1999), and Zanin et al. (2005) argued that, as an ecosystem unit, an urban park has the potential to provide services of direct and indirect impact on human health and security. As previously explained, these services include regulating services (microclimate regulation, air pollution regulation, noise reduction, and run-off reduction) and cultural service (recreational service).

Numerous urban adaptation strategies have been proposed to increase the provisioning units of ecosystem services to answer the increasing demand in urban areas (Givoni, 1991; Gill et al., 2007; Bowler, 2010). For example the 'green city movement' in Indonesia (source?). The general idea is to increase the amount of ecosystem services by increasing the abundance and coverage of vegetation in urban areas. However, although creation of green spaces is the most commonly cited individual adaptation to climate change activity (Carbon Disclosure Project, 2012) and large budgeting has been assigned to the development and management of urban parks, most countries (especially the less-developed countries) still take the benefits of urban parks for granted.

The ecosystem services provided by the urban parks are often not delivered to the population that actually need the services. This condition happens because of a spatial mismatch. Or in simpler words; the park is not located at a suitable location. These

mismatches happen because there is a knowledge gap about ecosystem service delivery and the effect of park location to the services it provides. Many urban decision makers still believe that any addition of urban parks would provide citywide benefit. Such understanding leads to development of parks without considering the location in relation to the demand (population and/or hotspots of ecosystem problems). Commonly, planning standards only specify the amount of area required and their proximity to settlements (Yeh and Chow, 1996). However, they seldom specify *where* the public facilities should be located in relation to the problem they attempt to address.

Most studies on urban ecosystems focus on the benefit of green open spaces in comparison to their adjacent brown (built-up) areas (Kuttler and Strassburger, 1999; Lam et al., 2005; Yin et al., 2011; Cavanagh et al., 2009; Cohen and Potcher, 2012). For ecosystem services, most studies focus on identifying where the services are generated (Tallis, et al., 2013). In many cases however the actual delivery of services (especially regulating services) to specific parts of the population is affected by the location of the service providing unit (SPU) to the beneficiaries and the problem sources (Tallis, et al., 2013). Many studies have shown that urbanization-generated problems such as air pollution and noise disturbance decrease after a certain distance from the source (Klepeis et al., 2009; Venkatram et al., 2009; Vailshery, 2013; Merbitz et al., 2012). But there are only a handful of studies that focus on the implication of location to the quality of ecosystem services provided by urban green spaces (Yeh and Chow, 1996; Neema and Ohgai, 2010). Even fewer studies propose methods to select the optimum location for the development of green open spaces.

This paper aims to specifically explain the effect of a location selection to the ecosystem service provided by a park and to find an alternative location for a new service providing unit. Section 3 gives a more detailed explanation about the factors that determine the production ecosystem services, their demand, and their delivery. The method and framework to allocate urban parks based on ecosystem service production and delivery is discussed in section 4, followed by the conclusions with a special focus on further research needs in section 5.

2. Methods and results

This paper is an exploratory study to develop the framework for (I) explaining the factors that determine the production of ecosystem services, (II) ecosystem service's demand formation, (III) linkages between the supply and demand of ecosystem services, and the (IV) methods for park allocation planning. The following key questions have been of special relevance for the development of the concept on location planning of a park as an SPU:

- What factors determine the provisioning of ecosystem functions (supply) by an urban park and how spatially variable are they?
- What factors determine the demand of ecosystem services by urban populations, and how spatially variable are they?
- What is the spatial relationship between the supply and demand of ecosystem services?

Querys on the Web of science database were done to select articles on ecosystem services, ecosystem service assessment methods, and the five prominent ecosystem services that can be supplied by urban parks. This returned 488 unique records. The articles were filtered based on the criteria in table 1, which lead to 144 articles. A snowballing method based on the references list in those 144 articles was implemented to reduce literature gap that might

be created due to the limitation of the database. This extended search added 54 more articles.

Criterion	Possible/searched entries
Type of region where the case study is located	Urban areas
Type(s) of Ecosystem service (ES) are analysed	Gas regulation, micro-climate regulation, disturbance regulation, water regulation, cultural/recreational values
Does the paper explicitly mention “urban ecosystem services”?	Yes/no but mention at least one of the services
Does the paper deal with ES potential (supply) or demand and provisioning?	Only supply, demand and provision, only demand

Table 1: Filtering criteria

From 144 articles found in the literature search, only 34 articles explicitly mentioned ecosystem services. This shows that even though the awareness about the benefit urban parks provide is increasing, they are still not directly connected to the provision of ecosystem services. The articles that specifically mention ecosystem services mostly only approach the concept from either the supply (66%) or the demand side (29%). Only 36% consider the relation between supply and demand of ecosystem services.

The selected articles did not mention park or SPU’s spatial requirement explicitly. However, they did mention the ability of ecosystem functions and problems to disperse from their sources. The park location requirements can be concluded based on these conditions. (explained further in section 3).

3. Synthesis

3.1 Factors that determine the ecosystem functions production by an urban park

As an ecosystem unit a park can filter noise and air pollution, regulate heat, act as a sink for surface runoff, and provides recreational space. These functions are formed by the ecosystem processes, by the vegetation, soil, and water in the park. These are again influenced by the size of the park and the soil type in the of the park. Those factors can also be called the determining factors for the ecosystem functions of a park (see table 2).

Functions	Determining Factors						
	Site Size	Site design	Percentage of Green coverage	Types of vegetation	Soil type	Time of day	Season
Air Pollution	V	V	V	V	-	V	V
Noise	V	V	V	V	V	-	V
Heat/microclimate	-	V	V	V	-	V	V
Surface Runoff	V	V	V	V	V	-	V
Recreation	-	V	-	-	-	-	-

Table 2: Factors Determining Ecosystem Functions (supply) (Tasyara, 2015)

Apart from the soil type, the factors are generally non-location specific and can be realized anywhere depending on the design, as seen in table 2. The soil type varies in each location, which can influence the types of vegetation to be used in a park. It also determines the ability to absorb noise and air pollution, and the water filtration and retention ability of a park (further elaborated in appendix two). However, the technological development in geology and park architecture lowers this dependency, which also lowers the spatial variability of this factor.

3.2 Factors that determine ecosystem service demand

The level of demand for an ecosystem service is determined by the four following conditions: (I) presence of problem(s); (II) severity of the problem(s); (III) presence of population suffering from the problem(s); and (IV) the vulnerability of the population to the problem(s). A demand is formed only when both problems and population are present. The more severe the problem and the larger the vulnerable population suffering from the problem, the more prominent the demand for ecosystem service as illustrated in figure 2a-c.

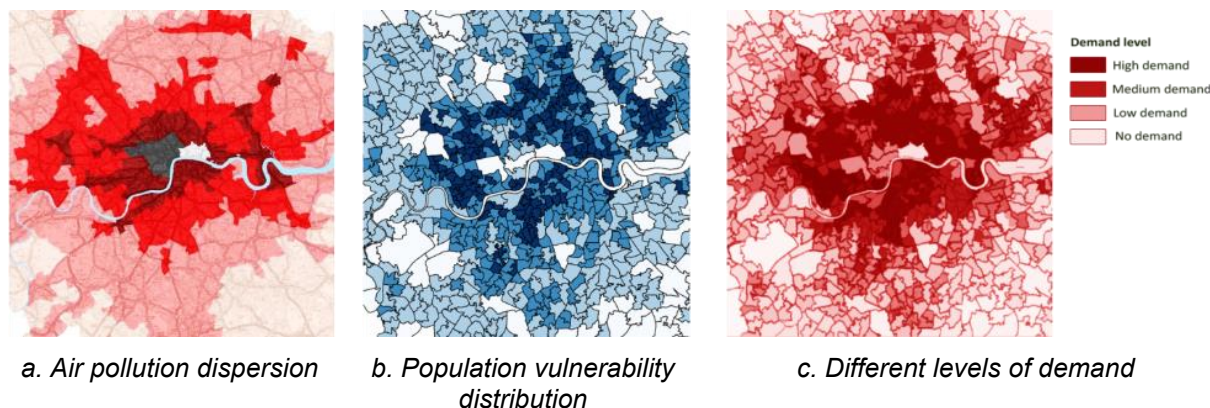

Figure 2: Demand formation (missing a legend for the blue colors)

(Image source for a and b: Camden Friends of the Earth (<http://www.camdenfoe.org.uk>), c: Tasyara (2015))

The four conditions mentioned above vary spatially. The presence of problems and their severity are determined by the sources which can be centred at (a) specific location(s) or spread throughout the landscape. The presence and the amount of a population and their vulnerability also vary in each location. There are also other factors that determine the severity of a problem, and the vulnerability of the population (summarized in table 3 and 4).

Problem	Determining Factors					
	Production at source	Topography/ Slope	Soil type	Land use	Time of day	Season
Air Pollution	V	V	-	V	V	V
Noise	V	V	-	V	V	V
Heat/microclimate	V	V	-	V	V	V
Surface Runoff	V	V	V	V	-	V
Stress level	V	-	-	V	V	-

Table 3: Factors determining problem severity (Tasyara, 2015)

Apart from the soil types and season, the determining factors in table 3 are not location specific. Those factors can be provided at any location and affected by the design of the park itself. The influence of each determining factor is often not a standalone effect, but a combination of two or more factors. For example, site size influences the design implemented in the park and the season influences the percentage of green coverage in the park (leave shedding in winter at temperate countries or during the drought in tropical countries). More explanation on how those factors determine the provisioning functions (supply) of ecosystem service can be found in Tasyara (2015).

Problem	Determining factor							
	Population density	Socio-economic status	Age	Gender	Special needs Populations	Education	Economic activities	Building densities
Air Pollution	V	V	V	V	V	V	V	V
Noise	V	V	V	V	V	V	V	V
Heat	V	V	V	V	V	V	V	V
Surface Runoff	V	V	-	-	V	-	V	V
Stress level	V	V	V	V	V	V	V	V

Table 4: Factors determining population vulnerability (adapted from Cutter, et al., 2013; Rodrigues-Loinaz, et al., 2015)

Vulnerability varies geographically, over time, and among different social groups, as seen in table 4. Social vulnerability is partially the product of social inequalities. It also includes spatial inequalities, including the characteristics of communities and the built environment, such as the level of urbanization, population character, and economic condition, that contribute to the social vulnerability of places.

3.3 Factors that determine the delivery of ecosystem services – location requirement

Based on table 2, 3 and 4, we can conclude that demand varies spatially, while supply – as long as it is not strongly controlled by soil type - can be realized almost anywhere. However, in ecosystem services, the delivery is important, and the delivery can happen only when there is a strong spatial relationship between problem source, the park, and the beneficiaries.

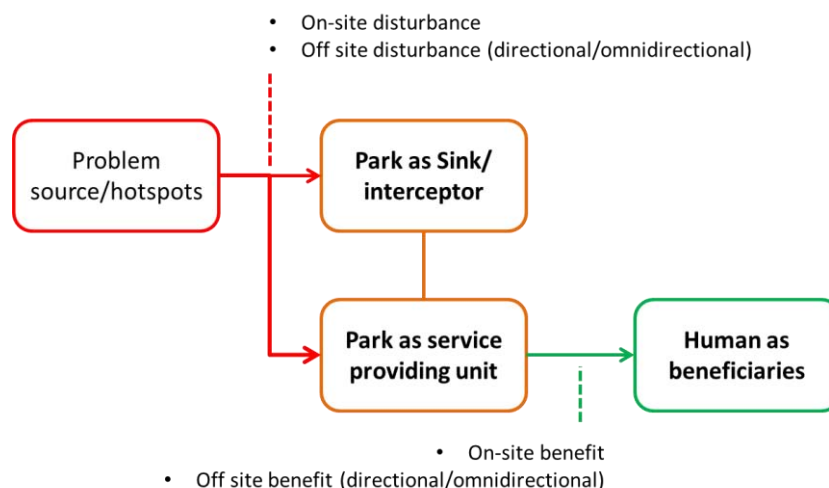

Figure 3: Relationship between the supply and demand of ecosystem services (Tasyara, 2015)

There has to be an overlap between the people with the problem to create demand, also between people and the park or the ecosystem functions that are provided by the park (for people to obtain benefit and for the park to become an ecosystem service provider). Fisher et al. (2009) and Syrbe & Waltz (2012) explain this overlap with the term “spatial relationship”. According to Fisher, et al. (2009) and Syrbe & Walz (2012) there are three possible spatial relationships; on-site (in-situ), off site without directional bias (omnidirectional), and off-site with a directional bias (directional). The off-site relationship can happen because a carrier

disperses the problem or function out of the source in a certain flow path. The spatial relationships are created by the overlap between the sources or the carrier flow path (of ecosystem functions or problem) with people as illustrated in figure 3.

A problem source can produce on-site or off-site disturbance. Usually when the problem is dispersed off-site, a park can act as a sink that intercepts the problem carrier before it reaches a population and at the same time produces ecosystem functions which benefit a population. This benefit can be delivered either on-site only or off-site (by a carrier) to individuals. When the problem stays on-site, the park acts mostly as a service provider, not as an interceptor. When the functions and problems disperse off-site, the relationship is determined by how it disperses from the source and to where. When neither the service, nor the problems disperse from the source, then people's movements determine the ecosystem service delivery.

There is a contradiction about the location requirements for the five services focused on this research. First, we can see it from the supply side. When a park can produce an off-site benefit, the park can be located at a distance from the people. The distance is determined by the function dispersal characteristic (e.g. the flow of cool wind). When the benefit can only be provided on-site the park has to be accessible by people. Second, from the demand side; to regulate disturbances that happen off-site, a park should be located in the location that can intercept the problem. The dispersal characteristics of the problem (e.g. air pollutant's mixing height and distance) determine the effectivity of the park to intercept the problem. To regulate problems that are locally generated a park should be located in close proximity to the beneficiaries. However, when we want to allocate a park to provide ecosystem services we need to see from both the supply and the demand side, which lead us to table 5.

Service	Ability to disperse/travel			Benefit received	Park location (spatial) requirement
	Function	Problem	People		
noise regulation	no	yes	not expected	Off-site	proximity to problem source
air pollution reduction	yes	yes	Optional	On and off-site	proximity to problem source and physical accessibility
surface runoff reduction	no	yes	not expected	Off-site	proximity to beneficiaries
heat reduction	yes	no	Optional	On and off-site	proximity to beneficiaries and physical accessibility
recreation	no	no	expected	On-site	physical accessibility

Table 5: Overview of the transport ability and location requirement for a park to provide ecosystem services to people (Tasyara, 2015)

Looking at the contradicting location requirement, it would be more realistic to limit the goal of park planning by focusing on the provision of ecosystem services that have similar requirements (e.g. a park to regulate noise and air pollution, or a park to reduce surface runoff volume and heat). We can base the goal on the actual demand.

4. Ecosystem service-based allocation planning

Once the required ecosystem service and the level of demand have been determined a park can be allocated as a service providing unit. This can be determined based on the nature of the problem and the number of people vulnerable to and suffering from this problem. Second, we need to know how the demand is formed; does the problem disperse from the source by a carrier or does it happen on-site? Third, we need to know how the service can be

delivered; does the ecosystem function disperse from the source out of the park, or do we expect people to travel to obtain the benefit from the ecosystem functions? The answers will determine where the park should be located. These questions can be illustrated more clearly with the framework in figure 4.

This framework can be divided into three main steps: the first is to determine the demand hotspots, second step is to determine potential locations, and then the third step is to further exclude or pinpoint the most appropriate location. In the first step, we need data about the occurring problem in the area and the vulnerabilityⁱⁱ of the population. When we overlap those data, we can map the demand in an area and pinpoint the locations with the highest demand for ecosystem service(s). This demand map acts not as an end-product, but as an input for the next step.

In the second step, we determine possible locations around the demand hotspots that can be developed as a park. These possible locations should include not only open spaces owned by the government, but also privately owned leftover or brown spaces. The locations can be selected simply by listing open spaces in the region, with buffering methods in GIS application, or any other Geo-spatial methods. After we have this list of possible locations, we need to narrow down the options based on a set of physical criteria that determine the supply production. We need to exclude any locations that do not fulfil the criteria, and then we will have a map with potential locationⁱⁱⁱ.

In the third step, we take the selection process further by answering three consecutive questions which also act as adjustment points: “does the problem disperse from the source?”, “does the function disperse from the source?”, and “are people expected to travel?”. The answers determine the methods needed to be applied to the location selection.

In condition ‘a’, when the problem does not disperse from the source, usually the demand is generated at the same site as the source (*on-site/in-situ* spatial relationship). This problem can be regulated by a park which is located where it is highly demanded, or in a close proximity to the area with the highest demand for the service to ensure site access. But when the problem disperse from the source (condition ‘b’) then the park can still be placed at a distance from the people to intercept the problem before it reaches the population. In this case, the location of the park has to be adjusted based on the problem spatial flow analysis. The flow analysis is needed to provide information about the spatial relationship between the problem and the people, which include:

- How the problem disperses from the source to the people;
- Direction of the transport (directional or omnidirectional); and
- The effect of the transport to the severity of the problem.

This information will determine whether it should be located closer to the problem source or to the people, direction from the source and people (e.g. upwind or downwind), and the physical structure needed to be included in the park because different physical structures are needed for different carriers. The physical structures that disturb wind movement may not disturb water flow and vice versa.

After finding out whether the problems disperse from the source, then we need to know whether the functions disperse from the source to become service (by providing benefit) to people. When the function can only provide benefit on-site/can’t disperse from the source (condition ‘c’) then the park should be located based on the result of the previous query (condition ‘a’ or ‘b’). However, when the functions disperse from where they are produced

(condition 'd'), then the park location should be adjusted based on the flow analysis of the ecosystem service. The flow analysis will provide information about the spatial relationship between the park and intended beneficiaries which include:

- How the function disperses from the source;
- The direction of the dispersal (directional or omnidirectional); and
- The dispersal distance.

This information will determine how far away the park can be located from the population and the direction of the park from the source and people (e.g. upwind or downwind). This condition will expand or reduce the options for park allocation.

The last question to be answered is "Are people expected to travel?". When ecosystem service can be obtained off-site, people's mobility is not expected (condition e). However, for certain ecosystem services (e.g. recreation), people have to travel to a park (condition f) to get the benefit on-site. In this condition then the location should be adjusted according to an accessibility analysis. The accessibility analysis can also be accompanied by an analysis regarding people's willingness to travel so that the location still be in accordance with people's preference.

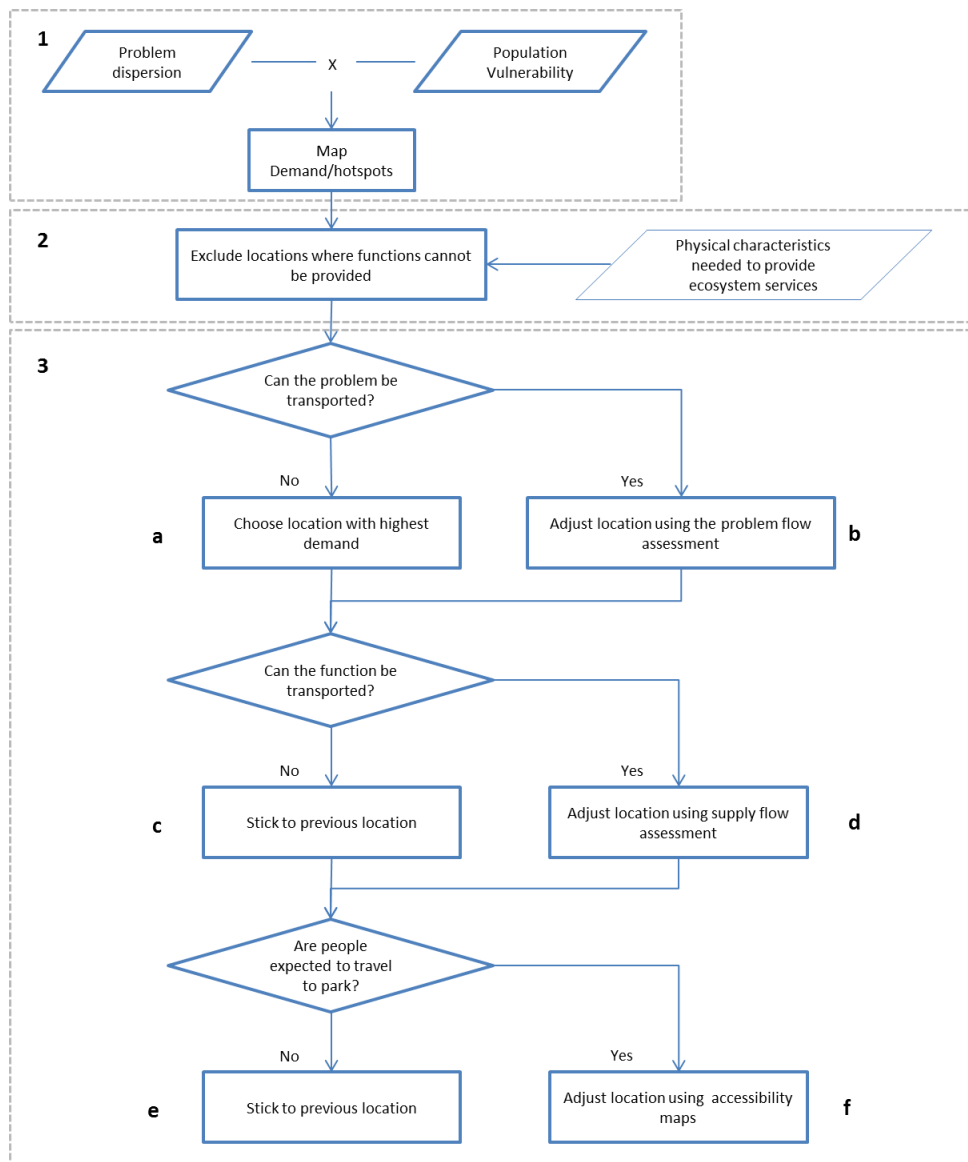

Figure 4: Park Allocation Planning Framework (Tasyara, 2015)

This framework incorporates many spatial planning techniques and spatial analysis. The spatial analysis can be done with the application of GIS in the raster format. The raster data model is the more suitable technique because the structure of raster data is grid cell based which can easily delineate suitable sites. Raster data also facilitate the carrying out of a weighted overlay on numerous layers. There are other spatial analysis methods that can be used either to analyse the demand, or to model the expected provision ecosystem services.

5. Concluding Remarks

Ecosystem service is a complex matter, and planning the allocation of a park as an SPU needs analysis of many components in different layers and scales. Three key findings are important for park location selection:

1. The concept of ecosystem service has a strict coupling to human utilization where ecosystem function has only become a service once it is actually used or consumed by people as beneficiaries (Serna-Chaveza, et al., 2014; Millennium Ecosystem Assessment, 2003);
2. The benefit received by people is often valued differently, depending on the context (Tallis, et al., 2013). This context is determined by human needs and demand for this service by the society (Paetzold, et al., 2010) which are determined by the problem severity and the population's vulnerability;
3. Ecosystem services are provided by an urban park to the beneficiaries (people) either on-site or at off-site by a carrier (Serna-Chaveza, et al., 2014) along a flow path.

This research has tried to dissect the determinants of the five most relatable services to urban areas that can easily be provided by parks, an asset long considered more of its aesthetic value than anything else. The service to mitigate microclimate, attenuate air pollution and noise disturbance, regulate surface runoff, and to provide recreation are affected by the distance between the park and the service demand. Each ecosystem service has different distance requirement to be able to deliver its benefit which create a spatial contradiction.

This report proposed a framework that planners and decision makers can implement to select suitable locations for urban parks based on the spatial requirements to be able to provide ecosystem services. However, this report advice for the allocation planning to limit the goal of park planning by focusing on the provision of ecosystem services that has more similar spatial requirements. It should also be noted that this framework is compiled based on literature reviews. There needs to be further research to test this framework on an actual case. Other than that, there are other factors than location that determine the condition of services provisioned by parks, such as the physical structure of the park itself (the size, the vegetation used, etc.) and the physical structure of the area surrounding the park (see table 3) Nevertheless, the proposed method still provides a new insight on the park allocation planning and ecosystem services; which is to plan supply based on its demand.

End notes:

ⁱ Recreation/cultural service can be combined with any other services and will only affect the location selection slightly because the delivery of the service depends highly on people's access

ii Weight is assigned to each factor that determines the vulnerability of the population. We can analyze the vulnerability value of a location/population with software such as the Weighted Linear Combination in ArcGIS.

iii In this report “possible location” is described differently from “potential location”. The term “possible” used in refer to vacant lands that can still be developed as a park while the term “potential” is used in refer to the condition that the land is not only possible to be developed as a park but also fulfil the physical criteria to provide ecosystem services

A NEW PLANNING CULTURE COOPERATIVE PLANNING PROCESSES CASE STUDIES IN VIENNA, AUSTRIA

AUTHOR SILJA TILLNER, ARCHITECTS TILLNER & WILLINGER,
51ST ISOCARP CONGRESS 2015

Fig. 1: Cooperative planning workshop "Altes Gaswerk Neu Leopoldau," a former gasworks site

1 SYNOPSIS

Cooperative planning workshops have replaced planning studies and master plans in Vienna. In the last four years the city has experienced a transformation of its planning culture from a closed to an open process. The zoning process is no longer an act of planning reserved for professionals, e.g., planning department staff and selected expert consultants, followed by political debates, but has become transparent and opened up to include citizens, neighbors and interested professionals. A new format was created to structure the work: the "cooperative planning workshop." These recent changes in the planning culture have had a positive impact on the public debate, yet the results vary in their quality and are sometimes controversial. The analysis of the various types of planning workshops will be followed by a proposal for an ideal scenario, based on the experiences of the author as an active member of several of these recent workshops.

2 INTRODUCTION

The paper will analyze recent cooperative planning workshops that have replaced planning studies and master plans in Vienna since 2011. Before, whenever a zoning change was required, the planning department either contracted a study or launched an invited urban design competition, depending on the size of the area. Since 2011, Vienna has experienced a

change of its planning culture from a closed to an open process – cooperative planning workshops are publicly announced and applications are reviewed by an independent jury. This transformation occurred, on the one hand, for political reasons, on the other hand, due to international trends. While the openness and transparency of these new procedures are generally viewed positively and considered as a step forward, the results vary widely. Sometimes they produce a solid base for the following competitions, at other times they lead to controversies or are criticized for their weak quality, mostly due to inadequate time allowance for the planning process. On some occasions only a few days were reserved for complex sites, leading inadvertently to a certain level of superficiality and lack of understanding for the area. At other times, too many stakeholders were involved in the process and influenced the working team by pushing for their required minimum building mass, which often contradicts respect for the context and desired qualities of the public realm.

3 COOPERATIVE PLANNING WORKSHOPS – THREE CASE STUDIES IN VIENNA

Currently, in the City of Vienna, as in many other European cities after Stuttgart 21 and the financial crisis of 2008, urban planners and architects can no longer conceive a comprehensive master plan for an urban area and then hope to see it implemented as planned. The era of long-term master planning has long gone. It has been replaced by a more open system that addresses flexibility for future changes of developments. Participatory processes of all kinds, largely structured so that they are inclusive for all stakeholders, planners, community members and politicians, have developed. In these processes the planners retreat into the background; they are invited to develop creative ideas in discussion groups and interdisciplinary working groups. The advantage of this process is clearly the inclusion of all parties, as well as the amicable and open atmosphere in which all issues are discussed before the planning process starts. The potential disadvantage of this type of process is that with the disappearance of an “author,” a sense of responsibility also vanishes. Several recent planning projects that were organized as a “cooperative workshop” ended without a clear result. In the absence of agreed-upon planning and urban design guidelines, the following architectural competitions sometimes were not based on univocal terms and therefore did not deliver results that used the full potential of their designers.

This new trend is analyzed and illustrated with several planning workshops in Neu Leopoldau, $\frac{1}{4}$ 2, Stadtpark in Vienna and one current project in Klosterneuburg, Lower Austria.

3.1 “Altes Gaswerk Neu Leopoldau”

Fig. 2: Current situation on the former gasworks site “Neu Leopoldau” (photo Silja Tillner)

Site condition and strategy: On the former gasworks site “Neu Leopoldau,” the expectations at the beginning of the process were not yet specific, because the land was owned by a semi-public entity. The site of the former gasworks was long used by the Vienna Energy Department and was industrially zoned. Once the use for the gasworks ended, the site became available for development, but due to severe contamination it was obvious that a successful reuse depended on the prior clean-up of the land. Moreover, the accessibility to the site by public transportation as well as by car is not yet adequate to accommodate new residents and new trips. The adjacent neighborhoods have very low density and consist mostly of small-scale single-family homes. The neighbors were alerted by the prospect of new development and worried about noise pollution and traffic congestion. Currently, the site is burdened with a high level of noise pollution due to freight trains on one side and a bus terminal on the other.

Due to this challenging context and the high level of public interest, a regular planning process would have faced many obstacles. The decision to start a “cooperative planning workshop” instead enabled the planning department and the semi-public owner, Wien Holding, to gather all the stakeholders and interested parties in the same process as the professionals. A group of three architects and urbanists was selected after a highly competitive open call for applications. The requirements, besides having had experience with interactive participatory planning processes, included the personal social competence of the team members and the quality of the proposed strategy.

Process and result: The planners envisioned a large variety of building typologies in a lively, mixed-use neighborhood that is car-free thanks to decentralized parking in three garages at the edges. The proposal was developed during the course of eight-day workshops over a period of three winter months that were held on-site in a large, loft-like hall with no heating. The eight historic buildings on the site are mostly protected monuments and were to be incorporated into the urban design.

Fig. 3: “Neu Leopoldau” workshop location on-site in a protected historic, loft-like hall (photo Silja Tillner)

To ensure that they retain their character, a strategy was developed to exclude them from future economic development pressure with a utilization concept that allows for creative or public uses thanks to affordable rents. The planners could work freely in a truly cooperative manner. Local politicians and delegates of the neighborhood association also participated and several invited guest critics commented on the proposals in presentations at the end of the day. There was an intermediate public presentation for all the neighbors, which was attended by approximately 100 people. Their comments were incorporated into the work and the final results presented to the public, where it was met with great acceptance. The three teams worked cooperatively on several alternatives, but prioritized them and agreed upon the final recommendations for the site. After the workshops had been completed, zoning was changed and the site divided into 23 smaller lots with varying densities and building heights. The architectural competitions will start at the end of the summer of 2015.²⁾

Fig. 4: The “Neu Leopoldau” site was divided into 23 building lots and 3 parks (green). The historic buildings (brown) are surrounded by open space (yellow).²⁾

Conclusion: The project has so far been a success, because the semi-public landownership allowed for some flexibility with regard to the expected rate of return on investment and removed the developmental pressure from the historic buildings. The cooperative planning method will continue in the second phase of the architectural competitions, where selected teams will cooperate across the site borders and the public will stay involved. Nevertheless, the period of time and the number of workshops were barely sufficient to absorb all the complex site conditions and develop a high-quality proposal; it would have been desirable to have more time for in-depth planning.

3.2 “Trabrennbahn - ¼ 2 Plus” Trotting Course

Site condition and strategy: The attractive site at the edge of the green “Prater” was formerly popular for its trotting races, which attracted huge crowds. Since the late 1960s the public lost interest in this sport, the stands were closed and subsequently fell into disrepair. Today, few owners keep their horses in the stables and use the trotting course, causing financial problems for the club, which then agreed to reduce the course in size and sell part of its land to a private developer. The prestigious setting of the site and the zoning for “recreation and sport” were the reasons why the city required the private developer to finance a cooperative planning workshop rather than contract a master plan.

Fig. 5: "Trabrennbahn - ¼ 2 Plus" trotting course with the closed stands and the green "Prater" in the background (photo Silja Tillner)

Process and result: The result was to divide the area into five neighborhood clusters that will be developed in phases over the next five to ten years. Although each cluster is generally mixed-use and should have active ground floor uses, each area has a main emphasis, e.g., working and temporary living, high-end residential and leisure at the "Prater's edge," residential and cultural uses in the former stables, a creative work environment for start-up companies in the former stands, affordable housing of varying sizes with schools and kindergartens. The whole neighborhood shall be car-free on the surface, but with an underground garage. The proposal was developed during the course of four two-day workshops over a period of two summer months that were held on-site in a former stand with great atmosphere and no cooling, allowing for 34-degree indoor temperatures. The historic stables and stands on the site are mostly protected monuments and were to be incorporated into the urban design. Since they occupy large portions of the site and are in a dilapidated condition, the initial goal of the developer was to have most of them removed. This caused some controversy and no common decision could be reached on this point. Consequently, several alternative scenarios were developed. The whole area was rezoned to mixed-use and the clusters without historic buildings were the subject of subsequent architectural competitions, where the winners only partially followed the recommendations and urban design guidelines.

Fig. 6: "Trabrennbahn - ¼ 2 Plus" trotting course, aerial view of the site (red), planning perimeter (yellow) and the location in Vienna ³⁾

Conclusion: The project has so far been a success because the site owner is also the developer who is based in this area and follows high quality standards in his developments. Therefore, the developer and his team took a high interest in the process and the outcome of the workshops and were actively engaged throughout. The three teams worked cooperatively on several alternatives, but prioritized them and agreed upon the final recommendations for the site. 3) The number of workshops would have been sufficient, had the city representatives not ruled out high-rise buildings at a late point in the process. As a result, not all of the urban design guidelines were clearly understandable and therefore partially ignored. The fact that the stakeholders and the property owners were part of the planning process did somewhat impede the independent design work of the planners, who were urged to submit the calculated amounts of square footage because the land had already been purchased. Two architectural competitions for the areas without historic buildings were already held in 2014, and the winners awarded contracts; construction started in 2015.

3.3 “Eislaufverein”– Ice Skating Rink / Intercontinental Site

Fig. 7: “Eislaufverein” site with summer use and the proposed tower (red), Wiener Zeitung, 11.7.2013

Site condition and strategy: The prestigious and exclusive site of the Hotel Intercontinental, an early 44-meter high-rise building from 1964 at the edge of the Stadtpark and the historic city centre with a large ice skating rink next to it, makes this probably the most attractive development site in all of Vienna. The developer and owner of the hotel was able to buy the adjacent 6000 m² site between the hotel and the concert hall “Konzerthaus Wien,” where for decades Vienna’s only centrally located ice skating rink has been located. Although it is somewhat odd to find this type of usage in such a setting, it is heavily used by citizens and especially schoolchildren. Since the site was owned by the Federal Government, the change of ownership could not be influenced by the city of Vienna. Once it became clear that massive development – potentially even a high-rise – was feasible, the city demanded that the private developer finance cooperative planning workshops and a subsequent architectural competition.

Fig. 8: "Eislaufverein" site in winter with the proposed tower and the new square, EG-WertInvest Hotelbeteiligungs GmbH, 26.05.2015 ⁴⁾

Process and result: Three workshops were held and three different teams of architects developed competing strategies. The question whether to safeguard the existing high-rise building and place the new development in context or tear down the hotel and plan entirely new buildings in its place, either a high-rise with open space around it or a medium-rise, occupied the teams supported by university professors throughout the process. Although members of the public could not participate in the workshops, they were interviewed beforehand. Finally, the architects proposed alternatives, but could not agree on a prioritization. The cooperative planning workshops ended with no clear result and in a somewhat competitive atmosphere.

Conclusion: The subsequent mistake was to launch the two-phased architectural competition in spite of this undefined urban design strategy. A decision should have been taken with regard to erecting a new high-rise building on this sensitive site and risking the loss of the UNESCO World Heritage status before starting a more detailed planning phase. The question of demolition or rebuilding and of the appropriate height was delegated to the competing participants. The architects not only had to deal with these tricky questions, but to also fulfill a complex program that was far too detailed. The results varied widely but were, for the most part, not convincing. The jury selected six projects for a second phase and finally a winning project that kept the hotel and placed a second higher tower next to it. Protests arose when the result was presented to the public and have yet to subside. The reasons are, on one hand, the height of approx. 80 meters, which would cause the loss of the UNESCO World Heritage status, and the old-fashioned appearance of the high-rise building's design, on the other hand. Other protests focus on the fact that the tower will house luxury apartments. In any case, the positive aspect is that an attractive public plaza will be created next to the tower and the ice-skating rink will be kept and incorporated into the design. Also on the positive side is the fact that the developer and site owner meticulously followed all the recommendations that the City of Vienna gave to him and organized all the workshops and competitions accordingly. Therefore, the result of the international competition should be binding.

4 COMPARISON OF DIFFERENT TYPES OF COOPERATIVE PLANNING WORKSHOPS

Fig. 9: "Former army base," Klosterneuburg⁵⁾

4.1 Competitive or Cooperative?

The main difference lies in the selected type of cooperation among the team members. The clients and the jury members often prefer a competitive approach, for the application as well as for the actual workshop. The clients believe that through competition they will achieve a wider variety of results; the professional jury members believe that through an urban design competition the application process is more open for younger and inexperienced architects/planners. The analysis in the study¹⁾ by Robert Temel, for which he interviewed different participants of the first nine cooperative workshops from the end of 2011 until the beginning

of 2013 in Vienna, clearly shows that the workshops without competition not only led to higher satisfaction with the process among all the participants, but also to better results. The reason for this is that the participants, after having worked cooperatively on testing different alternatives, unanimously selected one preferred solution and developed guidelines for the following zoning and architecture competitions. In the competitive workshops, on the other hand, the participants start into the process from the beginning with an individual design concept. This idea is often contradictory to other possible solutions, but nevertheless defended until the end of the workshops. Frequently, no clear result is achieved because of this. Decision-making is thus postponed to the architecture competitions – as was the case at the Ice Skating Rink / Intercontinental site at the Stadtpark.

The author's personal experience through active participation in the "Trabrennbahn - ¼ 2 Plus" Trotting Course, the "Altes Gaswerk Neu Leopoldau" and the "Kasernenareal Klosterneuburg" workshops is congruent with the findings in this study. "Cooperative Planning Workshops" are more successful when they are driven by team spirit rather than individuality.

4.2 The Role of Stakeholders and Clients

Another difference lies in the ownership of the site. If the land is still publicly owned, planners have much more freedom to search for the appropriate density and building typology, hence, the best solution for the site. If, on the other hand, the land is privately owned, planners and architects usually face higher pressure to achieve a minimum of gross floor space on the site and develop economical building typologies. It is therefore preferable to hold the workshops before actually selling the land in parcels, as happened in Neu Leopoldau. The site of the "Trabrennbahn - ¼ 2 Plus" trotting course had originally been publically owned, but was sold before the new planning philosophy was implemented.

4.2 The Timeframe for the Process

Time is never sufficient. One obvious disadvantage for the planners is that necessary planning time is reduced to a minimum in these workshops. There have been cases where complex sites were supposed to be planned in only three days. The clients, on the other hand, prefer the rapid process, as they achieve the zoning faster and with fewer controversies, especially with less opposition from the neighbors, who are often opposed to rezoning ambitions when they are not involved and do not feel well-informed.

5 PUBLIC PARTICIPATION OVER A LONGER TIME PERIOD – HOW TO KEEP INTEREST ALIVE THROUGH PHASED IMPLEMENTATION AND SMALLER PROJECTS

Generally, planning and urban design projects that are focused on the public realm and are not immediately linked to building projects quite often face a long timeframe until implementation actually starts. Therefore, strategies that can secure support for these projects over a long timeframe have to be developed. Public awareness is high when projects begin with public meetings, participation processes, etc. But if the process continues too long, with little or no sign of pending implementation, dwindling public interest is the consequence. Once formerly active community members have retreated from the process, it is difficult to rekindle their enthusiasm. Therefore, it is advisable to include in the overall plan smaller projects that can be implemented quickly and without problems. The planners must actively search for these situations on the site in order to successfully organize their separate implementation.

5.1 Strategies to Start with Small-Scale, Short-Term Projects as a Way of Actively Engaging the Community

One strategy that can help start immediate implementation is to plan on several levels and for parallel processes. Short-term measures that can be realized quickly and with small budgets are to be conceived along with an overall planning concept for the mid- and long-term.

The advantage of this strategy is that first steps can be approved and financed more easily than in large-scale projects, where the public debate and the political agenda can delay implementation ad infinitum. These exemplary projects not only have a high quality of their own, but also act as “scouts” and represent the overall planning concept.

The public, the client and the planners can readjust the concept after the first experiences have been made. Since community participation has become quite common as a way of accommodating different needs in a changing society and increasing identification with the neighborhoods, the test case can actually reinforce and deepen community involvement.

6 CONCLUSION AND FUTURE RECOMMENDATIONS

Recommendations for the future processes are proposed based on the experiences gained by the author and the recent evaluations by the City of Vienna.

- Cooperative Planning Workshops should not be competitive, but cooperative. The plans should be developed with team spirit, alternatives should be tested, but in the end one preferred solution should be recommended by the team.
- The allotted timeframe for the workshops should be generously calculated and depend on the size and the complexity of the site.
- The roles of the team should be clearly defined at the beginning; especially the role of the moderator should be neutral; currently, moderators often participate in the design process, too, thereby risking their neutrality.
- The desired qualities of the result should be discussed and defined at the beginning of the process, e.g., a lively, car-free, walking neighborhood with ecological, energy-efficient buildings.
- The future application of the workshop results should be presented by the client.
- An intermediate phase after the cooperative planning workshop is advisable in order to draft a plan in due time before the zoning is finalized. The team should either be commissioned with this task or at least be involved in this process. As it is now, the team of architects and planners is usually no longer involved in the further developments of their proposals.
- Architecture competitions should only be started if potentially controversial topics are resolved beforehand, e.g., density and height should be defined.

The new tool of “temporary zoning” should be applied for difficult sites in order to allow the planning authorities to revoke zoning changes in case the desired qualities are not delivered.

In order to not only conceive but also implement long-term planning projects that improve the public realm within the built-up city fabric, the active engagement of the community has clearly become necessary. However, the “incremental planning” process additionally helps to maintain public interest and heighten public enthusiasm while allowing ideas to be tested and the plans adapted, if necessary.

The applicability of this strategy of incremental planning to similar challenges is self-evident. In times of dwindling city budgets and growing media attention, authorities and planners no longer have the time to develop elaborate plans.

Working within the *human* context

Tine VAN HERCK & Peter CASIER, PTA, Belgium

Figure 1: logo PTA

1 Practice based research

What should be the attitude of a designer in today's society where all certainties threaten to disappear? How to contribute something small to society in order to create a stronger tissue, a safety net, a solid foundation. How to pursue a *Joie de vivre* for the users, passers and ourselves ...? What is or could be the role of the designer in this complex world. Those questions are inherent for the practice of architecture, urbanism, an urban design and planning.

In this frame of questions and ambitions, we search for a human based design process. The developing of the method is a research through design, based on the practice of **PTA**.

This practice based research has the goal to develop a method that can be used for **real assignments**, with clients, budgets, realistic programs and restrictions. It is a method based on and made for everyday projects.

2 Method for a *human* based design process

Before introducing the method, we underline that the proposed method is a possible designer attitude. It is not our intention to develop an objective instrument of quality control. There will always be different kinds of architects with different attitudes and interests, which is good.

2.1 Scale indifferent

The method can be used to projects of different scale : from interior architecture to landscape strategies. It is scale indifferent. We think this is important because we believe in **multiscale and transdisciplinary projects**. The distinction between disciplines and scales ((interior) architecture, urbanism, urban planning, ...) is blurring.

2.2 Human context

This paper is an introduction to the (re)search. With the human based design process we aim to attribute something to the human context. We introduce the term human context as : **people alone or in all kinds of compositions** : a couple, a family, a neighbourhood, an age group, a city, a region, ...

Human context means people and **society and all its processes** and actuality.

The human context is in the centre of the presented design method. The method for a human based design process can be summarized in a diagram (fig.2).

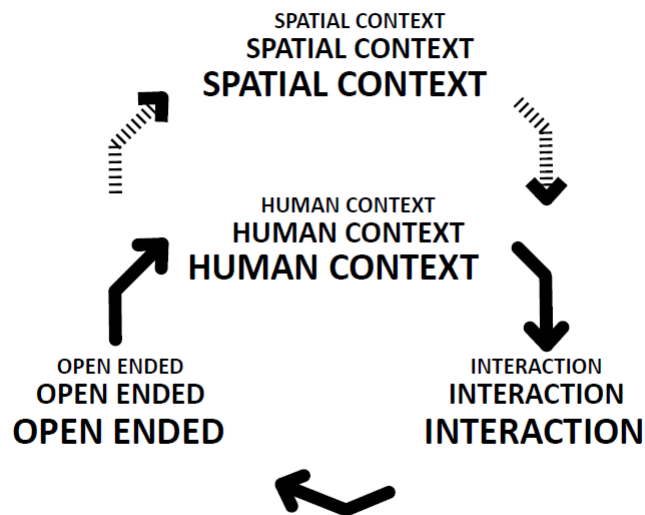

Figure 2: diagram

All assignments, indifferent their scale start from the **spatial context**. The method insist in analyzing the spatial context in different scales and adds the human context as a major precondition of the design process. A good analysis of the human context combines objective and subjective elements, findings and interpretations, text and images, and is the base for a human based design process. There is attention for the different scales and for the dimension of time.

All the relevant information of the human and spatial context can be put together in a **biographical frame** of a plot/ neighbourhood/ This frame is the starting point of the design process and it is the foundation of the project. Relevant aspects of a human context can be:

- To much public space causes little of contact

- Elderly and their integration in society
- Braindrain in a panoramic landscape
- People of all ages living together in the city
- ...

2.3 Interactions

Starting from the human context, the method proposes to seek for interactions. It can be interactions of all kinds : between people, between generations, between functions, between inside and outside, between private and public, between rural and city, between human and animal, between present and future, The interactions can be situated within the scale of the assignment, but they can also be on a very different scale.

The designer is tempted to search in each design process for assignment relevant interactions. We believe that incorporating interactions of all kind attribute to the human context. This is due to the fact that an interaction enlarges the human context of the project.

We illustrate with some examples :

- an open facade for a private housing building augments the liveliness of the public space;
- connecting different neighbourhoods in an art trial (**fig.3**);
- interactions between generations in a masterplan (**fig.4**);
- incorporating a public bar at the ground floor of a private office building;
- ...

Figure 3: Art Trial Foto Kanal, Brussels

Figure 4: Masterplan Huis Perrekes Geel

2.4 Open ended thinking

Afterwards or simultaneously the designer is asked to take into account **what we don't know yet**. The method believes in open ended thinking. Today's society evolves very quickly in contrast with building or planning processes which generally keep taking several years. The design has to take this into account and leave enough room for adaptation or evolution.

For example this aspect can be incorporated by :

- creating multifunctional spaces, using flexible structures, ...
- designing basic buildings with room for a self-expressing infill, ...

But this aim can also be achieved by :

- rethinking the use of heritage in a flexible way (**fig.5**)
- incorporating a timeline in the design and making it evolutive
- ...

Figure 5: Vision on development heritage

The open ended design method resulting in an evolutive design, is illustrated by the project of PTA for the Cadix square in Antwerp. The design incorporates the idea that the current and future inhabitants can rethink parts of the park in function of evolving needs and wishes (fig.6).

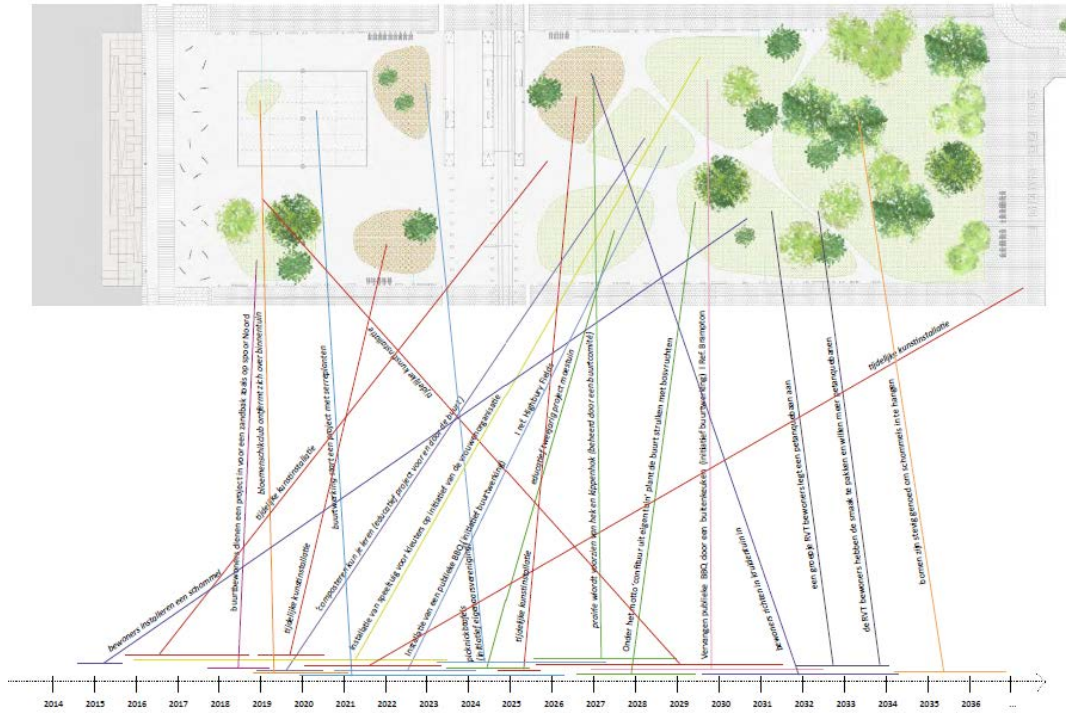

Figure 6: Cadix square Antwerp – evolving design

3 Evaluation

The goal of the proposed method is to attribute something to the human context. The design can differ from type and scale :

- a visible and open community centre inviting neighbours to meet
- a cohousing project where people enjoy life (fig.7);
- a art trail trying to break trough prejudices of bad neighbourhoods;
- a masterplan in which the interface between private elderly housing and public space has been maximalized to integrate those people in society (fig.8);
- the project for the cadix square in wich people are activator of transformation (fig.9).

Figure 7: Cohousing project (© Bart Azare)

Figure 8. Masterplan Extra Muros Eldery housing

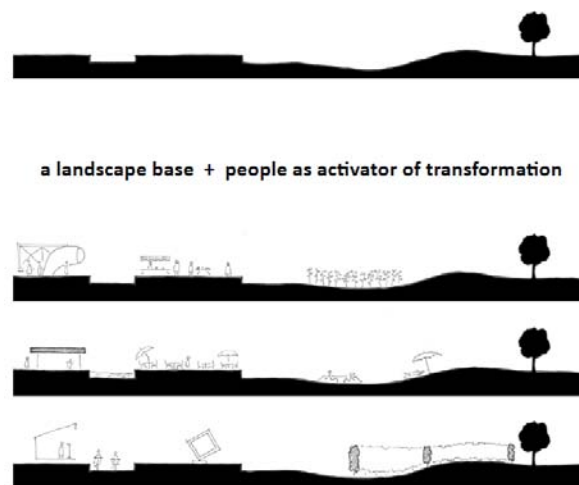

Figure 9. Cadix square Antwerp – concept scheme

An Italian architecture critic Bernardina Borra wrote about the design for the Cadix square (fig. 10):

*'Cadix is a neighbourhood in progress in the old harbour district Eilandje in the north of Antwerp. Massive housing projects are planned and population will multiply in a few years. The park/square is designed to be evolutionary just like the neighbourhood itself. A tram line will cross the square and the former warehouse will be re-used as a covered public space. The landscape gradually turns from park into square in order to collect different potential open space use according to inhabitants wishes and seasonal changes. Around the square are planned new housing, a school, and services for elderly people. The area will cater a diverse social mix in terms of origin and age of the people using the open space in different modes and times of the day during the whole year.'*¹

Curating complexity in systems transitions

51st ISOCARP Congress 2015

Stephan KAMPELMANN (ULB)¹, Michael KAETHLER (KUL)², Adrian VICKERY HILL (BUUR)¹

*“esperti locali ed internazionali
sono stati i nostri canali
imprese e cittadini
nel lavoro sono stati vicini
terra, acqua e sole
piu fatti e meno parole”*

Fragment of a poem composed by participants during the workshop in Rome.

1. Introduction

Engagement of local actors and stakeholders in urban areas is increasingly considered a prime leverage point for transitions towards sustainability (Loorbach, 2007; Vandebroec 2012). In practice it is a field imbued with complexity and conflict and awkward to navigate. While planning practitioners increasingly accept complexity as a fundamental challenge within the transition processes, they struggle with tools and approaches that accommodate it. Drawing on the notion of the curatorial from art and design, we are exploring a novel approach that engages directly and constructively with complex problems evident with multi-scalar, multi-actor and multi-dimensional urban planning projects.

Our approach proposes a novel and practical method to compress this diversity within time and place - such as during multi-party stakeholder discussions - in what we call a “curatorial approach to system transitions”. This paper describes the theoretical basis of this approach and why it is a relevant lens in which to approach complexity and conflict in urban areas. We also present empirical evidence from its application to a real-world sustainability transition related to the governance of a large urban asset in the city of Rome.

In Section 2 we identify three problematic qualities evident in urban planning situations that give rise to complexity. Section 3 shows how this complexity can be addressed and presents the theoretical basis and a process method of our curatorial approach. Section 4 describes a case study in which we applied this method to a participatory planning problem related to the Parco Agricolo Casal del Marmo in the Lazio region in Italy. We notably describe the context of this case, the implementation of the curatorial cycle and the main results of a participatory workshop. Section 5 concludes.

2. Problem statement: The complexity of urban transitions

Deliberate strategies to effect 'sustainable transitions' in urban areas have recently been a subject of intense research within the field of Transition Management (Geels 2010, Loorbach 2007). It is now widely recognised that conflicts and complexities common in sustainability transitions are increasingly questioning traditional scientific methods developed in specialised disciplines and call for more integrated, adaptive and creative frameworks. Armitage et al (2008), who explored complexity in sustainability transitions, notes that "social-ecological complexity" should be addressed through new ways of managing knowledge and a diversity of scales and actors. We will now analyse in more detail the relevance of diverse knowledge, actors and scales for the case of urban sustainability transitions.

Knowledge: The interdisciplinary literature at the intersection between the natural and social sciences has emphasised the importance of interdependencies between different dimensions of sustainability interventions (Ostrom 2007). For instance, it is crucial to understand how economic behaviour is affected by physical interventions. Practices in urban planning, however, reflect the disciplinary specialisation of professionals so that economists, architects, agronomists, engineers, sociologists, urban planners and so on lack practical tools permitting meaningful dialogues on specific projects (Buchanan 1992). While there is an increasing consensus for the need of interdisciplinary approaches to urban transitions, cooperating across disciplinary boundaries is still confronted by incommensurate semantics, work approaches and demands extremely time consuming methodological and conceptual translations.

Actors + Stakeholders: Planning processes involve a wide range of actors that have to be concerted, convinced or consulted. There has been a surge in tools and methods to select and integrate many of these actors in planning processes, most recently under the banner of "Participatory Design Workshops" (Cox et al 2015). Most of these tools have led to disappointing results. A lack of political will and institutional entropy provides rocky terrain for methods and tools to take root, resulting in overstrained time and resources of different groups, in what is referred to as 'participation fatigue' (Kaszynska et al 2012). There is also a more general concern that a focus on "key stakeholders" overemphasised economic and political power over alternative criteria such as being personally affected by the planning processes, professional and lay knowledge about the site or civic leadership in the concerned area. Drawing on empirical studies of common-pool resources that are often structurally similar to urban assets, one of the design principles advocated by Ostrom (2008) is to authorize most of the individuals affected by a resource regime to participate in making and modifying the rules of the regime. This creates the need for frameworks that allow the incorporation of a more complex set of stakeholders into planning processes in a meaningful and operational way.

Scales: Changing urban form typically affects functioning at multiple scales. Scales are deeply intertwined so that interventions at a particular scale need to understand and anticipate interrelationships with lower and higher scales (Omann and Spangenberg 2002). Moreover, without a nuanced understanding of the different nature of scale levels, policy

making can easily become fragmented and inconsistent resulting in confusion and distrust (Swyngedouw, 2005). These can also be interpreted as scales involving time, ranging between the immediate and long term futures of the space. This complexity constitutes one of the core themes of the planning profession and has inspired visual and conceptual tools to address multi-scalar problems. However, in practice planners face time constraints and relatively narrow mandates so that multiple scales often continue to be a poorly resolved issue.

3. A curatorial approach to system transitions

3.1 Complexity is not chaos: adopting a systems perspective

Due to the different drivers of complexity that characterise urban sustainability transitions, urban planning situations typically accept no clear problem definition. The staggering quantity of interconnected variables and relationships also means that they normally defy conventional scientific methods based on reductionism. As a consequence, they resemble “Wicked Problems” found in societal contexts involving issues such as environmental, economic, or public policy within a pluralistic society where there is no objective definition of a public good (Rittel & Webber 1973). Churchman (1967) has described such problems as “ill-formulated, where the information is confusing, where there are many clients and decision makers with conflicting values”.

Complexity should, however, not be confused with chaos and there are several longstanding academic traditions that have successfully addressed complex social problems. One of the most powerful ways to capture complexity is through thinking through systems - from the Greek *systema*, “organized whole, a whole compounded of parts” - that adopts a holistic perspective in order to examine how the elements of a system “stand together”. While system thinking was long crowded out by theological explanations of observed complexity, it reappeared in Western philosophy during the Enlightenment, as in Goethe’s lifelong struggle to understand “what keeps the world together in its core”. In the 1970s, system thinking revolutionised the understanding of complex biotopes such as forests or oceans by framing them as intelligible “ecosystems” (Duvigneaud 1975). Around the same time, MIT scientists applied system thinking to global biophysical developments and charted “the limits to growth” beyond which global production systems would become unstable (Meadows et al, 1972). Historically and intellectually rooted in engineering science, system analysis is today an academic discipline in its own right, while other disciplines have developed specific theories on monetary systems, mobility systems, legal systems or approaches to systems thinking.

The mainstreaming of sustainability as overarching policy goal has led to an increasing necessity for holistic approaches in order to understand the interrelationships between economic, social, environmental and cultural systems at different scales. Emphasising the connectedness of biophysical and anthropogenic systems, many authors refer to their nexus as “social-ecological systems” (Dietz et al 2003). Although it is rarely adopted in urban planning and spatial design, we argue that a “system perspective” provides considerable mileage for dealing with the different forms of complexity associated with them. It invites the participants in a planning situation to consider how different particulars (such as a new building, a new economic activity, a new park etc) together form a whole.

The kind of systems encountered in urban planning situations are, however, intrinsically different from “hard” systems applied to natural science and engineering. The presence of multiple types of knowledge and actors mean that the understanding of social-ecological systems requires dealing with multiple overlapping perspectives as any specific discipline or body of knowledge will always be partial and provisional (Brown et al 2010, Midgley 1991, Moulaert and Van Dyck 2013). As such, dealing with the transition of social-ecological systems is a natural bedfellow with inter- and transdisciplinary approaches and practices. They defy overly rational approaches and tools and call for a plurality of voices, lenses, and instruments. This is notably due to the fact that key elements of the system - its stakeholders and their knowledge - are not exogenous to the analysis of the system. They can for instance decide on the goals and the rules of the system and, on a more fundamental level, assign *meaning* to the system. The curatorial approach we present in the next section offers an innovative and conscious effort to adopt system thinking in a setting in which the meaning of the system is subject to interpersonal dynamics that are part of the planning situation.

3.2 The curatorial as a framework for systems

While much has been written about potential tools for tackling wicked problems, considerably less is written about influential roles that can facilitate these, as individual approaches or assemblages, within a participatory setting. Roles like organiser, facilitator, or moderator tend to reflect the logic of tame problems that can be ‘fixed’ through analytical decomposition and are not relevant for wicked problems; additionally, roles, such as these, and associated tools, carry with them considerable institutional baggage (Van den Broeck 2011). With this in mind, we argue instead for a curatorial role, a position that deals with complexity and conflict using multiple approaches, methods and logics.

Figure 1: Challenges of wicked problems + the basic aspects of curating

The Swedish curator Maria Lind (2010) defines the curatorial, as “...a way of thinking in terms of interconnections: linking objects, images, processes, people, locations, history and discourses in physical space like an active catalyst generating twists, turns and tensions.” In today’s art and design world, the curator plays an important role as translator and mediator between the artefact and different audiences. He/she is intimately connected to the artefact itself and deeply concerned with the output of the translation, actively giving it form but plays a role which is neither the cultural producer nor the audience. The curator, having been provided with institutional or cultural legitimacy, has a wide arsenal of techniques for engaging audiences and translating the story of the artefact and its significance.

3.2.1 Three Guiding Principles of Curation: We argue that framing urban planning situations as wicked problems and adopting a curatorial approach with systems at its heart, provides considerable mileage for moving forward, untangling stand-offs and making such problems accessible to relevant actors. This can be derived by looking at three guiding

principles that characterise *our* curatorial approach to system transitions: 1) a focus on 'meaning', 2) knowledge emerges and is transferred from multiple sources, which need not be analytical or cognitive, and 3) an oscillation between the particular and the whole.

1. *Meaning:* At the heart of the curatorial is an affinity and partiality for the subject matter. It is not value-neutral. It assumes a position of relationality, whereby the curator recognises his/her own subjectivity in the process of their work. The term curator originates from the latin *cura*, to care for. The role of the curator, originally, was a caretaker of objects and artefacts and today the curator is concerned with what the artefacts 'mean' to different audiences. We adopted both of these roles, a deep consideration and care for the context and its potential futures as well as translators--helping communicate the context's meaning according to local stakeholder positions.

We argue that taking a disinterested position as neutral facilitator does a disservice to the context, rendering analysis and propositions as scientific, concerned more with what 'is' than what 'could be' and limiting the different means to explore the problem and possible solutions. By situating the organiser's role as deeply 'caring' for the context and its outcome, it refocuses discussions and interactions. To do this, we invoke strategies that aim to penetrate below the levels of 'interest' and 'position', to reach points of significance. These strategies include addressing emotive and experiential facets of stakeholders through visual, creative, experiential and reflective modes of action.

2. *Multiple ways of knowing:* In line with the a systems perspective, the curatorial affirms that there are multiple ways of knowing—equally so, this is paired with a multiplicity of forms of communication. System transitions not only require tapping into the different bodies of specialised knowledge associated with the canon of academic and professional disciplines but also require uprooting accepted knowledge hierarchies--the thinking which has given us these problems in the first place-- such as giving preferences to art over science, or a designed artefact over a policy document.

Multiple ways of knowing also implies a considerable amount of demystification of the problem being addressed, whereby individuals learn to see and accept their own perspective as part of a much the broader discourse. This can bring about a greater openness to a variety of ways of knowing and an active integration of types of knowing through action, as found in problematisation (Miciukiewicz et al. 2012). We seek to combine multiple forms of knowing and expression, as a way of tapping into the wholeness of our experience as humans, accepting intangible feelings, dreams, nostalgias, or sentiments as valid and useful for the workshop process.

Expression is made meaningful and real through processes of reification, which is the translation or congealing of ideas into 'things' such as artefacts, relationships or even concepts such as 'justice'. The materiality or concreteness involved provides a milieu for inquisition and exploration enabling negotiations among participants with very different interests or skills. Afterwards we are left with an artefact that represents the moment of codification when the knowledge of the group is synthesised into a material and symbolic system, which is embedded with the consequent social, political, cultural and institutional negotiations inherent in its production, what Gherardi and Nicolini (2000), call a "complex form of social and technical bricolage". From this, the artefact or concept, with all its implicit

combinations of knowledge, embodies a new context of use and thus also a new starting point within an on-going process upon which dialogue is sustained.

3. Elements within a whole: To work with complexity, it is necessary to work between the individual elements that constitute the whole. Dan Hill (2012) refers to this as skipping between the 'meta' (the big picture) and the 'matter' (the material detail). Taking from the curatorial and systems thinking tradition, we contend that the particular and the whole cannot be understood without the other, therefore, moving towards systems transitions requires change to occur at the individual *and* structural levels. The curatorial draws the agency from the individual level into the systems level, through this oscillation of scales.

3.2.2 Curatorial Cycle (the workshop structure)

Time constraints remain a considerable challenge in the context of stakeholder meetings. Motivating relevant stakeholders to sit together is a difficult task, often requiring factors such as incentives (“what’s in it for me?”), which are difficult to sustain for longer periods. Another important challenge is communicating the urgency of the problem at hand—the need to act and overcome pre-existing barriers in knowledge creation and shared action.

We recognise the impediments and opportunities of short-term workshops. We frame scenarios as interventions, creating a spatial/temporal break, disrupting habitual patterns of thinking on the subject matter. We seek to use features such as time and risk as an intrinsic part of the workshop — a compressed multi-experiential event evoking strong emotions, memories, ideas, and beliefs. Our curatorial approach aims to limit what commonly are long and drawn out ‘negotiations’ over entrenched stakeholder positions. In this way discussions can be much more frank, open and direct.

Figure 2: The workshop cycle; the curatorial frames the steps in the process

The workshop process functions as a six step cycle. The first Step (1) opens up the discussion and frames the focus area - this can be seen as divergent thinking and can be quite abstract. The following three Steps (2-4) involve splitting the focus area into smaller themes that invokes emergent thinking. Specific problems can be discussed in detail to test the concept defined in the focus area. It also explores action areas that may be explored further after the workshop. The fifth Step (5) uses knowledge gained in Steps 2-4 to review ideas noted in Step 1 through an exhibition of the work produced - this is a moment where the themes are compared and the vision tested. These five Steps are what we, in the context of a workshop, call a curatorial cycle, which can occur numerous times over the course of the workshop. Once the general focus area has been defined, it is possible to refine a vision and define specific actions. The final Step (6) evidently involves documenting the process and defining further steps forward.

1. Framing

- > *Process*: to begin bringing together different ideas, worldviews, hopes and fears.
- > *Curatorial intention*: to start with the holistic vision of problem area, which is a curated working hypothesis. This is the basis for exploration using different means available, such as artefacts, images, research material or presentations, which set the tone without directly addressing the specific context.
- > *Outcome*: The basic building blocks of a coordinated vision that allow for discussions to funnel towards specific issues.

3. Engaging through signification

- > *Process*: to personally reflect and identify concrete actions, artefacts or conditions for addressing a part of the problem.
- > *Curatorial intention*: to create the conditions for individuals or small sub-groups to personally identify with the problem or solution and to find a unique voice within the wider discussions.
- > *Outcome*: The emergence of specific action points for a small part of the larger problem.

5. Reframing

- > *Process*: Bring the groups to a point of exchange to review and refine the vision.
- > *Curatorial intention*: Negotiation of knowledge(s) through bringing together tensions, juxtapositions, complementarities et to catalyse responses and resonance with the proposed vision.
- > *Outcome*: A closer consolidation of particular proposed solutions within the vision.

2. Channelling

- > *Process*: Break down the vision of the problem as a system composed of multiple tangible problems, which can be individually addressed.
- > *Curatorial intention*: to predefine the themes before the workshop in order to channel the focus of the participants.
- > *Outcome*: Participants are not lost within the complexity of breaking down a large problem. Instead, this activates discussions and accelerates the collaborative process towards pre-determined useful themes.

4. Rechannelling

- > *Process*: Integrate different particular solutions within a larger body of solutions.
- > *Curatorial intention*: valorising leverage points.
- > *Outcome*: A deepened knowledge of how the particular parts fit within the whole.

6. Positioning

- > *Process*: Document and communicate the ideas from the previous steps into a meaningful and memorable form.
- > *Curatorial intention*: To support multiple voices and expressions in translating different ideas into a visual representation.
- > *Outcome*: a visual representation that incorporates the complexity of the problem and the nuances of the multiple solutions provided.

4. Curating a system transition in the Parco Agricolo Casal del Marmo

4.1. Genesis of the project

The area referred to as “Parco Agricolo Casal del Marmo” is a 460 ha site situated in the North-West of Rome. Most of the Parco was left fallow after real estate speculation progressively crowded out agricultural uses since the 1970s (Suchiarelli 2002). The site is zoned ‘collective interest area’ as an ‘agricultural park’ - a political decision that translated into a considerable financial loss for landowners seeking to develop the land (Bollettino Ufficiale 2014).

In October 2014, the authors were approached by the regional public business innovation agency (BIC Lazio) and the local municipality (Municipio XIV Roma Capitale) to consider the Parco Agricolo in the context of our work on TURAS, a European research project on sustainable and resilient cities. The site clearly fits Rittel’s description of a wicked problem (2012). Firstly, the problem statement was ill-formulated, information was confusing, including outputs of previous participatory planning actions for the site (Associazione Comitato 2012). There were likewise numerous clients and stakeholders with conflicting values; we were asked to work with local and regional agencies with different agendas and interests in the site and also had to consider a wide range of other private stakeholders such as the landowners. Part of the local business community and civil society has also (potential) interest in the development of the Parco. Finally the ramifications of a project at such a large scale within the political and economic hub of the city of Rome has implications for social and natural systems at different scales.

Step 1. Framing

Step 2. Channeling

Step 3. Engage via signification

Step 4. Rechanneling

Step 5. Reframing

Step 6. Positioning

Figure 4.1-4.6: workshop steps

4.2 Applying the curatorial cycle in a three-day participatory workshop

In this section we describe how we applied the curatorial cycle described in Figure 2 (section 2 above) to the “wicked problem” we faced at the Parco. Our first action was to create a curatorial situation. We achieved this by suggesting to the local authorities that the complexities of the Parco’s development could be addressed by compressing a large variety of viewpoints and forms of knowledge in time and space, a compression that took the form of a three-day, on-site, hands-on workshop with around 60 participants from the area that was organised in June 2015. The workshop also includes five external international experts that help provide inspiration. The overall architecture of the workshop was structured in the form of the six steps of the curatorial approach presented above.

Step 1. Framing. Our working definition of the overall problem area of the Parco embraced a non-neutral and political stance: we decided to engage with the local stakeholders and the site in order to help co-constructing a meaningful vision. We wanted to promote a positive vision that would suggest to the local and regional decision makers that the Parco could play a completely different role in the urban system. While the representatives of the local municipality shared our non-neutral assessment from the beginning, we further curated the narrative to help narrow the focus of the workshop. We clearly stated in all communications that the purpose of the workshop was to “create a community-based food system” of which the Parco was to be the heart.

We then further framed the workshop experience through a mix of visual artefacts, physical exposure and presentations. For instance, we prepared and exhibited on the site of the Parco a series of large photos and descriptions of community-based food projects from different contexts across the globe. Day 1 started with a guided walk around the site. This was followed by short presentations that again focused on community-supported food projects in other cities given by the five external experts.

Step 2. Channelling. Moving from the whole to the particular was achieved by channeling participants and conversations into a limited set of themes: Steps 2-4 thus took place within thematic groups composed of 10-15 participants that were predefined according to interest and expertise. This allocation was based on the municipality’s assessment of each participant’s knowledge, interests and professional training. This being said, participants were free to affiliate and follow other themes as well - and many did.

The themes were similar to the ‘principles of relevance’ that designers identify when addressing wicked problems (Buchanan 1992) including: agriculture, urban integration, landscape, energy and resources, and economy. These themes were predefined by the organisers in order to save time and ongoing discussion during the workshop.

Each theme was framed as a ‘subsystem’ of the site as a whole. During Step 2, the groups formed by each theme were given a set of clear objectives and exercises that aimed at developing systematic thinking, including intermediate objectives such as: “understanding system analysis”, “understanding system maps”, “identifying the elements of the system” and

so forth. While the themes were somewhat elaborated for the teams, it was expected that the team validated or redefined them as they saw it.

The municipality had identified two knowledgeable individuals for each group and assigned them as “coordinator” and “facilitator”. In addition, the research team (curators) assigned an international mentor to each group with the intention to provide references to community-based food systems at the sub-system level. The coordinators/facilitators were then handed over a detailed script including the objectives and suggested ways to reach them. In hindsight, group leadership turned out to be a big challenge and would likely have been more effective through self-organisation within the groups.

We found that the act of drawing a system, even a simple system (i.e how a carrot travels from farm to fork) was enough to set a common vocabulary, defined by the participants, to help integrate actors in the map-making process. This self-interpretation and “rule-making” within the group allowed a critical step forward. We observed that groups that did not start to draw a visual representation of “their” system either struggled to structure their ideas and lost time talking abstractly or otherwise resorted to a communication language that fit their predominant vocation and lead to a partial analysis (such as schematic design drawings for the landscape group). The workshop confirmed that people are rarely trained to think in systems and will clutter down, focusing on their specialisation if left to their own accord. The basic concept of systems thinking proved to be quite didactic and helped individuals to express their knowledge in a way that would be commensurate with other conversations.

Step 3. Engaging through signification. Step 3 is pivotal in our framework as it strives to create situations in which all three curatorial aspects come into play. Step 3 further splits the thematic groups into more specific issues and groups of 2-4 individuals that would be most likely to lead to meaningful exchange on a personal level (*aspect of meaning*). Second, these more intimate conversations would span a broader and deeper spectrum of human communication, and participants were encouraged to walk around the site so as to situate Step 3 in the landscape (*multiple ways of knowing* and rooting that ‘knowing’ in *meaning*). Third, the conversations were framed as a mid-point of the cycle whole-particular-whole (*elements within a whole*).

The precise content of the conversations in Step 3 was to some extent left to the groups to define, as long as these conversations were oriented towards creating a vision for the thematic sub-system that could be later incorporated into the vision for the whole system. On Day 1 most conversations focused on the values or overall objective that the development of the Parco should pursue, therefore touching not only on analytic but also on personal and emotional aspects that are difficult to discuss in larger groups. The conversations on Day 2 were directed at exploring and defining concrete actions for transitioning towards the overall vision established in Step 5 of the first cycle. Discussing specific interventions in personal conversations proved to be instrumental for keeping discussions relevant and interesting while also fostering commitment and tangible steps towards implementation, as most conversations involved specific actions that individuals wanted to be and could feel personally involved in.

We felt that Step 3 was extremely valuable for the entire workshop process and featured deep conversations about actions that are too often missing from other participatory approaches to planning. The diversity of situated conversations also rendered the work on

each theme more resilient: while not all conversations made equal progress, having many of them simultaneously on each theme ensured that the groups could build on a diverse mix of creative, constructive, visionary, and realistic conversations. Also, as the team members could freely engage with other groups, cross-pollination of ideas allowed both collaboration and competition and propelled the groups forward.

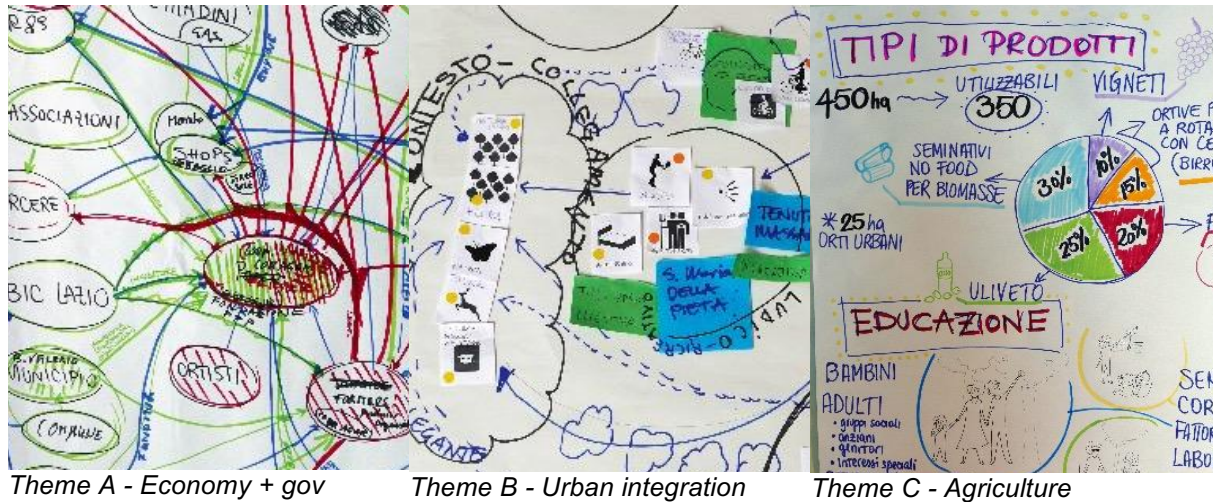

Step 4. Rechannelling. Step 4 is the last step at theme-level and serves to redefine or update the results of Step 2. We set the objective of this step as identifying the action areas with the highest leverage for transitioning the Parco's system in the desired direction. For this purpose, overlapping conversations could be merged and irrelevant or conflicting ones discussed and discarded.

Step 4 was instrumental as a bridge between the personal conversations of Step 3 and the plenary presentation in Step 5. We believe that the symmetric nature of the curatorial cycle allowed to keep the group-level discussions relevant and constructive: results from the personal conversations were presented as contributions to the thematic objectives as well as in the context and language of the framework that the group defined together prior to splitting. This meant that members of the group perceived themselves as "playing for the same team" without excluding the psychologically rewarding sensation of proposing a particularly creative or useful individual contribution.

Step 5. Reframing. In this workshop the step took the form of a plenary session in which a collage of visual material (including vision drawings and subsystem maps) was exhibited as a backdrop. Representatives of each thematic group presented in turn the main outcomes of Steps 2-4 to the plenary, again in an atmosphere of "playing for the same team" since the thematic work was framed as specialised contributions towards the overall vision for the Parco.

At the end the end of Step 5 the group naturally produced a rather heteroclite collage of ideas, concepts, propositions and partial visions. But presenting these elements side-by-side as a first step towards a more coherent vision nevertheless created the impression of an ensemble. It also provided material for fertile interactions between the thematic groups since we observed that many substantial and procedural achievements of Day 1 appeared in the work of other groups in Day 2. On any account, we believe that the exhibition of the results fostered a deep sense of ownership for both the partial results and the vision for the whole.

Many participants referred to the process as "our method" and the research team's main achievement as "having brought us all together so that we can work this out". At the end of the three-day workshop, we proceeded to Step 6 which positions the workshop output through different elements of documentation that are presented in the next section.

Figures 5.1-5.6: Examples of the styles of the maps produced for the final exhibition.

Step 6. Positioning. The following Figures 5.1-5.6 (above) shows the range of ideas developed within the groups. This is only a sample of the output however shows the diversity of the material developed by the participants and how they represented their ideation process. The groups were asked to include 3-5 'action areas' based on the most significant priorities - many of these were those explored during Step 3. The compilation of all of these diagrams helped define overlaps and the main leverage points for the project as a whole. In this case one of the main conclusions from the workshop was that an independent organisation, we refer to as a 'community interest company', was necessary to represent the vision, drive and negotiate change.

5. Conclusions

Local communities, especially in Southern Europe, experience the confluence of fiscal austerity, environmental degradation and social tensions. These crises, however, also release financial, physical and human resources that were so far oriented towards business-as-usual approaches for assets such as public land, vacant real estate or defunct industrial

sites. While the integration of such assets into community-based initiatives is becoming an increasingly popular strategy with policy makers and civil society organisations interested in sustainability, we observe narrow and shallow approaches for engaging with the complex and conflictual nature of the “wicked problems” that such transitions typically imply. This paper contributes to filling this gap by presenting the theoretical and empirical basis of what we call a “curatorial approach” aimed at locally grounded system transitions.

Our theoretical contribution proposes that real-world sustainability transitions call for a fundamental re-thinking of the role of planning professionals in participatory processes. Most urban interventions have repercussions on multiple scales, involve multiple sets of stakeholders and have ramifications on multiple dimensions of social-ecological systems. The combination of these multiplicities means that they should be regarded as “wicked problems” whose complex and conflictual nature defies standard research methods oriented towards analytical, specialised and value-neutral disciplines where outcomes are relatively clear.

The curatorial approach developed in this paper addresses wicked problems through two complementary strategies. First, by re-thinking the role of planning professionals as “curators” whose interventions are guided by the principles of creating meaning, caring for the context, fostering diverse ways of knowing, and oscillating between the particular and the whole. The curatorial here provides a unique set of instruments for dealing with different knowledge parcels as well a useful metaphor for thinking of the role of the planner in ecological projects--a caretaker and guardian. Secondly by embedding the curatorial approach in a system perspective, stakeholders are encouraged to simultaneously think in terms of individual and structural actions that are necessary for sustainability transitions. In the case of our work in Rome, the combination of these two strategies led us to develop a “curatorial cycle”, which offers an example for planners to navigate through the different steps involved in real-world system transitions.

We have applied this new approach in the context of the development of the Parco Agricolo Casal del Marmo, a site of undeniable economic, environmental and social potential situated in the periphery of Rome. The empirical evidence showed that our approach allows for stakeholders to effectively address the complex and conflictual nature of sustainability transitions. Stakeholders notably felt empowered to make meaningful contributions to the transition of the site towards becoming a hub of a community-based food system and felt confident that the inevitable *fuzziness* of the transition process could be overcome by aligning all stakeholders through a strong common vision. This is a first large-scale application of the curatorial approach, further empirical testing is nevertheless warranted so as to assess its external validity in other contexts.

Abstract

In 2014, the Grand Canal (China) was included on the World Cultural Heritage List. As the cradle city of the Grand Canal, Yangzhou is now facing the challenge and also opportunity of conservation practice in the context of rapid urbanization. Our research uses the approach of 2011 UNESCO's Historic Urban Landscape Recommendation, based on an inventory of the historic waterway landscape system in Yangzhou through a cultural mapping, analyzes the deterioration of the historic water reaches, related heritage sites and sense of places, proposes and discusses the ways of sustainable historic urban landscape regeneration to enhance the historic cultural significance.

Key words: World Heritage Grand Canal, City of Yangzhou, Historic Urban Water Landscape, Cultural Landscape Reconstruction

Introduction

The Historic Urban Landscape approach(2011 UNESCO) is an updated heritage management approach based on the recognition and identification of a layering of values present in any historic city and the need to integrate the different disciplines for the analysis and planning of the urban conservation process, in order not to separate it from the planning and development of the contemporary city – in other words, the HUL approach seeks to reconnect historic quarters with the new city, urban conservation with the planning and development process, and the different cultural traditions and socio-economic dynamics that are present in any contemporary city.

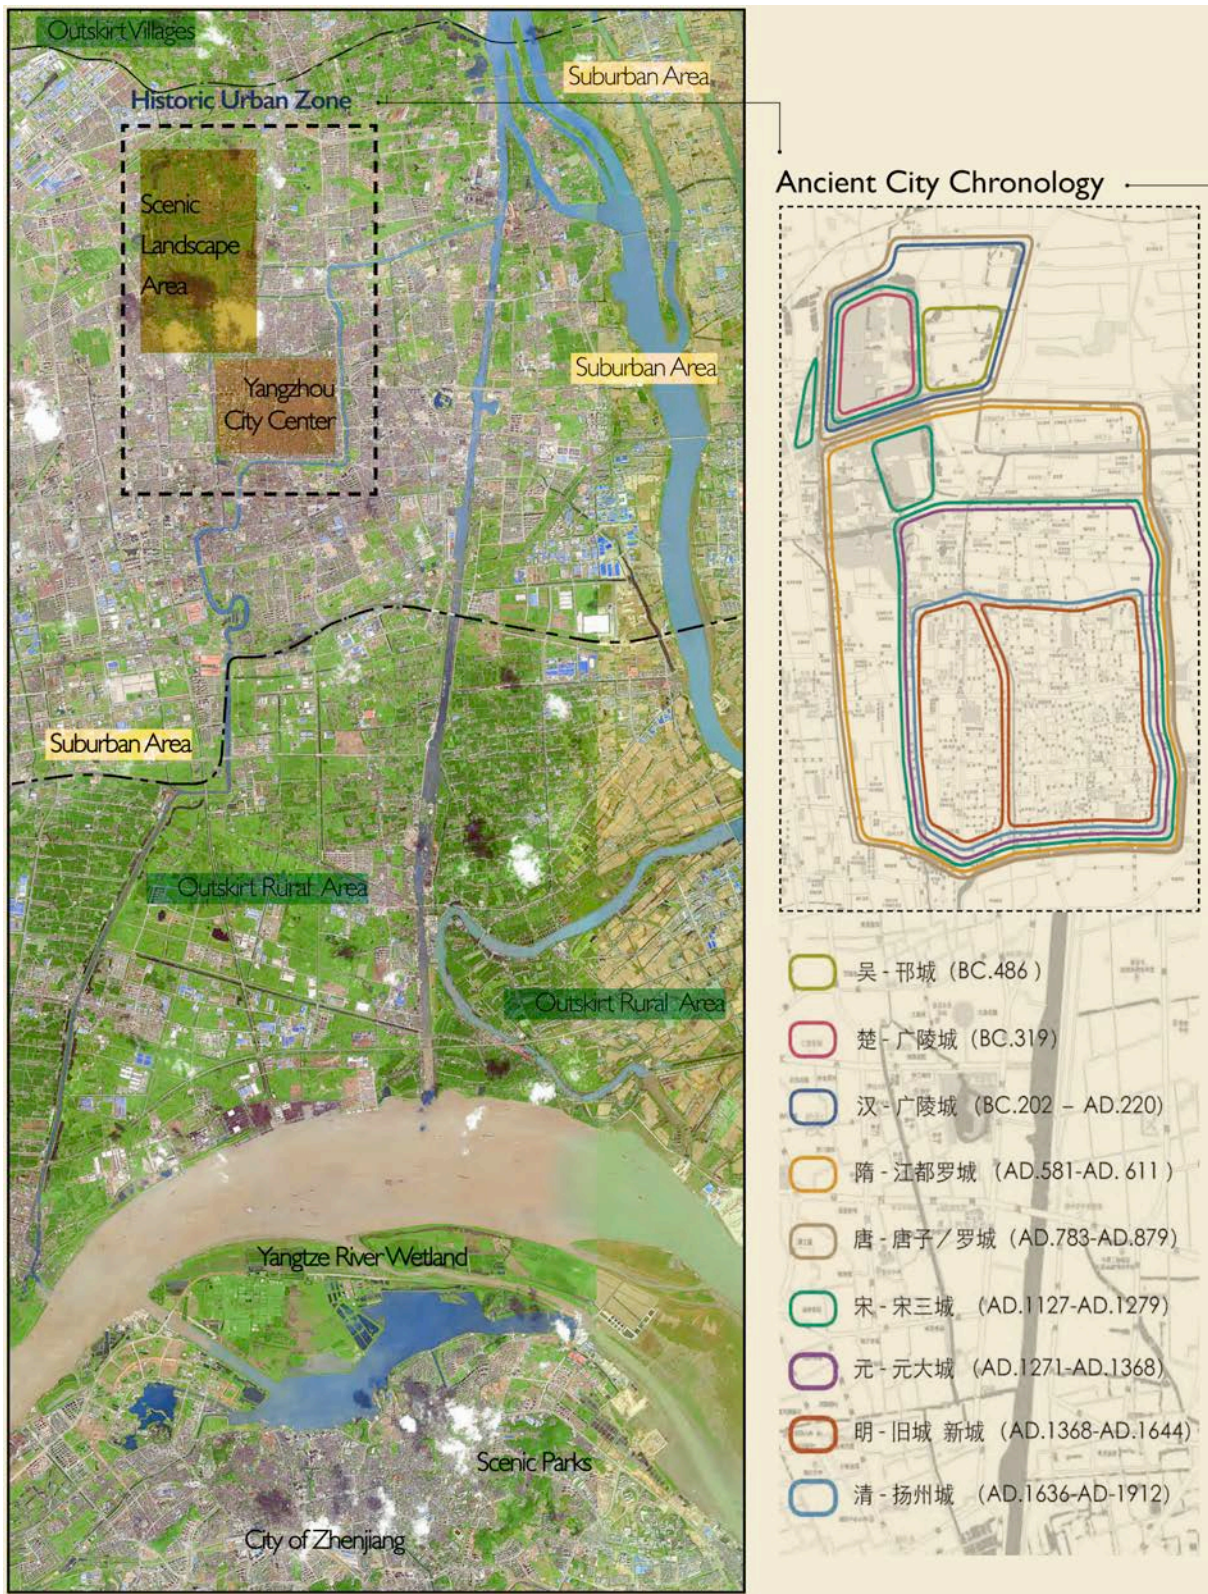

Figure 1. Satellite Image(2014 google map) of Yangzhou and Ancient City Chronology

In the case of Yangzhou, for more than 2500 years, the urban historic waterway systemⁱ grew from the old Canal has spread more than 22km² area of the historic city center (Fig.1), the evolution of which writes not only an epic textbook of the comprehensive history of the canal and the city, but also the domestic history of China as the Grand Canal evolution's cradle for thousands of years. In the nomination of Grand Canal World Heritage, Yangzhou play a critical role to lead the conservation of canal heritage as example for other cities along the Grand Canal. However, the authenticity and integrity problem became a debate in the sense of holistic historic urban landscape conservation under the evolving context of urbanization in China.

Figure 2: Throat Location of Yangzhou with Yangtze River and Grand Canal

In the research, comprehensive cultural mapping was organized to examine the deterioration of the historic waterway system in Yangzhou shows that nearly 70% related historical evidence has been lost. Online and offline questionnaire survey to understand how citizens concern about the related knowledge and memory, the result is not positive neither that the existing condition of the water landscapes on most of the water branches could hardly present their genuine historic sense. Regardless of the impacts of wars and urban renewal during the recent 100 years, from the perspective of cultural landscape theory, urban landscape is evolving rather than “conscious stained”, which means the value under different age would be diverse and follow their own way of mechanism. Thus the question leads to what is the value of the historic water landscape of Yangzhou should be cherished in this contemporary age and pass on to next generation.

1. Evolution Mechanism of Yangzhou Canal Landscape

For 2500 years, the Yangzhou waterway grew from a single old canal (古邗沟) to a holistic waterway network that run through the center of the city. Over time the function of the waterway system shifts back and forth from canal to city defensive moats, water supply infrastructure to urban scenic landscape, or multiple concurrent functions. From 487.B.C to 1912.A.D, the City of Yangzhou experienced 16 dynasties, and 4 periods of time, witnessed the epic history of its war and peace, glory then destitution. The waterway landscape was like the soul of the city, described in poems of Tang Dynasty as “a city full of mist and fantasy”.

Based on cultural landscape theories, the research reviewed the co-evolution process of the natural environment and human society, as well as the cultural dynamics in between that generated this cultural landscape.

1.1 The Natural Context of the City

There are two great component parts of the natural setting of the city Yangzhou, one is Yangtze River that formed the hydrological canal pattern; the other is Shugang Hill forming the geographic base for the settlement pattern. Over the last 100 years, the hydrological connection with Yangtze River continued to evolve; as well several significant conservancy projects were undertaken to enhance the connection. In contrast, although the built-environment of Yangzhou has changed significantly during the contemporary era of urbanization, the topographic pattern of Shugang Hill and the alluvial plain below remain; particularly because Shugang Hill has been a historical Buddhist place thus protecting the massif (Fig.3ⁱⁱ). The Yangzhou Shanshui context (山水文脉) suggests “the city ought to be located on axis with Shugang Hill and maintain the livelihood with canals”ⁱⁱⁱ.

Figure 3: The Natural Shanshui Context and the manufacture waterway system

1.2 The Evolution of The Canal Route

From Spring and Autumn Period to Tang Dynasty(700BC-894AD), Yangtze River shoreline and estuary coastline kept moving to the south-east, had a decisive influence on the expansion of the city territory, most important, caused the route extension of the Grand Canal to reach the Yangtze River. Generally, the Canal Route change over 5 period of time: 1. The starting point of the original old canal Hangou(邗沟 486-457BC) along with Hancheng Fortress on the Shugang Hill, mainly for military use; 2. The Han Dynasty (汉, 202BC-220AD), Hangou extend to the south to reach the moving Yangtze River Coastline, also grew a branch as Salt Canal run all the way to the east sea; 3. Sui Dynasty(隋, 581-618), based on the Old Canal of Yangzhou, the Grand Canal Project was Launched by the Emperor of Sui Yang Di(569–618) linking Beijing and Hangzhou, and became a strong domestic transportation route. Yangzhou grow to a very critical crossroad position of Yangtze River and Grand Canal;

4. Tan Dynasty (唐, 783-879) to Qing Dynasty(清, 1636-1912), the Grand Canal route moved out of the city along the east wall and moat in mid-Tang ,and last until the end of Qing.

From the perspective of society, the economic linkage with the Yangtze River formed by Grand Canal has always been the essential evolving dynamic of the city. Knots of the Canal always consist of religious spot with pier, market and bazaar, as well as institutions governing water transportation of salt and other goods. When the canal route goes across the city, the knots became the city center, outside the city wall and in the suburb they activate the growth of small market towns.

1.3 The Historic Waterway Landscape System Activate by the Canal

The Canal brought prosperity and culture exchange to Yangzhou, so-called a city on boat as Venice. Inspired by a map of Ming Dynasty (Fig.5), a certain sense the vitality of the city is illustrated from the interaction between human society and the waterway network. Six categories of historic water landscapes formed by culture engine has been identified:

- A. Shipping and Trading Canal Landscape, inside and outside the city – formed by Canal Economic
- B. Ancient City Wall and Moats Landscape – formed by City Defensive Infrastructure
- C. Slender West Lake Water Gardens And Urban Scenic Water Landscape – formed by Religious and Elite Culture
- D. Water Streets within the City – formed by Water Transportation Route and Pier Markets/Bazaars
- E. Rural Water-field Landscape on moat in the countryside – formed by Agriculture and Rural Life

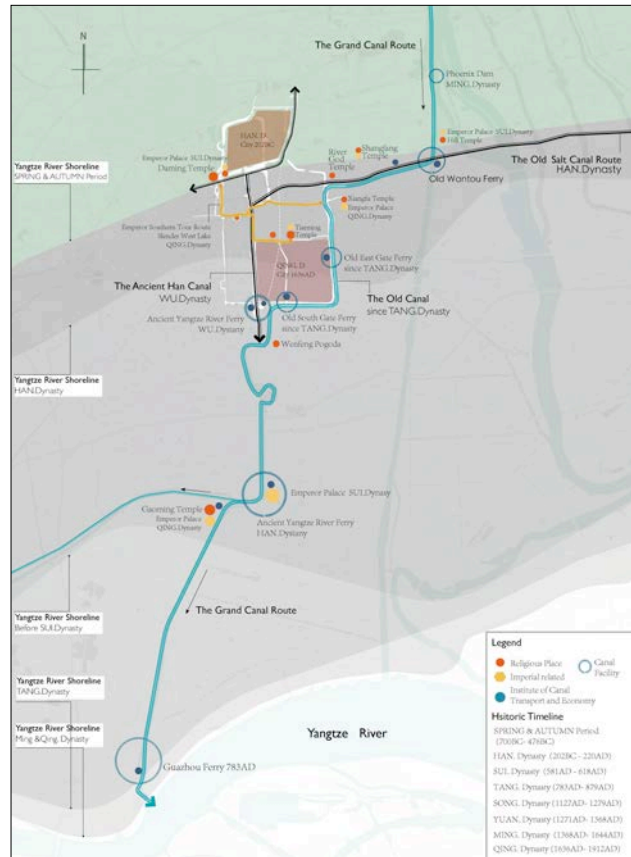

Figure 4: The Evolution of Canal Route 487BC-1912AD

Figure 5: Map of Yangzhou, Ming Dynasty(1573-1620)

F. Waterfront Performing Landscape (intangible) – formed by Elite and Folk Entertainment

These landscape categories are considered to represent and integrate the whole Yangzhou Historic Waterway Landscape System, unveiled the dramatic changing dynamic of waterway network through the history. Vice versa, these landscape provide habitat for diverse city culture, including Canal Economic Culture, Elite Culture, Imperial Culture, Religious Culture, Ancient Military Culture, and Water-town Folk Culture, etc. Together they drew a fantastic realm of ideal living environment combine North and South Chinese Shanshui City in the ancient time.

2. The Deterioration of Historic Landscape and Memory in Yangzhou

After a whole century, however, such historical meanings are blurred and being forgotten in visionary scenery today. What is worrying is not only the loss of essence landscape destroyed in historical wars, but also the historical confidence. Once a historical city lost its most precious confidence, it lost its way for future. At this moment, Yangzhou has such worries. During today's rapid urbanization process, Yangzhou is keen to find its location in regional and national level, trying to get back its historical position, but has not found its way yet. Although new city Yangzhou is developing very fast, the land context, water context and human context are not continuing. The value system is not interpreted and not fully understood.

2.1 The Information System of Landscape Value Carriers

To address the loss of numerous aspects of the heritage of canal waterway landscape over the last century, as well as to identify the landscape heritage value, comprehensive mapping needs to be undertaken. Based on the landscape categories derived from the evolution process of Grand Canal, an integral historic landscape information system is built up, including the landscape value carriers from natural to cultural, tangible to intangible elements (Chart.1). This system includes more carriers than the existing heritage listed in the local government administration and would be a breakthrough for conservation of a range of

I-地形地貌 Topography	I-A 蜀冈地形地貌 Shugang Hills	I-B 冈下古城地形地貌 Alluvial Plain	I-C 水系与地貌关联节点 Cultural related nodes
II-水系河道 Waterways	II-A 水系历史断代及基础功能 Historic Waterways	II-B 运河经济相关载体 Canal Economic landscape	II-C 城濠及相关载体 City Wall and Moat Landscape
III-重点历史水系景观段 Significant Landscapes	III-A 蜀冈山水类 Shanshui Scenic Landscape	III-B 寺院庭苑类 Riverside Temples and Yards	III-C 瘦西湖水上园林类 Slender West Lake Riverside Water Gardens
	III-D 水路街市类 Water Street Landscape	III-E 花洞村舍类 Rural Moat Water Field and Village	III-F 滨水演艺类 Waterfront Performing Art Landscape

historic urban landscapes, thus including more opportunities for renaissance of more value carriers that have been previously neglected or destroyed.

2.2 Mapping the Lost of Canal Landscape Historic Evidence

The illustration process including historical information mapping and existing historic place mapping, the comparison in-between shows clearly what kind and how much of the history evidence had been lost and where we lost them. In the history, there were 14 reaches of the waterway network used to be canals, 3 of them were filled and became roads around 60s. Waterway transportation function has been stopped for the past century, only tourist boats occupied the Qing's imperial waterway route from the city center to the Slender West Lake. Canal related historic landscape elements recorded in historic documents including 57 bridges and pier infrastructures, 12 market streets, 2 market towns, 17 religious and culture spots. But the existing condition is disappointing, that only 17 elements left with physical evidence, that's a lost more than 80%. It is clearly illustrated in the mapping between historic information and existing evidence(Fig.6, Fig.7) that the canal waterway structure still exists, but the cultural lineage used to connect the city and the canal through urban spaces has left just blank.

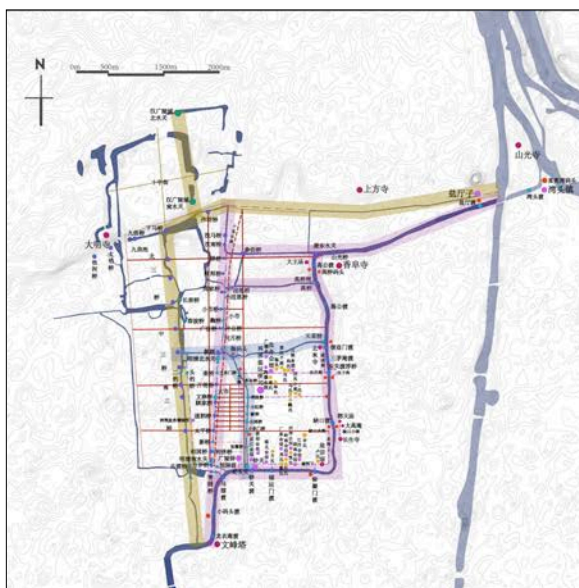

Figure.6 Canal Landscape-Historical Info

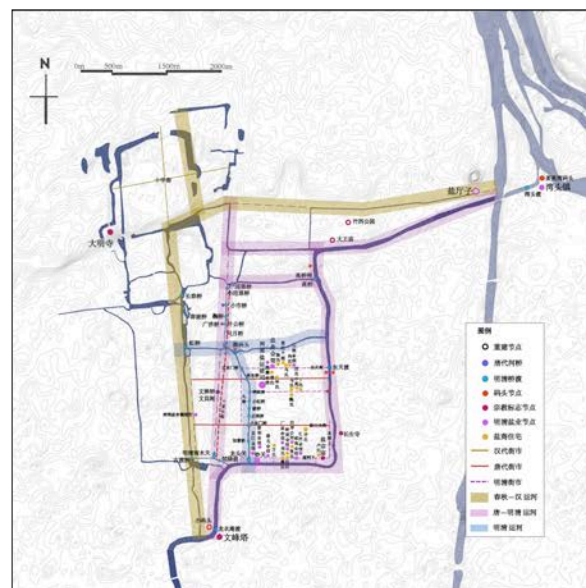

Figure.7 Canal Landscape- Existing Info

2.3 The Social Process of Canal Heritage Damage

The cultural mapping formed a prototype of historic landscape information framework, which recorded the history and the existing condition of urban heritages as well as intangible knowledge and memory of the city. Yangzhou once was famed as the 'City on Boats'. From the canal port to city center, then to the suburb and rural areas, the waterway was the most

convenient transportation system to explore one's way of living, resulting in prosperous economic and cultural activities. During the past century, roads and cars have replaced the waterway transportation mode, nevertheless the water conservancy system hasn't been functioning as a whole and enhanced its efficiency until the last decades.

After 1912, rivers and moats in the Yangzhou region had been continuously narrowed and silt to the extent that the total area had been halved, yet only remained the pattern of the space network. After 1949, the city walls were knocked down and many waterways were filled to be roads, numerous historic bridges were removed at the same time. Later during the 60s Cultural Revolution, lots of temples by the canal piers were destroyed, together with other significant cultural buildings and celebrity gardens. Since 1978, a series of urbanization planning and regulation projects of river and canal have been undertaken, thus erasing much of the historic imprints of the waterway landscape. Although the Slender West Lake water gardens were restored later, according to our authenticity research of landscape character and interview result (200 samples), the historic sense of most waterway landscapes is excessively low; except for 4 reaches out of 13 were seen as fair.

3. Strong Public Expectation and Local Government Response

Despite the different time age and places around the world, there are always commonalities in history that local expectation for reconstruct traditional culture after damages would be extremely strong. Of course, efforts has been taken during recent decades, and showed on the satellite image clearly that the historic waterway network runs throughout the urban and suburban areas again resulting in a tremendous and unique urban form. In our research in 2013-2014, online and offline questionnaire survey of more than 200 samples was organized to understand how citizens concern the related knowledge and memory about Yangzhou's historic waterway landscape. On the other hand, the research reviewed the local planning and regulation tools referring to the future of canal heritage.

3.1 The Public Expectation of Canal Heritage

First, the survey examined the familiar extent between Canal Culture and Canal Heritage places, the result shows ironically that people taken the questionnaire knows Canal Culture as a general concept of Yangzhou's city culture, without knowing the most important Canal knots in the history. Second, compare to Slender West Lake, very few people chose to go to landscape places along the Canal, despite its important heritage value. It

Figure 8. Cross-over cognition analysis of Canal Heritage Value and Historic Knots

despite its important heritage value. It

was gratifying to be in the know among all the expectation for canal heritage, history and culture display get 87% the highest response, and not very fond of reviving active functions such as transportation, activities and commercial spots. Half of the respondents expect for the Canal landscape regeneration.

3.2 The Local Response and Government Planning

In fact, during the past a few years, the Old Canal has already been restored and regenerated several times but fell into the dilemma that the sense of the historic places has totally lost. Essentially the blank needs to be relink with good design that help to seek the spirit of the place back. There are some business projects

along the waterways combine historic elements into new designs have made some progress on

connecting the sense of history that remind us that instead of moaning for the lost of the history, the blank could also be opportunity for creativity.

Based on the experience of the urban development in the recent decades, and thanks for the application process of World Heritage. The government of Yangzhou has realized the importance of a coherent relationship between the historic waterway network and urban renewal opportunity. In the latest City Comprehensive Planning (2012-2020), proposals related to the management and planning of the historic waterways in three planning sections : Water System Planning, Green Space System Planning and Historic City Conservation Planning. The City Plan clearly recognizes that multiple functions of the canal waterway landscape are integrated together, suggesting the dynamic of the land use pattern is going to continue in the future planning.

4. Reconnect the City with Canal Cultural Routes

As history and culture accumulate on the Grand Canal, the research pointed out primarily that the Canal Heritage is a System including natural setting and culture landscape elements , historic evidence and cultural memory imbedded in the city rather than a single waterway. In the case of Yangzhou, historic Canal landscape has lost so much both physical and spiritually, it is undeniable that a renovation needs to inject to the city. Hence the weakness might become a challenge and also opportunity of Yangzhou. Inspired by the HUL Recommendation on creativity of heritage place, four representative cultural routes that can

Figure 9. Yangzhou City Comprehensive Planning - Historic City Conservation Plan(2012-2020)

be illustrated through urban spaces to interpret different stories about Yangzhou as a Canal City. 1) The moats on the Shugang Hill represent the city and canal-moat format before the end of Han Dynasty (486BC-457AD), called Guangling town at that time, and reached the remarkable city defensive infrastructure system in Song Dynasty half century later. 2) The waterways from the foot of Shugang Hill run through Slender West Lake all the way to the Old South City Gate represent the highest level of urban scenic landscape sequence in the history transformed from canal and moats. 3)

On the east side of the city, the Old Canal represents the most prosperous canal economic corridor since Tang Dynasty. 4) In the city center, the water streets, small piers and markets represent the land use pattern and daily life style formed by waterway networks that continually existed in this city.

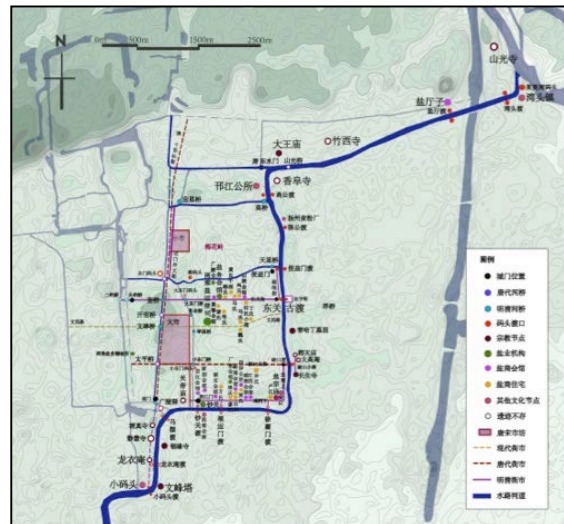

Figure 10. Canal Landscape Culture Route

Conclusion

The proposal of cultural route try to refill the gap caused by the lost of tangible and intangible urban culture heritage, reconnect the city urban space with its deep history essence. Primarily, all the lost sites of the Canal Heritage System should be relocate in the urban space, information display is necessary to response to the heritage site. If allowed, virtual 3D guide would help greatly to interpret the value and tell the story. At the site of critical importance, landscape regeneration should be carefully designed, help to find the historic character of the site and the spirit of Canal landscape. In the future, mobile technology will became more and more advance for heritage information display and guidance, the cultural route have the potential to became a platform for the voice of citizens as “users” to actually activate the historic urban landscape in a democratic way.

Center Redevelopment of Productive City Based on System Coupling and Function Optimization

Jianqiang YANG, Southeast University, China

Abstract: City center redevelopment is one of the important subjects of current urban development at a time of unprecedented global urbanization. This paper analyzes the situation and existent problems of China's city center redevelopment, and makes suggestions on how to improve city center redevelopment in the aspects of basic theories, technology, methods, evaluation and planning formulation and so on. It select Changzhou as an example to introduce in detail the overall urban strategies in practice, summarizes the significance of holistic urban strategies. All of the results will improve the theoretical system of city center redevelopment, strong the scientific, technical and operational of planning, and promote a comprehensive and sustainable development for the renewal of old city center area.

Keywords: center redevelopment, global urbanization, system coupling, function optimization, Changzhou

1. Introduction and background

(1) Seeing from the macro background of city development, Chinese urban development has entered the middle and the late stages of urbanization characterized by rapid development and structural adjustment. The newly published *National New Urbanization Plan (2014-2020)* indicates that in contemporary China, "urbanization shall enter the new stage of transformational development that focuses on enhancing the quality", it also puts forward the standpoint to optimize the internal space structure of the city to cater to the requirement in compact development of the city.

(2) Seeing from the city industrial structure upgrade, city social economy has entered into the real implementation stage of reconstructing and transforming the industrial layout, type and structure. With the upgrade of industrial structure and evolution of the social formation, the services industry especially productive service industry will become the important factor that determines functions and status of city in the regional urban system. As the most brisk and concentrated area in city service industry, city center will play an important role in the transformation of urban industrial structure.

(3) Seeing from the development of the urban center, in the planned economy period, at the influence of the city development policies of so called "first production, then living" and "turning consuming city into productive city", Chinese city center shows complex mixture of industry, living, enterprise and facility land usage, development of economic core functions of the center district is seriously restricted. With the apparent change in the economic structure and profound revolution in society in all aspects, there are requirements of higher level on the development of urban center.

2. Deficiencies in the redevelopment of city center

According to the investigation on the current conditions of Chinese city center, universal problems are mainly including:

(1) Blind target position and mode choice of center redevelopment, it is lack of correct judgment on developing stage of city.

(2) Limitations on independent section of land and individual commercial projects, insufficient emphasis on the structural adjustment and enhancement of entire functions of the center organization system.

(3) Current commercial level of the center district is universally low, unreasonable land allocation and low central intensity, it can't fully show the due land value of the center and satisfy the need of modern service industry.

(4) It is short of effective dimensional transportation organization and reasonable layout, congestion in the center district is serious.

(5) It lacks space for humanity activity and featured environment. The vitality in the center district is not enough and can't satisfy the requirement of multi-diversity and high quality of activities in the center.

With the great function changing, city center is never just to satisfy the need of city citizens in daily life and consumption. As the social, economic, cultural and information center of the city, it has more important functions on the development of the city. Therefore, we have to further discuss how to scientifically locate the functions of the old center and combine the center district into the macro adjustment of city industrial structure and development of modern service industry based on the complicated system of the city and on the macro background of Chinese economic development. And meanwhile, we will study how to realize the cooperative coupling of the internal organization system and optimization of the functional structure with the help of the center redevelopment.

3. Important issues needed to study in the center redevelopment

3.1 Analysis of the internal structure and system evolution mechanism of the old center

It has to analyze the inner law of the evolution of the functions of city center in different development stages of urbanization, suburbanization, counter-urbanization and reurbanization, and it has to especially analyze and study the essential meaning of new phenomena such as "multi-centralization", "networking", "decentralization" and "recentralization", and the influences brought by these tendencies on the old center district. More importantly, based on national conditions of China, it will analyze and summarize the industrial structure, district activities, functional structure, space formation and alternating rules of change of internal organization in the old center district, through tracking and investigation on the current social economic development and space environmental conditions in the recession and transformation of the old center.

3.2 Judgements on the internal structural features and actual conditions of the old center

Internal structure of the city is the dissipative system made up by sub systems of functions, land usage, space and transportation, it is the complicated system formed by the interrelation and interactions of its material space and social economic internet. Firstly, we should surpass the usual method of explanation and descriptions on factors of center city scale, center grade and land usage in the past ; Secondly, on the basis of four fundamental factors of functions, industry, activities and environment, we have qualitative and quantitative description on land allocation, structural features, coupling degree, transportation development level, and land usage concentration and so on; In the end, we can objectively master the internal function change and real status of the urban center.

3.3 Study on the important problems for the center redevelopment planning

In the city construction practice, upgrading and redevelopment of the old center district is one long and complicated system project, which has to be carried out with sequential procedures under the general guidance of the city planning. It needs to choose the typical case study of the redevelopment of the different types of urban center districts. Based on the internal system coupling and enhancement of the entire functions of the city center, we will study

some important issue such as the structural adjustment and functional adjustment, interaction of the new district and old district, structure optimization of the land layout, center land concentration usage, environment capacity control and road transportation system adjustment and optimization and so on. Therefore, it let us to explore to realize effective planning means and comprehensive redevelopment mode.

4. Empirical Research ----taking the old center of Changzhou as an example

4.1 Brief introduction

Changzhou is one of the districts developed at the earliest time in the Yangtze River Delta. It is also one famous economic and cultural city with long history. In the history, Changzhou city was prospered by the canal. The construction of road and railway between Shanghai and Nanjing in contemporary age made Changzhou as one important middle joint between two regional center city of Shanghai and Nanjing. Now Changzhou is the central city, modernized industrial and historical cultural city in Yangtze River Delta of China. (Figure 1)

Figure 1: Aerial view of the central area of Changzhou

Old city district of Changzhou has long been the focus of city development construction and gathering district of the center functions. It is the area that gathers comprehensive elements of history, culture, commercial finance, public services and living of the entire city. In recent years, under the background of the quick urbanization, due to the lack of comprehensive and effective policy guidance, problems such as traffic congestion, environmental degradation, industry homogeneity, and features fading have been serious more and more. Therefore, how to evaluate the internal structure? And how to determine rationally the function? And how to transform central function? And how to regenerate land resources? And how to optimize the function and structure? All of these will have significant realistic meaning for the sustainable development of the old center district.

4.2 The evolution of the spatial form of Changzhou (Figure 2)

4.2.1 City space expansion propelled by the national industrial development in modern times (1910s-1940s)

Changzhou has been an important industrial and commercial city before the POC (the Public of China) era. During this period, urban industry and commerce aggregated in the riparian area. In the POC era, national industry boomed and affected Changzhou. Relying on the Grand Canal and Jing-Hu railway line, the industry and commerce of Changzhou made further development. Industries sprawled along the river and the other functions like retail, office formed gradually in the area surrounded by rivers. By this time, the urban form has established.

4.2.2 City space expansion propelled by the industrial development in priority in the planned economy age (1950s-1970s)

In the planned economy era, the city was under the guidance of the policy of first production and later living, the development of industry was the primary content of urban construction for the principle, and the sprawl of industrial lands became the main feature of city shape development. Relying on the canal and railway, industrial lands expanded from old city to west and east along the river and rail. Moreover, new communal faculties were built in old city with the way of making use of every bit of space.

4.2.3 City space expansion propelled by the mixed development of industry and service industry in the initial stage of the reform and opening-up policy (1980s-1990s)

Since the reform and open, the city area had continued to expand on the east and west along river and rail. Meanwhile, new built-up areas were appearing on the south and north of city. Industrial areas extended on the east, west and south supported by the convenient traffic conditions and infrastructure, and formed the development pattern along the transport gallery.

4.2.4 City space reconstruction propelled by the industry transfer and structural adjustment (1990s-now)

After the 1990s, with the city sprawling continuously, the urban shape transformed from diamond to cross, and the north and the south become the main expanding direction. With zoning adjustment implemented, the industry was gradually removed from the inner city to five industrial zones located in suburbs, according to the policy with suppress the second industry and develop the third industry. Meanwhile, central business sprung up and prompted the concentration of service industries. On the change of spatial structure, urban shape has transformed from single core to multi-core with one center and two sub-centers.

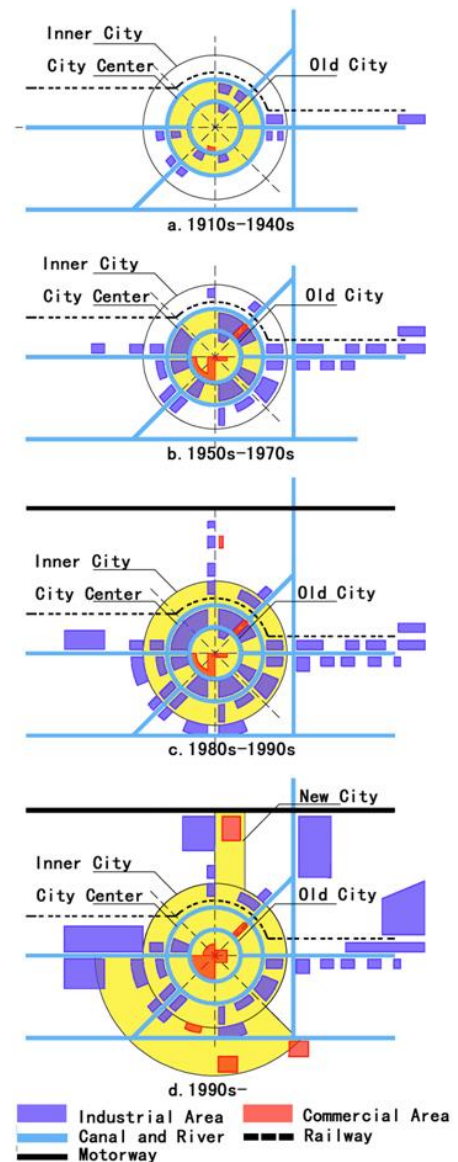

Figure 2: The space evolution of the main city of Changzhou

4.3 Realistic background of the transformation of the functions

4.3.1 It is gradually entering into the middle and late phase of industrialization

Changzhou city is in the middle and late phase of industrialization, the adjustment tendency of the industrial structure is mainly switching from the labor intensive industry to capital intensive and technology intensive industry, while in the industrial layout, it will advance into the direction of large scale and clustering development. Correspondingly, it requires the development of matching industries directly related to the manufacturing industry in the third industry to meet the requirement of manufacturing upgrade and expansion, traditional service industry will have much increase in the scale and level.

4.3.2 Profound influence brought by the economic globalization

With the wide influence and deepening of the economic globalization in the world, Yangtze River Delta in China and its great advantages in location, industrial base, system environment and advanced culture have tightly held the pulses of the world economy and become the regional economical block of China that firstly docks with the world economy. The developing tendency of world economy globalization has made one networking city system, the flow of production elements such as capital, energy, information and technology

has broken the limit of the radiation system with the shape of traditional closed layer. Changzhou belongs to the influential scope in the radius of 300KM pan-Shanghai urban circle, as the important city in Suzhou-Wuxi-Changzhou city group, its overall development has already integrated into the regional economic system and city system of Yangtze River Delta that has the core of Shanghai. This means Changzhou has much self-development space and many chances except powerful organizational functions in the core cities of regions like Shanghai and Nanjing. (Figure 3)

4.4 Current situations and problems of space structure of the old center

4.4.1 Land usage structure

(1) Insufficient development space of the functions in the center

We can find when comparing Changzhou with main big cities in China, development of business land in the center district of Changzhou is relatively low in the total volume as far as the own economic scale of the city is concerned. Also it is mainly the business retailing, and corresponding business service functions have low proportion. Besides, the old city now has small land area for development, those land are scattered and hard to develop in concentration. This is not good for the formation of concentrated business functions in large scale.

(2) Low concentration of land usage

Total land usage of industry within the old center district is about 9.86 km², taking up 12.75% of the total area of the center district. The old industrial district has problems of scattered layout, much pollution, and inconformity with the city function, low location effects and dilemma in the self-development of the company. Total area of the old residential district is about 4.71 km², taking up 6.3% of the total area, it has shortages of scattered layout, aging building, insufficient infrastructure, aging population and deficiency in the community management. In addition, in the old center, there are in total 56 administrative villages and 429 natural villages with the area of 114000 km², taking up 15% of the total area. It has problems of scattered layout, poor environment, low-income for the residents and difficulty in managing residents. (Figure 4)

(3) Land adjustment can hardly adapt to the development.

After the implementation of policy, suppress the second industry and develop the third industry, the industry located in city center and surrounding area were moved out on a large scale. According to statistics, there were 371ha industrial land replaced to another functions, of which the proportion of new land supply sorted by scale are residential, commercial-resident, green land, commercial-office, commercial-resident-living, commercial, transport, middle and primary school, municipal facilities. Since the development of tertiary industry is not sufficient, most of lands replaced were used to build houses affected by short-term benefits and didn't transform as the plan of industrial restructure.

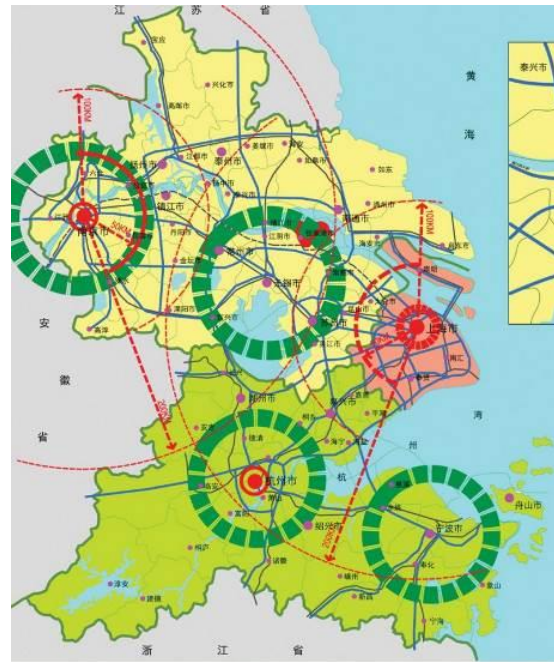

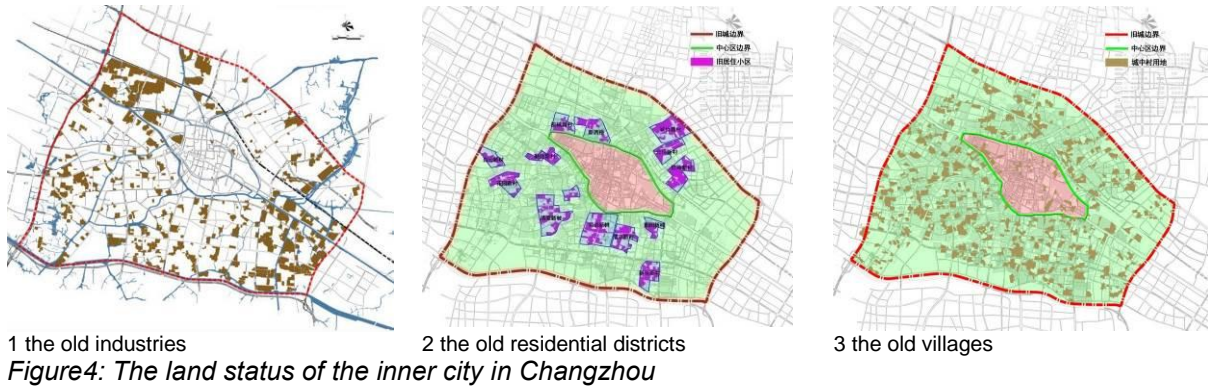

Figure 3: Yangtze River Delta

4.4.2 Road traffic system

(1) Multi barriers in the connections between districts

Now the connection between the center district and other external districts is mainly depending on the main road, the sub roads and branch roads have low connection, at the influence of natural waterways, park and railway, center district has the universal density of lower than 1km/ km² in the main road of passing railway and waterways. There are many barriers in the transportation between the center district and external district.

(2) Low density of the internal road network

The branch road network in the center district has obviously low density, it is just 2.56km/ km². The shortage of branch roads is neither good for the effective organization and evacuation of the road transportation flow nor for the expansion and coverage of the public route network. Thus the road net transportation flow space is unevenly distributed, the transportation flow mainly gathers in the main road. In the static transportation, the center district lacks of parking space and has unreasonable distribution. (Figure 5)

Figure 5: The traffic status of the inner city in Changzhou

(3) Insufficient evacuation ability of the surrounding road for the external transportation facilities

Changzhou railway station, bus station and other external transport facilities are concentrated in the central area, which is good for the external connection of city center. However, due to road network surrounding the external transport facilities insufficient, which leads to only several main roads surrounding these facilities undertake the traffic pressure and causes traffic congestion.

4.4.3 Population distribution structure

The growth rate of the population of the old city in recent years is lower than the entire city and areas outside the inner city. The average growth rate of the population in the inner city in the recent three years is -0.69%, while in other areas, the average growth rate of population is 0.89%. The overall population density of the old city is 9000 people/ km², the distribution of residents is uneven, the population density in the center district is 18000 people/ km², but the population density outside the center district is mostly 1000-5000 people/ km², it is because of the existence of numerous villages in the areas outside the center district and insufficient land development to a greater extent.

4.4.4 Intensity of development and usage

According to the analysis, land development in the inner city of Changzhou has apparently showed circular distribution in the scope of 1-4Km away from the center, it is showing the gradually decreasing tendency from the center district. In the first circle, there is much intensity of development for the main business development sections; in the second and third circle, intensity of development for canal in the west and east of the center and stream of the Guan River is evidently lower than that in the land which is outside the canal and in the

direction of north-south. In the development of the most external circle, land usage appears evident inconsecutive conditions and much of enclave field come up. (Figure 6)

Figure 6 The analysis for spatial height of the centre in Changzhou

4.5 Planning strategy of the redevelopment of the old center

4.5.1 Reinforcement and enhancement of the central functions

The enhancement of the industrial structure is the inner impetus of the transformation adjustment of Changzhou center district. For the large scale city with more comprehensive functions, with the change of city industrial structure, its factors that maintain the attraction of the city are gradually turning from industry to the service industry, the city space will then switch from the space structure that mainly adapts to the industry to the space structure that mainly adapts to the service industry. Facing the demand for upgrading of producer services, with the completion of inter-city rail and Beijing-Shanghai high speed rail providing chances for the development of high-level producer service, the plan encourages the development of business services, retail trade, and upgrades the service level and environment of commercial retail.

4.5.2 Development interaction of new and old city district

We can come to below conclusion through the analysis of the current and tendency on the basis of the internal law and external conditions of the city development: development in single direction or the simple choice on any two directions will bring a series of problems and contradictions, it will also disobey the idea of compact development and symbiotic ecosystem. Henceforth, in the adjustment of the space structure, new city or the external area of the urban center shall have interaction with the old center in new joints or constructions of joints to absorb and develop the spillover function of the old city. The old center district will lessen the pressure of the old city in space, environment and facilities through scattering population and employment, it connects to the high level manufacturing and service industry in the functions with the main focus of business office, trading leisure, cultural travel, life logistics, conversion of passenger transportation and city manufacturing. The new city in the north mainly bears the functions of administration, living, exhibition and industry distributed from the old city. The city in the south mainly takes over the functions of residence, industry and education distributed from the old city. Group of east and west of the city mainly takes over the transferred industrial functions from the old city. (Figure 7)

Figure 7: Interaction between old city and new city

Figure 8 The improvement of the branch network of the inner city

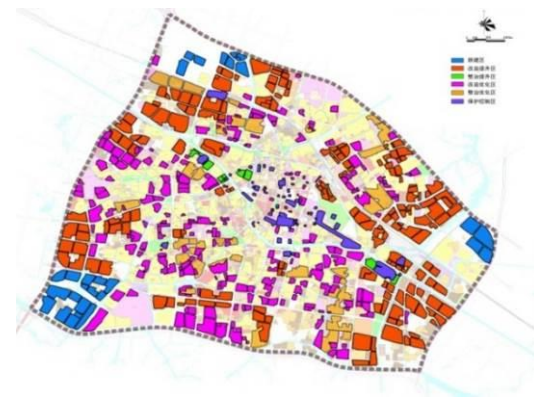

Figure 9: The redevelopment land layout map of the inner city

4.5.3 Adjustment and optimization of the transportation system

Since there are problems of many transportation barriers, much influence of through-traffic, insufficient sub-road systems, immense interference of transport distribution in current traffic situations in the center district, the upgrading and transformation of the transportation system shall develop towards the direction of public transportation and going on foot. First of all, break the barriers to the external transportation and enhance the connection between center district with outside; Second, increase passing railways and waterways, construct and improve existing road network system; Thirdly, reinforce the outer connecting ability of the center district to the secondary road and branch roads, and lower the transportation pressure in the main roads; Fourth, the improvement of non-motorized traffic network should optimize the walk conditions of existing roads, construct the public traffic including walk system and create a pleasant walking space so that promoting and guiding people to shift to non-motorized transport mode. (Figure 8)

4.5.4 Choice and definition of the upgrading mode

According to the six factors, which are the development location of the inner city, the distribution of update dynamic points and large-scale transportation facilities, the guidance of public space, the assessment of building quality and the analysis of renewable areas, the plan delimits the inner city as protection and controlled zone, remediation and optimization zone, transformation and optimization zone, remediation and upgrade zone, transformation and upgrade zone (Figure 9). In the old city, the regeneration should choose protection as the main pattern. In the central area, the regeneration should be implemented based on the principle of remediation and optimization. In the outside of the central area, it should be based on transformation and optimization. In the regeneration of the inner city, the planning and guidance mode should various, flexibility and enhance the operability of renovation and implementation, so that adapting the transformation of function and space.

5. Conclusion

Chinese city development has entered into the middle and late phase of the urbanization with the features of interrelation and interaction of fast development and structural adjustment. As the public service facility and the concentrated area of the city, city center district will necessarily actively function in the city development through system coupling and function enhancement.

In the transformation of the center district, relations among the elements in the city are not single directional, which is the result of the comprehensive function of many factors such as city industry, space, transportation, activity and environment in different directions.

Redevelopment of the old center district of Changzhou reflects the general law of the development of center district in middle and late phase of urbanization in China in some

certain degree. The empirical research is targeting on problems of industry homogeneity, low land usage efficiency, traffic congestion and decrease of environmental quality. On the basis of objectively grasping the rules of the function evolution of the old center district and comprehensively evaluating the actual conditions of the old center district, it proposes to actively conduct the general space strategy of function enhancement, interaction between new and old district, optimization of the structure, land concentrated usage and adjustment of road traffic system, which is no doubt of great significance on realizing the sustainable development of the old center district.

1. Introduction

In the context of China's rapid urbanization, expansion has become a situation almost every Chinese city is facing. During the process of urban expansion, the new urban form is becoming more and more different from the existing, because of economic increase, population growth and policies by authoritarian governments (Whitehand, 2011) which is distinctive in China. Chinese traditional cities have usually presented a characteristic of horizontal growth, in consequence of fine urban texture and suitable dimension for people; however, due to the pursuit of big development quantity and novel form, newly-built cities become more and more huge and lost of human dimensions. When these two different urban texture and dimension collage discordant, conflict emerged, which is especially obvious in urban fringe belts.

The concept of urban fringe belt could be retroactive to the geography study on urban form in 19th century, first proposed by German geographer Herbert Louis. Then M.K.G.conzen, who is most responsible for its development, made it an important part of urban morphology research. In western countries, the growth of cities is frequently the result of the development of the market economy, so the urban planning is closely related to the development of the economy. In this situation, the growth of city is a slow process, during which, the fringe belts will be retained, and showing a similar ring structure, such as Louis' research in Berlin and Conzen's research in Alnwick (Whitehand, 2007, Wang, 2011).

Meanwhile in China, the land use is influenced more by the planned economy (especially before the reform and opening up in China) and the government's intervention. In addition, the rapid growth of China's population has exerted huge pressure on the reconstruction of fringe belts. In most Chinese cities, fringe belt has not showed a ring structure, but was submerged in the rapid process of urbanization. During the large-scale reconstruction of fringe belts, different dimensions directly collide together, resulting in urban texture breakage. So, under the background of China's planning context, urban fringe belt is facing greater complexity and more contradictions. For China's urban designers and architects, the biggest problem is how to suture the broken urban texture with appropriate strategies in the changing fringe belts.

This paper is attempting to explore these issues from different levels based on an example of Expansion Project of the Second Middle School in Xuancheng, a small China southern traditional city. First in urban level, the study of the evolution of urban form shows the urban environment of the project and suggests that there has been increasing demand to develop these fringe belt plots, and then turns into building level, looking for design strategies facing different dimension and texture in fringe belts.

2. Planning Context

Xuancheng is a famous historical and cultural city in Anhui Province, with more than 1700 years of history since the city wall was built, and the old city has formed a very unique space form. At

the same time, Xuancheng is also an important economic hub connecting Anhui Province and Yangtze River Delta Urban Agglomerations. In this way, the development of Xuancheng is facing both the protection of traditional context and the growing challenges of the international dimension.

Relevant scholars has divided the evolution of the urban form of Xuancheng into four stages (Sun 2011), the first stage is from around AD 326 to 1939, during which Xuancheng has experienced the whole process from construction to demolition of the city wall. The rest of the other three stages are separated by 1987 and 1999, which are two important time nodes for the administrative divisions adjustment of Xuancheng, the former is update from county to county-level city, and the latter is to prefecture-level city. This classification does not follow the general classification of the political period, but concerns more about the space limit of the city wall and the urban expansion under the influence of different policies and economy.

In this classification, the definition of the first sage is relatively clear because of the city wall's important influence on city form. However, the division between stage II and stage III is arguable. Compare to the administrative divisions adjustment of Xuancheng in 1987, the impact of the reform and opening up in China in 1978 was much greater, because of the change from the planned economy to market economy, city development began to accelerate. Thus, this paper divides the evolution of Xuancheng urban form into following four stages:

2.1 Stage I (326-1939)

Natural topography plays a very important role in the origin of urban form. The initial location of Xuancheng was surrounded by rivers and mountains, with unique geographical conditions. Wanxi River flows through the east side of the city, and Jingting Mountain sets as the northwest background, which follows the traditional Chinese Fengshui Theory, fronting water and with hills on the back. The unique natural and geographical environment is not only the demand of people's living, but also the consistent with the requirements of the defense of the city at that time.

Recorded Xuancheng city wall was first built around AD 326, and rebuild in 964 for the defense from the north. Since then, the city developed within the walls and the fringe belt was in a steady state for about 1000 years (Figure 1, Figure 2). Until 1933, before Second Sino-Japanese War, to resist the Japanese occupation and using the walls as stronghold, the anti-Japanese soldiers and civilians dismantle all the walls twice, deployed more than 30000 people. Then, urban development has entered a new stage.

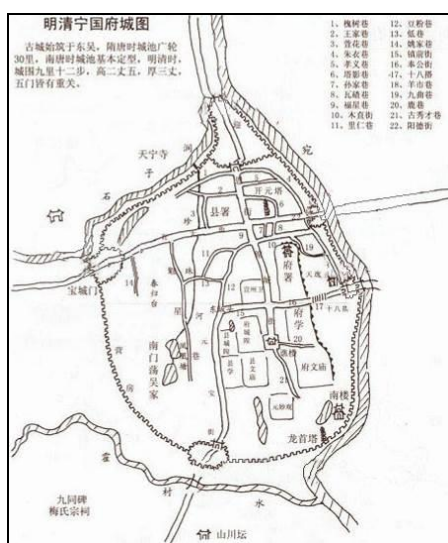

Figure 1: Ancient Map of Xuancheng, Qing Dynasty

Figure 2: Urban Form of Xuancheng, Stage I

2.2 Stage II (1939-1978)

In this stage, due to the demolition of the walls, urban space of Xuancheng began to expand along several major roads to the south, north and west parts, forming three main development axes. However, because of the destroy of the war and the Cultural Revolution, the city was under a turbulent social environment and the construction was focusing on building urban infrastructure, improving environment and so on. The expansion of urban space was limited, urban built-up area increased from 5 square kilometers in 1949 to 6.7 square kilometers in 1978 (Figure 3).

Besides, from 1949 to 1957, the social and economic system in China had a fundamental change. Under the guidance of the urban development policy of "changing consumption city to productive city", the city build the first industrial zone, which also marked the formation of the industrial zone in the west (Sun 2011).

Figure 3: Urban Form of Xuancheng, Stage II

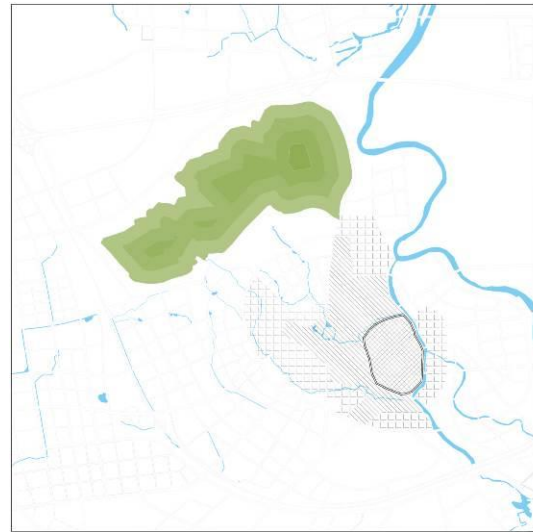

Figure 4: Urban Form of Xuancheng, Stage III

2.3 Stage III (1978-2000)

Since the reform and opening up, China has gradually realized the transition from planned economy to market economy. With the rapid economical development and the increase of population, the city form continued to expand. Between the original development axes, new urban land was constantly filled in. As of 1999, total urban built-up area increased to 16.7 square kilometers (Figure 4).

2.4 Stage IV (2000-)

After the Establishment of prefecture-level City, urban form of Xuancheng has been largely changed with the rapid development of traffic and economy. First, the construction of Shanghai-Chongqing Highway, which is passing through the south, has brought new opportunities to the city. However, it also has formed the new boundary of the main city, along with Jingting Mountain and Wanxi River. Secondly, the existing west industrial zone has expanded further, meanwhile, two more has been built in the north beyond Jingting Mountain and in the east crossing Wanxi River. Counting the southern part, which is going to be built as cultural and creative industry district on the basis of ecological protection, the overall structure of city is becoming "one main city with four areas" (Figure 5, Figure 6).

Figure 5: Urban Form of Xuancheng, Stage IV

Figure 6: Overall Structure of Xuancheng

Through the four stages of the evolution of urban form, it can be seen that Xuancheng had developed within the walls for about 1000 years slowly. After the dismantlement of the walls, the city began to expand firstly along several main roads, and then between them. From the reform and opening up of China, especially since the 21st century, the development of urban space was accelerating, showing a strong demand for space. With the expansion of main city, a new boundary has formed by specific geographical conditions, mainly including Jingting Mountain in the north and Wanxi River in the east, and the newly-built highway.

According to the latest satellite map (Figure 7), Wanling Lake district in the southern city is the only remaining for further construction. This region based on beautiful natural conditions of Wanling Lake, will be constructed an important cultural and public activity center, connecting main city and the southern area. Besides, this region is locating in the southern portal of Xuancheng city, which means it has to be responsible for showing the image of city and big scale natural environment.

Figure 7: Satellite Map of Xuancheng, 2015

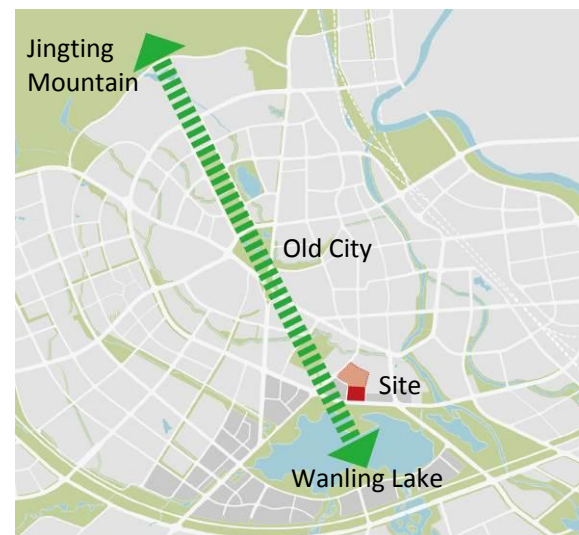

Figure 8: The Location of the Expansion Project

3. Architectural Strategy

The expansion project of Xuancheng second middle school is just locating in the Wanling Lake district, facing exchange from urban fringe belt to cultural and public activity center (Figure 8). By the comparison of the status of satellite map (Figure 9) and the master plan of Wanling Lake

district urban design (Figure 10), it could be clearly perceived the different urban environments between the existing school campus and the expansion. The former was opening to Xunhua Road in the west, adjacent to residential areas in the north and east. Main buildings are in series with the L-type central main road, which is consistent with the context of surrounding blocks. However, the expansion campus is adjacent to the Shuiyangjiang Avenue in the south, directly facing the Wanling Lake. There are large commercial complex and important cultural buildings, such as cultural center and library under construction in the adjacent plots. The existing campus and the expansion are facing totally different urban context and dimension.

Figure 9: Satellite Map of Xuancheng, 2012

Figure 10: Master Plan of Urban Design

In the Wanling Lake district urban design, two important principles have been put forward clearly: firstly, the north and west parts should form compact continuous public interface along the lake (Figure 11), setting Jingting mountain and urban built-up area as the background. Secondly, green space should be wedged into the plots around the lake, to form radial ecological network around the lake (Figure 12). These principles require the expansion project along with surrounding commercial, cultural and other large public buildings to form continuous interface and create northern border of Wanling Lake, besides, establish green, open campus, to take part in the lake ecological system.

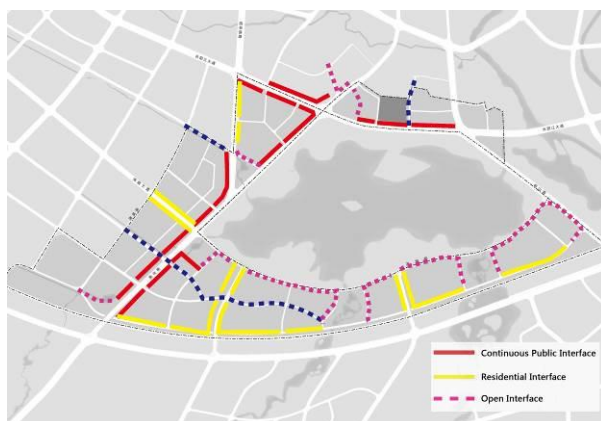

Figure 11: Different Kinds of Interface along Wanling Lake

Figure 12: Ecological Network around Wanling Lake.

At the same time, the expansion project is a kind of extension and supplement to the existing campus, which needs to form a unified whole in the dimension, space structure, traffic organization and function. The expansion project is not only an independent one to take part in teaching activities, but also an organic combination with the existing campus.

Through the analysis of existing expectations and new challenges, goals of the design is becoming clearly. For the existing expectations, the expansion project should follow the original space structure, improve the functional layout and traffic organization; for the new challenges, should form continuous public interface with the surrounding buildings along Wanling Lake, shaping the image of the city.

3.1 Layout Comparison

The expansion project has four main functions: teaching building, science and technology building, lecture hall and gymnasium. In order to create a continuous boundary on the north shore of Wanling Lake, different layout type, such as scattered, centralized and courtyard style should be studied first (*Figure 13*). Specifically, scattered layout has the advantages of easily satisfied the basic physical requirements of different functions, and forming a uniform texture with the existing campus; however, scattered layout is not conducive to form the overall image and continuous interface together with other buildings, resulting in broken urban interface of Wanling Lake on the north shore. Centralized layout is more overall, but it is too difficult to organize four different functions into one volume, and other basic problem such as ventilation and lighting also cannot be solved. What's more, due to the limit of the total size of the building, entirely centralized layout cannot occupy the whole plot and shape city image. Compared to the other two, courtyard style layout is more suitable, from the point of view of the city, the elevation facing lake can be extended, which could not only form a continuous urban interface with other surrounding large public buildings together, but also be consistent with the texture of surrounding blocks. And from the angle of function, around a central courtyard, four different functions can be flexibly combined, both independent and related to each other.

Figure 13: Layout Comparison

For the dual demands of urban image and function, two different layout types combine in a horizontal way, in other words, using the lower scattered boxes to support the upper part (*Figure 14*). The upper part is teaching building and science building around a main courtyard, the north side is occupied by teaching space which is more private and closer to the original teaching buildings on southeast of the existing campus, forming a complete teaching area, and the south part faces Wanling Lake, with a concise and complete facade design to continue the public interface on the northern shore of Wanling Lake. The east and west sides accommodate some assistant functions and set different scales of shared space and especially, a grand staircase on the corridor of the sixth floor to the roof platform, to provide students with break and communication space.

The lower part is comprised of several boxes like lecture hall, gymnasium and library. Among them, gymnasium is located in the west side, close to the old stadium and new basketball courts. Lecture hall is placed in the northeast side of the courtyard, where is convenient for students to arrive. A long ramp is around the hall leading to the roof, where can be used as space for communication and activities, and the irregular shape of the hall is designed to become the focus of courtyard space (*Figure 15*). By scattered layout of the boxes, openings are formed in

different scales, in order to making an open and free-flowing courtyard space. On the south side the main entrance opens to the Shuiyangjiang Avenue, while the north side opening continues of space axis from the existing campus. And other accesses in east and west direction are respectively leading to the stadium and other playgrounds.

Figure 14: Composition

Figure 15: Function

3.2 Space Structure

In terms of space structure, more thinking is focused on the relationship between the old and new campus. In the existing campus, the main entrance opens to Xunhua Road in the west, the main spatial axis where essential educational facilities distributed on both sides presented “L” shape extending to the east and then turning to the south. Such a space structure has been continued in the expansion project with a courtyard layout and kept the axis extending to the south. The main entrance is moved to Shuiyangjiang Avenue in the south, directly opening to Wanling Lake. Besides, the introduction of the courtyard space to the vacant axis not only enhances the spatial interactivity, but also accords with the characteristic of traditional Chinese architecture layout (Figure 16).

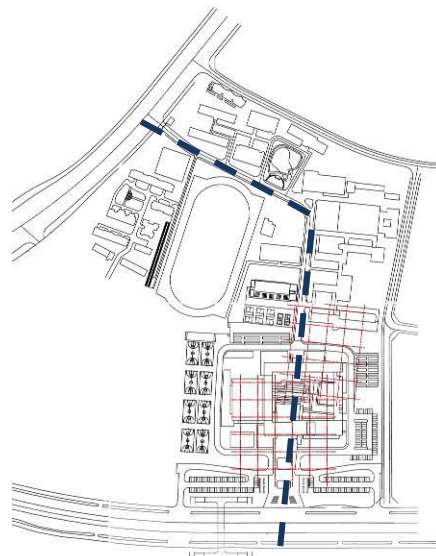

Figure 16: Space Structure

Two kinds of control grid are set up in the expansion project. The main educational facilities follow the direction of Shuiyangjiang Avenue for grid control, while the lecture hall and courtyards adhere to the grid of the original campus. In this way, new building could not only integrate into the urban texture of northern Wanling Lake, but also ensure good spacial continuity from the existing campus. The contradiction of two gridding gives birth to a vibrant and passionate experience when approaching the enclosed courtyard. (Figure 17, 18)

Figure 17: South Facade

Figure 18: Courtyard

3.3 Section Design

In the section design, based on the Wanling Lake district urban design, the major objectivity is to wedge green space into the plots around the lake. On one hand, the main building is 80 meters retreated from Shuiyangjiang Avenue, as a consequence of which, a large public green space is vacated in front of the campus, bringing the greening system through the public green space, and extending to the original campus. And on the other hand, using the height difference of the site and public platforms establish a stereoscopic transportation system, leading students to the viewing platforms on third and roof floor. In this way, the special connectivity from Wanling Lake to campus is achieved from both outside-inside and inside-outside directions. (Figure 19)

Figure 19: Section

Through the above strategies of layout comparison, space structure and section design, the expansion project could be fully integrated into the public interface on the northern shore of Wanling Lake, make full use of beautiful natural landscape of Wanling Lake, and promote the extension of green ecological system to the interior of the campus.

Figure 20: Bird View of the Project

4. Conclusion

Like many European cities, Xuancheng, the small historic city in southeast China, also has trouble to combine the expectations of maintaining its traditional urban form and the necessity to develop its international dimension. The rapid development of Chinese urbanization makes this trouble more prominent, during which, cities expand to the suburbs, lots of farmlands are transformed into urban construction land to create new city center, which inevitably brings the differences in texture and dimension between old city and newly-built district.

This research is based on an expansion project locating in a changing fringe belt, trying to find out architectural inheritance and innovation strategies through Typo-Morphological Research. Firstly, to establish a sound basis on which to view cities, understand their present, and plan their future it is important to appreciate their past (Whitehand, 2011). Through the study on evolution of Xuancheng city's expansion and behind which, the physical, economy and policy influence in different periods, a conclusion comes out that this project is locating in the last district remaining for further construction within the main city and it is an important district connecting old city and the southern area. Based on natural conditions of Wanling Lake, this district will be reconstructed to an important cultural and public activity center and be responsible for showing the image of city and big scale natural environment. In this context, new building in this district should not only coordinate with the texture and function of the old city, but also present large scale international image of the city.

This paper attempts to investigate architectural design methods based on an under construction project in Xuancheng. It also aims to bridge the gap from urban planning to individual building design through the typo-morphological research.

How to create a sustainable
knowledge region?

A new approach to the planning of European cities

Jan Brouwer, ABF Culture, The Netherlands

ISOCARP conference, Rotterdam, October 2015

Intro

Urban planning in Europe is entering a new phase. Cities across Europe have experienced a long period of growth. Since the industrial revolution, there has been growth despite crisis and wars. The population rose sharply and moreover economic growth was on average during the 20th century around 3%. This means that national income in that period has become about 20 times larger. The built environment also rose sharply by more homes, businesses, services and infrastructure. The built-up area in the Netherlands for instance increased by 2% per year or by a factor of 7, especially at the expense of use for agriculture and nature. On almost all areas of society such as labour participation, mobility, education, income, real estate there was growth. Urban and regional planning was during that period a question of management and allocation of growth. This situation has clearly changed. There are a number of signs showing that the quantitative growth will not be as spectacular and integral as in the past. Potential growth will be more of a qualitative nature. That means we have to find another way of spatial planning.

Features traditional planning

Is the current method of planning appropriate to deal with the new situation and if this is not the case, then the question is how to deal with this new situation? One could simply say that there is so much going on that the old procedure must be revised. Yet it is sensible to look at a number of characteristics in order to get a clear answer to the question whether the old method is still appropriate.

A first characteristic is the strong sectoral approach in combination with growth. The planning of housing, business locations, schools, health care, infrastructure and so on were all separated and focused on growth. Then there are some sectors where there is hardly any coordinated planning. For example, the office market in the Netherlands has large fluctuations and nowadays also has a large amount of vacancy's as the most basic form of planning is missing. Due to the long preparation, this is further enhanced. The same is true for the market of stores. Both of these extremes, namely, too much or no planning, are actually not desired, and also the separation of the sectors, will lead to undesirable situations. If growth is the normal course of development than growth solves problems often in spite of bad or no planning.

The second characteristic is the problematic dealing with different spatial scales. Each sector often has its own scale on which planning takes place. Basically you can say that there is always a kind of planning but the scale varies by sector. In a free market like the office market, planning is done at the level of the building. At that level the initiator reflects on the future, the use of resources and the desired quality. Coordination with spots in the area, activities in the same sector or other sectors will not take place. In sectors such as school construction there is coordination. The alignment takes place within the own sector. For each sector, the scale on which the coordination takes place differs. We know in the Netherlands transport areas, housing areas, health regions and so on. In addition, administrative units such as provinces and municipalities function as well as a coordination framework.

The sectoral approach seems awkward because space covers all sectors. The coordination between the sectors occurred in the past during the design of new areas. Every sector filled a claim with the adoption of the plan and so it is clear to what extent the various claims could be met. Where the pressure was greatest, the claim could best be realized. Now as there are no major land claims anymore, this system no longer works.

The third characteristic is the dominance of the government. Spatial plans in excess of the scale of the individual building were mostly set by the government. Moreover, there was also a strong financial involvement of the government. Therefore, there was a large dominance of the public sector with respect to the spatial planning. This dominance gave security but was also seen as unbalanced. The government had (too) many faces: director, quality controller, investor, financier and grant giver. In the Netherlands all subsidies for the built environment were abolished from 2015. The role as an investor and financier is limited to infrastructure and public space. Many government buildings are obsolete. The role of government has become much clearer. It actually makes little sense to spend more words to the traditional method. We need to find an alternative.

Need for planning

Next, the question must be answered, whether there should be a need for spatial planning now expanding the built environment is limited. Should not there just be a free market within a limited spatial field. In some countries this is the case, but in most European countries there is spatial planning. This is because the major interests that are involved in the built environment. The infrastructure and public space are the responsibility of the government. The government sets standards for the quality of the space and the buildings. The private sector will benefit from a well organized form of planning because the quality of the own building is highly dependent on the quality of the environment. Statistical analyzes of the differences in price levels have shown that about 50% of the value of real estate is

determined by the environment. Moreover, the built environment depends on large investments with a long life, which mostly needs to be realized with borrowed money. The value of our savings depends partly on the value of the environment. Thinking about the future of an area is than a necessity. That means that both the public and the private sector are interested in good planning but with a new approach.

New circumstances

In the last couple of years we have seen a crisis in many areas. There will certainly be recovery, but in a different way. Various conditions no longer apply. The population hardly increases, and in many places there is shrinkage. The level of education have reached limits. The size of the workforce will probably even start to fall. The individualization which presented an additional increase in the number of households seems to be in its final phase. Many markets have become replacement markets. This also applies to the built environment. At many places one can say that the built environment is spacious enough to accommodate the expected activities. This situation does not mean that we can stop paying attention to the built environment. On the contrary. Over the coming decades, there will be a large-scale adjustment, transformation and redevelopment. There are several reasons:

- The aging of the population creates different priorities and different needs for housing and amenities.
- The welfare society is under great pressure. This will have implications for the nature and size of the facilities.
- The climate crisis is no longer denied. The pursuit of sustainability is widely accepted and will lead to another use of space.
- The information technology will have major implications for the design of cities, similar to the introduction of electricity.
- After the current crisis a shift in economic activities will also be of great importance for spatial planning.

There are undoubtedly more transformations and changes that are currently not provided, but do occur. A new approach with clear principles is needed in order to be prepared.

Principles for a new approach in spatial planning

In order to face the new situation, a number of principles are formulated for spatial planning. Those are:

Planning based on communal values and attention to existing values.

All people are different. There are differences in abilities, needs and values. In a democratic society everyone is a free decision-making centre and equal before the law. Decisions must be taken both individually and collectively. By giving communal values a central role in spatial planning, it is easier to overcome the gap between individual and collective decision-making. The democratic credentials of the process can be improved. Moreover, most political parties are oriented around certain values. This is a major reason for a different approach, but there are more reasons:

- The value approach shows the value of the existing environment in relation to the changes resulting from new investments.
- The use of the same language of values makes it possible to bridge the gap between spatial scales and between different sectors.
- A sectoral approach loses sight on potential synergies. The significance of many investments often is in other areas. A values approach gives the opportunity to do so.
- Spatial planning is not a technocratic process. Every choice has a moral aspect. The values approach also brings that element in decision making.

The city and its surroundings are the central spatial unit

The connection between various spatial functions is nowhere greater than in the city. It is obvious to choose the city and its surroundings as the unit of planning. Inside this unit the same planning rules and communal values can be applied. Moreover, the city and its surroundings are facing an important task. That is bringing a better balance in the flows coming into the city and the flows leaving the city. A nice word for this task is a healthy metabolic of the city.

Art and culture should form an integral part of physical planning

Years ago there was a fixed percentage of the costs of each construction project to invest in art. The money was intended primarily for the beautification of the building. This is a sympathetic measure but does not do justice to the importance of art and culture. Physical investments do change the culture of an area and there is art and culture asked to be aware of it, or even give shape to it. Art can play a role in discovering the past, giving shape of the building process and is helpful in the search for a new identity of the area. In all cases new connections and new images occur.

Maximum transfer of information to all relevant parties.

The emphasis on the transformation of the existing built environment, leads to new and other stakeholders. Especially in today's information age, there is really only one possible strategy in such a situation and that is openness. The transformation of the existing built environment requires maximum openness or transparency.

Distinction between perspectives and projects.

Perspectives are sustainable pictures of the future based on individual and communal values and which play an active role in society. Perspectives are shared by (large) groups of people, sometimes united in interest groups or political parties, but often not. One discovers mostly in

practice that there is a shared vision. Projects are specific physical investments with a beginning and an end, an initiator, clients and a financial settlement. A spatial project requires in every case a perspective on the future. Therefore, a project is always the result of one or more perspectives, sometimes it's a result of a conflict between different views and sometimes a compromise. Recognition of lasting differences of opinion and at the same time an ongoing effort to bridge these differences creates dynamism in society.

Process that focuses on the best of all possible by co-creation

A process that focuses on the best result sounds like a cliché, but it is not. Just then an approach based on communal values must be able to prove his services. It is a good tool to search for synergy. Often, the process is different and aimed at the least worst outcome. A result with which everyone can live, but also just that nobody is really happy with. In the first case, there is value creation at several levels, and not in the second case. Therefore a major role in the process is reserved for the creative ability of the parties involved and the strength of the design. That will always have to take place in cooperation with the parties concerned. A nice word for it is co-creation.

Contributing to the learning ability of the society

The last principle is that each project must contribute to the learning ability of society. The least is that all participants in a project learn something from it, but that is not enough. There is by doing so, no active knowledge development. This requires proper documentation of projects and proper evaluation. The learning ability can only increase significantly if there is also outside the immediate circle of the stakeholders, an active knowledge transfer about projects. In the Netherlands there is an extensive record of facts about areas but virtually nothing about projects in those areas. We see changes, but do not know how they come about. Proper documentation is also provided in order to achieve impact analyzes and thereby strengthen learning capacity.

What are communal values and how to adopt them?

Definition communal values

Four themes are distinguished, namely a cultural, social, economic and physical approach to define values. Communal values may relate to the population or to the physical context. So, eight values are emerging. Essentially, there are of course infinitely many different values, but in the political debate a number is constantly brought forward and these can be used. In the figure, these values are displayed.

Cultural diversity

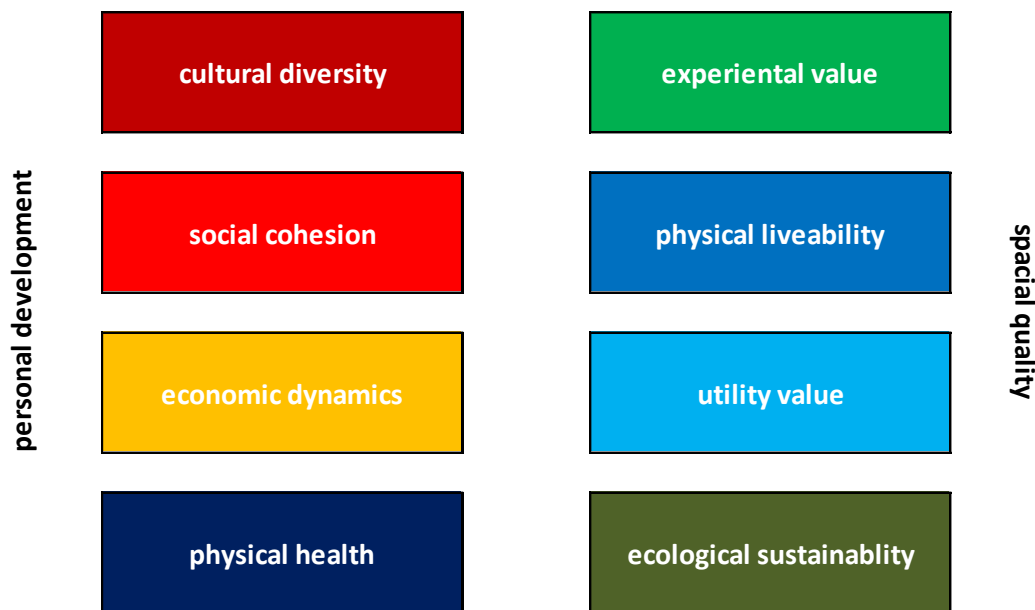

Cultural diversity is the value that indicates whether a community possesses the possibility of free expression. The Netherlands as most European nations is a free country and everyone can express himself freely. However, there are differences in the degree to which use is made of this space. In areas where there are many cultural activities or areas with a large creative industry that space is used more intensively. Culture is essentially about the tension between preservation and change. Lack of diversity can lead to rigidity and thus deterioration and too much diversity may lead to chaos and confusion.

Social cohesion

Social cohesion is also an essential communal value. It shows the degree of solidarity in a society. Partly this solidarity is regulated by the state through a variety of social insurance.

But certainly this time of economic crisis shows that the state does not cover all or some say cannot provide here. Social cohesion is also a matter of the locals. This is evident by the extent to which people are living together, in the way people are dealing with neighbours and are participating in social processes through associations and volunteering. An essential dimension to social cohesion is the tension between alone or together. Individualism is a widely-held value. It gives space to own actions and own responsibility. There seems to be a change coming up. In many places, people are looking for new forms of collectivism. But conversely doing everything together and nothing alone, can be oppressive. It leads in the extreme case to exclusion.

Figure 1: communal values

Economic dynamics

Economic dynamics are required to provide for the maintenance of life. Here is a tension between growth and contraction. How far should we go in order to allow growth and shrinkage which leads to big problems? The economic sector has its own value indicator, which is the domestic product.

Physical health

Health is a value which is largely attached by many people. Health care has evolved over the years and became the largest item in the national budget. And not only the state but also individuals spend a lot of money to get healthy and to stay healthy. Sport is popular, healthy food is in and the book sales with advice on healthy living are doing particularly well. Indicators of health include life expectancy, absenteeism, obesity and the appreciation of the public for their own health. Health is about the tension between homogeneity and heterogeneity. Solid and stable patterns provide stability but are vulnerable to changes.

Spatial quality

The communal values from the population, have in a certain sense a counterpart in spatial quality. The cultural, social, economic and physical value of the environment in which we live

is mentioned: experiential value, physical liveability, physical utility and ecological sustainability. Three of the four values are derived from Vitruvius. Only liveability is not at Vitruvius.

The experiential value or beauty has never been a big issue in the Netherlands. It's a miracle that we have produced so many great artists. Our greatest painters like Van Gogh (France), Mondriaan (USA), and de Koning(USA), moved abroad and Rembrandt died in poverty. The first alderman has yet to be turned away because he or she has approved a disgusting building.

The physical liveability mainly came up in the 80s and 90s. There were even political parties founded on this theme. It is still an important item.

The most important item was over the years the physical utility of the environment and mostly focussing on one sectoral aspect such as housing shortages, congestion, waiting lists for healthcare or safety against flooding.

Environmental sustainability has in recent years become a major theme. Also around this theme new political parties are emerged.

The measurement of values

Values have a double meaning. On the one hand, there are objectively by anyone to determine indicators. On the other hand values are highly subjective and related to individual or communal goals such as quality of life or social cohesion. In the different applications a combination is used. First, there are objective indicators that can be set for each area, such as density, dwelling size, income, education level and so on. These indicators can be used to determine the score on a particular value. This is a proven method applied by multiple agencies and institutions. There are reasonably acceptable measures of economic dynamism, quality of life and the like. On the other hand, there are studies of the population in which they asked for the appreciation of all aspects of society. These subjective measures are also used. Together they should provide a reasonable picture of the diverse communal values at all spatial scales. Nevertheless more debate is needed in order to come up with generally accepted values.

Spatial planning based on communal values

Now that the basic principles have been established and we know how to measure communal values, the approach can be developed. Every action consists of four elements. This applies to small daily actions and to investments for major spatial transformations, whether we work according to a new or an old way of spatial planning. These steps recur again and again and stand in figure 2.

Every action requires initiative. Without initiative, nothing happens. Then follows communication about what we do and how we do it. After communication execution follows and, finally, transfer to the surroundings. Even at the smallest action, there is a transmission to the surroundings. If I move from one place to another, I take an initiative. There is communication in order to determine the direction. Then follows execution. The transfer to the environment is minimal, but present, namely the change in the air around me, and the footprints I leave behind.

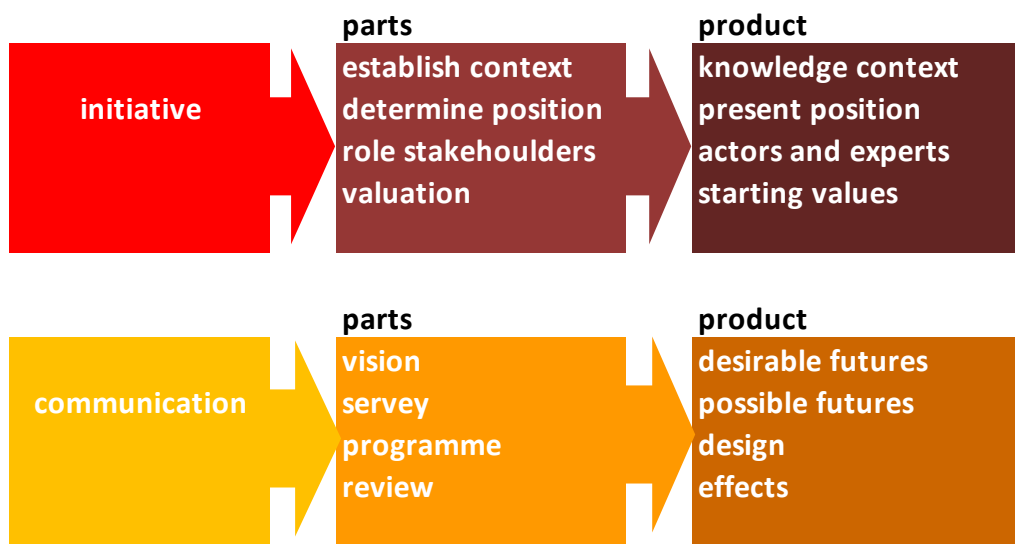

Figure 2: action in 4 steps

An act always has a circular and a linear side. The parts follow each other (linear), but after the transfer there will be a new beginning. A displacement is an endless series of new initiatives to get anywhere. A spatial investment is part of an endless series of initiatives in urban development.

For large spatial projects we can therefore identify the same parts. Spatial planning refers to the first two parts: initiative and communication. Implementation and transfer often require some new players and a new game and is not considered here. In spatial investments each step consists of a number of smaller parts. These are also again based on the components of the above figure. It creates a series of actions that ultimately lead to a completed physical investment.

Figure 3: composition spatial planning

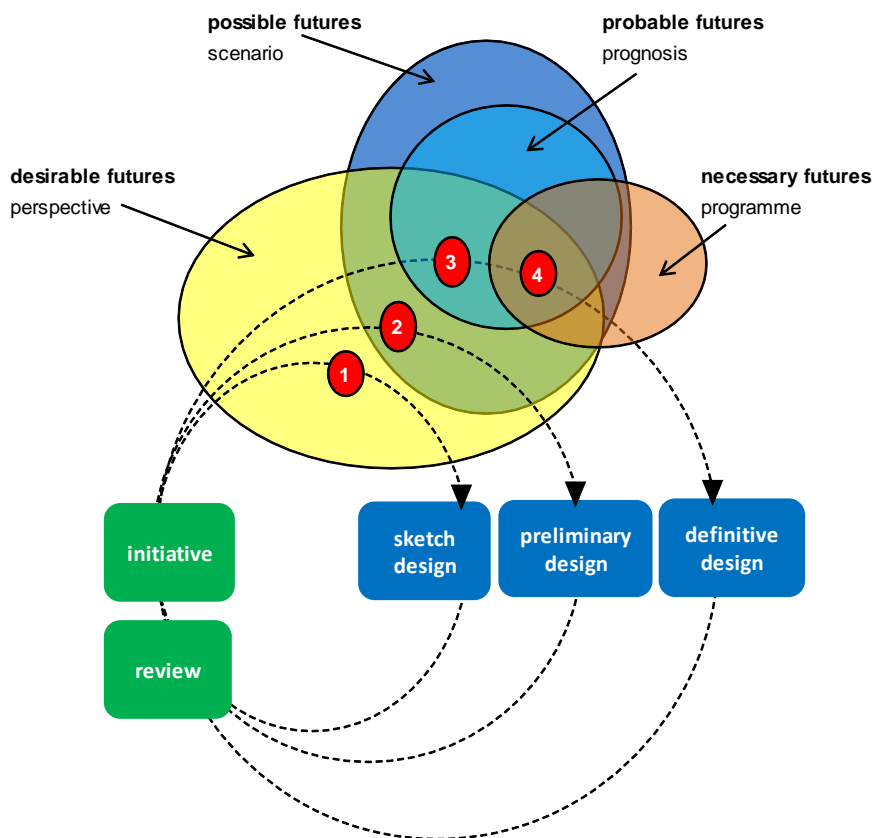

The main components of the initiative are in figure 3. The initiative consists of establishing the context and the own position within that context. In spatial investments multiple parties are always involved. In the old situation the initiative was mainly owned by a limited number of parties, government and developers. In the new situation, there are more and there is a much greater variety of parties. This requires a complete inventory of the people involved

and their roles. Finally, the starting values regarding communal development must be established.

The communication component is further unfolded because this component is essential in the new spatial planning. If something goes wrong, it's usually in this event. It involves mostly a complicated process and it is therefore important to clarify that.

A spatial investment always requires a vision and the resources to make it happen. During the process, the vision must be so sharp that it can be implemented and there should be sufficient resources for the implementation. It is a combination of narrowing and widening. If one of the two fails then the project will fail. The result is shown in figure 4. This probably looks somewhat complex but closer inspection shows that it's not so bad. The upper part of the figure shows the collection of futures for an individual or a group. A distinction is made in desirable, possible, probable and necessary futures. It is true that the probable futures are always a part of the possible futures. The desirable futures not only fall about probable and possible futures, but can also fall outside these collections. The same is true for the necessary futures. By doing so there arise 10 subsets, each with its own character and its consequences. In the middle are the necessary, desirable, likely and possible futures. Everything goes on smoothly. Completely outside are standing the futures that are not possible, not probable, not wanted and not needed and therefore not very interesting. All other combinations have their own significance. Interesting combinations are the futures that are desirable and possible, but not likely. There is work to be done. This also applies to futures that are probable and possible, but not desirable.

Figure 4: process with respect to communication

The purpose of spatial planning is to formulate a necessary plan. All parties support the plan, which still fits within the desirable and possible futures. Very schematically, one would first have to define the desired future (1). We call the result a sketch plan and it is the realization of one or more perspectives. If that's beyond the possible future then a new step is to be undertaken. It can be on any basis. The spot is not appropriate, not enough money, the design does not meet the requirements, not all stakeholders are satisfied and so on. The new preliminary design must fit within the possible futures (2). The move to a probable future can be made as all resources are put in effect (3) and the plan is necessary if anyone has committed them self to the implementation process (4).

The designs are always tested for their contribution to the various individual and communal values. That means the question is answered whether the initiative is continued until a final design.

Examples

An approach based on these principles is by no way a generally accepted approach. Methods that have worked for a long time do not end over one night. The current crisis could perhaps bring a gear for a different approach. In the following, projects are mentioned in which the author experienced with the new approach. In all examples, use was made of the value approach and co-creation. Until 2005 it only involves theoretical exercises. Later it concerns practical projects and the approach was focused on implementation.

1998: The Metropolitan Debate: Developing a new method for decision-making, together with TU Delft, University of Amsterdam and the HMD foundation. The principles are similar to the principles in this article. The method was applied in the project NL2030 in the preparation of the Fifth National Note on Spatial Planning in the year 2000.

1998: Het Nieuwe Ommeland: Application of the decision-making method in the rural areas. Project together with LTO Netherlands.

1999: Northward: Search for new projects with district Amsterdam Noord, community groups and institutions from Amsterdam Noord. Residents groups were supported by designers and artists.

2002: Where is my money? National debate on the use of ICES funds (natural gas revenues). Project together with the Institute for Public and Politics.

2005: Bacinol debates: Search for new projects in Delft along with creative industry in Delft. Project has resulted in several new initiatives.

2006: Valuable interventions in districts: Project along with several housing associations. Quest for meaningful projects and effect analysis.

2010: Delft sizzles: Development of perspectives and projects in Delft South East together with TU Delft, DUWO student housing, community groups, water board, municipality of Delft and the foundation called "Living with Water". Deadlock around building in this district gave way for new projects.

2013: New Wealth: Development of perspectives and projects in the centre of Leeuwarden with community groups, associations of retailers, municipality of Leeuwarden and institutions.

2013: SPOTS: redevelopment of boiler houses to cultural centres as part of Kosice 2013 European Capital of Culture. Project together with community groups and the organization of SPOTS.

2014: Perspective Region Zwolle: Development of perspectives and projects with provinces and municipalities of the region Zwolle.

2003-2015: CPO (collective private organizations): Various projects with Hulshof Architects around CPO. The method follows the principles and the steps as described above. The projects were always undertaken together with community groups, municipalities and sometimes with housing associations, banks and other institutions.

Recommendations

An open planning driven by communal values and established through co-creation is playing for years but is still far from commonplace. The current crisis is bringing a nice momentum in order to change this. This requires:

- A number of important players such as governments and social institutions should act according to these principles: One party must begin and it is obvious that the government and the social institutions of the government can do that. There are still too many projects where these principles are violated and where the taxpayer pays the bill. A few municipalities did start. Look for instance at the Almere principles.
- Communicate principles: The familiarity with this method will have to increase. This can be done by showing examples. Through publications and through teaching, people can be made familiar with the approach.
- Government as director: The government had too many roles. Director of spatial processes according to the given rules is a good step forward.
- Art and culture as a catalyst: Art as a catalyst is only sporadically applied. Where this was the case, it was a great success. For example, see the Metamorfose Poptahof in Delft and Hotel Transvaal in The Hague. More experiments are required.
- Recording of values: At present, the core of the national statistics is the commitment of the economic value added. This is the holy grail of economic dynamism. The other values must be recorded with the same bet.
- Documentation of projects: Better documentation of projects is absolutely necessary. Projects are what people do. This shows who cooperates, what goes in and where it leads to. Projects above a certain amount of money should be recorded much better, if only on a sample basis. There were some large scandals with building projects in the past, but practically nothing is done in order to prevent that in the future and to start a learning process.
- Communicating results: A better registration and documentation of projects and values paves the way to a greater capacity to learn about spatial investments. It also paves the way towards the integration with non spatial projects.

Landscape Design Promotes Sustainable Development of cities ——Case of "Sino-Singapore Guangzhou Knowledge City" Urban Design

Bin Gong, Guangdong Urban & Rural Planning and Design Institute, Guangzhou, China
Jie Zhuang, Guangdong Urban & Rural Planning and Design Institute, Guangzhou, China

1. Introduction

In order to cope with industrial upgrade and transformation of economic growth pattern in Pearl River Delta which is considered as the world manufacturing center, Guangdong government expects to transform the development mode from "manufacturing" to "innovation" by constructing an innovative area, introducing high-quality talents and establishing high-technology industries. With this in mind, The Chinese and Singapore governments came up with the idea of establishing a "Sino-Singapore Guangzhou Knowledge City". The city will become an engine to promote industrial transformation and upgrading of the Pearl River Delta. It will become a regional innovation center for China and the Association of Southeast Asian Nations (ASEAN).

Figure 1: The position of Sino-Singapore Guangzhou Knowledge City in Guangzhou

The Sino-Singapore Guangzhou Knowledge City in the valley area of northeast of Guangzhou, is respectively 30 kilometers and 24 kilometers away from the downtown of Guangzhou and Guangzhou Baiyun International Airport, belonging to the area with good ecological environment (Figure 1). With about 123 square kilometers of available land, and about 60 square kilometers of developed land, Guangzhou Knowledge City has the potential to accommodate 500,000 residents.

It becomes a key issue for urban ecological security that how to maintain the continuity and integrity of the regional landscape pattern during the process of building a new city from

scratch (Yu Kongjian, 2003). During the process of urban design, the landscape infrastructure could be as open space system to connect regional scale, urban scale and block scale to maintain the fusion development of urban artificial systems and natural systems, which is an important aspect of sustainable development. Based on the research findings of "Sino-Singapore Guangzhou Knowledge City", this paper introduces the practice of urban design which applies the theory of landscape urbanism to design a new town in a valley. It is a right way to promote sustainable development of a city through protecting its ecosystem to construct an urban form with the city and nature organically integrated.

2. Influence of design paradigm

During the rapid process of urbanization in the past three decades, modern urbanism was the basic paradigm of urban design in china. The basic characteristic of it was to freely place buildings in the superblocs formed by a road network which is suitable for motorized traffic, and then used the commercial, residential and other types of high-rise buildings as the main tools to present a city's image. Under the modern urbanism dominated pattern of urban design, new cities in China appeared quickly with similar forms without regarding to the relationship between urban expansion and the protection of natural systems. Therefore, urban expansion has exerted a negative influence on ecosystems around cities and the ecological safety of cities themselves. It mainly includes the following two aspects.

On the one hand, it was in the inner of a city that modern urbanism urban design usually reflected nature in a city from the perspective of urban landscaping. Nature in a city was in the form of isolated ornaments like urban parks and the green areas in residential quarters dotting the urban road network while the existing green patches, corridors and the interconnections between them has never been truly considered. This kind of design pattern is just to copy the nature in the inner city, which results in the fragmentation of natural landscape in the city as well as the completely opposite pattern of natural systems and urban artificial systems.

On the other hand, it is at peri-urban that due to the expansion of the city, the natural systems were taken by artificial transformation models, such as river straightening, reclaiming land from lakes, and the disappearance of natural habitats. Natural systems were replaced by urban artificial systems, and the continuous natural process was cut off by the expansion of cities. Because of the lack of consideration of peri-urban natural systems as a whole, the horizontal ecological processes of natural systems were ignored. This lead to a serious impact on peri-urban natural ecosystems as well as the security of cities themselves such as the frequent occurrence of storm water disasters (Figure 2) in cities and the reduction of biodiversity and other issues. With the rapid expansion of cities in China, it is kind of a challenge which our cities have to face that how to build a harmonious and

Figure 2: Storm water disasters in cities

sustainable pattern during the development processes nowadays.

3. Landscape urbanism and design framework

3.1 Landscape urbanism

Modern urbanism dominated the large-scale urbanization in the world after World War II. Along with urban sprawl, the imbalance of ecological environment and other urban issues, planners and urban designers began to rethink the impact of modern urbanism on the ecological environment (Waldheim, Charles 2006). Urban design was modified by absorbing ecology and landscape ecology theory and designers began to pay attention to the relationship between urban development and nature conservation at urban scale and regional scale. For example, emphasizing both the concept of green infrastructure (Li, Juanjuan, etc. 2012) and a landscape security pattern (Yu, Kongjian, 2003) takes the landscape that embodies natural processes as the framework of urban form. Landscape becomes the key factor to shape the form of cities. The core idea of landscape urbanism is to consider urban issues from the perspective of the landscape and take the ecological strategies as the starting point to solve these problems. This approach puts a city into a larger natural environment for investigation, analysis and evaluation prior to land planning and design.

In European and North American, there are two types of urban design projects explored from the perspective of landscape urbanism. For undeveloped areas, ecological corridors and green spaces that embody natural processes are protected as landscape infrastructure, and then they are introduced into the inner of a city. For developed areas, urban designers changed the artificial environment that destroyed natural process into a new artificial nature during the process of urban renewal. They try to create nature or restore nature in artificial spaces, which emphasized the leading role of urban design. By building a new artificial nature that reflects the natural process, the ecological value and the livability of a city can be improved (Zhai, Jun, 2011).

3.2 Integrated urban design framework

Ian L. McHarg believes that the ideal urban form should include two kinds of systems. One is the open space system in accordance with the natural evolution process, and the other is the system of the urban development (McHarg, Ian L, 1991). These two systems are interrelated and form the landscape unit with land mosaic mode (Forman, Richard T.T., 2008). It is the ideal model of urban and natural integration. From the perspective of urban form, urban design can be divided into four scales: region, urban, block and lot (Liang, Jiang & Sun Hui, 2007). As the background of urban development, natural systems are considered as organic systems and should maintain the continuity of the horizontal ecological process at the three scales: region, urban and block. The theory of landscape ecology analyzes the relationship between cities and nature at regional scale and urban scale based on the schema language of patch, corridor and matrix (Forman, Richard T.T., 2008). Combined with these two theories, we think that the key point of urban design at regional scale is to make sure the relationship between the land for urban development and the surrounding natural elements (farmland, wetland, forest, floodplain, etc.), then to select the appropriate area for urban development in natural context. At urban scale, urban design shall pay attention to protecting or restoring the landscape infrastructure like patch and corridor that reflect the natural process in the land for urban development, thereby defining urban form through the protection of natural processes.

4. Urban design practice from the perspective of landscape urbanism

Based on the requirements of Guangzhou city development for livable ecological environment, the scheme design of Sino-Singapore Guangzhou Knowledge City determines the natural patch and corridor that possess sustainable development value for urban

ecological environment via the analysis for the ecological background of the site. Through the protection of landscape infrastructure, we can determine the form of lands for urban development, so as to achieve the integration of urban artificial systems and natural systems. The urban landscape changes from an "isolated landscape" to a "flowing landscape". The "isolated landscape" is the main feature of modern urbanism, but landscape urbanism emphasizes the "flowing landscape" which reflects natural processes (Yang, Perry, 2010). The flowing process shapes continuous spaces at three scales region, urban and block, which lays a foundation for a livable and sustainable urban form.

4.1 Ecological condition of the site

The Guangzhou Knowledge City is located in the valley between Maofeng Mountain and Fuhe Mountain in north Guangzhou. The site belongs to the area combined with hills and terrace. It is the transition region formed by Guangzhou northern mountain area and the southern alluvial plain. Overall, the valley is flat, obvious dendritic. The surface wetland of this valley is dense and the groundwater is abundant. There are dozens of small streams within the area that form two major rivers, which offer rich water resources to this site. The local climate is favorable and nourishes a wide variety of living creatures. Due to the impact of human development, however, the majority of woodland has become artificial or semi-artificial woodland, and the landscape of the site has been gradually eroded.

We used the remote sensing data covering the four periods in 1990, 2000, 2005 and 2009 during the preliminary research of the project. Then the data were interpreted with EADRAS software to calculate Normalized Difference Vegetation Index (NDVI) of the four periods, so as to conduct the comparison and analysis among them. From the point of view of the NDVI spatial distribution, in the 1990s, because there was no large-scale urban development, there are several obvious vegetation corridors along the valley. With the rapid development of the city, the vegetation corridors disappeared in 2009 and obvious segments appeared in the valley area between the two mountains. According to the mean values and standard deviations of NDVI, from 1990 to 2009, the ecological environment within the scope of Guangzhou Knowledge City experienced the process of the early destruction and then gradual restoration of vegetation, and the total vegetation coverage showed the ecological environment was getting better and better (Figure 3).

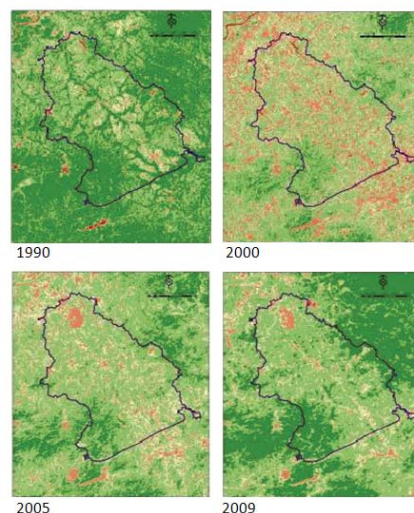

Figure 3: NDVI analysis of the four periods in 1990, 2000, 2005 and 2009
Source: CAUPD

4.2 Land suitability analysis

The research from the point of view of landscape ecology by Richard T.T. Forman, the professor of Harvard University, suggests that the flow of natural processes create different types of landscape patterns, and the patterns will affect the flow of natural processes in turn,

such as the flow of animals, plants, water and materials. If we ignore the landscape pattern to go against nature, and create the city pattern only in accordance with the wishes of the humanity, then we will pay a heavy price finally. The Steep slope is located in the East and west of Guangzhou knowledge city. Once the surface vegetation of the steep slope is destroyed, there might be ecological disasters such as landslides and floods in the storm season. It is a great threat to the life and property of the residents in the city. In this project, we apply the method of landscape ecology into the analysis for the ecological background of the site in order to determine the position of development lands (patch) in natural ecosystems (matrix), and protect landscape pattern (natural corridors and patches) in development lands. More then, it also puts forward suggestions on the construction of landscape security pattern for the main ecological environmental problems. This is an important content of urban design at urban scale.

The analysis for the ecological background of Guangzhou Knowledge City site include the comprehensive evaluation on elevation, slope, flood submerged area, surface water type, NDVI, forest protected area, land use type and other factors. According to the superposition and comprehensive evaluation of various evaluation factors, the land use status within the site could be obtained, which concentrates to manifest the impact of human activities on the natural environment. Based on the size of different land use ecological contributions, the ecological weight value could be determined, and then the protected scope of natural ecosystem could be identified. The area of Guangzhou Knowledge City is divided into three types (Figure 4). The ecological reserve area, the restricted development area and the suitable development area are 52, 29.3 and 41.7 square kilometers. In basis of the assessment results of ecological suitability, the city will prefer to take the suitable development area as urban development land, the followed optional by the restricted development area. The ecological protection area strictly prohibited to use for construction. In addition, the restricted development area are adopted the development mode with a low environmental impact, so as to reduce the impact of urban development on the ecological environment.

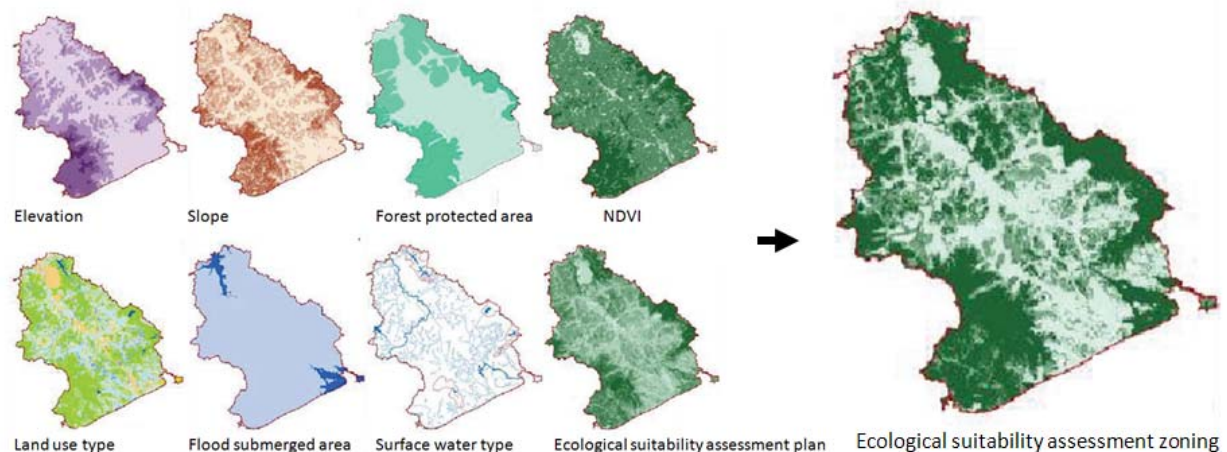

Figure 4: Land suitability analysis
Source: CAUPD

4.3 Landscape as a framework of urban form

In the process of urban development, the construction contents on urban lands are constantly changing, while the landscape infrastructures which are composed of river systems, wetlands, woodlands, and flood submerged area in natural systems will serve for a city forever (Yu, Kongjian, 2003). Modernistic urban design causes the fracture between urban form and site characterization, and ignores the natural systems as the matrix is an

organic system, which leads to be lack of the continuity and integrity of natural system under the three scales: region, urban and block.

The urban design of Sino-Singapore Guangzhou Knowledge City changes the design paradigm that modern urbanism takes a road network as a development framework for a city and generates urban form through urban functions. The project takes landscape infrastructure which reflects the natural process as a framework of urban development, and shapes the urban form by the process of ecological flow. The design proposal combines with the analysis of the horizontal ecological process on the surface to protect the original hydrologic system in the site and form continuous ecological corridors, which could provide the biological migration, the flow of surface water and other natural processes with a protection frame, as well as lays a solid base for the formation, development and evolution of urban form. The design pattern began to change from the intervention of road network to the intervention of landscape infrastructure. It is also an effective way for the design scheme to build the urban characteristic by combining the natural features of the site, the protection and the construction of the landscape infrastructure network in advance. For example, at the urban scale, the urban design scheme controls the building height based on the valley characteristics. Guangzhou Knowledge City is located between Maofeng Mountain and Fuhe Mountain, and the urban form presents a band shape. The scheme controls the overall skyline of the city through the analysis on the view of both sides of the mountains. The major high-rise buildings in the city are laid out surrounding the subway station along the valleys, with the height of the tallest building not exceeding 2/3 of Maofeng Mountain, which ensure that the contour lines of the mountains on both sides will not be destroyed by high-rise buildings (Figure 5).

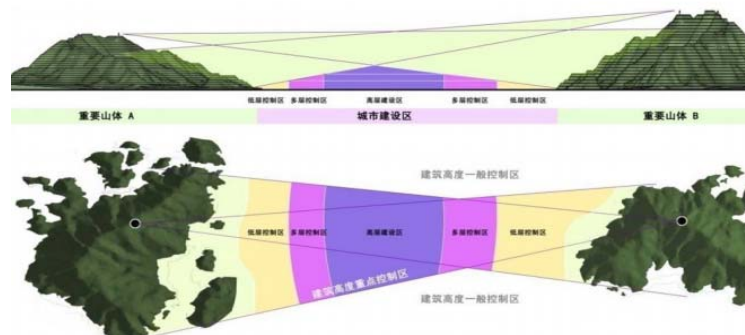

Figure 5: The analysis of controlling building height
Source: CAUPD

4.4 Ecological corridor as the landscape infrastructure

In this project, the ecological corridor which is considered as the landscape infrastructure can be classified into the biological migration channel and the surface runoff channel. The pre-constructed ecological corridor within a city could avoid the lack of necessary natural open space during the process of urban expansion. The ecological corridor reflects the natural process in the inner city, and connects with the patch and the natural system between the inner and outside the city, so as to maintain the continuity of green open space system for cities.

Guangzhou knowledge city is located in a range of mountains and the width of mountain corridor is about 32.5 km (Figure 6). How wide the ecological corridor shall be protected in Guangzhou Knowledge City if we don't want to affect the ecological function of the area? According to previous studies, we should reserve the ecological corridors of 2 km width in the area, and the minimum width of an ecological corridor shall not be less than 0.6 km, so as to keep the basic ecological functions of the regional ecological corridor. Through the recognition of the ecological corridor with high degree of naturalness within the site, there are

three biological migration channels with the width of 2.2 km in total (Figure 7). In the inner city, according to the research of river ecological corridor, we need to retain 60 meters width at least on both sides of the main river systems, such as Phoenix River and Pinggang River within the site, and 15 meters width of green buffer on both sides of the other tributaries.

Figure 6: The width of the existing ecological corridor
Source: CAUPD

From the perspective of development of urban land, the open space networks, which are interrelated with each other, could enhance the development value of land. In this project, the urban ecological corridors that are considered as open space carriers can contain the space of pedestrian lanes and bicycle lanes, which can provide daily exercises opportunities for residents, so as to improve the overall health level of urban residents. The proposal of urban design puts forward that the urban greenways are along Kowloon Avenue, as well as the foothills of Maofeng Mountain and the Fuhe Mountain (Figure 8). The greenways are composed of urban greenway and community greenway. The urban greenway is about 71 kilometers, and the community greenway is about 62 kilometers in total. By constructing the slow-traffic network at urban scale, it could improve the accessibility of slow traffic system and urban diversity. On the other hand, due to the static wind frequency of the valley reached 33%, the urban ventilation corridor formed by the ecological corridor is helpful to ease the issues of air pollution and urban heat island. Therefore, the ecological corridor in urban is an important aspect of the livable environment of a city.

4.5 Function of landscape

Under the background of rapid development of Chinese cities, the development model of modern urbanism often leads to the fragmentation of the landscape. The processes of incremental development are lack of overall consideration of natural systems around cities, which destroys the continuity and integrity of natural systems. Furthermore, it is very difficult to maintain biodiversity in the isolated parks and green areas that are dotting among urban road networks. Therefore, we need to link the fragmented landscape, and use a kind of continuous and natural form to design. What's more, we should not only consider the retention and continuation of the existing natural process, but also think about how to recovery the natural process that has been destroyed. We should build the connections of natural landscape inside and outside of cities to establish networks of landscape infrastructure.

Before the establishment of urban road system in this project, we analyzed the land suitability, and established the ecological corridor, which can maximally retain the original natural process within the site. Landscape infrastructure and land of urban development are mixed together in the form of land mosaic. The form of landscape changed from the "isolated landscape" to "flowing landscape". We want to reduce the interference and damage to the natural system as much as possible, and design according to the natural process. Landscape infrastructure is a kind of landscape with ecological function. We reserve the water system and the catchment channels for surface water in the city, and let nature work, which could effectively reduce the speed of surface water collection and flow, and purify the water quality. There are others benefits for the city, such as maintaining biodiversity, replenishing groundwater circulation, controlling soil erosion, decreasing the rain and flood pressure on municipal facilities (Zhai, Jun, 2010).

5. Discussion

With the development of landscape urbanism theory in the field of urban design, the urban design paradigm evolves from "separation from nature" to "fusion with nature", and "function generating form" to "natural flow generating form" (Yang, Perry, 2010). The urban design based landscape urbanism connects the three scales of the urban form via the landscape infrastructure, which reflects respecting nature, restoring nature and creating nature in design processes. Through the protection of the natural process in undeveloped areas and the ecological design involved in urban renewal to create artificial nature (Zhai, Jun, 2013), the urban development could be integrated into nature, thereby reducing the impact of urban development on the ecological environment. Landscape urbanism theory could be a new design paradigm for urban environmental issues in the course of China's rapid urbanization.

A city in a stage of rapid development is often faced with uncertainty in the process of urban expansion. For example, the construction of new highways and high-speed railways will have a great impact on the development direction of a city. It is the dilemma of modern urbanism that how to establish the relationship between urban development and natural ecosystem. Based on the ecological planning cases of Barcelona in Urban Region written by Professor Richard T.T. Forman and the viewpoint of Professor Yu Kongjian about landscape security pattern, the framework of urban development should be constructed at regional scale and urban scale. Outside of the built-up urban areas, we should make sure the suitable areas for the development of a city and the landscape infrastructure network to show a possibility of urban form, so as to cope with the uncertainty of urban development in the future. In addition, the sprawling development should be prevented from eroding the natural system surrounding a city and causing damage to the integrity of natural process. More then, in this way, we can also provide a clear suggestion for the development of the regional highway or railway in the future, which can create an active connection between the development of a city, the landscape infrastructure and the external contact channels.

DED Delft E Design - Bottom Up approach towards a sustainable existing housing stock

Ineke HULSHOF, Hulshof Architecten B.V., The Netherlands

In Delft in 2013 an initiative of Delft Design, a local society of designers, resulted in a cooperation of designers, architects, scientists and dwelling owners in the city of Delft. At first the cooperation aimed to find European funds for an innovative approach to the existing housing stock and its inhabitants. This turned out to be difficult as the funds were merely aimed at research and knowledge innovation. The cooperation then turned to the city and the local housing corporations to find ways of practising a bottom up method with the users themselves.

Delft E Design, DED, is a cooperative of ten small firms specialized in sustainable techniques, architecture and consultancy. DED is supported by the Delft University of Technology, Faculty of Architecture, housing society Woonbron and the City of Delft. With foundation De Witte Roos a program of sharing knowledge is active.

With the city of Delft a so called "E-deal" is agreed on. With this deal the city commits to providing a fund of 4 times € 25.000,- in a period of four years starting in 2014. The cooperating companies agree to invest knowledge and labour, in order to develop a scheme in which the financial savings made possible can and will be invested in energy saving or producing adjustments by the house owners and tenants.

Goal:

DED aims to develop experimental projects with, and undertaken by, the owners and inhabitants of existing dwellings; houses, apartments, monuments, all varying in age. This is done by developing and practicing ways to enable people to establish an energy neutral house and if possible an energy producing house.

The following figure shows the existing energy label in average houses in The Netherlands related to their construction period. Our pilots will cover the three eldest periods.

ENERGIE LABELS

With a small group a start will be made to show and interest more people in undertaking sustainable ways in living en using their dwellings. The approach is one of a testing ground

or living lab, to demonstrate and try out physical interventions. Most important is to share experiences and to see how behaviour combined with techniques can change more with less. With four pilot areas defined to start with, there is a great variety of people and constructions, housing types and neighbourhoods. Also the influence of the environment is considered. Empty grounds can be used for local gardening, energy harvesting and more. With these pilots a pool of ambassadors can be developed and the approach can spread, not only in the pilot areas as well as all over Delft and anywhere.

With the Delft University of Technology research is done on the existing energy use in the pilot areas and simulations are made to show different possible effects. Also executed interventions are evaluated to show the effects to a wider circle. Students are helping by making presentations and doing questionnaires in apartment buildings.

Result:

The result is two sided, one is an approach to achieve large scale user powered energy saving and production in the existing housing stock, to start with awareness. The second is to realize 40% less energy use in 120 dwellings in a period of four years. In the end DED wants to continue the campaign addressing all possible clients.

Approach:

DED will be active in the pilot areas for a long time – preferably extending over the first test period of four years - to continue the pilot and to enable society to adapt and renew the approach permanently. To start DED will investigate the real question and need of the inhabitants. The potential of energy savings possible will be investigated. The cooperation members of DED will advise inhabitants on possible personal and collective measures, both regarding behaviour and physical interventions. DED will help them to find contractors and products best fitting their needs. At this moment for example, several bids are considered on insulation and PV installation. Sharing the experiences makes a profit possible for all the participants. With about twenty families living in the city centre, mostly monuments, kitchen table conversations already result in an average saving of 20% with no money invested. DED will help people to contract the right firms and check the executed performance.

Monitoring the pilots with research members of DED will enable the exchange of new ways to save and produce energy.

Four pilot areas and their specific character.

The pilot areas are:

- Verzetstrijdersbuurt (postal 2507)
- Poptahof (postal code 2400-2401)
- Agnethapark (postal code 1301)
- City centre (postal code 1102-1104+1106-1109)

These neighbourhoods can be described according to several characteristic urban aspects like density in volume, people, amenities, green space, empty space, traffic space, housing typology and climate.

The inhabitants can be characterised by income, education, cultural background and ages. During and after the first four years of the project we will try to relate these figures to the results. At this moment we are still investigating on most figures.

In general the average house serves 2,07 persons. In the pilot areas we don't see much difference in this figure.

In the following a short outline per pilot is given as well as the result up till now, July 2015.

Verzetstrijdersbuurt.

This is a neighbourhood constructed in the 60-70 ties, after the war and with a layout we call Cauliflower. This was supposed to be very 'gezellig' or cosy. In total there are 500 family houses, mostly in rows and some semi detached.

Typical street view, google

Overall layout, google earth

Most houses are privately owned by the inhabitant. All are terraced single family homes. The building density is a total of 1.285 houses on an area of 33,5 ha or 335.000 m² and thus 38.38 houses /ha.

The average income is € 41.300,-hh/year.

General knowledge

In 2008-9 the municipality was active in the neighbourhood with an energy saving program. The response was very disappointing as only 2% of the households joined the program and invested in technical measures like insulation, PV and sun collectors.

Pilot approach

In this area we are doing a follow up on the previous campaign with the former participants to show and act as ambassadors towards their neighbours. Now together with these people we find more people interested. We have reached about 22 more households who want to invest in more technical adaption's of their houses. All joined the questionnaire and now individual visits are going on.

So now there are four ways and routes for further action;

- Through the ambassadors
- Through information meetings
- By offering monitoring the use of electricity
- By offering a complete energy scan

Up till now about 15 reports were made on the possible savings per household. These reports now need a follow up by contacting these households through the ambassador and finding suitable offers fitting the needs we found.

Most important here are the possibilities of insulation and PV electricity. Students have also analysed the technical state of the average house and came up with more ideas about the possible adjustments. Also popular are behavioural changes. These were suggested in the meetings and are an item in the personal follow up.

Poptahof

This neighbourhood was constructed in the 60 ties and the layout is an open Grid, very popular after Ciam and Corbusier. The general design was made by Van Embden, original a co-founder of ISOCARP.

Aerial view Poptahof

An area renewal plan made in 2005 till 2010 was only implemented in about 1/4 of the area and the program was stopped in 2014 because of the economical crises. We consider the existing old housing stock in our pilot. All these houses are owned by Woonbron, a social housing society. All are apartments in four and twelve floor high buildings. The building density is 1231 houses in an area of 21,6 ha, and a density of 57,1 houses /ha. The average income is € 22.000,-/year

General knowledge

The collective heating system is outdated and causing a big energy loss. For the renewal and new buildings constructed in the period from 2005 till 2014 the stoves were replaced and the system upgraded. The old buildings though were kept with the old energy wasting system. The tenants pay their monthly cost based on the total use and the m2 of their apartment.

This causes a lack of interest in individual saving.

Pilot approach

Delft Energie Design (DED) wants to show the opportunities of upgrading and energy saving operations in this neighbourhood opposed to the former plans for replacing most buildings. One approach is to investigate the possible renewal with and through the inhabitants. To start one five floor flat can be transformed as a showcase if the owner can be convinced with a affordable plan. Calculations with the so called "Klushuizen" formula are made and discussed with Woonbron, the owner. A saving of 50% in energy use can be achieved.

At the same time with the tenants and their association an effort is made to help them save energy by the use of their houses and the attitude in their uses.

Several scenarios will be developed with the tenants in workshops and by making interviews to improve the houses as well as the environment. The vast amount of open space in the neighbourhood allows more use and gives several opportunities depending on the interest of the tenants. Scenarios for different degrees of adjustments will be made and calculated starting with a minimum which allows the tenant to stay in the apartment during the construction and in steps towards a complete makeover to realize a zero energy house. In each scenario the possibility of self help will be considered. Also possible sale of apartments will be considered resulting in the housing association to be helpful to tenants as well as towards the new owners.

At this moment talks are going on about the approach of the inhabitants. DED is in touch with the tenants through their association. The association had troubles contacting Woonbron for at least three years. Now with this pilot DED might be able to add to the communication between the owner and the tenants.

To start with an investigation is made on the needs of the current inhabitants of the old buildings. Also information is collected on their energy use/consumption and whether they can do jobs themselves. Next autumn a questionnaire will be spread with the help of tenants in a high rise apartment building and in one of the lower buildings. By analysing the answers first a general advise on the use of the apartments can be made to save energy without any technical intervention. With that DED will get back to the tenants and see what can be done by themselves.

Together with Woonbron further investigation will be done on the technical possibilities. We think of;

- Enlarge the first floor apartments by adding space on the ground floor. With that a garden is made possible and the use of the open space can be more differentiated. It can also add to the social security in the neighbourhood.
- The roofs can be used for terraces or terrace rooms, PV panels and gardening.
- Kitchens can be enlarged
- Individualizing energy use for heating by smart measuring in each apartment and changing the distribution of heating.
- Adding comfort with new technology like monitoring systems on tablet or phone including a control system to the main building entrances.

With the contact made with the tenants they can be made more active as DED gives suggestions on savings to start with for free. By monitoring their savings the possible profit by investing a part of the rent together with the help of Woonbron is more secure for the tenant than before. To plan technical interventions DED wants to find a method to ensure the agreement with all the tenants of a building, a 100% agreement is necessary because these buildings are not suitable for an individual approach on technical interventions concerning the heating system and insulation..

With the approach of the first two buildings DED want to find supporters that can act as ambassadors in the other buildings. To inform everyone meetings will be organised and a meeting point will become active in the neighbourhood.

The first goal is to create more awareness. With the possible control system on the entrances also monitoring software can be developed to see the individual energy use and compare this with others. People can chose to stay anonymous off course. As the dwellings are very comparable maybe some competition can give incentives to further savings.

Agnethapark

The pilot concentrates on the oldest part constructed before the war in the layout of a garden city by Mr and Mrs van Marken, owners of the most important Delft industry, the yeast factory, where also penicillin was invented and produced. The complete neighbourhood was declared a national monument in 1989.

Birdseye's view Agnethapark

The typology of houses is varied, but mostly consists of small dwellings of 2 or 3 floors. Some apartment buildings in the same architecture are present. The building density of the entire neighbourhood, including more than the pilot area, is 554 houses in an area of 199.066 m² or 27,83 houses /ha. The pilot area consists of 219 houses.

The average income is € 38.500,-/year

General knowledge

In the area about 75% of the housing stock is rented to old tenants of which most were working in the factory. The factory sold the houses to an investment company who aims to sell all houses eventually.

The result is a low interest in energy saving programs as most people are old of age and paying low rents.

The house owners, now approximately 25%, are obliged by the municipality to be organized in an owners association that is responsible for the upkeep of the green hedges and the exterior woodworks. In 1990 the houses were renovated in a very modest manner. Glazing is still single and in a lot of houses there is no central heating.

Pilot approach

Because all houses are considered National monuments the efforts concentrate on making invisible or nearly invisible adjustments. As the neighbourhood is designed as a garden city a strong architectural identity is found. This can be useful to create identical adjustments, which makes working together beyond ownership a possible option to investigate.

Because the level of the facilities in the houses is still rather low and energy saving measures are still scarcely found, much can be gained, also with small and cheap adjustments.

Typical houses of the 2nd part built in de 20ties

typical architecture of the first part built in de 19th century

The following organisations have been contacted first to get more knowledge:

- Agnetapark BV and DSM Gist Holding BV
- Owners association Agnetapark
- Tenant association Agnetapark

With DSM the possible use of the wasted warm cooling water of the installations can be investigated as the factory is located next to the neighbourhood.

The housing association, Agnetapark BV, is only interested in selling the houses and is just there to keep the houses in a sellable condition. As people tend to live happily in this neighbourhood and are reluctant to leave, the selling process that started in 2005 is progressing slowly.

After half a year talking with the owners association and tenants association, DED became a trusted partner for them. Apparently former municipal interaction had been too confronting for them and a period of getting acquainted was necessary. DED was invited to a formal tenants meeting and a follow up meeting will be organised in the next autumn. The annual BBQ will be used to advertise DED and a questionnaire will be spread door to door.

Depending on the typology of the house and the ownership different measures are possible. Ownership makes a more individual approach possible as the investment can be calculated individually, especially in the single houses.

As there are lots of unused open spaces between the housing rows the possible use for growing food and the instalment of (collective) energy saving devices can be discussed with the inhabitants and the municipality. With Delft Design a project investigating empty space in the city is connected to DED pilots.

After the next meeting a series of interviews on energy use and comfort will be started with those who are interested. The questionnaire will be used as this is being developed by DED for the use of all pilots. At the same time the status quo of the houses will be charted. By doing this DED also aims to find ambassadors to spread the word and take on tasks like interviewing their neighbours and so on.

The city centre

Here we find a monumental environment with a lot of private owned houses. Also areas with new housing complexes, from 10 apartments to over 200 apartments sharing parking and facilities. In the pilot we try to contact the different typologies.

Originally the city centre is medieval, houses originate from 1500 to 1850 of which most are considered monuments. Therefore the whole city centre is protected area. This also causes constraints for technical interventions.

Delft city centre, google earth

Monuments along a canal "de Kolk", google streetview

The building density is 5533 houses in an area slightly over one km². To compare this results in a density of 55,3 h/ha.

The average income is € 35.000,-/year. This figure is misleading because of the relatively great amount of students living in the city centre.

General knowledge

There is a big difference in culture of live between the students in de city centre and the older residents, mostly owners and often of a National monument. In the new buildings and the quarter in the east side of the centre we find a lot of young families who moved there the last 10 years. We notice a tendency to more appreciation of the old city centre as a living area with nice facilities.

Here in the city centre we find inhabitants organised in several area organisations of inhabitants. With these groups initiated by the people we find easy contact and the interest to talk to individual households is growing. After a year of general informing these groups the step to personal contact depending on the public attention and the interaction between the house owners individually is improving slowly.

The rich history of the houses, historic solutions for heating, ventilation, insulation and against overheating as well as the chances offered by the historic design for the use of modern materials and techniques, can inspire the inhabitants to invest and understand the limitations of their houses.

At this moment over twenty households have been in touch and at least the reports made individually give them opportunities to save 20% in their energy use by changing their behaviour without any investment.

Pilot approach

After meeting all the operational organisations and giving general information on DED as well, individual owners are visited. Next to the neighbourhood organisations DED is currently contacting several owners associations operational for apartment buildings in the city centre. DED calls the individual meetings "Kitchen table talks" in which the same questionnaire is used as is used in the other pilots. At the table adjustments to measure the situation are made of course. The result is a report with a so called "Bottom up design recommendation". This allows people to question DED on the impact of architectural or technical solutions they found themselves. Often they are already planning changes because of comfort reasons or necessary up keeping.

This approach is appalling;

- For the inhabitant because they can ask for technical and/or architectural advice.
- For the DED adviser because this can cause more interaction and an extra job
- For the DED designer because the unique opportunity to custom design.

DED aims with this "no cure no pay" approach to strengthen the attractiveness to join the pilot on saving energy; more individual customized advice.

DED found several ambassadors, people who invested in energy saving with great results with quite different technical solutions like heat pumps, solar devices, insulation and so on. With the people already interviewed and these ambassadors a meeting will be organised in the Prinsenkwartier to show and exchange the results. Also possible clients will be invited to join with special attention for the owners united in owners associations. DED will organize an exhibition of ideas next year, the current installation of 68 PV panels on the roof of the Prinsenkwartier building being a mayor item.

DED wants in this way to create trust and to give several opportunities to people to join the pilot.

Also now the following activities are being developed;

- To help and monitor the execution of adjustments, to find suitable contractors and check the results
- To start collective projects by connecting people and buildings. Sharing flat roofs or roofs of public buildings can join individuals and add to collectives.
- The development of new methods in saving like through new ways of ventilation.
- To work together with the University with several faculties on the design for the recommendations

Status and findings so far.

The project is now in a critical phase as we are starting to get the first results.

A Comparison of the results in the different pilot areas up till now shows big differences, possibly related to income and density of volume and people in the area. DED will investigate these relations in the near future.

In the Verzetstrijdersbuurt and the City centre we find most activity going on. There it was relatively easy to find ambassadors and activate individual households as they own their houses. In these neighbourhoods DED is now collecting offers for technical adjustments and connecting people.

In the Agnethapark this process can be started in the coming period. With Woonbron a break through is expected in the Poptahof and here DED hopes to find an approach useful in other areas alike which are consisting of a great stock of G to C labelled dwellings.

Currently, offers are collected for several insulation items as well as for the application of PV. This is done with a joined effort through the DED cooperative. In doing this, a transparent approach is made by showing the advantage of the joined efforts to all participants. With the pilots a profit can be made compared to stand alone initiatives. For instance by doing this with the cooperative we can make the work done by the participating companies affordable for the house owners joining the project.

A mayor result is realized together with the Cooperation Prinsenkwartier. We found a new way of funding placing PV panels on the roof of the monument The Prinsenkwartier are renting from the municipality. This is one of the first Monuments in Delft with a licence to do so and 68 panels are installed. The energy production is monitored and available on an App for the users. As this project concerns a public building the app will be shown to the public to inform people about the project and the energy production involved. The investment also is part of the project as the Prinsenkwartier is a peoples initiative with gifts and private loans only. With the saving in energy costs the panels will pay themselves within a period of 9 years.

PV panels on the roof of Prinsenkwartier

Energy monitor app solar edge

DED wants to know more about the personal value differences between inhabitants in a pilot area as well as the difference between inhabitants in different pilot areas as this can help the approach of people in other areas.

It is interesting to see the difference in approach related to the neighbourhood specifications. It seems young people are a better target for saving programs because they use a lot of energy in their households. They own a lot of energy-consuming machines and live a very consuming life. Another example: the owners of old houses in the city centre, mostly monuments, are more serious about energy saving than the owners of new houses in this area. The latter often assume that because of the age of their house most energy saving measures are already taken. They rather invest in more comfort than in saving or producing energy. This is opposite to the attitude of the owners of monuments. They are proud of their house and are very concerned about energy saving by behaviour changes first.

DED will explore whether differences in education, profession, culture and lifestyle also present such differences in focus.. It may be sensible to go into these differences deeper in order to get the different groups to inspire each other.

DED's next steps involve an investigation of how the technical data of the existing housing stock in each neighbourhood can be specified in connection to the energy consumption, as well as how big the existing energy consumption is - on average and more specifically per household. With this information we hope to see whether there is a connection between the household characteristic and the behaviour concerning energy use.

To gain more information and exchange experiences, DED is currently connecting to other local initiatives, such as the Delft Design project NAO on the possible use of all kinds of Empty Spaces, Delft becomes green, Stichting de Witte Roos and their project "de Challenge-4-Change".

**Research on the Strategies of Cultural Heritage in Villages and Towns
Characterized by Aboriginal Participation
The Role**

Chao Ma, YingXia Yun, Tianjin University, China

ABSTRACT: Rural culture contains collective interests, and confronts with the mixture and integration of foreign cultures. The strategy of cultural heritage carried by planning achievements is inseparable from a sustainable vision. Moreover, the authenticity of local culture needs to be further consolidated. With aboriginal participation as the characteristics, the paper tries to explore the strategies of cultural heritage in villages and towns based on the technical level beyond traditional planning methods. When the effectiveness of cultural inheritance resulted by planning system mode at the present stage is recognized and inherent advantages of rural culture are provided by aboriginals, with the help from enlightenment of public participation and rural planning methodology characterized by civil participation in Japan, the more effective approach of rural culture heritage is explored in this paper.

Two new methods (aboriginal participation and aboriginal autonomy) used to seek for the strategies of cultural heritage with planning formulation mode are proposed in this paper. Role change, participation level, the perseverance of authenticity in aboriginal planning formulation, and evaluation standards for cultural heritage are also purposed from a new perspective.

KEYWORDS: authenticity, rural culture, aboriginal participation, cultural heritage

Although rural culture has a valuable heritage, over time, it gradually faces new challenges, especially in terms of tourist activity. Regional cultures that have a floating population are widely divergent; some may be relatively intact, while others tend to be discrete symbols, and more fragmented. The ability of rural cultures to be carried forward with authenticity, with a local context and regional characteristics, and to meet new cultural demands, have become hotspot problems for cultural heritage.

In protecting the intangible cultural heritage, two contrasting perspectives have been voiced, represented by: “Do not turn heritage into regret.” and “Do not turn heritage into remains.” (Xie & Chen 2001, p. 43-45; Wei, 2002). These views reflect the two extremes of cultural heritage authenticity – from disappearance to inflexible protection. According to the *Venice Charter*, [ref] “the authenticity of historical sites and relics shall be inherited from generation to generation.” In addition, *The Nara Document on Authenticity*[ref] fully defined authenticity: as being “viewed with a developing foresight, and cultural heritage value and authenticity shall be judged and surveyed under the background, in which such culture is presented.”

1. Purpose of the Research

1.1 Inheritance of Traditional Rural Culture

To regain humanistic information about cultural spaces and to reestablish technical connotations for historical buildings, the carrier of culture must be designed with an ideology for historical buildings, artistic aesthetics of historical buildings or landscapes, the process features of historical buildings, and the use experience of historical buildings or landscapes. They must also be compressive and synthetic (Ruan, 2010). Rural cultures are comprised of lifestyle, convention, tradition, social practice, and folk-custom. In fact, the two terms, “rural culture” and “rural life” relocate the dance, song, music, image art, story, and other related presentation elements. Nevertheless, these elements are not fully recorded by characters, which may be learned by words and dictations, instead of systematic instructions. Historical context evolves continuously with the passage of time. The valuation of rural culture also depends on various information sources, such as culture that is propagated among aboriginals in villages and towns, especially among prestigious and respected people that leads to the highest purity.

Inheritance consists of written culture and oral propagation. If generalized according to linear correlations, the former is more convenient. In other words, culture disseminators often mark important written cultures with dates. Those topics that have a longer history usually draw more attention and gain wider respect. With regards to the time-honored social ages, “the oldest residence in the village” or “the oldest granary in the records,” they represent the social characteristics in those days. To comprehend the ideologies or production modes from earlier periods, we need to rely on inheritance sources that have the highest recognition level or longest history. In contrast, culture passed on in oral forms has no word records, and instead, it is taught by prestigious and respected people through word-of-mouth or by the knowledge production of the period (William, 2012). In rural society where knowledge was taught orally, tradition and faith were developing and interchanging, and being reinterpreted after oral propagation and modification. The authenticity was barely maintained, making it difficult to qualify or quantify culture sources without comprehensive research. Aboriginals showed a stronger ability to differentiate and interpret the origin, development, and change processes of local rural culture. Thus, inviting aboriginals to participate in the inheritance, development, and future planning of local culture is an effective way to maintain authenticity.

2. The Opportunity for Aboriginals to Participate in Planning Formation

2.1 Dilemma in Rural Culture Inheritance

“Culture is a product of social life, and the essence of national spirit. Every nation and every social group has their respective and unique cultural pattern and personality.” (Shan 2006, p.103) The cultural heritage in villages and towns needs to be fully appreciated, and the local culture of aboriginals needs to be respected. The aboriginal knowledge system that has been passed on for centuries also needs to be objectively recorded. Through cross-discipline and cross-culture research, mutual cooperation can help promote local culture and absorb foreign culture while developing the principle of “syncretism between heaven and man,” and according to “locality-oriented” and “self-inherited” characteristics. From generation to generation, from one village to another, and from researchers to the people being researched, the cultural axis is crossing and mingling, finally forming a systematic cultural network. Under the current social environment, and following the rule of survival of the fittest, relatively weaker cultures may be affected and even assimilated, which erodes the authenticity of the original culture. The resulting rural culture variations should be avoided.

For example, the rural Nuo opera of the Dong minority, located in regions south of the Yangtze River, used to be performed on the seventh day of the lunar new year, which was also referred to as “man day” (Jing, 2007). Nevertheless, as the young people of the village had to return to work after the spring festival, the event was advanced to the second day. The Nuo opera, advocating a “ritual system and traditional custom,” eventually broke from the historical rules (Li & Wan, 2008).

2.2 Aboriginals’ Urgent Demand for Cultural Inheritance and the Advantages

The impacts of foreign culture can have a significant influence on the authenticity of rural culture. Intrinsic instable factors are also key sources of influence. (Zhao, 2008, Table 1) This problem also exists in other nations and in tribes around the world. For example, service facilities may be gradually substituted by tourist commodities and high-priced restaurants. Because of the long production cycle or raw material shortages, folk materials and techniques used by aboriginals may be gradually marginalized and separated from their original form. The public spaces for ceremony and neighborhood communication can be occupied by tourists, and aboriginals may lack the space to carry out activities or events in their villages or towns. Even if new public space is provided, the “Ship of Theseus” problem can easily occur, raising doubts about the authenticity. The daylong bustle of tourists breaks from the original tranquility and residents’ private and semi-private spaces may become invaded. A permanent floating population has only a rough connection to the original rural culture, which can lead to a severe vulgarization and invasion of the local culture (e.g., the Di opera performance of *Riding Alone for Thousands of Miles* resulting from the misunderstanding of Lijiang culture) (Zhang, 2012). These problems can affect the daily lives of aboriginals in villages and towns, retard the maintenance, cultivation, and development of local traditional culture, and lead to situations of low price selling and decay. With respect to the authenticity of customs, handcrafts, and anecdotes, the family manuscripts of aboriginals and the narrations of prestigious and respected people are the backbone for correcting errors in local culture. They play an indispensable role in stripping off additional cultures that may have been introduced from other sources.

Warning Information	Internal Sources	External Sources
Folk Culture	Outward migration of local residents and the decrease in population growth rate	Inflow of large numbers of external workers and merchants

	Drop of local residents' living standard	Inflow of overloaded and excessive tourists
	Aging of local residents	Impact of external thoughts and Western culture
	Changes in traditional production process and lifestyle	Impact from modern lifestyle and communication tools
	Elapse of traditional festivals and etiquette concept	
	Decrease in local residents' satisfaction about current life	

Table 1: Early Warning Signs with respect to Rural Protection. (Zhao, Y 2008, Theory and Method for Protection of Historically Famous Villages and Towns in China, China Architecture & Building Press, Beijing).

2.3 Resistance and Feasibility of Aboriginal Participation

2.3.1 Incompleteness of Aboriginal Participation

Practical inheritance of the rural culture is reflected by the orientation of rural planning, and decisions related to short-term and long-term planning. The local property of aboriginals plays an important role in this process. Planning activities in China have no mature public participation system so far. Even in the period of surveying before planning formulation, personnel from different departments and at different levels may try to understand the aboriginals' view and suggestions for planning by field survey, questionnaire survey, discussion, literature, etc. In planning formation; however, aboriginal participation is seldom emphasized. Moreover, in planning activities, the suggestions of residents are seldom comprehensively analyzed. Consequently, few of the aboriginal opinions are accepted. In later stages, few aboriginal interactions are considered and the initiative for aboriginal participation gradually declines. This is also part of our administrative system, which affects the aboriginals' overall quality.

2.3.2 Mature Public Participation Modes in Planning

In the US, small town planning greatly emphasizes aboriginal (public) participation. For example, town planning in Union Bridge, Maryland was comprised of six phases. The first phase was to research the current land use and economic development. In the second phase, questionnaires were sent to the public to collect their suggestions about the goal of the planning. In the third phase, a planning draft was formulated according to the preliminary research and public suggestions. In the fourth phase, the public was invited to discuss the draft, to collect the views of people. This was a key link in the whole planning activity, as it determined whether or not the draft needed to be revised. In the fifth phase, the planning was modified and finalized according to the draft, after the collection of public suggestions. In the sixth phase, after two months of publicity, a hearing was held and the case entered the legislative procedure of city council. In three of the six phases, public participation was required. These three key phases also determined whether or not the planning would be approved. During the planning formulation, residents participated because they realized that the overall planning of the city was closely related to their interests. Moreover, they attached great importance to their influence of the planning, which would affect their lives and employment. Eventually, their valuable suggestions were incorporated into the planning (Zheng et al. 2010,p.100-101). The shared decision-making power realized by public participation was fully brought into play in the planning formation for Union Bridge.

3. Rural Planning based on Rural Culture Inheritance and Aboriginal Participation Method

Seen from a macroscopic dimension, rural planning will have plenty of generalities in the next century. In conforming to the demand for rural economic development, a regional rural system will be established to fully meet the demand of production and living standard improvement in terms of overall construction deployment. Rural constructions will be comprehensively planned and arranged for a coordinated development (Zhang & Cui, 2008) The components that constitute rural planning formation are referred to as “elements in the planning system,” Which are derived from theoretical extensions, instead of planning formation. For example, aboriginals are introduced for the planning method research system. They are regarded as new elements added beyond the planning subjects, and they appeal to points in planning formation that differ from the traditional formulation method. We are trying to observe the influence of such additional elements on the cultural heritage method. As shown in Fig. 1, the roles of aboriginals in planning participation are in “aboriginal participation” and “aboriginal autonomy”. Both of these methods are based on the strategy for research involving aboriginals.

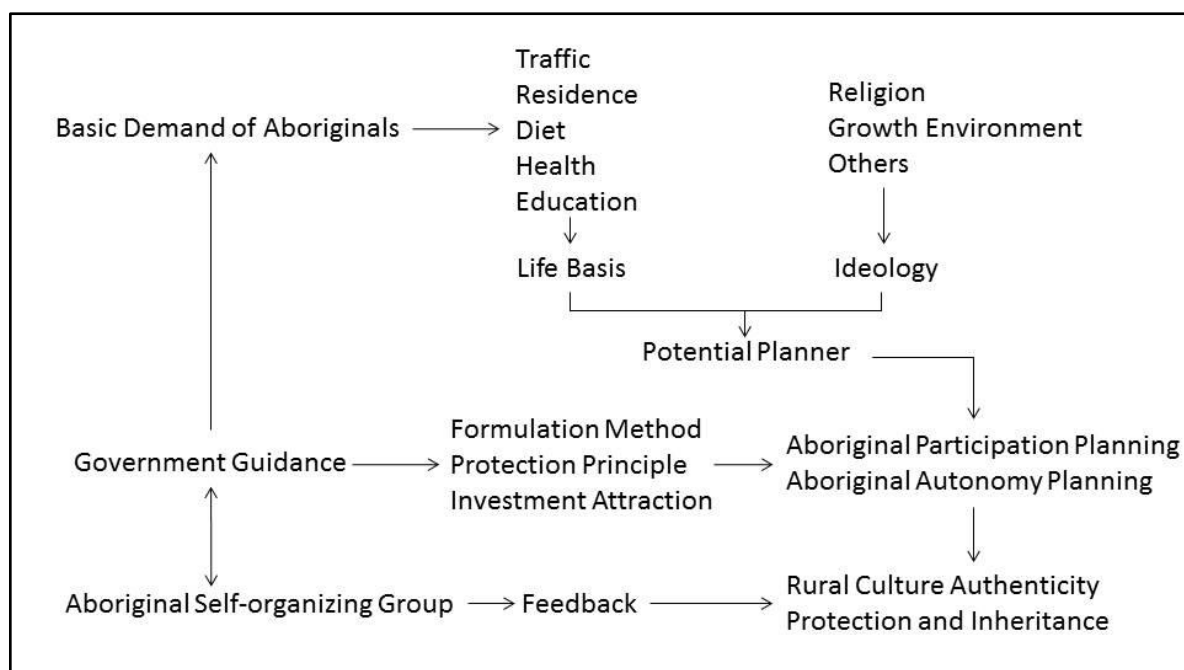

Figure 1: Schema of Aboriginal Participation (by the author).

3.1 Aboriginal Participation

Japan was one of the earliest countries to consider the participation of villagers in rural planning. In the late-1970s, “Rural Planning and Villager Participation” was selected as a topic for the First Annual Meeting (1982) of the Japan Rural Planning Academy, which was regarded as a milestone for developing planning theory based on villager participation. In the seminar, Fujimoto Nobuyoshi presented research on the application of public participation in primal rural planning in Japan. Professor Ushino Tadashi also released a research report on rural planning, with villagers as the main subject: the mode of *かんでむら* (Hoshino & Wang 2010, pp.54-60). In terms of villager participation, these two scholars advocated for planning with the rural village as the unit.

Planning formation based on aboriginal participation differs from the mode led by governmental authorities and undertaken by expert planners. It is interpreted as a new planning method and ideology. The method generally involves: relying on the experience from birth to growth, aboriginals summarizing the characteristics of their village from their

perspective, taking the village as a permanent place of residence, exploring and exchanging ideas based on the aboriginals' view of life and with family as the minimum unit. Aboriginals draw a "blueprint" for the development of the village, focusing on the smallest units for the orientation of construction direction. They gather together prestigious and respected people in the village to integrate their similarities and differences, record or list the village's cultural characteristics, and jointly complete related works. These characteristics have a number of advantages like the familiarity of aboriginals with the culture in the village. Apart from providing a primal authenticity of the village, the role of aboriginals is turned from "being planned" to "the planner". Thus, the contribution of their role is improved and their internal motivation is strengthened. In addition, this mode may also prevent planners from going off-track in planning formation, by ignoring certain folks, traditions, or prejudice.

The ideology of aboriginal participation is also reflected by new groups formed by aboriginals according to characteristics that differ from other groups, administratively. In terms of research and implementations, the age structure, gender structure, growth environment, marriage and birth customs, family and relative relations, and religious lives of members are recorded. According to original aboriginal planning ideology, and by integrating the organizational mechanisms, a solid foundation can be laid for developing villages and towns. This will help to further consolidate the cultural context and provide a unique sense of place for establishing authenticity (Table 2).

	Traditional Planning Formulation Strategy	Formulation Strategy Characterized by Aboriginal Participation
Belonging Sense of Villages and Towns	Residents have the sense of identity for themselves, the place, and the village or town	Aboriginal participation initiative is improved, playing an important role on behalf of their local group in the planning, with the sense of identity greatly improved
Group Attitude of Aboriginal	Partial objections to planning formulation, different attitude, playing a part in pre-stage investigation, limited influence	Playing an insider's role in the whole course as principal person affecting the future of the village or town, shouldering historical responsibility, with influence expanded
Public Acceptance	Except for some famous historical and cultural villages, other villages and towns tend to be similar, leading to the suspicion of imitation	The involvement of aboriginals in traditional planning scheme leads to the consequence that the reform is conditionally opposed, with changing period extended. However, preserved environment and intangible heritage are hereby attached with great significance

Table 2: Sense of Place Affiliated with Authenticity (by the author).

The transformation from the "top-to-bottom" traditional planning mode to the "bottom-to-top" aboriginal participation oriented planning mode is impeded by the system, and it is currently still in its pilot phase. Nevertheless, such transformation of planning form and system uses a scientific method developed from experts' and planners' long experience in rural planning, and the repeated and prudent exploration in practical surveys and work. In research related to rural planning, by comparing the efficiency and timeliness of the two planning methods, we find that the aboriginal participation method leads to an effect that perfectly fits the local conditions. Although it may not be able to fully substitute for the traditional formulation method, the two methods complement each other for mutual

improvement.

3.2 Aboriginal Autonomy

An ideological difference exists between aboriginal participation and aboriginal autonomy. The most significant difference is that the former is led by government with aboriginal participants. Registered personnel mainly come from sponsoring units. As for the latter mode, aboriginals are the principal part responsible for planning of their own villages and towns. The government and other departments only play a coordinating role. Nevertheless, limited by formulation technology, the aboriginal autonomy planning method only realizes full autonomy in the pre-stage communication and ideas. To implement such planning formation, support from other departments is necessary.

In the aboriginal autonomy-based planning, aboriginals' ideology will determine the process and direction of planning formation. It is uncertain whether or not regional disparity, other natural qualities, or cultural preservation will be independent and complete. Furthermore, the planning formation of villages and towns may also be different. As a result, the authenticity of cultural inheritance is not the same. Furthermore, in being affected by foreign cultures, the widely commended rural culture-based development mode is imitated all over the country. Aboriginals are familiar with their own situations and resources; however, without cultivation and training for the planning system, they lack connotations of style loss or characteristic obscurity caused by imitation and unrealistic expectation. As a result, the planning result is significantly different from what is expected. In any case, the planning system led by governmental authorities, and planning formation based on aboriginal autonomy has not yet been given significant responsibilities.

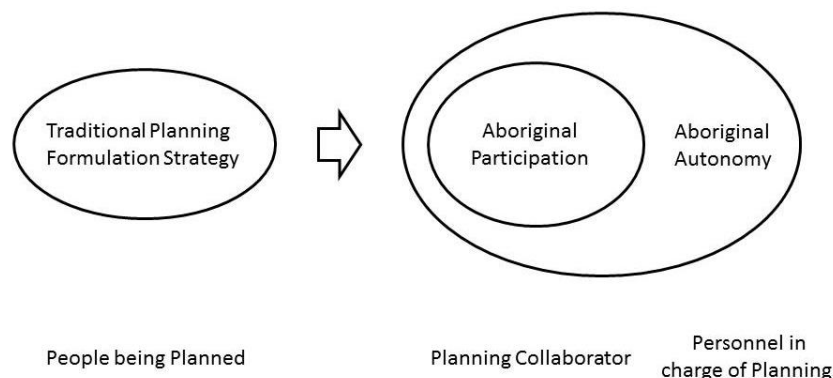

Figure 2: Change of Aboriginal Role in Planning Formation (By the Author)

3.3 Characteristics of Aboriginal Participation and Aboriginal Autonomy Planning Strategy

3.3.1 The Platform of Cultural Heritage is Expanded

The level of rural planning formation is comprised of result quality and implementation effect. Such planning is transformed from being independently completed by traditional planners to the effective participation of aboriginals. Thus, the vision of traditional planning formation is transferred from the technical mode that emphasizes technology, formulation skill, and source to the comprehensive mode based on high proportion of public participation.

3.3.2 Extensibility of Cultural Heritage after the Implementation of Planning

As the main subject and the director of planning formation, aboriginals' willingness will be eventually reflected by the final results; i.e., realization of the aboriginals' willingness and appeal. In the final planning management, such consequences would be more deliberate than the planning that results from expert planners. Accordingly, the efficiency of cultural inheritance and propagation is improved, for the whole course participation in

exploration, formulation, and administration.

3.3.3 Conversion of Evaluation Standard for Cultural Heritage Achievements

Previous cultural heritage evaluation standards have been determined by the planning text demonstration effect, public reaction, and market investment responses, such as providing greater economic motivation for cities, villages, and towns, or attracting wider domestic and overseas attention. Nevertheless, in aboriginal participation-based planning, the inheritance effect is mainly transferred to the aboriginals' contribution; i.e., whether or not the aboriginals' appeal for the village or town is satisfied. Commendations from the external world are no longer the ultimate evaluation standards for rural culture inheritance.

4. Other Reflections on the Strategy of Cultural Heritage Characterized by Aboriginal Participation

4.1 Participation Moderation and Aboriginal Appeal Intensity

In the investigation phase of planning formation, the moderation of survey content and aboriginal appeal intensity is the premise for successful planning. Here, traditional ideology of the aboriginals in villages and towns should be included, such as whether or not any dissatisfaction is felt about the current situation; whether or not psychological fluctuations occur after contact and communications with foreign cultures; whether or not aboriginals are well prepared for possible updates or remolding of the current situation, etc. Cultural heritage must be carried by the planning formation. In practice, the aboriginals' immediate interests and deep-rooted rural ideology are the major factors that promote or impede planning formulation.

4.2 The Power of Collective Willingness

As constituent elements of rural life, aboriginals are divided first, according to their blood relationships, second, by their ethnic relationships, and third, by their production cooperative partner. The diversity that is formed in planning implementation will directly affect the formulation results. The coordination level of collective willingness is connected with rural leadership structure, aboriginals' benefit distribution mode, and the trust level between planners and people being planned. To achieve better planning results, the internal relationships of aboriginals must be determined, which also clarifies their tendency for collective willingness.

4.3 Reflections on the Depth of Participation

Considering the authenticity of culture, the depth of aboriginal participation in planning formation should be maximized within the scope allowed by laws and regulations. According to the Japanese scholar にしお まさる(2013), the form of participation may be categorized in four ways, based on the villagers' privilege: campaign, enrollment of planning institution, communication, and autonomous administration. Following the development process of the traditional formulation method → aboriginal participation → aboriginal autonomy, the depth of aboriginal willingness and aboriginal participation is enhanced layer by layer, while the participation proportion of professional personnel is reduced accordingly. The development tendency of planning still needs to be explored in key steps, like planning institution enrollment and communication.

4.4 Decision-Making Power

According to our present planning formation system, administrative departments do not entitle their powers to aboriginals. Aboriginals may still be able to participate in planning, or even determine the planning formation. Nevertheless, before implementing engineering projects, administrative departments will review and determine whether or not such planning formation is feasible. Decision-making power is still a last threshold for cultural heritage with the planning result being the carrier.

5. Conclusion

The planning formation method will become increasingly detailed in its technical aspects, like software and method, and will become more widely accepted. From another dimension, as important parts in the planning formation, aboriginals will extend the technical level. Their comprehension and oversight ability for rural culture will be expanded from a traditional level to implementation practice. The sharing of decision-making power will improve the aboriginals' status and participation depth in planning formation, thus shortening the formulation period. Meanwhile, efficiently integrating the collective willingness of aboriginals is deeply rooted in the evaluation standards for rural planning formation. Besides guaranteeing the authenticity of cultural heritage, it helps the local culture to resist the impact of foreign cultures, and thus, it maintains authenticity. From aboriginal participation to aboriginal autonomy, the role of aboriginals is no longer to witness the process of planning formation. Their ideology and attitude will determine whether or not the authenticity of their rural culture will be seamlessly inherited. Granting aboriginals new roles and establishing a formulation strategy with aboriginal participation is new direction from the traditional route of planning technology research.

City Planning between Decline and Recovery - Perspectives for a “Communicative Turn” of Planning

Stephan REISS-SCHMIDT, Germany

Abstract

Compared with the heroic times of our discipline when ISOCARP was founded, in the last twenty years planning seems to struggle more and more in heavy weathers. Neo-liberal city development, driven by digitalization and a globalized market-economy, sees the planner more as a waiter than a cook. Facing a cooperative transformation of governance in cities, a “communicative turn of planning”, based on a coalition with civil society, could open perspectives for a new role of planners as intermediate actors. As advocates for the public interest and the commons, planners should not only be moderators. Based on their special competences for space, designing, integration and communication, planners could be catalysts of cooperative urban transformation processes. Preconditions of a possible recovery of public planning seem to be the reintegration of all dimensions of planning, the reorientation of planning education on real problems and not at least the search for more political influence through new alliances between planners and civil society.

1. Introduction

After fifty years of ISOCARP, it's time to reflect the decline of our profession. When ISOCARP was founded, city planning was in a tremendous upswing. Especially in the western world, the long post-war phase of economic growth and social oriented national and/or local governments used planning as a tool to provide housing and better living conditions for a broad majority. In the southern hemisphere, city planning became part of nation building and forming a new post-colonial identity. In the last twenty years with globalization and digitalization, planning seems to become a “dying out craft”. Is this process an inevitable fate, or is it reversible? Since the economization of the city and the representative democracy both lost legitimacy, a recovery of planning and a new self-image of planners seem to come in reach. Of course, there will be no way back to the god-like “master of the urban universe”.

2. Changing modes of city production and the role of planning

2.1 Planning: a flash in city history

Since more than 10'000 years, cities in the world had developed without city planners. Priests, land surveyors or fortification builders, building controllers, sanitation engineers, architects or the citizens themselves decided about the structure and form of urban settlements. Not more than hundred years ago, city planning emancipated as a discipline of its own from engineers and architects, bringing together social sciences, engineering, economics, geography with landscape and urban design. A special methodology, organization, a powerful legal system and national, regional and local administrations of planning evolved. Planning and planning control was originally (and in some aspects until today) hierarchical and top-down, using formalized planning instruments and strict regulations. City planning became a politically influential and important role during the time of growing industrial cities and even during the years of rebuilding cities after World War II. Until the first phase of the post-industrial transformation of European cities since the 1960ies, planners felt and acted like the “masters of the urban universe”. The mode of city production

was driven by technological innovation (infrastructures like sewage, energy supply, tramways, metro etc.), by (paternalistic) social welfare concepts (social housing, schools, kindergarten) and by a strong and active state, especially on the local level of city administration.

2.2 Driving forces of city development

The production modes of cities changed in history and at the same time the driving forces, the decision makers and the role of plans and planners (see MUMFORD 1961). The ancient cities of the Near East, Egypt, Greece and the Roman Empire were primarily produced by the ruling monarch or oligarchy as representative and religious capitals, military camps and fortifications, often combined with trade and manufacturing functions for a wider surrounding area. The medieval European town was a coproduction of its citizens - organized in councils of the owners and guilds of traders and craftsmen – sometimes in violent opposition to territorial rulers and the church. Where the city was residence of a territorial ruler, it was produced mainly by the sovereign and his visions and objectives. Sometimes the citizens' city, the bishops' city and the royal seat emerged side by side (see BRAUNFELS 1976).

Fig. 1: Renaissance Munich with its fortifications (1613), a coproduction of territorial ruler, church and citizens (source: City of Munich).

Since the 19th century, after de-fortification, the industrial city emerged - housing areas for the workers grouped around a cotton mill or a mine, rational street grids with terraced houses for the middle class and villas for the upper class. The industrial city was served by new developed and planned technical infrastructures like sewage, gas-, electricity and water-supply and got networks for public transport by tramways, metro or suburban rail. The production mode of the industrial city was genuine capitalist, financed and organized by landlords and private companies for housing, manufacturing or infrastructures, based on public concessions. Sometimes the latter was supplied by city or state, where private capital was not able or willing to supply the necessary infrastructure. Schools and hospitals and all other social infrastructures were mostly built and driven by city, state or church, sometimes by philanthropic landlords or industrialists. Citizens' rights were linked with property of land.

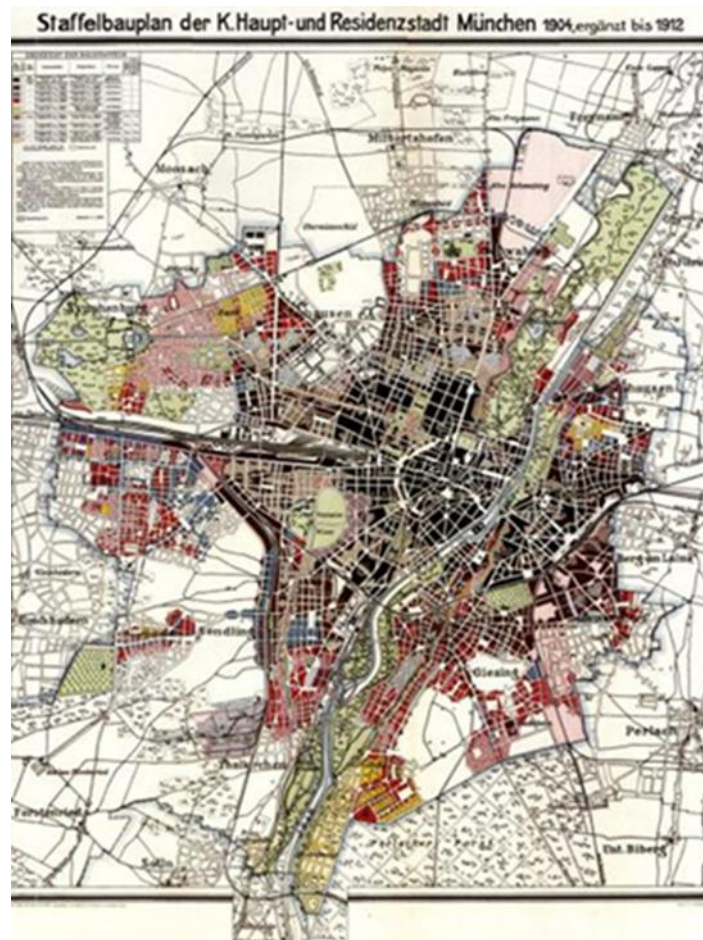

Fig. 2: Theodor Fischer's "Staffelbauplan" for the expansion of Munich (1904/12), the first regulatory plan for the growing industrial city (source: City of Munich).

After the end of the feudal systems (or their transformation into constitutional monarchies) in the beginning of the 20th century, the century of democratic urban development started. With election rights for every citizen, with elected mayors and city councils, the production of the city based more or less on democratic decisions.

2.3 Public planning in the social welfare state

During the 1920ties and after World War II in many European cities like Vienna, Lyon, Amsterdam, Stockholm, Berlin or Frankfurt socialist or social democratic majorities together with trade unions and cooperatives realized the city model of the democratic welfare state: schools, social housing sports facilities, parks and public transport made cities livable despite their growing density. The state sets strong and clear rules about property rights and social responsibilities of land owners, often accompanied by a special taxation of house ownership. Strong legal planning instruments were developed to control building rights and land use (density, kind of use). The state or the planner as his agent was in control of land use and development. These ages were the peak of the influence of city planning. The society lends their power to planners and gave them the resources to realize a rational planned city. In the ideal of the city of welfare state, the planner is a technical expert, who handles his expertise to make good plans and implement them. He is the advocate of the public interest, of coming generations and of those, who have no voice in the political arena. Planning changed from a kind of creative craft to a science-based practice. During the 20th century planning more and more widened its perspective from the mere technical and spatial questions to the economic,

social and environmental aspects of urban development (see ALBERS 1997). In Western Europe over most of the 20th century the democratic “welfare state-mode” of city production gave public planning a strong position. Affordable housing and a high quality of infrastructure was secured better than in the phase of capitalist growth of the industrial city during the second half of the 19th century.

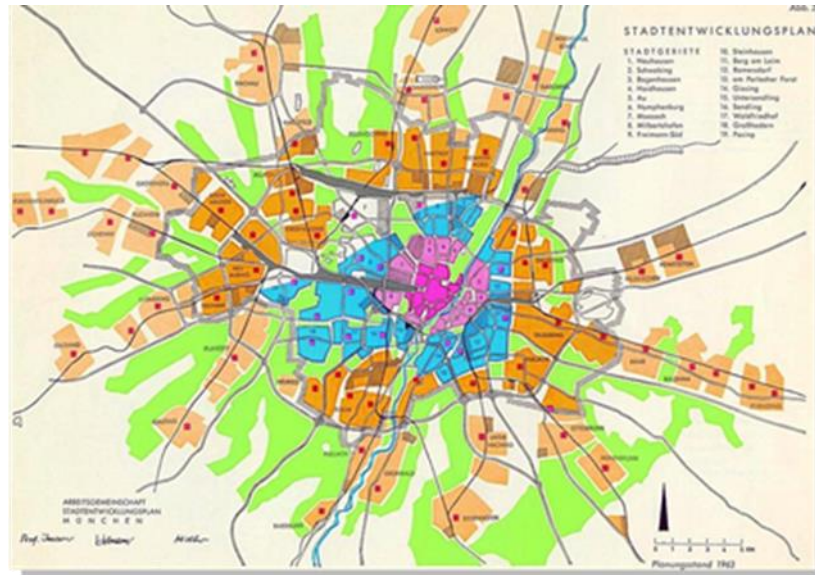

Fig. 3: Munich City Development Plan 1963 (“Jensen-Plan”) - guidelines for the spatial structure of an expanding city-region (source: City of Munich).

3. Decline of planning in the 21st century

3.1 The neo-liberal city: planning goes private

About the turn of the millennium, the model of the social balanced and democratic city came more and more in danger. Globalization with its neo-liberal concepts of a market-society influenced local policy. Almost worldwide the global finance industry became the main driver of urban development. Meanwhile the privatization and exploitation of land and infrastructure following the shareholder value principles of efficiency and maximum profits dominate. Planning in many countries is blamed as a socialist torture instrument, planners degenerate more and more from advocates of the public interest to servants for profit driven real estate or infrastructure investments. The players of the big Monopoly are more international dealing institutional anonymous actors like real-estate or hedge funds than personal private land owners.

Under these conditions, the democratic power of the elected city government becomes in many cases a thin façade. Important decisions about land use, infrastructures and spatial organization of the city are often driven by short term advantages and profit, centralized in the hands of a few powerful economic players. Public land, public housing, public responsibility for infrastructure and for urban quality had been replaced and atomized in many cities (but fortunately not in all, as cities like Vienna, Zurich, Lyon, Berlin, Hamburg and Munich prove) by privatization. The quantified space got forehand over the spatial and social quality of the urban environment. The production mode of urban environments changes step by step from plan- and policy-driven to market- and economy-driven.

New players come on the economized playing ground of urban development:

- Real estate brokers, bankers,
- developers, project managers
- marketing specialists,
- auditors, lawyers etc.

As a result of new players with new rules, the legal framework and the observation of established professional rules get rid of content and quality - it degenerates to a formal and legal issue with lawyers and auditors becoming more influential than planners. The planner himself sits between the chairs of public planning bodies/politics and private capital (owners, developers, shareholders). He becomes the position not of a cook, but a waiter, who serves private interests with a service for real estate development. At the end, city planners often feel like uninvited spectators of urban development.

In the recent issue 200 of *disp-The Planning Review* "The state of the Art of Planning in Europe" was documented with a survey among academics and practitioners in planning. In their conclusion based on 34 answers from 21 European cities, Klaus R. Kunzmann and Martina Koll-Schretzenmayr stated: "The answers show a black picture of the state of planning. Planning in Europe in 2015 seems to be in a state of re-orientation. (...) Changing political priorities, modifications in the regulatory system, or organizational changes are seen as the main reasons of the gradual decline of the status of planning in Europe. (...) Growth at any price - and if necessary even on green fields - seems to have priority in many places. As a rule, the financial interests of investors are placed well ahead of the efforts of planners to bring about a sustainable and resilient development of living spaces." (KUNZMANN, KOLL-SCHRETZENMAYR 2015. 86, 87)

Nevertheless, some self-confident, powerful, mostly economically well-off cities in Europe try to resist this economization of urban development and reject privatization of public housing, infrastructures and public land. With integrated urban development concepts (DST 2013) based on the principles of the Leipzig Charter (LEIPZIG CHARTA 2007) and high investments in public infrastructure, the above mentioned, but also many smaller cities in western Europe have established a social oriented, sustainable planning culture trying to control urban development politically (see CITY OF MUNICH 2005, 2007, 2015). Nevertheless, also these last bastions of a social inclusive, integrated urban development policy stay not unaffected of the ongoing economization of urban development and the further integration of the local real estate market into the globalized finance markets.

Fig.4: Integrated City Development Concept PERSPECTIVE MUNICH (2005) - polycentric spatial concept "compact, urban, green" (source: City of Munich).

3.2. Fragmentation of the planning disciplines

The “decline of planning” and the loss of influence of planners is not only caused by changing production modes and economic drivers of city development. It is also a result of necessity for a multi-disciplinary and integrated planning in a complex world.

No single planner is able to oversee all the facets of the field, even as a coordinator he had often been outscored by lawyers and project managers. Planning profession(s) are more and more fragmented in spatial, technical, social, economic and ecologic special expertise. Beginning in the 1970ties, preservation of heritage and identity, social issues like affordable housing and social-oriented urban renewal, climate change, energy efficiency and sustainable city development became important issues for city planning and enriched the discipline with new contents. At the same time, people wanted more and more to participate in planning issues. Citizens and market actors wanted to be involved as partners, not as objects into the transformation of the city. As a result of higher complexity, the integrated and integrating spatial planning disciplines got more and more atomized into partly contradictory competences such as:

- Traffic planners and -engineers
- landscape planners
- social geographers,
- environmental engineers,
- psychologists,
- event managers,
- mediators, moderators,
- architects, designers etc.

What originally was meant to make planning stronger, proved to disintegrate a holistic and comprehensive approach and to weaken planning against economic forces. The core content of the discipline disappeared in the haze of an increasingly complex setting of urban problems and challenges. As more and more new professional profiles emerged, the planner became one of dozens of specialists in even bigger multidisciplinary teams. They stood no longer on top of the hierarchy of those who plan and manage city development and urban structures.

3.3. Digitalization and acceleration

Scientific, cultural, economic and societal developments have tremendously accelerated since the turn of the century. Looking back on the changes of the last 50 years, presumably the same change rate will be reached in 20 years ahead of now. Not at least since the 1990ies the accelerating digitalization of our everyday life and our professional work as planners is one of the driving forces to change the “classical” planning methodology (see RAUTERBERG 2013). In principle the digital global economy is “space-less” and nearly independent of urban environments and infrastructures. Distances and time are reduced to zero - whereas urban space and the creation or transformation of built structures need a lot of time and space for development. They are physically permanent and used over many decades or often centuries. Planning on the other hand is a slow, analogue and long term business. Planners feel more and more being the last surviving “dinosaurs” of the welfare-state in a market driven, space-less and digitalized world. Not at least, the core content of planning as a discerned, scientific based and integrated practice seems to disappear in the haze of an increasingly complex setting, fragmented into innumerable specialists.

Digitalization did not only change the processes of research and design by an enormous growth of information and by acceleration the collecting and analyzing of data for planning. Emotion, intuition, subjective approaches of urban planning and design had been replaced more and more by routines, standardization and algorithms. Planning decisions seem to be more and more treated as a technical problem of data mining and information - management instead of a question of values and normative political specifications. Digital planning tools are able to analyze a big amount of data and to create uncountable alternatives. Obviously, that does not always makes the quality of our strategies and plans better or political decisions easier. The complexity and contradictory nature of planning problems mostly hinder pure rational solutions. On the other hand, flexible temporary and intermediate use of built structures, multi modal and sharing based mobility solutions or smart grids for energy supply using renewables are examples for the advantages of digitalization in urban development.

4. The “communicative turn”: opportunity for a recovery of planning?

4.1 Cooperative Governance and integrated planning

At the beginning of the third millennium, the neo-liberal, market - driven production of the city as well as the representative democracy seem to loose acceptance and legitimacy for many citizens. European cities face an accelerated process of multifaceted spatial transformations with complex social, economic and ecologic challenges:

- The growing south-north and east-west migration within Europe and from civil war-countries in Africa and the Middle East.
- The ongoing process of an urban renaissance in Europe with fast growing big cities, which makes integrated spatial planning and implementation-management necessary.
- The increasing worldwide scarcity of resources (land, water, energy, minerals, food etc.), which makes planning, management and regulations of the use of resources inevitable.
- The accelerated social-economic polarization between regions and city districts, based on market driven spatial development, which have to be counterbalanced for a sustainable, resilient urban development.
- The urgent search for resilient modes of spatial development, which is not possible without spatial analyses, scenarios, strategies and action plans – i.e. strategic and integrated planning.
- The advantages and risks of the digitalization (“Smart Cities” – “Smart Planning”), which has to be planned and managed as a public realm and under political leadership and responsibility, if it shall become more than a business case for the ICT-industries.

To meet these challenges, a sustainable urban transformation requires a fundamental change from hierarchical top-down towards discursive and reflexive processes: “governance by and as communication” (SCHUPPERT 2015. 1). Beside this cooperative urban governance a relaunch of an integrated public planning culture is necessary for a recovery (DEUTSCHER STÄDTETAG 2011).

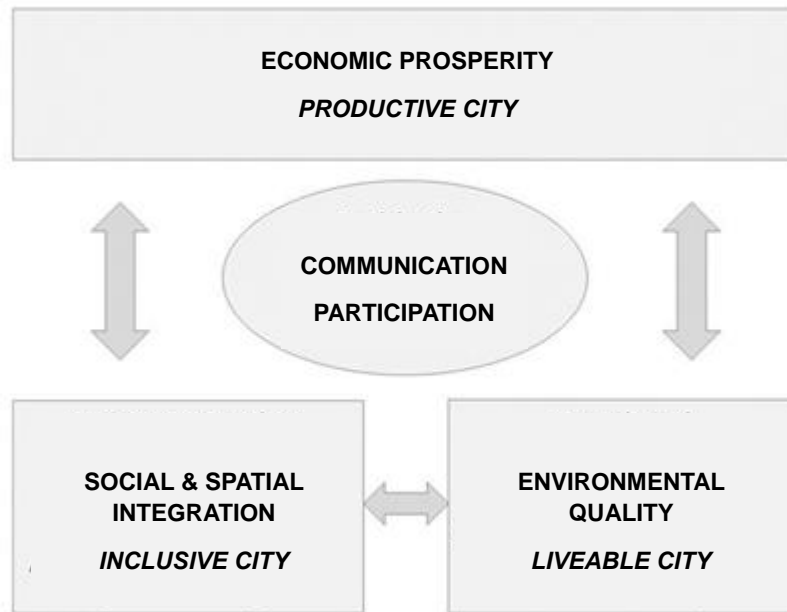

Fig. 5: Dimensions of integrated sustainable planning strategies
(source: DEUTSCHER STÄDTETAG 2011, modified by the author).

4.2 Planning by and as communication – a new role for planners?

Most important and challenging for the planning and decision processes are the fundamental changes of communication through internet, social media and other tools. Beyond the advantages of speed and transparency, the digital planning communication allows a broad information and participation of stakeholders and citizens. Networking not only among planners or the administration, but also with the public or community groups enriches planning discussions and finding the best solution. (see: <http://www.perspektive.muenchen-mitdenken.de>).

The production of the city itself becomes a communication process of many stakeholders from civil society, market and politics: planning by and as communication, taking effect not by power, but by persuasion. If you replace “government” by “planner” in the following citation, you get an idea of what the communicative turn means for our profession: “Power explains a governments ability to get decisions made. [...] For this, it does not help governments to be able to give orders, at least not very much: they need to be able to persuade. Persuasiveness is not contained in the weight of power; it depends on the strength of authority” (RINGEN 2008).

Planning will be organized (or will just happen) between the four poles of governance: politics/administration – market – science – civil society. This are the cornerstones of the urban “communicative arena” (SCHUPPERT 2015. 3), were planners act on the stage and prepare proposals backstage. Planners in the communicative arena will work not only in a unidirectional commission from a public body or a private land-owner/developer. Instead, they will become a new type of “intermediate actors” or “go-betweens”, acting as advocates of the public interest. As experts in the issues of spatial organization of society, planners also could play an important role as “translators” to facilitate communication about urban transformation between even more diverse social and cultural milieus. In that scenario, city

planners get their power not from the government, but from civil society and gain back influence by successful acting in the communicative arena of planning.

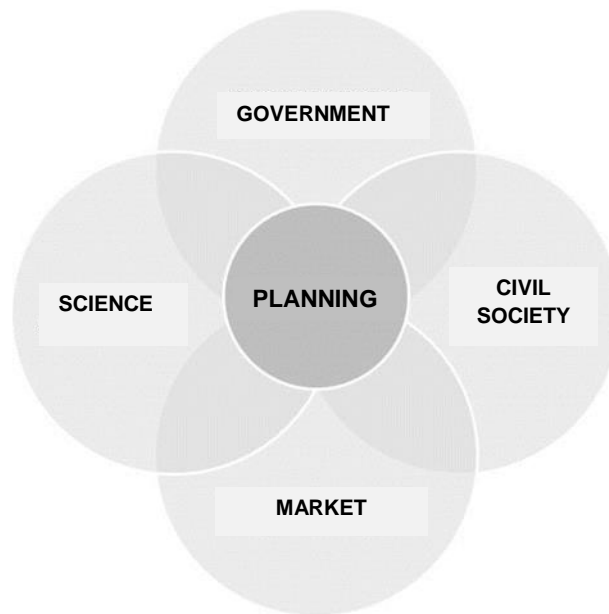

Fig. 6: Planning as intermediate action between different stakeholders
(source: DEUTSCHER STÄDTETAG 2011, modified by the author).

Communication and co-design instead of top-down decisions give city-planning a new legitimacy and urgency: a change of paradigms from “planning as a hierarchical technique of ruling” to “planning as and by communication, organizing complex and multilateral transformation processes” (DEUTSCHER STÄDTETAG 2013b).

4.3 New planning paradigms: core competences and education

Planners could become an active and influential stakeholder in the communicative arena, if they are empowered for “agenda setting” and organizing “advocacy coalitions” (SCHUPPERT 2015. 4) together with other intermediate actors like community groups, initiatives, political and societal groups, media and arts.

Anyway, planners are more than moderators:

- Planners are experts for urban and regional space as the core dimension of urban transformation.
- Planners are experts for designing (*Entwerfen*) as a creative method of thinking, analyzing and problem solving.
- Planners are advocates of the public interest and of spatial justice. Proposals shall base upon fair consideration of different private and public interests (*gerechte Abwägung*).
- Planners have to care about provisions for quality of life and an equal access to common goods (*Daseinsvorsorge*).

These professional competences, values and virtues empower planners for leadership in the communicative arena of urban transformation and in cooperative design-processes. In an

optimistic scenario, the present urban renaissance opens a window of opportunity also for a recovery of public planning.

Education and advanced vocational training in spatial planning have to follow (or better to anticipate) the future paradigm of “planning as and by communication”, focused on the specific core competences of our discipline:

- **SPACE:** spatial analysis and spatial strategies.
- **DESIGNING:** design as a method - design-thinking, innovative solutions - experiments and city labs.
- **INTEGRATION:** comprehensive, multi-disciplinary planning and implementation – integration and empowerment of all social and cultural milieus.
- **COMMUNICATION & COOPERATION:** networking – participation/co-deciding - co-designing/co-production - sharing/cooperatives.

To empower future planners for their new roles as intermediate actors, translators and advocates, the education must contain more social-communicative skills, more cooperation, more political, social and economic knowledge. Students must be confronted and challenged as early as possible in projects, workshops and “urban labs” with real problems, real people and planning practitioners (SCHOLL 2012). Planners should of course never try to become the better sociologists, real-estate economists or lawyers. Based on their core competences, they must be mind-open to communicate, cooperate and integrate knowledge with many other specialized professions. Taking into account the political dimension of planning and urban transformation, the struggle for more political influence and the search for coalitions with social, political and cultural movements are essential for a regeneration of planning. That does also mean:

- To be aware, that planning is not only a technical and rational, but an emotional and subjective challenge. Planners are responsible to protect and develop the identity of places and spaces.
- More involvement in implementation and evaluation - planners as managers of urban transformation. Making good plans is not enough!

4.4 Examples

Meanwhile, there are many examples in cities all over the world for the “communicative turn” of planning. Since the documentation of case studies would exceed the scope of this paper, the following links lead to three cases in Munich, which may stand exemplarily for the communicative turn and probably for a recovery of public planning:

- Creative Quarter:
<http://www.muenchen.de/rathaus/Stadtverwaltung/Referat-fuer-Stadtplanung-und-Bauordnung/Projekte/Dachauerstrasse-Werkstattgesprach.html>
- Cross-media participation “PERSPECTIVE MUNICH”: :
<http://www.perspektive.muenchen-mitdenken.de>
- Cooperative housing projects (*Genossenschaften, Baugemeinschaften*):
<http://www.muenchen.de/rathaus/Stadtverwaltung/Referat-fuer-Stadtplanung-und-Bauordnung/Wohnungsbau/Gemeinschaftliches-Bauen.html>

5. Questions for discussion and further research

- What are the differences between Europe and the other continents concerning rise, decline and regeneration of public city planning during the last centuries?
- What are the impacts of globalization and the recent crisis of the world financial market on real estate, urban development and the role of plans/planning?
- How far the fragmentation of the planning related disciplines is responsible for the decline of planning in the last decades - and is the fragmentation reversible?
- Is a sustainable and socially equal city development possible without public planning? Are there convincing examples anywhere in the world?
- What are the general political and structural preconditions (i.e. communication, democracy, land law, self-organization of civil society...) of communicative and cooperative planning processes?
- What consequence has the new paradigm of “the planner as intermediate actor and communicator” on the way planners see themselves and on the role of planners in the administration, freelance practice or academia?
- What are our core competences as planners? What specific virtues and skills do we need for co-design and co-production?
- How can planning education be linked better and systematic with planning practice and the needs of the urban society (“urban reality labs”)?
- How can planners motivate/empower social groups for participation in planning issues, which do not normally take part in debates and actions?
- Which opportunities are given by digitalization, open data and social media for communication, participation, cooperation and co-production in urban transformation (“smart planning”)?
- How can planners secure the interests of the public and of future generations in cooperative planning processes? How can group egoisms and short term goals be avoided to become predominant?

How urban fabric fosters knowledge transfer and innovation: the example of Barcelona

Mar Santamaria-Varas, 300.000 Km/s, Barcelona, Spain

Pablo Martinez-Diez, 300.000 Km/s, Barcelona, Spain

1. From an industrial past to a based-knowledge future

Barcelona has a long and well-established history of embracing new ideas and encouraging innovation. The symbiosis between research capacity and urban development is an important dynamic in the city. Whether it is new technologies, health or digital fabrication, its connections with major global companies, or its position as a leading city in the quality of life of workers, Barcelona is a vibrant place of innovation – and that stimulates job growth and opportunities for businesses and stakeholders alike.

As Mercè Tatjer (2006) highlights, since the late 18th century, Barcelona and its region (Catalonia) became the most important industrial centre in Spain, providing Spanish market with manufactured goods such as textiles or chemicals. From this early manufacturing period and almost in parallel with industrialization during the XIX century, industrial sites moved out from the inner city to outside the city walls.

This trend continued into the first third of the twentieth century, when an important industrial diversification began at the expense of textile sector. If industrial buildings continued to expand throughout the city both in the new Eixample Cerdà and small villages in Barcelona's plain such as Sant Antoni or Poble Nou, the development of a second industrial belt represented a major spatial change which serve as a starting-point of industrial growth at a metropolitan scale in the 1960s.

Indeed, the installation of large production centers in emerging sectors such as railway equipment, automotive (SEAT, Pegaso, Ducati) or business products (Hispano Olivetti) changed the scale and content of Barcelona's industrial landscape. Large and modern industrial factory complexes occupied large areas along the railway lines and the valleys of Besós and Llobregat rivers. At the same time, social welfare policies were implemented to respond to the needs of a growing immigrant population coming from the rest of Spain (housing, services and facilities for workers and their families).

By the end of the 1970s, the delocalization of production to new industrial, storage and distribution sites in the periphery became a reality due to technological changes, the crisis in the textile sector along with the emergence of new productive sectors (electronics, pharmaceuticals), the development of the metropolitan network of highways and the changes in maritime transport systems (the revolution of containers).

In the last forty years, the industrial economy has been replaced by an economy of services to production, people and knowledge¹. Barcelona has become a global tourist destination with almost 8 million visitor a year. At the same time, the city produces almost half the technical innovation and much of the research carried out in Catalonia². As facing a crucial moment when traditional stereotypes are being questioned under economical, sustainable and social agendas, defining the city urban model based on research strength or tourism economic activity is a matter of the utmost importance.

Barcelona possess the conditions to consolidate a global research centre. In fact, one of the drivers of Barcelona's success is the constant influx of new ideas and talent into the city. With 961 registered patents in the period 2005-2012, many relevant companies have located its headquarters in the city and its metropolitan area. Local and regional authorities have also implemented proactive policies aimed at facilitating the development of value-added knowledge based facilities, such as universities, while public and private consortia have fostered the development of new technology parks and business initiative support services.

A well-known paradigm of public-private partnership is the 22@ district, involving the transformation of an obsolete industrial environment into an area which is home to new activities related to knowledge. The concentration of these types of activities has allowed 22@ to become a dynamic environment in which the confluence with universities, support activities and accompanying services has produced positive results.

However, beyond the 22@ district example, Barcelona has more than 700 startups, leading companies and research centres that create a unique innovation ecosystem—a synergistic relationship between people, firms and place (the physical geography of the city). What makes Barcelona stand out? How can the city use the strengths of a compact urban model to attract more talent, companies, and investment?

This paper presents the main conclusions of the study 'Geographies of Innovation', commissioned in 2014 by Barcelona City Council to the design studio 300.000 Km/s. The research examines the necessary urban conditions to promote innovation, the relations established between innovative initiatives, the urban morphology of Barcelona's ecosystem and the transference of knowledge between different areas of the city.

Whereas prior studies have focused on entrepreneurial quality by excluding location-specific measures³ or the impact of research performance⁴ to define a city competitive advantage⁴, this study assesses the impact of research and innovation facilities on an urban scale beyond their individual success. We have worked with a database⁵ of successful initiatives including 562 startups, 78 leading companies and 59 research centres from key areas⁶ such as B2B (115 initiatives), E-Commerce (77 initiatives), Digital (72 initiatives), Biohealth (57 initiatives), Transmedia (53 initiatives), Mobile (51 initiatives) and Fab (43 initiatives).

The data and analysis in this study are intended to help drive evidence-based decisions on which companies and industries should invest in Barcelona and how planning and policy-making can augment this process. It looks at the research landscape underlying the urban landscape, highlighting opportunities for collaboration, innovation, and economic development.

2. Do urban conditions foster innovation?

As Katz and Wagner (2014) state in the report 'The Rise of Innovation Districts: A New Geography of Innovation in America', in recent years a rising number of innovative firms and talented workers are choosing to congregate and co-locate in compact, amenity-rich enclaves in the cores of central cities. Instead of building isolated science parks or reproducing the Silicon Valley Model - suburban corridors of spatially isolated corporate campuses, accessible only by car, with little emphasis on the quality of life or on integrating work, housing, and recreation-, innovation initiatives prefer sites that strength proximity and knowledge spillovers.

Consequently, the mash up of entrepreneurs and educational institutions, start-ups and schools, mixed-use development and medical innovations, bike-sharing and bankable investments -all connected by transit, powered by clean energy, wired for digital technology are important factors that influence the proliferation of innovative initiatives.

In the case of Barcelona, this study found an apparently uniform distribution of innovation facilities throughout the city. Innovative initiatives locate both in central areas with good accessibility to public transport and peripheral zones with low rents and a lack of local services. What are the socio-demographic, economic and urban factors that determine this contrasting situation?

We implemented our approach using demographic data and economic indicators from the Open Data Service of Barcelona City Council, cadastral information from the General Directorate for Cadastre, Google Places and Flickr services and transit data from Barcelona TMB public transport agency.

When we look at the economic and social fabric, innovative initiatives are more likely to success in neighborhoods with a high rate of young people and women (*Figure 2*), and an income per capita that remained stable or declined in the past 5 years. Economic dynamism and real state fluctuations play also an outsized role: innovative initiatives are located in areas where positive synergies between companies result in a high level of economic activity as well as areas with a growing rental cost of premises due to its central position or its limited availability (*Figure 4*). The 22@ district differs from the regular pattern as the quantity of initiatives exceeds the number of traditional companies (*Figure 2*) and rents are still affordable.

Regarding the morphology of urban fabric, innovative initiatives tend to be placed on consolidated urban zones, occupying small plots in the city centre (except co-working spaces) or larger surfaces when situated on the periphery (*Figure 3*). Generally, innovation spreads to mixed-use fabrics achieving a sustainable balance between residence, commerce, office and industry although, in some cases, innovative initiatives prefer mono-functional areas either office or industrial.

Neighbourhood services are an indicator of urban quality that influences the implementation of initiatives: local shops, financial services or restaurants can contribute to a better quality of life of workers even if this relationship is not linear (*Figure 5*). Once again, the 22@ district is an exception as the quarter has experienced major urban transformations and some parts provide almost no services to residents.

Centrality and representativeness play a secondary role. Likewise large industrial estates were traditionally located in proximity to railway network and main roads, innovative initiatives are regularly close to major public transport nodes (*Figure 6*). The location of innovative initiatives is generally at a certain distance of most representative areas of the city.

In short, environmental conditions (compactness, good accessibility to public transportation, cheap rentals, diversity of local services, etc.) influence the location of innovative initiatives. However, urban context is not always a crucial factor -each activity requires a specific background.

3. The role of leading companies and research institutions

From Almirall to Telefónica, from Desigual to Puig Group, Barcelona is already home to companies spanning a diverse range of business sectors such as biotechnology, digital technologies and fashion. Universities are also the cornerstone of the city's research and innovation offerings. Barcelona has recently promoted five Campus of International Excellence involving several institutions such as UPC-Barcelona Tech, the Autonomous University of Barcelona (UAB), Pompeu Fabra University (UPF) and the University of Barcelona (UB).

It has commonly been assumed that big companies and research clusters act as magnets for startups and small companies. In order to understand the role of these leading firms and R+D facilities in attracting innovative initiatives, we analysed the number of startups falling within a range of 50, 100 and 200 metres. In both scenarios, just a few companies and research centres are able to concentrate more than 7 innovative initiatives in its immediate perimeter: the quantity of innovative initiatives increases in inverse proportion to distance (*Figure 7*).

For instance, Desigual, which is a global fashion brand, has no innovative initiatives within a radius of more than one kilometre as it is located in a peripheral site on the shoreline that lacks of transportation and access to services. On the contrary, firms situated in the 22@ show the highest ratio of attractiveness.

The same applies to main universities and R+D facilities. Most campuses have a low concentration of such initiatives, except in certain cases like the Institute for Advanced Architecture or some science parks (Hospital Clínic, Poble Nou, BarcelonaTech North and Sarria-Bonanova campuses) where innovation is maintained beyond the university facilities.

The most likely cause of this absence of attractiveness is the difficulty to generate certain urbanity conditions (centrality, small size of plots, mixed-use activities, etc.) as frequently research campuses are the result of large-scale urban transformations (*Figure 8*).

However, we have identified several examples that bring together a significant number of initiatives like the Barcelona Media Park. Located in a central site along Diagonal Avenue, it congregates the new campus of Communication Sciences, MediaPro tower, MediaTic building, RTVE studios, Barcelona's building incubator and a number of small business related to media sector. In this case, attractiveness depends on the partnership between leading companies and research centres.

4. Spatial models, borders and opportunities

As discussed above, innovation creates a closely linked network, which is polarized around nodes concentrating a larger number of initiatives. If leading companies and research centres are important players in the innovation ecosystem, small companies and startups can also generate links and attractiveness for themselves.

We have explored from a spatial point of view how these different types of initiatives cluster in urban space using a gravity model and Delaunay triangulation.⁷ Morphological and environmental factors configure three different spatial models: line, network and centres. In the lineal model, innovative initiatives align geometrically along main civic axes as Diagonal and Passeig de Gracia, taking advantage of a well-connected area with high economic activity, small plots, local facilities and representative character. In contrast, the network model results from the concentration of a diversity of initiatives (startups, research centres and leading companies) in a short distance as is the case of the 22@ area near Diagonal.

In these first two cases, despite reflecting opposite situations (an area that concentrates representativeness and economic power with respect to a district with low rentals and large premises), innovative initiatives benefit from centrality and mixed-use. As explained earlier, the centre model is based on major anchor institutions mainly research hubs and university campuses.

Beyond these main archetypes, we have detected other sub-centres and neighbourhoods with a high potential to develop innovation, located in the east and north areas. Certain residential quarters and zones gathering large urban facilities could represent a barrier to connect existing innovation districts, even if the tendency is the spreading of innovation all over the city thanks to the diversity and compactness of urban fabric that enables a positive transference of innovation and knowledge. In addition, the location of large innovation facilities demands increased investment of public administration. Frequently, research centres and university campuses have been placed in apparently central sites (mountain, coastline) regardless of urban conditions. These operations didn't achieve maximum impact in contrast to other situations that profit from an existing vibrant urban fabric to implement successful development.

It is important to recall that in today's hyper-competitive, global knowledge economy, innovation initiatives will play a key role in generating economic growth and social prosperity, particularly when they work in the context of city-wide strategies for smart specialization. In this sense, the innovation ecosystem of Barcelona could become a reference for other urban areas. This model embraces those very attributes of urbanism—what Saskia Sassen (2008) calls “cityness”—that were denigrated and often destroyed in the 20th century: complexity, density, diversity of people and cultures, and a layering of the old and the new.

Rediscovering the College Town

Dhiru A. Thadani
Thadani Architects + Urbanists
Washington DC, USA

Nothing matches the energy and pulse of a college town. Universities throw off an infectious excitement that infuses their communities with culture, creativity, and a love of learning. Both retirees and young, knowledge-based workers are drawn to these places, as they offer a high quality of life at an affordable price and are smart financial investments. Retirees benefit from cultural events, continuing education, and great medical care if there is a university hospital. The young creative class tends to gravitate where like-minded individuals are in abundance, and that invariably leads to a college town.

Richard Florida observed that knowledge-based workers are attracted to places that possess the “three Ts,” the first being tolerance—of beliefs, religion, dress, and sexual preference. The second is an abundance of technology, to serve workers’ desire to be connected at all times. And thirdly, talent—talented people want to be around other talented people.

Universities need to respond to these criteria because they are always striving to attract young faculty, researchers, and graduate students. Universities are big businesses, and each has to attract its share of paying students as well as engage in research to secure financial grants. The notion that a student is a consumer and must be attracted to a place is slowly becoming an underlying premise of universities. Therefore it is incumbent to understand what criteria students use when selecting a town where they will spend four years.

Research in the United States indicates that for students, the number-one criterion for college towns is entertainment. This includes access to cinema, theatre, concerts, sports bars, pubs, and recreational entertainment such as bowling and billiards. The second is affordability, referring mostly to the cost of living, but also how cool the living space can be when one prefers the authentic, such as a wood-beamed attic instead of a pseudoloft. Number three is access to health, fitness, and recreational facilities, which may include gyms, yoga, aerobics and martial arts studios, bicycle trails, and outdoor sports fields. The remaining criteria include mobility, jobs, and overall uniqueness of the place. Mobility refers to easy access to other cities via inexpensive bus or rail transit, permitting students to visit friends or return home for family get-togethers and holidays. Surprisingly, access to jobs is less important, as most undergraduate students have access to student loans or parents able to finance their education. The overall uniqueness of a town or university refers to name recognition; students took pride in the fame and status of their college towns. For example, Lexington, Kentucky, is where the Kentucky Derby is held; Charleston, South Carolina, is known for the Piccolo Spoleto festival; and Ann Arbor, Michigan, has a winning football team: “Go Blue.”

The academic institution is an overwhelming presence in a college or university town; it pervades the economic and social life. Within the geographic boundaries of the college town, the university is the single-largest employer. Many businesses cater primarily to the university; and when school is in session, the academic community usually outnumbers the local population. There are two fundamental types of college towns. In one type, the town is intrinsically intertwined with the whole community, as in Chapel Hill, North Carolina, and Princeton, New Jersey. In the second type, the college-town precinct is one of many nodes within a larger, polycentric metropolis, such as University of Pennsylvania’s college-town district in Philadelphia. A third type is where there is no college town as the academic

institution is a district onto itself. A segregated precinct isolated from the town or city where it resides. The Technical University in Delft may be an example of this third type, where the edges are cauterized from the rest of the city.

Successful college towns have an identifiable main street where the majority of commercial activity is clustered. Historically, this main (or high) street developed because it was the primary access route to the university. Analysis shows that this thoroughfare was usually located along the topographic ridgeline—the highest ground affording the best natural drainage. Main streets are enfronted primarily by mixed-use buildings, which are a maximum of four stories in height. The uses within these buildings evolve to serve the student population and their needs. What was once a used book store may now be a hair salon; a franchised fast-food outlet may become an independently run coffee bar. Buildings with this resilience are needed to permit adaptation to changing needs.

Analysis and observation also indicate that east-west main streets usually have successful retail on the north side of the street (the sunny side), whereas north-south streets have retail stores on both sides of the street. Regardless of the street orientation, the frontage length of retail stores generally extends for 1,300 feet (400 meters), the equivalent of a five-minute walk. At an average building depth of 40 to 80 feet (12 to 24 meters) the total retail area ranges up to 80,000 square feet (7,500 square meters), irrespective of the student population. There are some exceptions to this number, but the findings suggest that 25,000 square feet (2,300 square meters) of retail means the college town is underserved, while 150,000 square feet (14,000 square meters) of retail suggests a regional market drawing from far beyond the boundaries of the college town.

In analyzing sales receipts for businesses in college towns, it was determined that students contribute about 25 percent of the total revenue of retail businesses. Food venues such as pizza parlors may receive 75 to 100 percent of their sales from students. However, the average student contribution to overall sales is remarkably low within most college town retail districts, in part because the majority of students attend school for only seven or eight months of the year. During the academic year, students contribute about a third of the retail sales revenue. This suggests that a successful college town is mostly supported by the nonacademic portion of the community. Students may provide the workforce and cool ambiance, but the actual revenue is generated by serving the needs of the community.

Not surprisingly, the main street in a college town typically carries from 15,000 to 20,000 cars per day. This level of automobile traffic helps the retail businesses survive, especially when school is closed for summer vacation. Connectivity, a robust street network, and ample short-term, on-street, metered parking help local businesses attract a steady flow of customers. Convenient midblock, off-street parking is also essential to satisfy long-term parking needs. Successful college towns embody the park-once concept, permitting multiple errands to be completed as a pedestrian. Additionally, adjacent dining, entertainment, cultural events, and sports venues in close proximity to strategically located parking ensure a vibrant nightlife for all age groups.

Universities offer their communities a wide range of cultural and socio-economic benefits. Residents have access to cultural events such as art shows, theatre performances, and music venues. The school embodies intellectual capital, promotes lifelong learning, and provides adult continuing-education courses for local residents.

College towns have proven to be great places to incubate businesses, which can take advantage of the educated employee base. Businesses that need a flexible workforce do well in college towns, finding an abundance of part-time employees. Businesses that rely on making deliveries, such as florists or pizzerias, are ideally located in college towns. Art-framing shops are completely flexible regarding when the actual framing work must be done; such

businesses are well-suited to employ students who work in the evening. Caterers can call on the student workforce on an as-needed basis.

Conversely, residents with large homes or rental properties may rent to students or university staff. Residents may employ students to help with yard work, babysitting, and other services. A healthy college town benefits from this symbiotic relationship between town residents and the academic community.

In the past, towns overlooked the positive benefits of having an academic institution in their backyard, and not all universities appreciated the importance of a vital town as their neighbor. The Technical University at Delft is not an exception when it come to buffering itself from the city. However, many institution who once built an alienating wall around their campus in the name of security or privacy have now come to realize that it is more beneficial to directly invest in the adjacent communities, play a leadership role, and aid in the social stability of their environs. Renowned academic institutions are noted for being powerful economic drivers in their communities and regions by functioning as technology innovators, employers, developers, and investors. Indeed, all of these support their primary academic mission.

Let's reinvent convivial regions: in the memory of Bill Twitchett

Dr Philippe VAILLANT, France

Abstract / Introduction

The world is limited. Our cities grow, extend, expand... In contrast, nature shrinks, biodiversity disappears, resources are running out... Now, we are faced with a search for balance between nature and city.

To find this balance, the notion of *convivial region* (Ref.1) with an indicative scale of 32000 km² (100 km radius), seem now to be unavoidable. That is the scale of the "living area", the "territory of belonging", based on human body. That is the scale of countries such as Holland, Belgium, Switzerland, Latvia, Slovenia, El Salvador...it is the scale of the 13 new metropolitan regions of France, and many parts of the world, as shown in the works of Bill (William) Twitchett (1995, Ref.2). The thesis of Philippe Vaillant (2008, Ref.3) deepened this notion. It was conducted in collaboration with him, after 28 years of common work in seminars and workshops at the Association Le Pavillon / Terre et Cité (*The Pavillion / Earth and City*) in Arras France. This last thesis was directed by Jean-Pierre Husson at the University of Lorraine in Nancy-CLSH Site, LOTERR Laboratory, directed by Michel Deshaies. Michel Deshaies was the director of the following Post-PhD (Ref.3b).

The convivial region is the result of a research led by Bill Twitchett since 1966. The pedagogy of the Association "La Chênaie de Mambré" allow to deepen the process through the dynamic of its workshops, based on *values*. Indeed, this process consist to *pass* from a power relations society (PRS) to a convivial society (Ref. 1b). This dynamic is organic, and a general expression is the approach of Carl Rodgers and A. N. Whitehead (*Process and Reality*, Ref. 4). On this basis, an organic geography and an organic planning can be created on Western references, like Augustin Berque did with Oriental references (*Ecumene*, Ref.5). The convivial region may then appear on this solid foundation as a new geographical object, that illustrate "the *passage* from being to the real " (Michel Serres, Ref.6, P.V. Thesis p.319). It's the *passage* from *pure potentiality* to *hybrid potentiality* and then *actual potential* (see Figure 5). These *passages* are replacing the old dualist distinction human / nonhuman.

This new approach to planning is developed here on 5 regions of the world, among which can be found: natural areas, developing areas and developed areas. Those regions are: the new "Between Vosges and Ardennes" region in France, baptized ACAL; the Aboriginal country of Nyikina in the Kimberley in Western Australia; that of Abidjan in the Ivory Coast; the region of Kashgar in Xinjiang, China; and the Mapuche country between Chile and Argentina.

It will be shown how some 2,100 convivial regions in the world, grouped by federation of regions, can expand and transform themselves. This approach combines globalism and globalization, and shows the process of sustainable convivial region creation. It develop the knowledge of this process.

1 The world is limited

	1	2	3	4	5	6	7
	TERRE (Mkm2)	Mers & Océans	Terres émergées (TE)	Océanumène (2/3 TE)	Marges (1/3 TE)	64% Terres 2p/km2	26% Terres (Reste Pop°)
	100%	71%	29%				
Mkm2	459,55	326,28	133,27	88,85	44,42	85,29	34,65
Mhab			6 512,57			170,59	6 469,92
Densité (hab/km2)			48,87			2,00	186,72

Figure 1 : Areas of Oceans and Earth ; Estimate of densities on the planet (Source: Universalis Atlas & P.J.Thumerelle, the peoples of the world), thesis P.Vaillant Ref.3 p. 502)

We now have to pay close attention to both the 'empty' and the 'full' regions. The overall balance of the planet is at stake. We speak of the emergence of *regional cities*: a name will have to be invented for the regions where nature still dominates. For urban areas, the concept of *metropolitan area* is now ripe (Ref. 7) but it will only become noteworthy when it is completely connected to the *natural regions*, in order to connect all the processes one with the other (see Figure 10 below). It's the concept of *convivial region*.

Indigenous peoples own approximately 26% of the global land. These lands are coveted by multi-national societies, thus endangering the traditional maintenance of these lands by their inhabitants as well as their preservation for the future generations (Ref.8 & 13). Autochthonous people are a model for humanity. Their stories, tales and legends are a *word* to share.

2 A decosmised world, a destructive modernity

Our modern society destroys nature. This fact is well-known and uncontested. Why is this? According to the Association "La Chênaie de Mambré", the relations are based on *power relations society*, instead of shared values, and *passages to a convivial society*. According to Whitehead, there is a "bifurcation of nature". According to Berque, there is a 'decosmisation' of the world. The first explanation can be found in André Rochais's Note (Ref.1b), the explanation for the second is in *Process and Reality* (Ref. 5) and the last is in *Ecumene : Introduction of the study of human environmental* (Ref.6). The key text that synthesizes the first explanation is Griffin's. It can be found in *Whitehead Radically Different Post Modern Philosophy: an Argument for Contemporary Relevance* (Ref. 9, Appendix) and the key text that synthesizes Berque has been written by himself in "Can we rationally speak of "nurturing science"" (shizengaku) ? » (Ref.10).

The three explanations, very different in their references (Western for the two first, Eastern for the third), lead all three to a critic -and not the removal- of the Aristotelian substance, to an outlet of the *dualism*, and a logic of the *included third*. The substance "which only needs itself to subsist", once the widespread interrelatedness of things scientifically acknowledged (quantum mechanics, Ref.11), gives way to the notion of *conviviality* for the Association MWC, of *society* for Whitehead, and *mediance* for Berque. Both place, next to a mathematical *topos*, a *chora* which is specific to a place of spatio temporal continuum (PR72). The *feeling* of HFC is whiteheadian *prehension*, or A.Berque's *trajection*.

Those two authors and thousands behind them are therefore inviting us to retrieve the *connection to places* (*Handbook for Whiteheadian Thought*, Ref.12 and figure 2). This 'connection' could be the Aboriginal *liyan* (Anne Poelina, Nyikina people, thesis, Ref. 13) expressed with cultural bases which are both Western and Eastern. Isn't that the special connection to the Land of the Indigenous Peoples of the planet? Is there not here a transcultural and transdisciplinary dialogue basis, traversing the three UNESCO vocations: scientific, cultural and educational? (Yamoussoukro forum, Ref. 14) Haven't we got here the basis for a civilization which respects cultural difference in the unity of alternative globalism (and not economic globalisation)? (Rene Passet, Ref. 15 and Ref.3 p263).

1. How to recosmise the world: a transcultural and transdisciplinary organic approach

It is therefore the philosophical basis of science that needs to be transformed by using the latest scientific achievements as summarised in the works of Pierce, James, Whitehead, Bergson, Dewey, Laszlo, Aspect, Prigogyne (Nobel Prize), Lyne Mc Taggart, Rupert Sheldrake, Dubro & Lapiere... This new paradigm was announced as early as 1983 by Prigogyne and Stengers in *The new Covenant* (Ref.16). It was later developed by many philosophers in its panexperientialist, constructive postmodern panpsychist sense (Ref.12).

3.1 The Augustin Berque scheme and its Oriental references

Berque gave the University of Corsica a series of conferences on You Tube (Ref. 5b aso.) which synthesizes the work of a lifetime. The key concepts are *médiance* (Ec Ref.5a p.124-126), *trajection* (Ec, Ref5a P.127-129), *existential moment* (Ec, Ref 5a id.), and *topos / chora* (Ec , Ref.5a, Ch.1 p.17-30).

There is precursors as René Dardel (Ref.16)

3.2 The whiteheadien scheme and its Western references

The key concepts are *society* (PR 94-110), *préhension* (PR 32-34), *conrescence* (PR 211), *morphological / genetical process* (PR 72).

Figure 2 : All domains and authors with whitehead thought

3.4 A link between the West and the East: a universal organic approach

The thesis I presented in December 2008 highlights focuses on the relation between the two preceding steps. Here is a small table which presents the link between Whitehead and Berque. This link will have to be completed by many research scientists and philosophers in their respective fields.

Alfred North WHITEHEAD	Augustin BERQUE
SOCIETY	« MEDIANCE »
PREHENSION	« TRAJECTION »
CONCRESCENCE	« EXISTENCIAL MOMENT »
SPACE-TEMPORAL CONTINUUM Morphological / <u>genetical</u> Process	TOPOS / CHORA

Figure 3: The links between the scheme of Augustin Berque and the scheme of A. N. Whitehead (Ref.3, page 257-260)

This table shows the universal character of Whitehead's *concrecence*. Geographic objects can be constructed on this scientific basis. In our rapidly changing world, these geographical objects go from *pure potentiality* to *hybrid potentiality* and integrate themselves to the objects of everyday life (*real potentiality*). In the words of Michel Serres, there is thus a "passage from the being to the real." Thus, thousands of years appeared Cities, agglomerations, metropolitan area, and now the *convivial region* (Figure 5).

The *concrecence* means "grow together". "Concretus, in Latin, it was the past participle of *concrecere*: grow together," explains A. Berque (REF.5 p.18). The world grow by *drops of experience*, expression borrowed by Whitehead to William James, who became synonymous with *passages* for HFC association. The whiteheadien technical term is *actual entity* (PR17) or *extensive quantum* (PR80) by reference to quantum mechanics. *Drops of experience* (DE) replace the atoms of Democritus. They are the place of emergence of the *Say*, and *creativity* in the world.

The first component of DE are *prehensions* with *subjective forms* (PR17) are the *values*: Sharing, No PRS, Common Good, Efficiency, Fraternity, Conviviality, ... This requires much time and many exchanges to agree on common values.

The diagram of the *Drop of Experience* (figure 4) can not have the effect if people doesn't change. It is an experience to do : if the pattern becomes a recipe it will hardly be effective. The way to build convivial regions is primarily a commitment for the men and women who participate, to a personal transformation path. "A man who is divided shape beings and the world in its own image" (Ref. 1, Note 1). It is necessary to be transformed by the tool.

Vaillant's thesis (2008, Ref.3) summarizes fifteen organic approaches in relation to the human, society, the territory and the cosmos (Ref. 17). The postdoctoral added eleven more, after a research between France and Australia in 2013-2014. Those twenty-six approaches are all consistent with the schema of the Whiteheadian *concrecence* (Ref. 18).

3 The convivial region is a tool to measure the individual and the social human body

4-1 – The organic aspect of B. Twitchett's approach

William Twitchett's approach (thesis 1995, Ref.2) does not escape from the organic character *de facto*, as shown in the diagram below (figure 6).

The deepening of the concept of convivial region in an organic sense was initiated by B. Twitchett himself in his contribution to the 2003 ISOCARP convention. Indeed, Bill Twitchett's contribution, *Friendly Versus Sprawl Regions: examples within Australia and within sub-continents of comparable physical scales*, 2008 44th Congress 2008 ISOCARP (Ref.2) illustrates the use of the "Drop of experience" and different phases with written reference to the thesis of P. Vaillant: *Vision*, page 3 alinea3, the *Proposal*, page 6 paragraph 6, the *Satisfaction*, page 9 paragraph 4.

It can be observed that this contribution implements only 3 of the 5 realities of Whitehead's *concrecence*: *Vision*, *Proposal*, *Satisfaction*. Two realities: remain: *Interactions* and *Decision*.

LES 5 REALITES DE LA "GOUTTE D'EXPERIENCE"

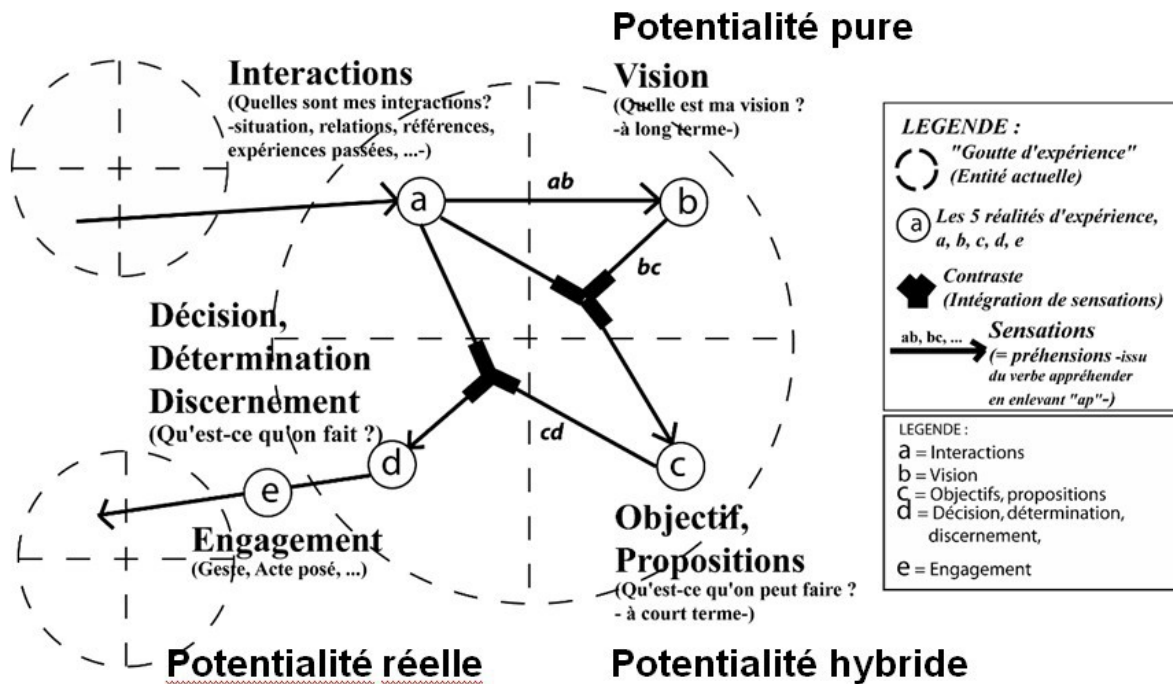

Figure 4 : the Whiteheadian concrescence (PR, III^{ème} partie)

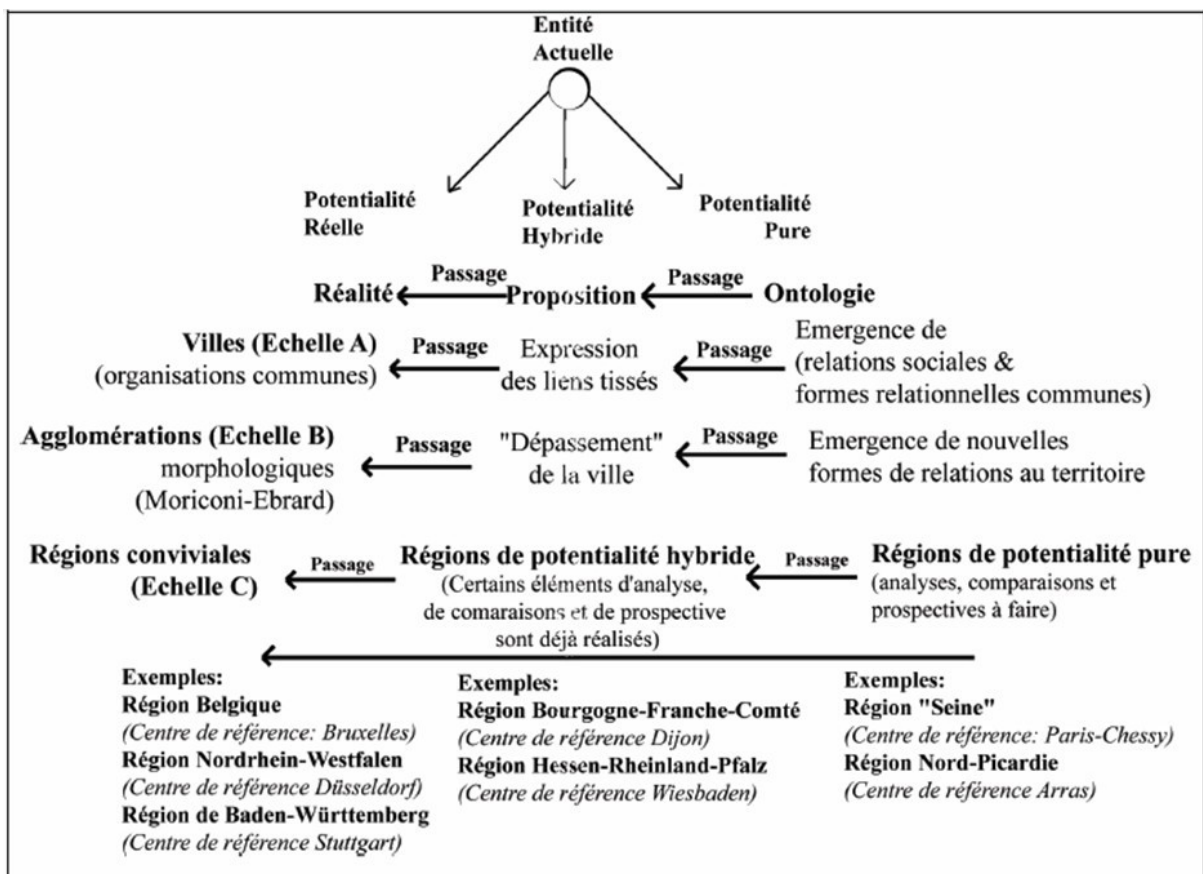

Figure 5 : « The passage from Being to the Real » of geographical objects (Source : Thesis PVaillant, page 440)

The first, *Interactions*, concerns the relationship to anchorage areas concerned and second, the *Decision* relates to the political process of implementation in the territory (as defined in Policy "management" -no *power relations*-). The road still to go on the spur of B.Twitchett appears to be interacting with local stakeholders, and contribute to generate a bottom-up process of local decision for the territories covered (logical bottom-up, not top-down). This is the process initiated by the 5 following examples.

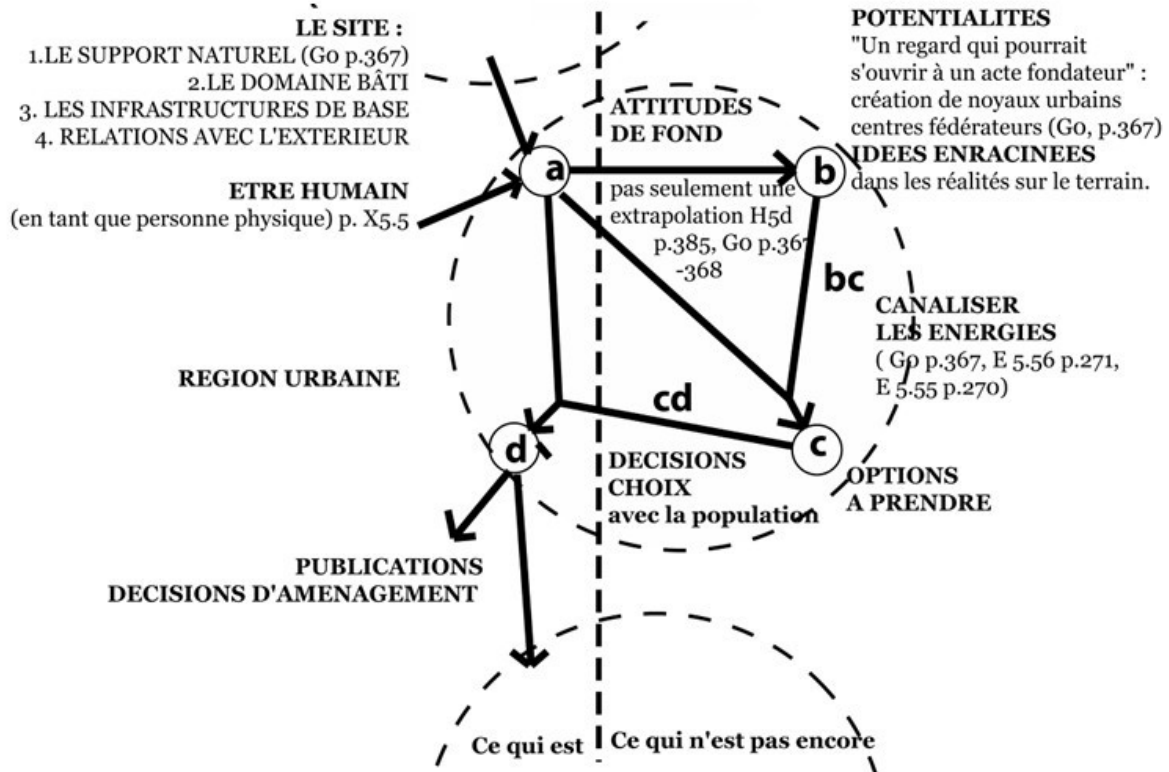

Figure 6 : Diagram of questioning geographical experience across the approach of W.Twitchett (1995). Source: Thesis P.Vaillant 2008 (Ref.3 p)

4.2 – The tool to analyze the scale of the territories

Here is a reminder of the tool of the territory scales as proposed by Bill Twitchett for an interlocking of the scales related to the human body.

Figure 7 : Outil d'emboîtement des échelles de la vie quotidienne W.Twitchett, Thèse 1995

The life of William Twitchett was devoted to seeing, under the tumultuous nature of the territories of the world, their potentialities as convivial regions, as sites of human development, in harmony with nature, be it potential, real, hybrid or pure.

A first comprehensive intuitive global approach was implemented in Atelier in 2008 (Ref.3) It takes into account the research led by Twitchett since 1966. These user-convivial areas are established (real potentiality), in training (hybrid potentiality), or simply prospective (pure

potentiality). *They are the Federating entity which exists or 'is to be created'*. This approach, our way, could find full achievement only in link with autonomous organization of inhabitants on considered regions. A network of correspondents which is to be weaved within each region and between those same regions.

Figure 9 : Synthesis of the organization of the planet in twenty one sub-continent. Source: Vaillant, dialogue with Twitchett (thesis p.507)

Out of the 193 countries registered at the United Nations (excluding Kosovo), forty states already have the size of a convivial region (including 12 States in Europe -EEE31-), in other words, one state out of five. Forty states are smaller than a convivial region. Conversely, seven states have the size of one or several subcontinents..

This approach allows to simultaneously take into account a finite world (finite resources, limited water, generalized interactions) and the importance of a local development which was, is or will be as autonomous as possible (application of the principle of subsidiarity). Here, in Figure 10 below, the 8 key processes of *convivial region*.

5 - Examples around the world

5.1 The convivial region of the 'Vosges-Ardennes' in France

Since the 2008 thesis when this region was only a *pure potentiality*, the regions of France were reduced from 22 to 13, and the FTAA region was created in 2015: it will be implemented on January 1, 2016.

This example clearly illustrates the "passage from the being to the reality" of a new spatial object.

This region can be a model for many other regions of the world as a creative process of a *convivial region*.

Correspondents: JJ Funke, C.Kieny. P. Vaillant and network AITF, including the Working Group GT DST-general

Figure 11: Map of a pure potentiality region in December 2008 from the thesis (P.450 Ref.2, which has become a real potential region in 2015 (official launching on January 1, 2016).

5.2 The convivial region of the Nyikina countries in the Kimberley, Australia

A post-doctoral research done in 2013-2014 helped forge strong links with the Nyikina People of Kimberley (*Interractions* reality). Recent events such as the acceptance of the Nyikina People's territory under the Native Title Act which recognizes them as the traditional owners.

This virgin territory would be appropriate to create an International Ecological Park. The unifying center could be Lower Livingina / Baldingjir, where a Wildlife University is soon ready for commissioning.

Correspondents: Anne Poelina Ian Perdrisat, Nyikina people (ref. 13). Other Links: Martin Préaud and Magali McDuffie

Figure 12: Map of convivial regions of the Kimberley according to Bill Twitchett (Ref 2.X, pX.). The circle was added to mark the "project area", between Broome and Looma.

The Nyikina aboriginal people is a "water people" of the Mardoowarra river (Fitzroy River). An approach of the Water Resource Integrated Management, which has not renewed since 2010, now appears to be urgent. Collaboration can be pursued with the International Water Centre (IWC) and the NGO Madjula Inc., with all the official partners.

5.3 - The convivial region of Abidjan in the Ivory Coast, Africa

The 3rd UNESCO-NGO Forum of Yamoussoukro in July 2014 raised great hopes on the vital issue of drinking water for all. It was also an opportunity to expose the organic approach adjusted to the Integrated Management of Water Resource (IWRM), called "drops of experience" (Ref. 14).

Water is a source of life, and one of the main criteria of the region is its convivial region at the service of each (REF.2, pX)

Correspondents: Jacqueline Adjale, network with Patrick Aubin Moulo and Moussa Cissé

Figure 13: Positioning the convivial region of Abidjan in the Côte d'Ivoire on river system background (FAO map)

5.4 The convivial region of Kashgar in Xinjiang, China

Kachgar (Kashgar, Kashi) (喀什 ; pinyin : Kāshí ; ouïgour : قەشقەر / Qeşqer, ou 2 ئېگىز شەھەر)

The traditional city of Kashgar is being destroyed in order to be replaced by buildings of international architecture, as shown in the picture on the left. A regional reflection is urgently needed to enable the preservation of this heritage, the safeguarding of the Uighur culture, and the mobilization in that sense of the local resources, in a dialogic approach (Paolo Freire).

Correspondent: a member of the Uighur community (8 million people)

Figure 14 :the convivial region of Kachgar, in Western China, Xinjiang (Ouïghour country). Source : <https://quinsadventure.wordpress.com/tag/kashgar/>

5.5 The convivial region of the Mapuche Indians, Chile, South America

The Mapuche territory extended over 1,700 km from the Pacific Ocean to the Atlantic.

The Mapuche people in Chile represents 600,000 people.

The emergence of a *convivial region* can be achieved with a dialogic and critical approach (Paolo Freire) in matters of mapping (Johnston, Hirt). The context is transcultural, after several centuries of concealment of the indigenous culture.

Correspondents: Chilean Beatrice Amblet.

Figure 15: Hirt Irène, Carte de la zone d'étude Chodoy lof mapu, <http://archive-ouverte.unige.ch/unige:12389> (réf.19-X, figure 1 p.10)

6 - Outcomes :

6.1 Connection to the Earth, generalized interconnection

More than 20 indigenous peoples gathered at X in X expressed this interconnection in the Redstone Declaration. Whitehead and Berque give this Declaration both its philosophical and scientific foundation. It proposes trans-... (cultural, disciplinary) concepts. Is there not here a basis for dialogic relation ? (Paolo Freire (author base ref. 13c)?

6.2 Food security: feeding the world

It is possible to feed the entire planet with organic farming (Olivier de Schutter and Patrick Bourguignon, Ref.20a). Indeed, while mono industrial agriculture has a ration of three to one (three calories produced / one calorie spent), agro-forestry has a 25/1 calorie ratio.

6.3 Climate change

If all the farmers of the planet stopped ploughing, the CO2 problem would be solved (Patrick Bourguignon, Ref. 20b).

To reach a 100% renewable energy in 2050 is a realistic scenario.

France has thus officially recognized four relevant scenarios, called Negawatt, Gas de France, Cler, and Ademe (Ref.21a) For the world, the scenario of X (Ref.21b) is a source of inspiration for each specific situation of a subcontinent, a group of regions or a convivial region.

The negative impact of shale gas on water, on the climate and on the territories is shown in numerous scientific researches. Unfortunately, a "commercial secret" is placed on a number of them, and the issues of immediate profit prevent any debates to take place. Indeed, the multi-national companies falsely claim that it is urgent to extract and use fossil resources.

This urgency is an illusion, as we know that the productivity of the wells drops by 90% by the end of the first year, which leads to new fracturing, with a huge consumption of water. This water remains unfit for any further use. Moreover, the groundwater tables are also polluted. (Ref.22)..

6.3 Integrated water resources management (IWRM)

We can only agree with Roger Lambert when he says that «water science is the science of spatial planning»

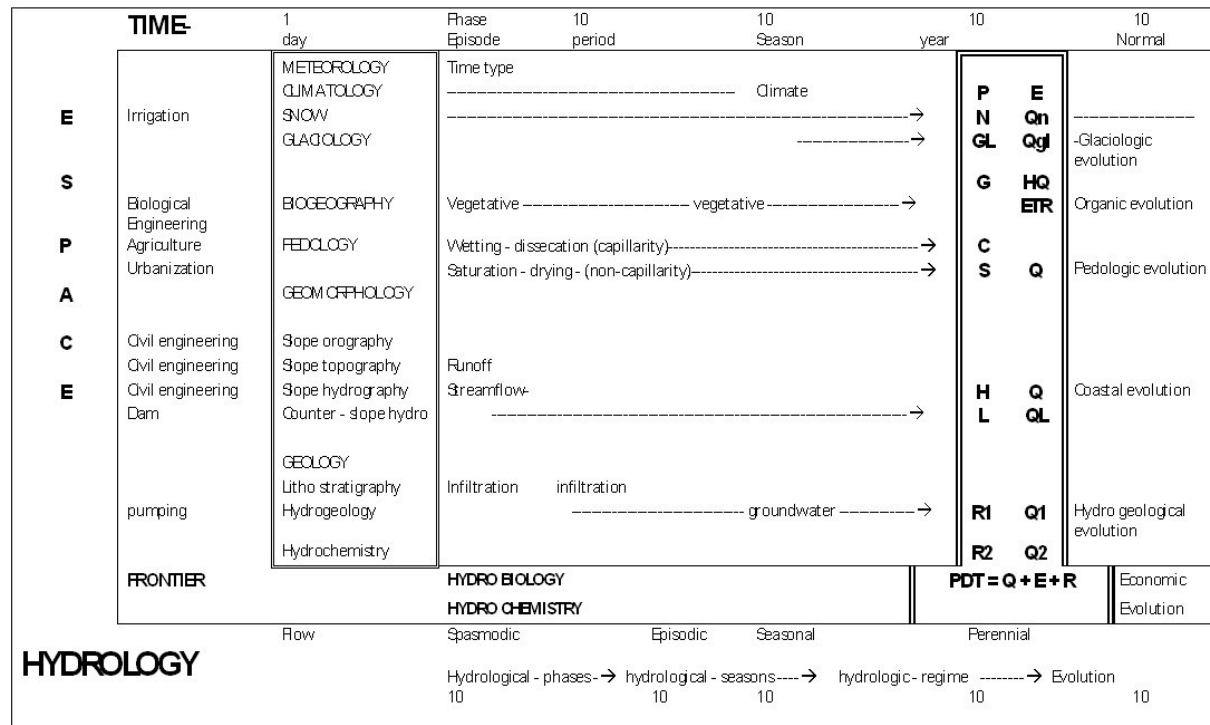

Figure 16 : Diagram of the various sciences contributing to the development of the spatial planning. (Source : Roger Lambert, *Geography of the Water Cycle*, P.U.M., Toulouse, 1996, 448 p. page 232. Ref.22)

As we can see, these various specialized sciences contribute to the study of convivial regions for the establishment of an IWRM. The method of the UNESCO is in strange immediate correspondence with Whitehead's drop of experience (see-above, and reference n ° 14 - Forum of Yamoussoukro-)

6.4 - The global pattern of regional dynamics:

Le schéma qui suit résume l'ensemble des thèmes à aborder pour l'émergence et la consolidation d'une région conviviale. Ce schéma a été mis au point dans le cadre du programme post-doctoral avec l'Australie. Il a été présenté à Brisbane au Congrès ISOCARP d'Octobre 2013.

6.5 Towards organic planning:

With the bursting of the modern approach and the standoff on the issue of interrelations between water, climate, Earth, and development, nature is no longer taken into account by modern planning. On the contrary, the modern approach goes AGAINST nature by demanding resources for the extraction without paying any attention to the consequences. Tools exist, but they are rarely employed in a comprehensive and complete manner (for instance, the ANZECC Guides are not used in the Kimberley on mining projects of Rey resources at Duchess Paradise).

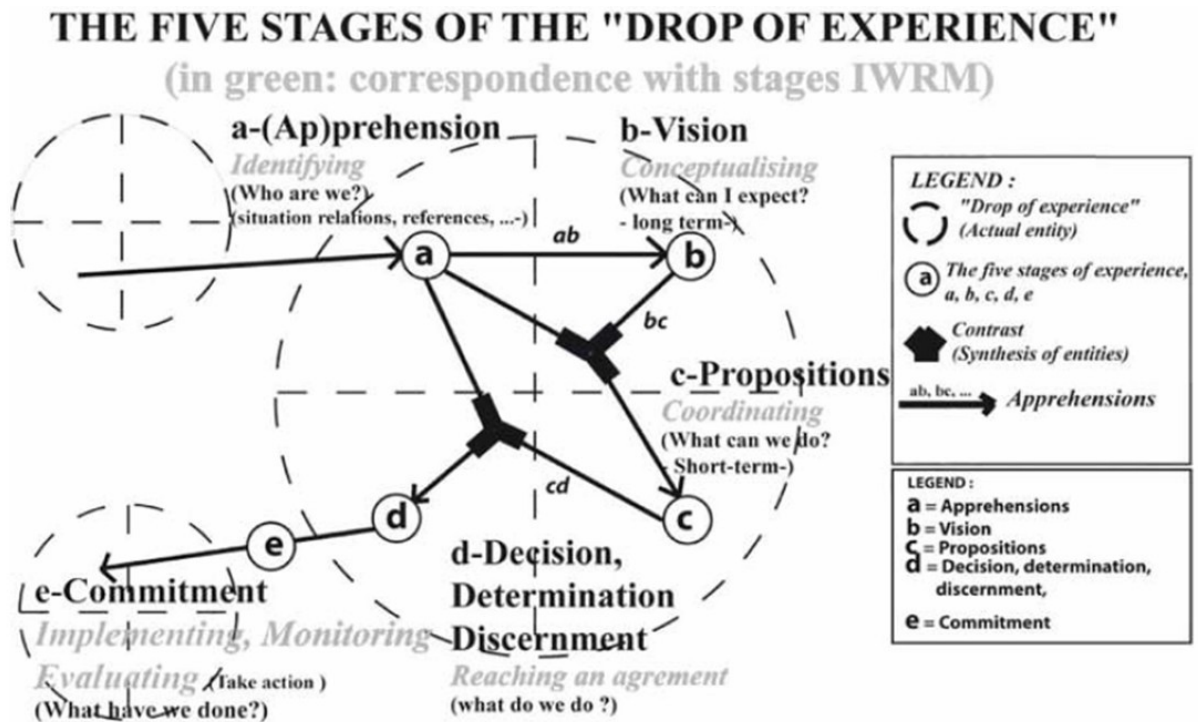

Figure 17: Scheme of the integrated management of water (IWRM) according to the UNESCO and the drop of experience.

AN ORGANIC METHOD FOR KIMBERLEY AND CANNING BASIN

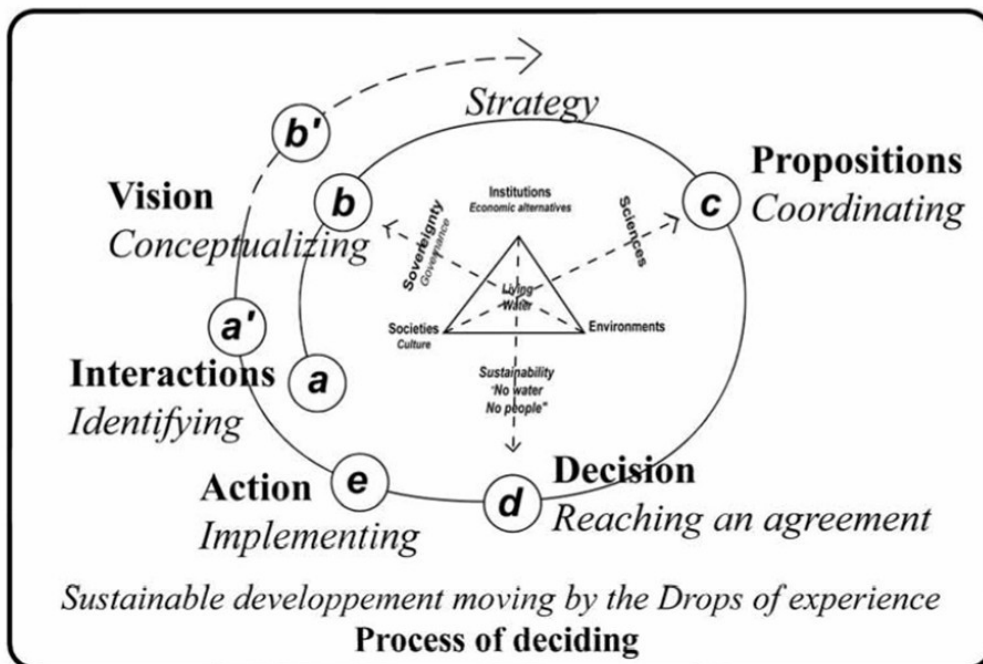

Figure 18: (Scheme presented to Brisbane at the 49th Congress ISOCARP with six research axes)

7 - Creating a guide for convivial regions?

With its *International Manuel of Planning Practice* (IMPP), initiated as early as 1983, and completed in 1995, the ISOCARP contributes greatly to a better understanding between the town planners of all the countries of the world.

This work of understanding between countries is being directed through the IMPP, so, is it not possible now to envision an approach which would be both philosophical and scientific (on the organic basis described above) ?

It is certainly not a normative approach, but a search of the appropriate scale between the local and the global, by successive trial, always in a "bottom-up" and not a «top-down» approach. These regions will need to have the maximum amount of autonomy under the principle of subsidiarity, find their identity in the geography, the history, the issues of the present, and the specific connection of mineral, animal, plant and human societies in this particular territory. The use of geography and ecology is therefore essential, as is that of the local culture, including that of the Aboriginal peoples.

The special role of water in the regional organization and in the local cultures should be noted. All those cultures see water as source of life which must be preserved.

7.1 History of the Guide (IMPP)

ISOCARP created a guide in order to compare the systems of planning for the countries of the world (I.M.P.P.). The starting point was a search for young professionals funded by the UNESCO in partnership with the ISOCARP in 1983. Dusko Bogunovič, Irene Wilson, Philippe Vaillant thus prepared a methodological guide entitled *Understanding the planning system of another country, report prepared for 21st ISOCARP Congress, December 1984*. A strong impetus had been given by Derek Lyndon during the Congress in Braga, Portugal. Then, the initiative was pursued by many other planners.

7.2 - Towards a Guide of convivial regions?

François Beautier's *Maxi Atlas* presents a small easily manageable Manual of 407 pages. The 195 countries of the world are included. Is it not possible to create a manual of about 450 pages for the 21 sub-continent which regroup approximately the 100 convivial regions? (see figure 9 above). The presentation could be done by groups of 20 regions at the most. Indeed, it is accepted that beyond 20 entities, it is difficult to organize a territory (ref. 2-X). 5 to 10 groups by sub-continent lead to a total of 105-210 groups. 2 pages by groups, and 2 pages by sub-continent means that we would have less than 450 pages.

Simultaneously, a presentation of each convivial region by sub-continent could be initiated, for a total of 21 guides.

4 Conclusion

Over the centuries, the notions of city, metropolitan area and cities went from pure potentiality to hybrid potential, and finally to daily reality. In the same manner, the concept of convivial area may become a regular reality, in an organic approach. Many references grouped around the emblematic figures of Whitehead and Berque can help us achieve that goal.

The pedagogy of the Association "Men and Women in the City" can sustain our interest and motivation, paying attention to the experience and the relationship first. The University of Lorraine, in Nancy-CLSH can bring scientific rigor of generalization. The ISOCARP can contribute to the development of a global network around the concept of convivial region. The UNESCO binds together science and culture / spirituality, pedagogy, around the value of Peace and Human Development in accordance to the Common House...

This is Bill Twitchett's basic text that enshrines the concept of *convivial region* in the wake of his thesis and Pavilion Workshops (and a Workshop for MWC Association " Policy Reality City").

He explained the origin of the use of the term "convivial" to describe the area in note 1.

Note 1: "1- Adjective Proposed by Philippe Vaillant, member of ISOCARP, During a Land & City "symposium in August 2002 and time immediately integrated into a group project. " ("Note 1 - [Friendly:] Adjective offers by Philippe Vaillant, member ISOCARP during a symposium in August 2002 and immediately integrated into the project group"). It was explained to the symposium that the term refers to the notes of Andrew Rochais "Power Relations Society... Convivial Society" PRH International 1992, in search of the Association "La Chênaie de Mambré" in Brainville-sur-Meuse, France. This association is one of those social transformation ferments described by Josée Landrieu and Edith Heurgon (2003).

Rey etymological and historical dictionary of the French language in section "friendly" refers to the following key work:

The Benefits of Surrounding Tongji University for Creative Industry Social Capital and Enterprise Community

(A case study of social capital and enterprise community)

Kaiyi ZHANG, College of architecture and urban planning, Tongji University, Shanghai

Abstract: This paper attempts to answer the questions that what functions does social capital play in the interaction between university and its surrounding industry, where does the social capital come from and how can we increase the stock of social capital for building a sustainable knowledge community. The enterprise community surrounding Tongji University is a spontaneous creative industry zone, containing a number of companies providing services on architectural design civil engineering, urban design and graphic design. University provides key elements such as social networks, generalized trust, open educational resources and liberal academic atmosphere which contribute to enhancing place-based knowledge community, forming an elastic labor market and facilitating the generation of social capital. Then university as the core of social capital creates relatively high-level and low-cost human capital and more efficient coordination mechanisms based on informal social rules and norms. Because the economic function of the coordination mechanisms is to reduce production costs and transaction costs, the enterprise community gains competitive advantages comparing with companies which must employ a fixed employees and rely on formal social norms like contracts. In return, the development of enterprise community increases social capital stock.

1 Introduction

With the advent of the knowledge economy era, creative industries play a key role in the transformation of urban functional structure under the context of post-industrial trends. Creative industries are characterized by localization and clustering effect which means clusters of creative enterprises in particular places. Therefore, it is worth exploring that the causes behind the creative firms' gathering location. The enterprise community surrounding Tongji University is a spontaneous creative industry zone, containing a number of companies providing services on architectural design, civil engineering, urban planning, urban design, graphic design and other core industries. The total output of "Tongji knowledge economy circle" increased from 1 billion Yuan in 2002 to 15 billion Yuan in 2010, 26.4 billion Yuan in 2014, showing an average annual growth of 15%. Among them, there are 14 high-tech enterprises whose annual revenue is more than 100 million. When interpreting the interaction mechanism of university and surrounding industry, previous studies tended to focus on the spillover effects that knowledge from universities can enhance the surrounding areas' human capital, ignoring the effect of social capital within the university and in the areas surrounding the university. This paper will review the history of the concept 'social capital', summarize the characteristics of creative industry cluster surrounding Tongji University based on data from Shanghai Second economic census(end of 2008), and explain the interaction mechanism, which is generated by social capital, between Tongji University and the surrounding creative industry.

2 Literature review

Firstly, this paper must clarify what is social capital. Then the paper has to figure out the core elements of the development of creative industries.

2.1 *Social capital*

For the understanding of social capital, until the 1980s, scholars have interpreted it as a collective public goods, or refer to the social environmental quality which will impact personal economic returns. Since the 1980s, driving by Bourdieu, Coleman, Putnam, Fukuyama, and Portes, the concept of social capital comes into the discourse system of social science research.

Bourdieu pioneered the study of social capital from social network analysis, pointing out that social capital is the aggregate of social networks, and the amount of social capital an individual has depends on the size of his network of relationships which can be effectively utilized. More broadly, Coleman argued that social capital originated from tightly linked social networks, and it plays a positive role in the creation, transfer and acquisition of human capital. In addition, he suggested that social capital and human capital were usually complementary. Coleman's definition of social capital was from the functionalism perspective, emphasizing the close ties, while ignoring the weak ties, and denied the possible negative impacts of social capital. Putnam acknowledged Coleman's point of view, but stressed the social norms of reciprocity and mutual trust which are resulting from the so-called dense network structure. Putnam has used the term in his study of democratic governance. He argued that social capital can be defined as some features of social organization, such as interpersonal trust, norms of reciprocity, social networks that will promote active participation by citizens in public community activities. As a consequence, the community shares high degree of interpersonal trust, contributing to cooperative actions which can enhance the social efficiency and bring beneficial outcomes. Fukuyama defines the term as 'an instantiated informal norm that promotes cooperation between two or more individuals'. He also noted that nations having an abundant stock of social capital are more likely to build cooperative relations and promote economy of scale. Therefore it contributes to the development of market capitalism, otherwise hinder it. Whereas Portes proposed the term of negative social capital, highlighting the negative effects of social capital like outsider exclusion, excessive obligations for the group members, and using norms to eliminate differences. He had emphasized it was weaker ties, rather than strong ties, that can be sources of new knowledge and resources. Individuals or groups owning weak ties can control and participate in the dissemination of valuable information, resulting in more resources and greater competitive advantage.

Through reviewing the development process of the concept 'social capital', this paper argues that there are three forms of social capital that must be examined: firstly, social capital can be illustrated as social networks; the second form of social capital is informal social norms and collective trust; the third form of social capital acts as a function of facilitating public interests. Compared with previous empirical research tended to examine social capital at individual level, this paper will illustrate the effect of social capital at group level. It will emphasize the collective property attribute of the social capital and focus on illustrating the interaction mechanisms between Tongji University and the surrounding creative industries from the perspective of collective social capital. The analysis of social capital will conduct from three angles: social networks, informal norms and collective trust, and function of promoting the collective interests.

2.2 The core elements of the development of creative industries

According to “embeddedness” concept proposed by the new economic sociologist Grnaoverttor, economic activities are rooted in the networks and institutions. Moreover, the network and institution is constructed by the society and has cultural significance. Since creative industry as an emerging industries, is the integration of culture, technology and economy, the spark of creative ideas depends heavily on face to face communications. Therefore creative industries demonstrates a notable spatial agglomeration characteristic. The gene of creativity will be rooted in the local organizational structure, forming formal or informal networks of exchanges and cooperation. In his book ‘creative city’, Landry proposed that creative industries embedded in the creative atmosphere, and creative atmosphere is a spatial concept. The core elements of creative atmosphere include both hardware and software. Hardware refers to infrastructure which can provide physical entity for innovative activities and build social networks, such as research institutions, educational institutions, cultural and sports facilities, and public places. Software refers to social networking, informal norms, and community participation which can promote creative thinking between individuals or among group members and organization through the network.

When concerning which kinds of capital creative industries make intensive use of, the answer is human capital and social capital, rather than physical capital. Physical capital, including various forms of wealth, exists outside social participants, but can be occupied by them. Human capital, such as knowledge, skills, creativity, internalizes in social participants, and the stock of human capital will not reduce along with using it. But repeated usage will lead to the reproduction of human capital. The third form of capital is social capital, which exists in the form of network of relationships between various social participants. In essence, social capital is the transferable resources embedded in the social networks. Anyone in the social network social cannot own such resources unilaterally. He can only accumulate and utilize such kind of resources through network itself. In short, social capital originated from interpersonal social relations. This kind of relationship is stable, not immediate. Additionally, unlike rigid relationship based on contracts, emotional involvement and behavior can bring changes to such kind of social relations.

This paper argues that the links between place and creativity can be important and influential in the creative process. And the core elements of the development of creative industries include two aspects: hardware and software. Hardware mainly refers to the specific urban space formed by the creative atmosphere and facilities, especially the public space and public facilities. Software is social networks of a certain region, and informal social norms, the learning organization culture, and local brands.

3 Characteristics of the creative industries cluster surrounding Tongji university

Based in Shanghai Second economic census (end of 2008), this paper intends to select the creative firms located in the study areas. Firstly, according to the census ID ‘310110009’ of Siping road, we can filter companies from all kinds of industries which are located in Siping road, Yangpu district, Shanghai. Then according to the national economy industry classification standard (GB/T4754-2002), we can select the creative companies whose industries code belongs to the creative industry. As a result, there are 624 creative

enterprises located at Siping road. Finally further screening the core industry of the surrounding areas of Tongji University: engineering technology and planning management, we find out a total of 301 enterprises. Then based on descriptive statistical analysis, the characteristics the creative industries cluster surrounding Tongji University were analyzed.

3.1 Spatial extent

Survey area locates in Yangpu district, Shanghai, with a total area of about 2.6 square kilometers (Fig1). The region centers on Siping road campus of Tongji University, and contain s three campus of the university. The north side of the survey area is zhongshan north 2 road. And the southwest side of the survey area is Dalian west road. Siping road is the main channel that connect survey area with the outside areas.

3.2 History of development

The rise and fall of Architectural design, urban planning and design, civil engineering consulting is closely related to the phase of a region’s urbanization development and the real estate market’s level of prosperity. Since the late 1990s, housing production and consumption in China started to transform from command economy to market economy. Accompanied by the rapid urbanization process, the prosperous real estate market has formed a strong market demand for engineering consulting, architectural design, and urban design industry. Therefore we can witness a foundation peak of creative companies around Tongji University during 2003-2005 (Fig 2).

Figure 2: Percentage of enterprises opened in different years

There are tightly links between surrounding creative industries and Tongji University. The preponderant disciplines of Tongji University: architecture, urban planning, landscape and civil engineering, provide abundant qualified workforce and the latest technology which guarantee the competitive advantage of creative industries around university. For instance, College of architecture and urban planning (CAUP) contains three core disciplines: architecture, urban planning and landscape. And the average amount of graduates from CAUP are about 600 per year (Fig 3). Meanwhile, the social relations between students, teachers, alumni, and colleagues have kept on updating and accumulating. Social capital which is rooted in and around Tongji University is continuously reproduced.

Year	Bachelor	Master	PhD	Total
2012	228	286	43	557
2013	200	276	52	528
2014	353	281	50	684

3.3 Characteristics of the creative industries cluster

Based on descriptive statistical analysis, the characteristics the creative industries cluster were illustrated.

3.3.1 More small enterprises than medium-size and large enterprises

Through conducting statistical analysis of employment size of 301 enterprises in engineering technology and planning management industries, it can be found that employment size below 10 accounts for 61.8% of the total business companies (Fig 4). Because in design industry, employers must make a large investment on human capital and social capital, while less investment in fixed assets, the foundation threshold of starting an enterprise in design industry is relatively low. Moreover, in financial operations, employment models, business expansion and other areas, small enterprises have flexibility and resilience, which large companies can hardly own. In addition, small enterprises can response to changes in market demand faster. Meanwhile to small enterprises, the corporation social capital can be substantially equivalent to the social capital of entrepreneurs. Therefore, the entrepreneurs can induce and control the positive effect of his social capital for business development.

Figure 4: percentage of employees of different size in enterprises

3.3.2 Main industries: engineering technology and planning management

According to the national economy industry classification standard (GB/T4754-2002), a classification statistics of 624 creative enterprises surrounding Tongji University was conducted. As a result, engineering technology and planning management (industry code: 767), which architectural design, civil engineering, urban design and planning belong to, accounts for 60.7% of all enterprises (Fig 5). The second place is the consulting and investigation services industry, accounting for 17.5%. The cluster's core industry greatly fits the professional advantages of Tongji University.

Figure 5: percentage of enterprises in different industries

3.3.3 The entrepreneurs and employees of surrounding creative industries: teachers, students and alumni from Tongji University

80% of the creative industries surrounding Tongji university is founded by teachers, students and alumni from the university. Teachers of the university and the graduates are the main driven force of entrepreneurship. By establishing studios, or running company, they can undertake actual project.

4 The interaction mechanisms of the university and surrounding creative industries from the perspective of the social capital

The mechanism of social capital accumulation around the university depends on the high-density social network system based on the social relations between teachers and students,

students, alumni, colleagues and so on. It also relies on information transferring and sharing mechanism based on social network system. In addition, high levels of interpersonal trust among group members, the monitoring mechanism relying on the reputation effect and social exchange mechanisms based on the informal norms are essential to the social capital accumulation.

4.1 High-density social network system

Contrary to science and technology parks based on the merchants, industrial clusters are formed on the basis of the university around the Tongji University. As a teaching institution, University always need to spend a longer period of time to complete the process of training qualified personnel (four-year undergraduate, three-year graduate, doctoral degree for three years or more). In fact, entrepreneurs of the surrounding industries have been living and learning for a long time in this space before starting their business. This period is helpful to accumulate social network relations, including students, teachers, classmates, friends, employer during internship and clients when assisting their tutors to do the projects. All of these have provided social capital for their entrepreneurship, such as project sources, access to valuable information, trusted partners and the directors in charge of business development or project implementation. These will soon be transferred into economic returns once they started their own business. Naturally, due to the familiarity and trust between each other, they only need to pay low transaction costs in the interactive process. It is very helpful for the development of emerging enterprises. This mutually beneficial relationship between industry and university continues to reproduce by labor mobility existing in surrounding creative industries and student mobility in school, which forms a long-term effect of the accumulation of social capital.

4.2 Information transferring and sharing mechanism

University, as an institution focusing on knowledge production and dissemination, often is the birthplace of the advanced technology, theory and concepts. New technologies and knowledge will spread quickly relying on the high-density social networks around the university. Existing studies have shown that university has notable knowledge spillover effect on its surrounding areas. University continually produces public knowledge, and improve the human capital stock surrounding areas by publishing up-to-date scientific achievements, holding exhibition, organizing academic exchange meeting, conducting short-term refresher training and providing a variety of informal communication channels. The interaction between Tongji University and the surrounding creative industries is a good example of the integration of industry-university. University provides qualified personnel, technologies and social capital for the development of surrounding industries. Meanwhile, the surrounding industries provide feedbacks like changes in market demand to university and provide practical experience. University and surrounding industries form a sustainable learning organization culture, such as the surrounding institute will conduct seminars to share project experiences and achievements. College students, through lectures and face to face communication with professional planners, can get practical knowledge in the discipline. University offers the openness of academic conferences, designer salons and other public exchange places. Public space characterized by intensive interaction is important space for informal learning and promoting positive innovation. Surrounding employee can acknowledge the latest scientific achievements of the related disciplines and design concepts, as well as access to industry information by communicating with teachers and students in school. It is worth paying attention to the spread of new ideas and technology based on Social network sites (SNSs). With the extensively use of SNSs such as Wechat, Weibo and QQ, online and offline networks of relations tend to be mutually reinforcing, which are conducive to effective information channel, as well as dissemination of new ideas and new technologies.

4.3 High level of interpersonal trust and monitoring mechanism relying on the reputation effect

One of social capital-rich manifestation is high level of interpersonal trust among group members. Trust often acts as a coordinating role in social networks, and trust as a moral resources, can make one's vision beyond their own self-interest category, which means group members under uncertain conditions, for instance, whether or not others will comply with the agreement, tend to choose cooperation. Through the promotion of cooperative actions, high-trust society will enhance its operating efficiency, promoting public interests. At the same time, the behavior of group members will build reputation in the social relations. Because opportunities for contact between group members are abundant, if a certain group members have a bad credit record, it is easy to rely on the networks to conduct the collective reward-punish system, and we will remove such kind of member from the social network.

4.4 social exchange mechanisms based on the informal norms

Informal norms is a concept compared to formal norms such as contract, institution, policy etc. The informal norms which are generated by interactive networks of social relations, can be reinforced by the evolutionary changes in social relations. The informal norms also have constraints on the behavior of group members, and have more flexibilities than formal norms. Compared with contract, hierarchy and bureaucratic rules which represent the terms of formal coordination mechanism, coordination based on informal norms, can significantly reduce the associated transaction costs. Taking temporary employment system as an example, this kind of employment is generally used in creative industry, forming an elastic labor market and facilitating the generation of social capital. Since the small companies generally are sensitive to the cost, temporary employment system provides them with a large number of qualified employees: students in the university. College students who directly involved in the project, can obtain practical experience, cultivate the market consciousness, and expand the social relations. While the enterprise through the temporary employment system can acquire a higher level of human resources, and reduce the operating costs.

4.5 Local identity – building a design brand of Tongji University

The sense of identity to Tongji University and its surrounding areas provides cultural identity on the development of university and industry. It makes it possible that different enterprise stakeholders establish close connection between each other and cooperate for maintaining a common design brand.

5 Conclusion

In this paper, the interaction mechanism of Tongji University and its peripheral creative industries is examined, illustrating the mechanism of social capital accumulation within and surrounding the university areas. Because the economic function of the coordination mechanisms, which is generated by social capital, is to reduce production costs and transaction costs, the creative enterprise community gains competitive advantages comparing with companies which must employ a fixed employees and rely on formal social norms like contracts. In return, the development of enterprise community increases social capital stock and reproduce social capital. The results of accumulation and proliferation of social capital are two: one can bring interpersonal trust and norms of reciprocity promoting collective participation, and the other is capable of creating a stable, integrated structure of

social networks. Because social capital can be created and used endlessly, the Tongji surrounding creative industries achieve sustainable competitive advantages.
