5.4.38 Sole West of Ireland (Division VIIb,c) ..... 269

### 5.1 Ecosystem Overview

### 5.1.1 Ecosystem components

## Bottom topography substrate and circulation

In the Celtic seas (ICES sub-areas VI and VII) the continental shelf is of variable width. The Celtic sea, south of Ireland is an extended shelf which most of the area is shallower than 100 m . It is limited to the west by the slope of the Porcupine seabight and the Goban Spur. In this area the slope is rather gentle and sedimentary. To the west of Ireland the Porcupine bank forms a large extension of the shelf limited to the west by the Rockall Trough, the transition between the Porcupine bank and the trough is a steep and rocky slope along which reefs of deepwater corals occur. Further North, to West of Scotland the slope of the Rockall Trough is closer to the coast line, particularly off NW Ireland, and the Hebrides. West of the shelf break and the Rockall Trough is the Rockall Plateau with depths of less than 200 m . The shelf area itself contains mixed substrates, generally with soft sediments (sand and mud) in the west and tending to more rocky, pinnacle areas to the east. The Irish Sea is shallow (less than 100 m deep in most places) and largely sheltered from the winds and currents of the North Atlantic, although relatively high salinity indicates the influence of oceanic water from the south. In the Irish Sea, the inshore Coastal Current carries water from St. Georges's Channel northwards through the North Channel, mixing with water from the outer Clyde.

At these latitudes $\left(55^{\circ}\right.$ to $\left.58^{\circ} \mathrm{N}\right)$ the continental slope is mainly sedimentary and a trawl fishery for mid slope fish such as roundnose grenadier, Blackscabbard fish, deep sea squalids, blue ling and Orange roughy have been operating since the late 80s. The eco-region also contains several important seamounts; Anton Dohrn, Hebrides and Rosemary Bank, which have soft sediments on top and rocky slopes.

The water circulation in this area is dominated by the poleward flowing slope current. This persists throughout the year north of Porcupine Bank, and is stronger in the summer. South of the bank the current is present in the winter months, but breaks down in the summer, when flow becomes complex. There is also a weaker current flowing north from Brittany and splitting east and west along the Irish coast. (source; OSPAR QSR 2000) Porcupine Bank and the Rockall plateau tend to be retention zones.

The main oceanographic front in the Atlantic region is the Irish Shelf Front that occurs to the south and west of Ireland (at c. $11^{\circ} \mathrm{W}$ ) around the 150 m isobath, and exists year-round. This front marks the boundary between water over the Irish shelf (often mixed vertically by the tide) and offshore North Atlantic water. The turbulence caused by the front may bring nutrients from deeper water to the surface where they promote the growth of phytoplankton, especially diatoms in spring, but also dinoflagellates where there is increased stratification. These may in-turn be fed on by swarms of zooplankton and associated with these, aggregations of fish (Reid et al. 2003).

Seasonal fronts occur at several other locations immediately west of Britain, including the Ushant Front in the English Channel, the Celtic Sea front at the southern entrance to the Irish Sea, and the Islay Front between Islay and the coast of Northern Ireland. The Islay Front persists through the winter due to stratification of water masses of different salinity. Similarly, where tides are moderate, uneven bottom topography can have a considerable mixing effect, for example in the seas around the Hebrides.

## Physical and chemical oceanography

## Temperature/salinity

The slope current introduces warm saline water from further south into the whole area. The ICES Annual Ocean Climate Status Summary (IAOCSS) does not deal with this ICES Advisory Region as a bloc, but data are available for the Rockall Trough area in detail. The report suggests that the Rockall trough has been warming steadily over recent years. Similar trends appear for salinity (see Figure 5.1.1 below).

Figure 5.1.1 . Rockall Trough temperature and salinity anomalies for the upper ocean ( $0-800 \mathrm{~m}$ ) of the northern Rockall Trough. Average across section, seasonal cycle removed.

Hydrographic observations for the area of the Northern Shelf (ICES area VI) were considered by WGNSDS in 2005 (ICES 2005a). Of particular note is the highlighted variability in local temperature observed in western waters (Figs 5.1.2and 5.1.3).

Figure 5.1.2 Difference of bottom temperature $\left({ }^{\circ} \mathrm{C}\right)$ in the Rockall Bank area in spring 2005 from temperature in 2002 (a), 2003 (b) and 2004 (c).

Figure 5.1.3 Yearly mean temperature in the areas west of the British Islands in 1986-2005: 1-Rockall Bank area, $55-58^{\circ} \mathrm{N} 14-18^{\circ} \mathrm{W}$ (surface temperature in January-March), 2 - west of the Porcupine Bank, $52-54^{\circ} \mathrm{N} 14-16^{\circ} \mathrm{W}$ (temperature from $50-600 \mathrm{~m}$ in March-April).

No new temperature and salinity data were available for the Rockall area in 2005, although the positive temperature and salinity anomalies observed since the mid 1990s were expected to continue. Modified Atlantic waters in the FaroeShetland channel were warmer and saltier in 2003 than at any period in the last 50 years. Temperature and salinity decreased a little in 2004, but remained higher than the long-term average, suggesting that the general warming trend observed over the last 20 years was continuing. The North Atlantic Oscillation index (NAO) was near median in the winter of 2004. Early indications for the winter in 2005 are that the index will also be only slightly below median (ICES, 2005).

Inshore waters off the west of Scotland have also continued to warm, consistent with open ocean conditions. At Millport, where monitoring has been conducted since 1953, gradual warming is apparent, and the more rapid warming that has taken place since the mid 1990s continued until the time of the last reported data in 2003 (FRS, 2005).

## Input of Freshwater

The major river inputs are into the Bristol channel, Irish Sea and The Malin Sea north of Ireland. These are locally important in reducing salinity in these areas. Because of the complex fjordic nature of west coast of Scotland there is also a substantial freshwater input from the numerous sea-lochs, notably the Firth of Lorne sealoch system.

## Broad-scale climate \& Oceanographic features

See general text on this topic in separate section on the NE Atlantic.

Figure 5.1.4 Spring chlorophyll (1998-2003).

## Phytoplankton

For phytoplankton, the main feature is the strong primary productivity found along the shelf break - see Figure 5.1.4. This is stimulated by the warmer, nutrient rich waters found here. Productivity is reasonably strong on the shelf but drops rapidly west of the shelf break. Based on CPR greenness records for this area the spring bloom occurs around April and collapses by October, although in recent years has continued into December. CPR data also suggest that there has been a steady increase in phytoplankton colour index across the whole area over at least the last 20 years. Details on the taxa involved have not been located but are assumed to be dominated by diatoms (at least in the spring bloom), but will also include dinoflaggelates.

## Zooplankton

Like the adjacent North Sea waters, the overall zooplankton abundance in this area has declined in recent years. CPR areas C5, D5 and E5 all show substantial drops in Calanus abundance and these are now below the long term mean. Calanus finmarchicus is known to overwinter in the Faroe-Shetland channel and the abundance of these is known to have been reduced in recent years. This species distribution in deep waters further south is unknown. More detailed information should be available from the CPR programme but this is not available at present.

Zooplankton monitoring data are available from one station in waters about 50 m deep in the English Channel. These data exhibited a decreasing trend from 1988 to 1995, but an increase thereafter until 1999. This increase was mainly due to two autumn developing small species of copepod, Euterpina sp. and Oncaea sp. In 1999 there was a decline in the zooplankton population, with the top ten species all below their typical average values (apart from Temora and Corycaeus, which exhibited very little variation). However, in 2000, 2001 and 2002 the abundance of zooplankton increased from a lower abundance level comparable to that of 1995-1998. (reported in ICES Zooplankton Monitoring Status Summary 2001/2002). Data for 2003, 2004 and 2005 are not yet available.

## Benthos, larger invertebrates, biogenic habitat taxa

The major commercial invertebrate species is Nephrops. It is targeted by trawl fisheries on the shelf west of Scotland. the Rockall plateau and south and west of Ireland. Cuttlefish is also exploited in the Celtic Sea, and scallops in the Irish Sea and west of Scotland.

Major fisheries dredging for scallops and some smaller bivalves exist in the western Channel. Irish Sea and west of Scotland. Pot fisheries exploit the lobster Homarus gamarus and brown crab Cancer pagurus in the water around the Channel Islands, off France (French landing about 150 t/year), and the west of Scotland. Estimated landings of whelk (Buccinum ondatum) are as high as 12000 t/year from at targeted pot fishery. Cuttlefish are also targeted by pot fishery but trawl catch are much higher and target juvenile in coastal water in some areas.

In addition to major aquaculture activity for oysters and mussels, some beds of oysters and buried bivalves such as cockles Cardium edule are exploited by professional and recreational fisheries.

The benthos of the Celtic seas (northern shelf, Irish Sea and Celtic Sea) is largely influenced by shelf sea dynamic processes that generate areas with high levels of seabed stress and erosion. Over 340 species of invertebrate and fish were captured in a survey of the epibenthos in ICES area VIIf-h (Ellis et al (2002), the most ubiquitous species being the hermit crab Pagurus prideaux and the spotted dragonet Callionymus maculatus, both of which are major prey items for commercial fish (Pinnegar et al.2003). Two epibenthic assemblages predominate in the Celtic Sea. The first is dominated by the anemone Actinauge richardi ( $41.8 \%$ of faunal biomass) and occurs along the shelf edge and slope in waters $132-350 \mathrm{~m}$ deep. The second assemblage is more widely distributed on the continental shelf (depth range: 66232 m ) and $P$. prideaux dominates along with other mobile invertebrates (shrimps and echinoderms), although there are some spatial differences in assemblage structure and relative abundance.

Biogenic reefs of horse mussels Modiolus modiolus, maerl and Serpulid worms occur in specific locations (Irish Sea, West coast of Scotland). The latter can support benthos of conservation interest such as sea fans and structurally complex bryozoans. Offshore areas on the shelf slope support reefs of deep water corals such as Lophelia pertusa.

## Fish Community

This ICES Advisory Region includes two distinct types of ecosystem; shelf seas and deep water communities. In the northern part of the area, (Irish Sea, West of Ireland and western Scotland) there are important commercial fisheries for Nephrops, cod, haddock and whiting and a number of flatfish species. Hake and angler fish are also fished across the whole area. The Rockall plateau is subject to a haddock and small-scale Nephrops fishery. Commercial fisheries for, cod, plaice and sole are conducted in the Irish Sea. The whole area is also characterised as a spawning area for a number of key wide ranging, migratory species, notably mackerel, horse mackerel and blue whiting. These species are also commercially exploited within the area. Key pelagic species are herring, considered as consisting of a number of different stocks, as well as sardine, in the southern part of the area, and sprat, particularly in the Celtic Sea proper. The area also accommodates considerable stocks of argentines (two species) and large numbers of small mesopelagic myctophids along the shelf break.

The shelf slope $(500-1800 \mathrm{~m})$ comprises a quite different species assemblage including roundnose grenadier, black scabbard fish, blue ling and orange roughy as well as deep sea squalids (sharks) and macrouridae. For the most part none of these species are subject to stock assessment, although some are likely to have been severely depleted by the deep water fisheries carried out in this area. A notable example would be orange roughy, which has probably been largely fished out. All these fish are characterised as being long lived, slow growing and having a low fecundity, making them very vulnerable to overfishing.

The Celtic sea groundfish community consists of over a hundred species and the most abundant 25 make up 99 percent of the total estimated biomass and around 93 percent of total estimated numbers (Trenkel and Rochet 2003). Population and community analyses have shown that fishing has impacted a number of commercial species, primarily because individuals of too small a size have been killed in the past (Trenkel and Rochet 2003). This can be considered as resulting partly from observed large discards (Rochet et al., 2002).

The size structure of the fish community has changed significantly over time, and that a decrease in the relative abundance of larger fish has been accompanied by an increase in smaller fish (4-25g) (Blanchard et al 2005; Trenkel et al 2004).. Temporal analyses of the effects of fishing and climate variation suggest that fishing generally has had a stronger effect on size-structure than changes in temperature. A marked decline in mean trophic level of the fish community over time has also been documented (Pinnegar et al 2003) and this resulted from a reduction in the abundance of large piscivorous fishes and an increase in smaller pelagic species which feed at a lower trophic level. Since 1990 the non-exploited species Capros aper has become particularly abundant in French and UK survey catches. This phenomenon has been reported as occurring elsewhere in the North Atlantic including the Bay of Biscay (Farina et al. 1997) and offshore seamounts (Fock et al. 2002).

## Trophic web

For the Celtic Sea, two sources of fish stomach data have recently been collated and these are described in UK researchers collected stomachs for 66 species during routine annual groundfish surveys from 1986 to 1994. French researchers (du Buit and co-workers) sampled stomachs of seven species aboard commercial fishing vessels, throughout the years 1977 to 1992 (in all seasons).

Several studies for fish stomach contents and diets have concluded that the main predator species in the Celtic Sea (hake, megrim, monkfish, whiting, cod, saithe) are generalist feeders which exhibit size-dependent, temporal and spatial prey-switching behaviour (Pinnegar et al.2003, Trenkel et al. 2005). Overall, there was general agreement between
higher prey densities in the environment and higher occurrences of particular prey species in predator stomachs, which lead to distinct spatial and temporal feeding patterns (Trenkel, et al. 2005). Blue whiting was found more often in predator stomachs over the shelf edge during the summer months while mackerel and Triopterus spp were relatively more prevalent in stomachs sampled on the continental shelf during the winter half year. The general impression is one of a highly interlinked food web, where several predators feed on the same prey resources, i.e. their trophic niche overlaps substantially. These results derive from the Celtic sea sensus stricto (the southern part of region E, limited to the North by Ireland, and between longitudes of $4^{\circ} \mathrm{E}$ and $12^{\circ} \mathrm{W}$ ). Less is known concerning trophic interactions among fish species in the Irish Sea and northwest Scotland (although see du Buit 1989; 1991a,b). No major studies of forage fish have been conducted in the north of the eco-region. Sand eel, sprat and Norway pout are known to be present, however their role and importance in the ecosystem is unclear.

Fish taken from the shelf edge areas of the Celtic Seas tend overall to be less planktivorous and from a higher trophic level than those in the North and Baltic Seas (2005a). For instance, the secondary production required per unit of landed fish from the southern part of the Celtic Seas is twice that for North Sea fish. In this area zooplankton production accounts for only a small fraction of the secondary production demands of the fisheries. In the Celtic Seas benthos production can be seen as a 'bottom-up' driver for fisheries production, which seems to be independent of variability in plankton production. As this situation is very different to the situation in the North Sea (see NS section), climate change and fishing pressures can be expected to influence these regional fisheries in very different ways. Overall, there appear to be strong spatial patterns in the fish food web structure and function, which should be important considerations in the establishment of regional management plans for fisheries (see Heath 2005b).

Heath (2005b) argues that, because the blue-whiting fishery is conducted mainly off the continental shelf, there is no rationale for a foodweb connection between the bulk of the blue whiting catch and the other landed species from the Celtic Sea and west of Scotland. By contrast, Pinnegar et al. (2003) and Trenkel et al. (2005) have both highlighted the importance of this species as a prey for fish on the shelf-edge, notably for hake and megrim.

For cod in the Irish Sea, the decapod Nephrops norvegicus is known to be an important prey item (Armstrong, 1982), whereas whiting, Norway-pout and Nephrops are known to be important for monkfish (Crozier 1985). In north-west of Scotland there have been additional studies focusing on inshore demersal assemblages (e.g. Gibson \& Ezzi, 1987). Feeding relationships among deep-water species on the Wyville Thomson ridge have also been examined (du Buit 1978).

## Vulnerable species

The blackspot (red) seabream (Pagellus bogaraveo) used to be an important target species of English fisheries in the 1930s (Desbrosses, 1932), catches in the Celtic seas declined well before the collapse of the fishery in region $G$ (see this chapter for a longer account on this species). The species can be considered as eradicated from the Celtic seas.

The red lobster (Palinurus elephas) was exploited by pot fisheries prior to the late 1990s, and current catches and the stock of this species can be considered as residual.

Skates are arguably the most vulnerable of exploited marine fishes because of their large size, slow growth rate, late maturity and low fecundity. Dulvy et al. (2000) discussed the disappearance of skate species (Dipturus oxyrhinchus, Rostooraja alba and D. batis) in the Irish Sea, and the widespread decline in the abundance of smaller species.

As mentioned above, several species of deep water fish are considered as being severely depleted and meriting protection.

## Birds, Mammals \& Large Elasmobranches

Basking shark (Cetorhinus maximus), are seen throughout the Celtic Sea, Irish Sea and Northern Shelf region, from April through to October. Basking shark is protected within British territorial waters. Blue shark (Prionace glauca) are found in the summer in the southern part of the area. They are subject to a variety of fisheries, both recreational and directed (longlines and gillnet) as well as bycatch in offshore tuna fisheries. Porbeagle (Lamna nasus) and tope (Galeorhinus galeus) are also targeted in both recreational and commercial fishing.

Six species of cetacean are regularly observed in this Advisory Region (Reid et al 2003). SCANS line transect surveys in 1994 estimated numbers of some of these occurring in the Celtic Sea.

Minke whale Balaenoptera acutorostrata is found throughout the region, particularly off western Scotland and Ireland. SCANS estimate was 1195 animals. Bottlenosed dolphin Tursiops truncatus occur in large numbers off western and southwest Ireland and in smaller numbers throughout the region. No SCANS estimate. Common dolphin Delphinus delphis are widely distributed in shelf waters throughout the region, especially in the Celtic Sea and adjacent waters.

SCANS estimate was 75500 animals. White-beaked dolphin and White-sided dolphin (Lagenorhynchus albirostris and L. acutus) occur over much shelf area, but are less common in the southwest part of the area. Harbour porpoise Phocoena phocoena is the smallest but by far the most numerous of the cetaceans found in the shelf area, particularly south-west Ireland, the Irish Sea and west of Scotland. SCANS estimate was 36280 animals.

Grey seals (Halichoerus grypus) are common in many parts of the area, with population estimates ranging from approximately 50,000 to 110,000 animals (SCOS 2005), the majority in the Hebrides and in Orkney. Common seals (Phoca vitulina) are also widespread in the northern part of the area with around 15,000 animals estimated (SCOS 2005). Smaller numbers are seen in Ireland (c. 4,000 ) and very few further south.

In 2002, the ICES Working Group on Seabird Ecology reported seabird population estimates within all ICES areas. For ICES Area VIa west of Scotland a total of 1.2 million pairs of breeding seabirds were reported. Auks, predominantly the common guillemot (Uria aalge), razorbill (Alca torda) and the Atlantic puffin (Fratercula arctica) accounted for $51 \%$ of the total, while petrels (including fulmar, Fulmarus glacialis; storm petrel, Hydrobates pelagicus; and Manx shearwater, (Puffinus puffinus) accounted for $29 \%$, Northern gannet accounted for $10 \%$, and gulls (particularly kittiwake and herring gull) $9 \%$ (ICES 2002). In the Irish Sea, Bristol Channel and English Channel (ICES areas VIIa,d,e,f) gulls predominate ( $47 \%, 66 \%, 90 \%, 68 \%$ respectively), in particular black-headed, lesser black-backed and herring gulls as well as guillemots. Petrels (fulmar and storm-petrel) dominate in the west of Ireland and Celtic Sea region (area VIIb,g.j $48 \%, 60 \%$ and $79 \%$ respectively) but there also large breeding colonies of kittiwake, guillemot and gannet.

Climate change is likely to impact on seabird populations. The breeding success of some seabird populations in the Celtic Sea has already been linked to climatic fluctuations in the North Atlantic, such as the North Atlantic Oscillation (NAO). Projected consequences of global warming, such as sea level rises, increased storminess and rises in sea/air temperatures are likely to have a direct impact on seabird populations.

## Knowledge gaps

In general this eco-region has attracted less attention than areas such as the North Sea. It is probably not that data do not exist, but that they have not been correlated and integrated. For example, the CPR programme has carried out sampling within the area, but detailed breakdown of these data has not been carried out. As noted above, the primary, and hence presumably secondary production change substantially from the shelf, to the shelf break to the open ocean. Therefore, data aggregated over all these systems is likely to be difficult to interpret. There is also no single assessment working group responsible for the fisheries in the area. These are covered by nine groups, including both northern and southern shelf demersal WGs,. This also makes the integration of data by eco-region more complex. There is currently no multispecies working group for this region, and hence there has been no coordinated effort towards exploring predator-prey relationships and inter-dependencies among commercial species.

### 5.1.2 Major environmental signals and implications

No obvious environmental signals were identified that should be considered in assessment or management in this area. The major trends in the ecosystem noted above are the steady warming of the area, particularly in the context of the slope current. The Rockall trough waters have been warming steadily for some years and are currently at an all time high. The general and continuing reduction of copepod abundance is also of major concern given the major role of these organisms in the food web.

Both these factors are likely to have an impact on the life histories of many species, but particularly on the migratory pelagic species; mackerel, horse mackerel and blue whiting. Both mackerel and horse mackerel migrations are closely associated with the slope current. Mackerel migration is known to be modulated by temperature (Reid et al 2001). Continued warming of the slope current is likely to affect the timing of this migration. The timing and location of spawning by all these species is also likely to be affected by warming. The impact on recruitment is difficult to assess, as mackerel generally recruits well, and the horse mackerel stock depends on very rare massive recruitments. No ecosystem link has been identified for either species.

The widespread and sudden increase in occurrence of non-commercial species such as Capros aper, particularly after 1990 (Pinnegar et al. 2003) might indicate some change in environmental conditions but mechanisms and consequences are poorly understood.

### 5.2.1 Fishery effects on benthos and fish communities

This ICES Advisory Region is characterized by the presence of a number of benthic features which are considered important and vulnerable to fishing activity. These include cold water corals (particularly Darwin mounds) other biogenic reefs and natural reefs. Cold water corals structures have been identified in many areas including Porcupine Bank, Rockall, the slope areas west of Scotland \& Ireland and on the seamounts. ICES has advised on the occurrence of cold-water corals in the North East Atlantic for the past two years. It has also advised that should managers wish to protect these habitats from the effects of fishing, the only effective way to do this is by closing them to all damaging fishing gear. In Subarea VI, one such area has been closed by fishery managers: the Darwin Mounds. This area lies to the south of the Wyville Thomson ridge (to the northeast in Figure 5.2.1). The Darwin Mounds have been impacted by towed bottom-fishing gear (ICES, 2002). There has been extensive use of bottom-set nets on shelf, slope and even deepsea areas. Although documentation is hard to acquire, there is substantial concern about ecosystem effects due to ghost fishing by lost gear from these fisheries, and about unsustainable fishing practices.

Figure 5.2.1 Distribution of cold-water coral records within ICES Subarea VI (from ICES, 2005a).
Not all of the records of cold-water coral in Figure 5.2.1 are of reefs: some records are of individual fragments trawled or dredged up from the seabed. Accurate determination of the existence and location of reefs requires either remote sonar surveys or visual inspection, either using cameras or manned submersibles, coupled with accurate geo-referencing of the seafloor. In Subarea VI, reefs have been found in UK internal waters to the east of Mingualay in the Outer Hebrides of Scotland (ICES, 2004), on the Rockall Bank (Figure 5.2.2), particularly on the northwestern and southeastern parts of the Bank. On the southeast Rockall Bank, the coral reefs are associated with large carbonate mounds (the Logachev Mound province) and are particularly well developed. Tangle nets and trawl scar marks have been observed in these reefs (ICES, 2005a).

Figure 5.2.2. The distribution of coral reefs on Rockall Bank from fishermen's records (J. Hall-Spencer, pers comm.). The cross-hatched areas indicate the presence of Lophelia reefs (From ICES. 2003).

The fishing activities on the shelf areas is likely to have impacted the fish-communities and there are numbers of depleted stocks in that area (e.g. cod, whiting and plaice). Trawling in the deep waters has almost certainly caused substantial changes in the community structures of the deeper waters west of the shelf break. Initial studies of catch rates from surveys west of Scotland in the 1980s compared to the last 5-10 years suggest substantial reductions in large, slow growing species and a switch to smaller faster growing fish.

The shelf slope ( $500-1800 \mathrm{~m}$ ) comprises a quite diverse species assemblage including roundnose grenadier, black scabbard fish, blue ling and orange roughy as well as deep sea squalids (sharks) and macrouridae. For the most part these species are not subject to regular stock assessment. However, some of these species are likely to have been severely depleted by the deep water fisheries carried out in this area. All these fish species are characterised as being long lived, slow growing and having a low fecundity, making populations very vulnerable to overfishing.

Based on the above, the sustainability of deep water trawling should be reconsidered given the vulnerability of both the fish communities and the benthic habitats.

Cetacean bycatch in fisheries has been acknowledged to be a threat to the conservation of cetaceans in this eco-region (CEC 2002a, Ross \& Isaacs 2004). As in other areas this mainly affects small cetaceans - i.e. dolphins, porpoises and the smaller toothed whales. Species caught in the region are primarily the harbour porpoise, common dolphin, striped dolphin, Atlantic white-sided dolphin, white-beaked dolphin, bottlenose dolphin and long-finned pilot whale (CEC 2002a). However, other larger cetaceans, such as the minke whale, can also be affected.

An extensive review of the bycatch of cetaceans in pelagic trawls was carried out for Greenpeace in 2004 (Ross \& Isaacs 2004). This report considered published and anecdotal information. In the Celtic Seas the report identified a small number of fisheries where cetacean bycatch could be documented. These were;

- Bass fishing in the western channel
- Mackerel and horse mackerel trawling SW of Ireland
- Gill netting for hake in the Celtic Sea

In the last two cases, the number of animals caught was low, however, it is probably higher in the bass fishery and has attracted considerable public attention. The report identified that many countries had initiated cetacean bycatch monitoring programmes, and had generally found little or no evidence that serious bycatch had occurred.

### 5.3 Assessments and advice

### 5.3.1 Assessment and advice regarding protection of biota and habitats

### 5.3.2 Assessments and advice regarding fisheries

## Mixed fisheries and fisheries interactions (Celtic Sea and western Channel)

Demersal fisheries in the area are mixed fisheries, with many stocks exploited together in various combinations in different fisheries. In these cases management advice must consider both the state of individual stocks and their simultaneous exploitation in demersal fisheries. The stocks in poorest condition, particularly those outside precautionary limits, necessarily become the overriding concern for the management of mixed fisheries where these stocks are exploited either as a targeted species or as a bycatch.

Many of the fleets in the area operate on a mixture of demersal species. As trends in stocks of various species are generally not in synchrony, advice provided on the basis of the status of individual species may result in advised fishing mortalities for a group of co-harvested species that cannot be realized simultaneously within the context of mixed fisheries.

The main interactions between the stocks in the Celtic Sea, Southwest of Ireland, and Western Channel, are between:

- anglerfish, megrim, and hake in the otter board trawl fishery in medium to deep water,
- Nephrops, cod, and whiting in the Nephrops fishery in the Celtic Sea, and between Nephrops and hake in the Bay of Biscay;
- gadoids (cod, haddock, and whiting) within the trawl fishery for roundfish, mainly within Divisions VIIf,g;
- sole and plaice in the beam trawl fishery in Divisions VIIf,g and VIIe, and sole and anglerfish in VIIIa,b;
- haddock, whiting, cod, sole, plaice, hake, megrim, anglerfish, squid, elasmobranchs, and other species within the mixed demersal trawl fisheries.

The directed fisheries for hake (trawl, longlines, and gillnets) and have few interactions with other stocks:
Table 5．3．1 Stock interactions－Celtic Sea and Western Channel．

| Anglerfish in Divisions VIIb k and VIIIa,b (L. piscatorius and L. budegassa) | Full reproductive capacity | Harvested sustainably | Overexploited | Not applicable | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | Fishing at $\mathbf{F}_{\mathrm{pa}}$ for L. budegassa is expected to result in landings of 7600 t . This corresponds to a fishing mortality of 0.21 for $L$. <br> piscatorius, corresponding to landings of at most 28400 t in 2007. | TAC $<36000$ t |
| Cod in Divisions VIIe-k | Reduced reproductive capacity | Harvested unsustainably | Overexploited | Not applicable | F is above $\mathbf{F}_{\text {max }}$ | It is not possible to identify any non-zero catch which would be compatible with the Precautionary Approach. | Zero TAC |
| Haddock in Divisions VIIb-k | Unknown | Unknown | Unknown | Not applicable | Unknown | Effort not allowed to increase, rather than TAC management. | No increase in effort |
| Hake - Northern stock (Division IIIa, Subareas IV, VI and VII, and Divisions VIIIa, b, d) | Full reproductive capacity | Harvested sustainably | Overexploited | The TAC in accordance to the agreed management plan is 50485 t | $F$ is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | A fishing mortality of $\mathbf{F}_{\mathrm{pa}}=$ 0.25 is expected to lead to landings of $53800 \mathrm{t} \text { in } 2007 .$ | TAC $<50485$ t |
| Megrim in Divisions VIIb,c,ek and VIIIa,b,d (L. <br> whiffiagonis and L. boscii) | Unknown | Unknown | Unknown | Not applicable | Unknown | Landings of $L$. wiffiagonis in 2007 should not exceed the average landings of 2003 2005. This corresponds to 14200 tonnes. | TAC $<14200$ t |
| Nephrops in Divisions VIIb, c, j,k | Unknown | Unknown | Unknown | Not applicable | Unknown | Nephrops fisheries should be constrained to recent levels of effort at an appropriate geographical scale (FU). | No increase in effort |
| Nephrops in Divisions VIIf,g,h, FU20-22 | Unknown | Unknown | Unknown | Not applicable | Unknown | Nephrops fisheries in this area should be constrained at recent levels of effort. | No increase in effort |
| Plaice in the Celtic Sea (Divisions VIIf and g) | Reduced reproductive capacity | Unknown | Overexploited | Not applicable | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | A $50 \%$ reduction in F is needed to increase SSB to around $\mathbf{B}_{\mathrm{pa}}$ in 2008. This corresponds to landings of less than 380 tonnes in 2007. | TAC $<380$ tor Recovery plan |

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single-stock exploitation boundary - Tonnes or effort in 2007 and \% reduction in F . |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high long-term yield | In relation to agreed management plan | in relation to high long-term yield | in relation to precautionary limits |  |
| Plaice in Division VIIe (Western Channel) | Increased risk | Increased risk | Overexploited | Not applicable | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | Substantial reduction in catch until the estimate of SSB is above $\mathbf{B}_{\mathrm{pa}}$ or other strong evidence of rebuilding is observed. | Substantial reduction in catch |
| Plaice Southwest of Ireland (Division VIIh-k) | Unknown | Unknown | Unknown | Not applicable | Unknown | Catches in 2005 should be no more than the recent average (2003-2005) of around 196 t . | TAC $<196$ t |
| Plaice West of Ireland (Division VIIb, c ) | Unknown | Unknown | Unknown | Not applicable | Unknown | Catches in 2005 should be no more than the recent average (2003-2005) of around 55 t . | TAC $<55$ t |
| Sole in the Celtic Sea (Divisions VIIf and g) | Full reproductive capacity | Increased risk | Overexploited | Not applicable | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | A $24 \%$ reduction in F is needed to reduce F below $\mathbf{F}_{\mathrm{pa}}$. This corresponds to landings of less than 840 tonnes in 2007. | TAC $<840$ t |
| Sole in Division VIIe (Western Channel) | Increased risk | Harvested unsustainably | Overexploited |  |  | Landings of around 350 tonnes in 2007 to bring SSB above $\mathbf{B}_{\mathrm{pa}}$; or recovery plan. | TAC $<350$ t or recovery plan |
| Sole Southwest of Ireland (Division VIIh-k) | Unknown | Unknown | Unknown | Not applicable | Unknown | Catches in 2005 should be no more than the recent average (2003-2005) of around 287 t . | TAC $<287$ t |
| Sole West of Ireland (Division VIIb, c) | Unknown | Unknown | Unknown | Not applicable | Unknown | Recent catches have been close to the TAC of 65 t . Catches should not be allowed to increase unless it can be shown that an expansion of the fishery is sustainable. | TAC $<64$ t |
| Whiting in Divisions VIIe - k | Unknown | Unknown | Unknown | Not applicable | Although F is ucertain, F is above $\mathbf{F}_{0.1}$ | The stock should be managed by ensuring that the effort is not allowed to increase. | No increase in effort |
| Celtic sea and Division VIIj herring | Uncertain | Unknown | Unknown | Not applicable | Unknown | No fishing should be allowed until a rebuilding plan is in place. | Zero TAC |
| Herring in VIa south and VIIb, c | Uncertain | Uncertain | Unknown | Not applicable | Unknown | No fishing should be allowed unless a rebuilding plan is in place. | Zero TAC |

Table 5.3.2 (Cont'd)

## Identification of critical stocks

The table above identifies the stocks outside precautionary reference points. Spurdog and cod in VIIe-k are in a critical state. Stocks for which a reduction in exploitation is required are sole and plaice in Divisions VIIfg; plaice and sole in Division VIIe; Celtic Sea herring; and VIa VIIbc herring.

These stocks are the overriding concerns in the management advice for all fisheries where the interactions between stocks taken in the same fisheries should be considered:

- For spurdog and cod in VIIe-k the advice is for a zero catch;
- For sole in Division VIIe; and plaice in Division VIIf,g: either catches in 2007 as indicated in the table above, or recovery plans to define the limits within which the fisheries can take place and which ensure a large reduction in F in 2006;
- Reduction in fishing mortality has been advised for sole in Divisions VIIfg; for plaice in Division VIIe; and for Celtic Sea herring and VIa VIIbc herring.

## Advice on fisheries management

Fisheries in the Celtic Sea, Southwest of Ireland, Western Channel, and northern part of the Bay of Biscay should in 2006 be managed according to the following rules, which should be applied simultaneously:

They should fish:

- With no catch or discard of spurdog and cod in VIIe-k;
- without jeopardizing the recommended reduction in fishing mortality of sole and plaice in Divisions VIIfg; plaice and sole in Division VIIe; and Celtic Sea herring and VIa VIIbe herring;
- concerning deepwater stocks fished in Subareas VII and VIII, see Volume 9;
- within the biological exploitation limits for all other stocks (see text table above).

Furthermore, unless ways can be found to harvest species caught in mixed fisheries within precautionary limits for all those species individually, then fishing should not be permitted.

## Celtic Sea and West of Scotland

## Fisheries to the West of Scotland and Rockall

The main fleets operating in Division VIa include the mixed roundfish otter trawl fleet, the Nephrops otter trawl fleet, the otter trawl fleet targeting anglerfish, megrim, and hake, and the fleet targeting saithe and/or deep-sea species. To a large extent, the roundfish fishery in Division VIa is an extension of the similar fishery in the North Sea. The demersal fisheries in Division VIa are predominantly conducted by otter trawlers fishing for cod, haddock, anglerfish, and whiting, with bycatches of saithe, megrim, and lemon sole.

The majority of the vessels in the demersal fishery are locally-based Scottish trawlers using light-trawls, but trawlers from Ireland, Northern Ireland, England, France, and Germany also participate in this fishery. The importance of Scottish seiners mainly targeting haddock has been declining in recent years as many of these vessels have been converted to trawlers. Part of the fleet of light trawlers has diversified into a fishery for anglerfish that has been expanding into deeper water off the northern coast of Scotland. Bycatches in this fishery include megrim, ling, and tusk.

About 200 Scottish trawlers also take part in the fisheries for Nephrops on inshore grounds. In recent years Irish vessels have also been targeting Nephrops in Division VIa, mainly on offshore grounds. These Nephrops vessels also land smaller quantities of haddock, cod, whiting, and small saithe, but discard large amounts of whiting and haddock.

The development of a directed fishery for anglerfish has led to considerable changes in the way the Scottish fleet operates. Part of this is a change in the distribution of fishing effort; effort in the roundfish fisheries has shifted away from the traditional inshore areas to more offshore areas and deeper waters. The expansion in area and depth-range of the fishery has been accompanied by the development of specific trawls and vessels to exploit the stock. These vessels mainly use large twin-rig otter trawls with $>100-\mathrm{mm}$ mesh. A smaller Irish fleet also targets anglerfish, megrim, and hake on the Stanton bank with $90-\mathrm{mm}$ to $100-\mathrm{mm}$ mesh. This fleet declined in numbers in recent years although there was a fleet modernisation scheme in the early 2000s whereby several large new vessels joined the fleet. More recently there has also been an Irish decommissioning scheme, involving around 40 fishing vessels ( $\sim 6000 \mathrm{GT}, 18000 \mathrm{~kW}$ ) which have been permanently withdrawn from the Irish fishing fleet and removed from the Register of Sea Fishing Vessels in 2005 and 2006. Several of these vessels have a track record of fishing in VI.

The fishery for anglerfish has expanded into deeper waters with an associated increase in catches. The expansion of this fishery has been further accelerated by the diversion of fishing effort from other stocks subject to more restrictive quotas in recent years, and by market opportunities. A gillnet fishery has developed on the continental slopes to the West of the British Isles, North of Shetland, at Rockall, and on the Hatton Bank. A preliminary investigation of this fishery suggests high levels of gear loss, widespread dumping of netting, high catch and discarding levels (particularly of monkfish), and a lack of effective management. These fisheries are occurring in areas believed to have been a refuge for adult anglerfish, increasing the vulnerability of the stock to overexploitation. Immature fish are subjected to exploitation for a number of years prior to first maturity.

The larger Scottish and Irish trawlers fish for haddock at Rockall when opportunities arise for good catches from the Division VIb stock. Vessels from the Russian Federation have fished for haddock and other demersal species at Rockall since 1999 when part of the Bank was designated as being in international waters. Although young saithe are caught by coastal trawlers in Subarea VI, the fishery for saithe essentially takes place on the shelf edge to the west and northwest of Scotland. Traditionally, this fishery has largely been operated by the larger deep-sea French trawlers. However, the number of these vessels has declined in recent years. Since the late 1980s, some of these vessels diverted their activity toward deep-sea species, notably orange roughy, and some medium-sized trawlers also participate in the fishery for deep-sea species during summer in some years.

The pelagic fishery for herring is mainly operated by UK, Dutch, and German vessels in the north, and by Irish vessels in the south. Substantial misreporting of catches from the North Sea and between the northern and southern stocks occurred in the past, but UK licensing regulations are thought to have reduced misreporting since 1997. In recent years TACs for the northern stock have not been restrictive, presumably because of low effort and a weak market. The Clyde herring fishery has declined sharply in recent years as the stock has suffered from a series of low recruitments. Recent TACs have not been taken and the catches have been less than 1000 t since 1991.

There is a directed trawl fishery for mackerel and horse mackerel in the area. The mackerel fishery mainly takes place in the fourth and first quarter of the year, when the mackerel is returning from the feeding area to the spawning area. The horse mackerel is mainly fished in the second half of the year. In addition, there are fisheries for blue whiting in the area.

The industrial fisheries in Division VIa are much smaller than in the North Sea. The Scottish sandeel fishery started in the early 1980s, peaking in 1986 and 1988. It is irregular, depending on the availability of the resource and of
processing facilities at Shetland, Denmark, and the Faroes. Bycatches in this fishery are very small. The Norway pout fishery is conducted mainly by Danish vessels.

## Recent fishing effort trends

Recent effort trends are available for the UK fleet in Subareas VI. Almost 50000 records over the period 1998 to 2005 were grouped into a series of nine gear categories, as shown in Figures 5.3.1 and 5.3.2. Note that only vessels over 10 m are included here and that gears such as pots, etc. are excluded. No attempt was made to compile an international data set since effort information from countries potentially making a significant contribution (such as France and Spain) were not yet available to ICES. Despite the incomplete nature of the data, the trends recorded for UK vessels (one of the main countries fishing in the area) provide useful indications of recent effort patterns.

Figure 5.3.1 shows that larger-meshed whitefish demersal trawls were the most important gears in VIa prior to 2002, but that there has since then been a marked decline in KW days by this category. This is principally explained by the recent, significant decommissioning schemes in the UK. Single-rig Nephrops trawls in the $70-$ to $99-\mathrm{mm}$ mesh category are the other major gears in use and effort by these seems to have been maintained at a fairly stable level throughout the time-series. Numerous other gears generally make small contributions to the overall effort and the pattern in most of these has either been a downward trend (e.g. seine nets and midwater trawls) or fluctuation without trend (e.g. fixed nets). Taken together the picture suggests that overall, effort has declined in recent years in Area VIa and that declines in particular categories have not been compensated for by rises in other categories.

Figure 5.3 .2 shows the results for VIb , again only for UK vessels. The effort (KW-days) figures are smaller in this area (mostly reflecting fishing at Rockall) and fewer gears are used extensively. Most gears are only recorded sporadically and some (e.g. Nephrops trawls and Nephrops twin trawls) are essentially not used in this area at all. Whitefish demersal trawls are the most important gears in use, particularly larger-mesh ones and the pattern of these in recent years has been a slight rise followed by a decline since 2003. Fixed nets and longlines are the other significant category and the trend in these has been downward.

## Fisheries interactions to the West of Scotland and Rockall

Demersal fisheries in the area are mixed fisheries, with many stocks exploited together in various combinations in different fisheries. Roundfish are caught in otter trawl and seine fisheries, with a $120-\mathrm{mm}$ minimum mesh size that comprises mixed demersal fisheries with more specific targeting of individual species in some areas and/or seasons. Cod, haddock, and whiting form the predominant roundfish catch in the mixed fisheries, although there can be important bycatches of other species, notably saithe and anglerfish in the deeper water and of Nephrops on the more inshore Nephrops grounds. Static-gear fisheries with mesh sizes generally in excess of 140 mm are also used to target cod. Saithe are mainly taken in a directed trawl fishery in deeper water along the shelf in Subarea VI. There is thought to be little bycatch of other demersal species associated with the directed fishery.

Large Nephrops fisheries take place in discrete areas that comprise appropriate muddy seabed sediment. Targeted Nephrops fisheries on these grounds are taken predominantly in trawls with mesh sizes less than 100 mm (particularly in the more southerly regions) using single- or multiple-rig trawls. Nephrops fishing grounds are mainly inshore grounds, although there are smaller offshore fisheries at Stanton Bank and west of the Hebrides. The bycatch and discarding of other demersal species in the Nephrops fisheries is highly variable.

There are trawl and gillnet fisheries targeting hake and anglerfish and otter trawl fisheries targeting hake, megrim, and anglerfish in Subarea VI. The catch of other demersal species associated in these fisheries is uncertain.

There is an international fishery targeting haddock, grey gurnards, and other species at Rockall using small mesh. Successful application of TACs for this stock would require that there is a simple relationship between recorded landings and effort exerted. This assumption is unlikely to be true for Rockall haddock especially when coupled with ways of evading TACs including misreporting, high-grading, and discarding. In the case of Rockall haddock these may occur to a large extent due to the remote nature of the fishery and the processing of catches at sea by some fleets. Direct effort regulation is therefore suggested as a means of controlling fishing mortality on Rockall haddock.

Table 5.3.4 Single-stock exploitation boundaries and critical stocks (West of Scotland)
The state and the limits to exploitation of the individual stocks are presented in the stock sections. The state of the stocks and single-stock exploitation boundaries are summarised in the table below.

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single-stock exploitation boundary - Tonnes or effort in 2007 and \% reduction in $\mathbf{F}$. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high long-term yield | In relation to agreed management plan | in relation to high long-term yield | in relation to precautionary limits |  |
| Cod West of Scotland | Reduced reproductive capacity | Harvested unsustainably | Overexploited | ICES is not in a position to give quantitative forecasts. Simulations show that fishing should be closed for 3 years in order to bring SSB above $\mathbf{B}_{\text {lim }}$. | $F$ is above $\mathbf{F}_{\text {max }}$ | Given the very low SSB estimates, the high fishing mortalities and low recruitment in this stock, ICES advises zero catch of cod in 2007. | Zero TAC |
| Hake - Northern stock (Division IIIa, Subareas IV, VI and VII, and Divisions VIIIa, b, d) | Full reproductive capacity | Harvested sustainably | Overexploited | The TAC in accordance to the agreed management plan is 50485 t . | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | A fishing mortality of $\mathbf{F}_{\mathrm{pa}}$ 0.25 is expected to lead to landings of 53800 t in 2007. | TAC $<50485$ t |
| Cod in Division VIb (Rockall) | No assessment |  |  |  |  |  |  |
| Haddock West of Scotland | Full reproductive capacity | Risk of being harvested unsustainably | Overexploited | Not applicable | F is above $\mathbf{F}_{\text {max }}$ | In order to maintain SSB above $\mathbf{B}_{\mathrm{pa}}$ in 2008, ICES recommends a reduction in fishing mortality to less than 0.44. This corresponds to landings of less than 7200 t in 2007. | TAC $<7200$ t |
| Haddock in Division VIb (Rockall) | Full reproductive capacity | Harvested sustainably | Overexploited | Not applicable | F is above $\mathbf{F}_{\text {max }}$ | Fishing mortality should be less than $\mathbf{F}_{\mathrm{pa}}$, corresponding to catches of less than 7100 t in 2007. | TAC $<7100 \mathrm{t}$ |
| Whiting West of Scotland | Unknown | Unknown | Unknown | Not applicable | Unknown | Catches in 2007 should be reduced to the lowest possible level. | Zero TAC |
| Whiting in Division VIb (Rockall) | No assessment |  |  |  |  |  |  |
| Megrim in Subarea VI (West of Scotland and Rockall) | Unknown | Unknown | Unknown | Not applicable | Unknown | Catches in 2007 should be no more than the recent (20022004) landings of about 2100 t . This includes landings in Division VIa and VIb and unallocated landings in Subarea IV. | TAC $<2100$ t |

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single-stock exploitation boundary - Tonnes or effort in 2007 and $\%$ reduction in $\mathbf{F}$. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Anglerfish in Division IIIa, Subarea IV, and Subarea VI | Unknown | Unknown | Unknown | Not applicable | Unknown | The effort in fisheries that catch anglerfish should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data. | No increase in effort |
| Norway pout West of Scotland | No assessment |  |  |  |  |  |  |
| Sandeel in Division VIa | No assessment |  |  |  |  |  |  |
| Nephrops in Division VIa (FUs11,12,13) | Unknown | Unknown | Unknown | Not applicable | Unknown | Effort should not be allowed to increase relative to the past three years. In addition the exploitation ratio in this stock should be no more than $15 \%$. This corresponds to landings less than 3200 t for North Minch, 7200 t for the South Minch and 3800 t for the Firth of Clyde stock. Landings from other areas in Division VIa should be below the average of 2003-2005, corresponding to landings of 2100 t . | No increase in effort and <br> for North Minch (FU11) TAC $<3200$ t for South Minch (FU12) TAC $<7200$ t - for Firth of Clyde (FU13) TAC $<3800$ t for other VIa stocks TAC $<2100$ t |
| Herring West in Division Via North | Uncertain | Uncertain | Unknown | Not applicable | Unknown | Given that the perception of the stock is the same as last year, the 2006 TAC should be applicable in 2007 also. | TAC $<34000$ t |

## Identification of critical stocks

The table above identifies the stocks outside precautionary reference points. Spurdog, cod in Division Via, and whiting in VIa are in a critical state. Stocks for which reduction in exploitation is required is haddock in Division Via.

The following stocks are the overriding concerns in the management advice of all demersal fisheries:

- for spurdog and cod in Division VIa ICES recommends a zero catch;
- for whiting in VIa ICES recommends the lowest possible catch;
- reduction in fishing mortality has been advised for haddock in Division VIa.

Advice on fisheries management
Demersal fisheries in Subarea VI should in 2006 be managed according to the following rules, which should be applied simultaneously:

They should fish:

- without catch or discards of cod in Subarea VI;
- with the lowest possible catch for whiting in Via;
- without catch or discards of spurdog;
- without jeopardizing the recommended reduction in fishing mortality of haddock in Division Via;
- concerning deep water stocks fished in Subarea VI, see Volume 9;
- within the biological exploitation limits for all other stocks (see table above).

Furthermore, unless ways can be found to harvest species caught in mixed fisheries within precautionary limits for all those species individually, then fishing should not be permitted.

## Fisheries in the Irish Sea

The majority of vessels in the Irish Sea target Nephrops with either single- or twin-rig otter trawls. These vessels use either $70-\mathrm{mm}$ diamond mesh with an $80-\mathrm{mm}$ square mesh panel or an $80-\mathrm{mm}$ diamond mesh in their codends, and (by regulation) their landings must consist of at least $35 \%$ Nephrops by live weight. These vessels have bycatches of whiting (most of which are discarded), and haddock, cod, and plaice. Twin-rig otter trawl were first introduced in the early 1990s. Recent studies show that the use of twin-rigs increases the proportion of roundfish bycatch in Nephrops fisheries compared with single-rig otter trawls. Nephrops catches are highly seasonal, with the highest Nephrops catches seen in the summer months. Catch rates are also dependent on tidal conditions, with higher catches during periods of weak tide.

The roundfish fisheries in the Irish Sea are conducted primarily by vessels from the UK and Ireland. A Northern Irish semi-pelagic trawling for cod and whiting developed in the early 1980s. As the availability of whiting declined this fleet switched to mainly targeting cod and haddock. Irish, Northern Irish, and English and Welsh otter trawlers target plaice, haddock, whiting, and cod, with smaller bycatches of anglerfish, hake, and sole. Some Irish vessels participate in a fishery for rays in the southern Irish Sea. Since 2001, these trawlers have adopted mesh sizes of $100-120 \mathrm{~mm}$ and other gear modifications, depending on the requirements of recent EU technical conservation regulations and national legislation.

There is also a beam trawl fishery which takes place mainly in the eastern Irish Sea with vessels from Belgium, Ireland, and the UK. This fishery mainly catches sole with important bycatches of plaice, rays, brill, turbot, anglerfish, and cod. The fishing effort of the Belgian beam-trawl fleet varies in response to the catch rates of sole in the Irish Sea relative to catch rates in other areas in which the fleet operates. Fishing effort peaked in the late 1980s following a series of strong year classes of sole, but is presently only about $60 \%$ of the peak value.

The other gears used to catch demersal species are gillnets and tangle nets, notably by inshore boats targeting cod, bass, grey mullet, sole, and plaice, and the bottom VHVO trawl targeting hake.

The main pelagic fishery in the Irish Sea is for herring. In recent years, it has been predominantly operated by one pair of trawlers from Northern Ireland. The size of this fleet has declined to a very low level in recent years.

There are also a number of inshore fisheries in the Irish Sea that target stocks not currently assessed by ICES. These include pot fisheries for crab, lobster, and whelk, hydraulic dredge fisheries for razor clams, and dredge fisheries for scallops.

Decommissioning at the end of 2003 permanently removed 19 out of 237 UK demersal vessels that operated in the Irish Sea, representing a loss of $8 \%$ of the fleet by number and $9.3 \%$ by tonnage. Of these vessels, 13 were vessels that had used demersal trawls with mesh size $>=100 \mathrm{~mm}$ and had more than $5 \%$ cod in their reported landings. The previous round of decommissioning in 2001 removed 29 UK(NI) Nephrops and whitefish vessels and 4 UK(E\&W) vessels registered in Irish Sea ports at the end of 2001. Of these, 13 were vessels that used demersal trawls with mesh size $>=100 \mathrm{~mm}$ and had more than $5 \%$ cod in their reported landings.

The Irish fleet has also declined in numbers in recent years although there has been some modernisation particularly since 2000 , whereby several large newer vessels joined the fleet. More recently there has also been an Irish decommissioning scheme, whereby around 40 fishing vessels ( $\sim 6000 \mathrm{GT}, 18000 \mathrm{~kW}$ ) have been permanently withdrawn from the Irish fishing fleet and removed from the Register of Sea Fishing Vessels in 2005 and 2006. Several of these vessels have a track record of fishing in VIIa.

Fishing effort in the semi-pelagic effort increased rapidly between the early 1980s and early 1990s before decreasing somewhat in the mid-1990s. Fishing effort in the England and Wales otter trawl vessels longer than 12 m declined rapidly after 1989 , and from 1999 to 2004 was less than $25 \%$ of the effort reported in the 1980 s. There has been a declining trend in fishing effort for Northern Irish otter trawlers also since the early 1990s. Fishing effort for Irish otter trawlers has declined in recent years as many vessels switched from targeting roundfish to Nephrops.

## Recent fishing effort trends

Within the gear and mesh categories 4A (trawls, seines etc., $\geq 100 \mathrm{~mm}$ ) and 4E (trawls, seines etc., $70-$ to $99-\mathrm{mm}$ ) gears in the Irish Sea, there is a range of fishing gears of a quite different design. Demersal trawls in the 4A category include a variety of single- and multiple-rig otter trawls used for gadoids, rays, and other demersal fish, and semi-pelagic (midwater) trawls that have been used extensively in the deeper waters of the Irish Sea to target hake, whiting, cod, and haddock since the 1980s. Category 4E includes single-rig and multiple-rig Nephrops trawls, and whitefish trawls targeting species such as plaice and whiting where catch composition rules permit this mesh size. The change in mesh
size regulations in 2000 , requiring the use of $100-\mathrm{mm}$ mesh for vessels targeting species such as cod, resulted in a change in the distribution of effort between mesh bands.

The nominal effort trends in kW-days for VIIa given by STECF-SGRST and updated by ICES are given in Table 5.3.2. The data are split by more gear-types in Table 5.3.2 than were given by STECF. In the case of UK vessels, the figures for the gear types sum to the aggregated STECF figures for 2000-2004. Figures for Belgium have been revised slightly. Major revisions were supplied by Ireland. Specifically, effort data by mesh band for Ireland were not available for 2000-2002, and the figures given by STECF for these years may not be accurate or complete.

The majority of nominal effort is in the gear grouping for otter trawls with mesh sizes between 70 and 99 mm . Most of the effort in this mesh band is attributable to Nephrops trawlers, but it also includes vessels targeting plaice, whiting or other species where the catch-composition rules permit $70-$ to $99-\mathrm{mm}$ trawls. These are included in the "whitefish otter trawl" category, although the distinction between Nephrops trawls and whitefish trawls using $70-$ to $99-\mathrm{mm}$ mesh is blurred because many vessels use gears optimised to catch Nephrops with a whitefish bycatch. The more restricted days-at-sea allowances for $4 \mathrm{~A}(100 \mathrm{~mm}+$ ) otter trawls has resulted in some vessels returning to $70-$ to $99-\mathrm{mm}$ trawls to obtain more days per month. A number of UK(NI) vessels switch between semi-pelagic trawls and twin-rig Nephrops trawls according to fishing opportunities, including access to the cod spawning closure where there is a derogation for Nephrops vessels. The effort of the two series tends to vary in opposite directions.

The fishing effort for UK 4A gear types has declined in the last few years in VIIa. Specifically, fishing effort of midwater whitefish trawlers has declined by $50 \%$ between 2003 and 2005, and effort of Irish otter trawlers ( $100 \mathrm{~mm}+$ ) has declined by over $80 \%$ in the same period (Figure. 5.3.1). Single-rig Nephrops effort has declined by $33 \%$ since 2001. The combined effort of towed gears and static gears (gillnets and longlines) has declined by 33\% since 2001 (Figure 5.3.2).

Taking Irish and Belgian fleets into account, an almost threefold decline international effort of $100 \mathrm{~mm}+$ demersal trawls is evident between 2003 and 2005, whilst otter trawls in the $70-$ to $99-\mathrm{mm}$ mesh band have slightly increased their effort over this period (Figure 5.3.3). Beam trawl effort declined slightly between 2000 and 2002, and gillnet effort has halved over these three years.

Although the trends in kW -days are indicative of recent trends in fleet activities in recent years, the relationship with fishing mortality will be affected by changes in the amount of fishing per day at sea, technological improvements, and changes in species targeting and fishing practices resulting from management restrictions and changing fish availability. An analysis of catchability ( F generated per unit of effort) will require more highly resolved data, (both spatially and temporally), accurate catch and effort data for suitably disaggregated fleet/gear combinations, and sufficiently accurate assessment estimates of $F$. Recent trends in $F$ are very poorly determined for most of the stocks assessed by WGNSDS. However, very large apparent changes in mortality (e.g. the large decline in estimates of F in Vla haddock, mirroring a similar large decline in F estimates for North Sea haddock stock in recent years), should be reflected in recent trends in kW -days in fleets targeting the species.

## Fisheries interactions in the Irish Sea

Demersal fisheries in the area are mixed fisheries, with many stocks exploited together in various combinations in different fisheries. In these cases management advice must consider both the state of individual stocks and their simultaneous exploitation in demersal fisheries. Stocks in the poorest condition, particularly the critical stocks, necessarily become the overriding concern for the management of mixed fisheries where these stocks are exploited either as a targeted species or as a bycatch.

Four main fishery units can be described in the Irish Sea: these are Nephrops otter trawlers, roundfish otter trawlers, semi-pelagic trawlers, and beam trawlers. As trends in stocks of various species are generally not in synchrony, advice provided on the basis of the status of individual species may result in advised fishing mortalities for a group of coharvested species that cannot be realized simultaneously within the context of mixed fisheries. Stocks in need of special conservation efforts, such as those affected by recovery plans, present particularly difficult challenges. For instance, the reduction of fishing mortality (and effort) required for cod makes it very unlikely that TACs, which would be sustainable for healthier stocks in the mixed fisheries could be taken. The needs of the stock(s) under recovery plans could be met most directly by simply setting the TACs for all species in mixed fisheries to correspond to the fishing mortality intended for the species under recovery plans, which would result in large foregone yields in many healthier stocks. The foregone yield could be reduced somewhat if effort could be adjusted on a fleet-by-fleet basis to comply with the total fishing mortality in the proposed recovery plan, while allowing as much harvesting of other species as possible. However, such an approach requires reliable information on the catch-at-age for all species in all fisheries, and is still likely to leave substantial potential harvestable biomass of several species unavailable to any fishery.

Possibly the strongest mixed fishery interaction in the Irish Sea is between the Nephrops fishery and the whiting stock. Discard estimates for fleets targeting Nephrops are incomplete and considered imprecise, but demonstrate that the selectivity of Nephrops trawls for whiting remains relatively poor despite the obligatory use of square mesh panels for vessels targeting Nephrops with a $70-\mathrm{mm}$ codend mesh since 1994. ICES points out that in addition to effort restrictions, further technical measures (e.g. increased codend and square mesh panel mesh sizes, separator panels, and fixed grids) should be investigated and this may substantially reduce bycatch and discarding of whiting in this Nephrops fishery.

The cod fishery was traditionally carried out by otter trawlers targeting spawning cod in spring and juvenile cod in autumn and winter. Activities of these vessels have decreased, whilst a fishery for cod and haddock using large pelagic trawls increased substantially during the 1990s. Cod are also taken as a bycatch in the Nephrops-directed fishery Although discard estimates for cod in the Irish Sea are not available discard rates are not thought to be substantial. However, misreporting and underreporting of cod is thought to occur in some VIIa fisheries. Estimates of misreporting for some nations are included in the assessment, but the scientific advice for zero catch of the cod stock requires that the practice be terminated.

The extent to which the stocks are taken in the same fisheries cannot be quantified on basis of the available data. The existing information suggests that the stocks are caught together to a high (H), medium (M), low (L) extent, or not at all (0), as indicated in the table below. The information in the table relates to catches and the linkage is thus indicated as high also in cases where the catches of most of one stock taken in a fishery with another stock is discarded.

This corresponds to catches of less than 6500 t in 2007. | TAC $<6500 \mathrm{t}$ |
| Sole VIIa | Reduced <br> Reproductive Capacity | Overexploited | Overexploited | Not applicable | F is above $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$ | It is not possible to identify any non-zero catch compatible with the precautionary approach; or a Recovery Plan. | Zero TAC or Recovery Plan |
| Herring VIIa | Uncertain | Uncertain | Unknown | Not applicable | Unknown | The TAC of $4800 t$ which has been implemented in recent years is not expected to be detrimental to the stock. | TAC $<4800$ t |

## Identification of critical stocks

The table above identifies the stocks outside precautionary reference points. The critical stocks are spurdog. cod. whiting. and sole. For haddock a reduction in exploitation is required.

These stocks are the overriding concerns in the management advice for all fisheries where the interactions between stocks taken in the same fisheries should be considered:

- for cod the advice is for zero catch;
- for spurdog the advice is for zero catch;
- for sole the advice is a zero catch or recovery plan that ensures safe and rapid rebuilding of SSB to levels above $\mathbf{B}_{\mathrm{pa}}$;
- for whiting the advice is to reduce catch to the lowest possible levels;
- for haddock a reduction in exploitation is required.

## Advice on fisheries management

Fisheries in the Irish Sea should in 2006 be managed according to the following rules, which should be applied simultaneously:

## They should fish:

- without bycatch or discards of cod, sole, and spurdog, and with minimal catch of whiting;
- without jeopardizing the recommended reduction in fishing mortality of haddock;
- within the biological exploitation limits for all other stocks (see text table above).

Furthermore, unless ways can be found to harvest species caught in mixed fisheries within precautionary limits for all those species individually, then fishing should not be permitted.

### 5.3.3 Special requests

### 5.3.3.1 NEAFC Special Request on Rockall box

## Request

The NEAFC Commission requests ICES to provide information on the effect of the Rockall Box in protecting juvenile haddock and possible revisions of the boundary of the Box.

## Background

The Rockall box is one ICES rectangle and is partly in the NEAFC area and partly in the EU waters. The NEAFC closed area was effective from 2001 and the closed area in the EU waters came into effect in 2002 . The objective of the Rockall box was to protect juvenile haddock and to improve the selection pattern.

## Introduction

ICES dealt with the Rockall haddock box in 2001 (ICES 2002) and in 2002 (ICES 2003). In 2001 ICES reported on the spatial and seasonal patterns in fishing activity and in the haddock stock and carried out analysis of short and mediumterm effects of changes in mesh size on haddock catches and SSB but did not make any specific conclusions on seasonal or area closures (ICES 2001, section 3.7.3.c, p. 361-398). In 2002 ICES specifically considered the newly introduced area closure for Rockall haddock but concluded that " $i$ it] is too early to quantify the effect this closure has had on the haddock stock. It is difficult to predict actual fishing mortality as fleet behaviour will depend on fishing opportunities elsewhere." (ICES 2000, section 3.7.3.c, p. 358)

## ICES' response

Apart from the comparison in relative fishing mortality and the trends in UK fishing effort, there is no additional data to evaluate the effects of the Rockall box. With this limited information, ICES has not been able to quantify the effects of the closed area. ICES' previous advice remains unchanged but the need for access to future data has been highlighted. For details see the Annex below.

## Annex to the ICES' response

ICES has attempted to evaluate the effect of the Rockall Box and possible revision of the boundary of the Box. The Rockall box is a relatively small area where very detailed data will be needed to evaluate the effects of the closure of the box.

There is some survey information available from Scottish and Russian surveys but they do not cover the full period before and after the closure of the Rockall box.

Preliminary analysis suggests that the exploitation pattern has changed since the Rockall Box has been in force. Relative exploitation rate has decreased on age groups 1 and 2 (Figure 5.3.3.1.1) in the period after the closure compared to the period before the closure. However, discarding practices vary greatly between EU and international fleets and the poor estimation of discards means that estimates of fishing mortality at the younger age groups are very uncertain.

A detailed analysis of the UK effort data for all gears (except long-lines) shows that there has been a decline in UK effort across the Rockall Bank as a whole but an increase across the remaining VIb rectangles (figure 5.3.3.1.2). It is unknown what proportion of effort was applied directly to the haddock fishery.

Preliminary data from satellite tracking of all fishing vessels $>24 \mathrm{~m}$ in length over the northern Rockall Bank for 2002 are presented in figure 5.3.3.1.3 (Marrs and Hall-Spencer 2002; J. Hall-Spencer, unpublished, ICES 2005 vol 10, pp. 21-26). The VMS data show where the fishing vessels have been. The data do not show what types of gear were used by those vessels and does not discriminate between fishing and steaming.

In August 2006, NEAFC made the VMS data 2002-2005 available to ICES so that ICES could address the request on deepwater fisheries and deepwater corals. In section 1.5.4.1 ICES already concluded that the 2002 data could not be used because there was no gear information supplied and that the 2003-2005 could only be partially used because the majority of the records had no gear information. It was thus unclear what fishing gear was used in about half of the observations. From the records that were presented as OTB (Otter trawling), ICES was able to develop maps of effort allocation over the NEAFC area which were separated into fishing and steaming. This information could be used to plot effort distributions on the Rockall closed area. However, given the deficiencies noted above and the fact that the information was not available when the relevant expert group met, ICES has not generated these maps.

ICES did not have access to VMS data for the European waters.
Apart from the comparison in relative fishing mortality and the trends in UK fishing effort, there is no additional data to evaluate the effects of the Rockall box. With this limited information, ICES has not been able to evaluate the effects of the closed area.

In order to be able to evaluate the closed area in the future, ICES would need to have access to the following sets of information:

- VMS data for the NEAFC and EU area, preferably for as long time period as possible. These data should include the gear characteristics of the vessels.
- Logbook data for the same vessels and period, in order to be able to analyse the target species
- Survey data with catch rates by age group from before and during the closed period

### 5.4 Stock Summaries (Celtic Sea and West of Scotland)

### 5.4.1 Cod in Division VIIa (Irish Sea)

## State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in <br> relation to <br> precautionary limits | Fishing mortality in <br> relation to highest <br> yield | Fishing mortality <br> in relation to <br> agreed target | Comment <br> Reduced reproductive <br> capacity <br> Harvested <br> unsustainably <br> Overexploited |
| :--- | :--- | :--- | :--- | :--- |
| Not defined |  |  |  |  |

Based on the most recent estimates of SSB and fishing mortality, ICES classifies the stock as having reduced reproductive capacity and as being harvested unsustainably. Fishing mortality had been around $\mathbf{F}_{\mathrm{pa}}$ until the mid-1980s. It has increased close to or above $\mathbf{F}_{\text {lim }}$ since the late 1980s. SSB has been below $\mathbf{B}_{\text {lim }}$ since the mid-1990s. Recruitment has been below average for the past sixteen years, and the four most recent year classes are amongst the smallest on record. At the average rate of exploitation estimated for recent years, SSB will remain at sizes where the risk of continued poor recruitment is high.

## Management objectives

The European Commission has enacted a Council Regulation ((EC) No. 423/2004) which establishes measures for the recovery of cod stocks.

For stocks above $\boldsymbol{B}_{\text {lim, }}$, the harvest control rule (HCR) requires:

1. setting a TAC that achieves a $30 \%$ increase in the SSB from one year to the next,
2. limiting annual changes in TAC to $\pm 15 \%$ (except in the first year of application), and,
3. a rate of fishing mortality that does not exceed $\boldsymbol{F}_{p a}$.

For stocks below $\boldsymbol{B}_{\text {lim }}$ the Regulation specifies that:
4. conditions $1-3$ will apply when they are expected to result in an increase in $\operatorname{SSB}$ above $\boldsymbol{B}_{\text {lim }}$ in the year of application,
5. a TAC will be set lower than that calculated under conditions 1-3 when the application of conditions 1-3 is not expected to result in an increase in $S S B$ above $\boldsymbol{B}_{\text {lim }}$ in the year of application.

ICES has previously concluded that a precautionary recovery plan must include an adaptive element implying that fisheries for cod remain closed until an initial recovery of the cod SSB has been proven. Such an element of zero catch is not included in the existing plan. ICES therefore considers the recovery plan not to be consistent with the precautionary approach.

Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is 6000 t. | $\mathbf{B}_{\mathrm{p}}$ be set at 10000 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is 1.0. | $\mathbf{F}_{\mathrm{a}}$ be set at 0.72. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not defined. |

Yield and spawning biomass per Recruit (from 2004 Assessment)
$F$-reference points
Fish Mort Yield/R SSB/R

|  | Fish Mort <br> Ages 2-6 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| Average age 2-4 |  |  |  |
| $(2002-2004)$ | 1.03 | 1.677 | 1.869 |
| $\mathbf{F}_{\max }$ | 0.31 | 2.153 | 7.999 |
| $\mathbf{F}_{0.1}$ | 0.18 | 2.009 | 12.746 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

Technical basis:

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}:$ This is the previously agreed MBAL with signs of <br> reduced recruitment. It affords a high probability of <br> maintaining the SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. Below this value the <br> probability of below-average recruitment increases. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {med }}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {med }} * 0.72$. This F is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim }}$. Fishing mortalities above $\mathbf{F}_{\mathrm{pa}}$ <br> have been associated with the observed stock decline. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Fishing mortalities between $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\text {max }}$ can be considered as candidate target reference points, which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential. The present fishing mortality is well above the candidate reference point.

## Exploitation boundaries in relation to existing management plans

The most plausible forecast assumes a total removal in 2006 that is $55 \%$ greater than the agreed TAC. The forecast indicates that a zero catch in 2007 provides only $30 \%$ probability of rebuilding SSB to Blim in 2008. The simulations indicate that a $30 \%$ increase in SSB during 2007 could be achieved with a reduction in fishing mortality to below $75 \%$ of the 2005 level.

## Exploitation boundaries in relation to precautionary limits

Given the low stock size, recent poor recruitment, continued substantial catch well above the TAC, the uncertainty in the assessment, and the inability to reliably forecast catch, it is not possible to identify any non-zero catch which would be compatible to the precautionary approach.

## Conclusion on exploitation boundaries

Because the existing recovery plan does not include the elements or measures necessary for rebuilding the stock at the current SSB (well below $\mathrm{B}_{\mathrm{lim}}$ ), ICES continues to advise on exploitation boundaries in relation to precautionary limits and recommends that the fisheries for cod be closed until an initial recovery of the cod SSB has been proven. Any catches that are taken in 2007 will prolong the recovery to $B_{p a}$.

## Management considerations

Various emergency measures have been introduced for cod since 2000, effort control has been in place since 2003, and there have been various decommissioning schemes. These may translate into some reductions in fishing mortality of cod, but the current assessment does not provide sufficiently robust estimates of fishing to allow the possible reductions to be determined. It is clear that fishing mortality remains extremely high in this stock, and very few cod survive to age 4 in this stock. This is because:

- There are strong indications that the TAC management control is not effective in limiting the catch as landings are underreported;
- The effort reductions have not been sufficient although considerable effort reductions have been observed in some fleets (particularly vessels using $>100-\mathrm{mm}$ mesh);
- Cod is taken in mixed demersal fisheries (particularly haddock, sole, and Nephrops). Unless these fisheries can demonstrate zero bycatches of cod the effort in these fisheries also needs to be reduced substantially;
- Time and area closures have not been sufficient to lead to rebuilding of this stock.

Reducing fishing mortality to close to zero is required if the cod stock is to reach a level where it can regain historic productivity.

A resumption of sampling took place in 2005 at ports inaccessible for port sampling in 2003 and with only limited access in 2004. However, there will continue to be large uncertainties in the stock status and further deterioration in the ability to provide advice unless catches are accurately recorded.
Management plan evaluations

The management plan was evaluated and recovery to levels above $\mathbf{B}_{\mathrm{pa}}$ is expected to occur by about 2011. The result of the evaluation depends on a large number of assumptions, most importantly that fishing mortality can be reduced to zero in 2007 to allow the stock to increase above $\mathbf{B}_{\text {lim }}$.

However, there are reports of significant non-reported landings, and as a consequence the current TAC system is not able to regulate fishing mortality. Unless recovery measures are effective in restricting the fishery they cannot be considered precautionary. The management plan was tested with an implementation error of less than $25 \%$ (which means no implementation error for $\mathrm{F}=0$ ), but a larger and more realistic implementation error has not been investigated.

The plan depends primarily on annual estimates of SSB in relation to $\mathbf{B}_{\mathrm{pa}}$ but also on estimates of fishing mortality relative to $\mathbf{F}_{\mathrm{pa}}$. While SSB appears to be estimated well by this assessment, the level of fishing mortality is less well known and aspects of the management plan relating to maximum fishing mortality levels may be difficult to implement.

## Factors affecting the fisheries and the stock

## The effects of regulations

The fishery is managed by TACs that do not restrict landings.
Several regulations have been introduced in the Irish Sea in recent years. These regulations and their impact on the fisheries have been discussed in detail in the overview. To rebuild the SSB, a closure was introduced in 2000 for ten weeks from mid-February (EU Regulations $304 / 2000$ and 2549/2000). This closure was intended to maximize the reproductive output of the stock. The measures were revised in 2001, 2002, and 2003, involving a continued, but smaller spawning-ground closure, coupled with changes in net design to improve selectivity. Various derogations were introduced for gears not targeting cod.

These recovery measures have since been complemented by a system of fishing effort limitation. This is done by adjustment of the number of fishing days allowed for various vessel categories deploying gears with various mesh sizes. The introduction of effort regulation has effectively encouraged vessel operators to reduce mesh size and shift to other fisheries, particularly Nephrops trawling, in order to gain more days at sea.

It is not possible to evaluate whether the mesh size changes and effort limitations may have benefited cod without information on the level of adherence to catch composition regulations required when using smaller mesh sizes. Trends in nominal effort in this area are presented in section 17 of the 2006 WG report. STECF (2005) indicate an overall decrease in effort of $19 \%$ between 2000 and 2004.

The continued decline in the stock indicates that these measures alone have not proven sufficient to rebuild the stock to precautionary levels. Detailed analysis of the impact of the regulations will not be possible until data of sufficient quality become available.

## Scientific basis

## Data and methods

The assessment model is based on a catch-at-age analysis of reported landings, calibrated with several series of survey indices. In addition, the model estimates missing removals as a bias in landings, assuming that they have the same age composition as reported landings.

The assessment is indicative of stock trends, but cannot be used for precise forecasts.
Recent discard estimates available for some fleets indicate a variable, but very high discard rate of ages 0 and 1 . These estimates are not used in the assessment due to the short time-series available.

## Information from the fishing industry

The UK Fisheries Science Partnership (FSP) survey of the western Irish Sea cod spawning grounds in spring 20042006, carried out using a commercial pelagic trawler, indicated similar abundance and age structure of adult cod in both years, although catch rates were generally poor on the spawning grounds. The equivalent FSP survey of the eastern Irish Sea in spring 2005 and 2006 indicated low catch rates of 3-year-old and older cod.

The present stock estimates are highly uncertain. The quality of the commercial landings and catch-at-age data for this stock deteriorated in the 1990s following reductions in the TAC without associated control of fishing effort. Limited access to some ports in recent years has also resulted in reduced sampling coverage for estimating length and age compositions.

ICES previously attempted to overcome this problem by incorporating sample-based estimates of landings from three major ports in the WG landings figures from 1991 onwards. The sources of this information became more limited in 2003 and 2004. The large TAC reduction for cod from 2000 onwards, with only the spring cod closure as a means of restricting effort until days-at-sea restrictions came into force, may have caused more widespread problems with misreporting or over-quota discarding. Hence ICES considers the international landings figures from 2000 onwards to have potentially large inaccuracies that could lead to retrospective bias and other problems with an analytical assessment.

## Comparison with previous assessment and advice

Traditionally, ICES has included estimates of misreported landings within the unallocated landings figures reported for this stock. These unallocated landings have made adjustments to nominal landings figures, correcting either for misreporting or for differences between official statistics and data obtained by national scientists. As the misreporting estimates are for one country only, and there is evidence that the practice is more widespread, ICES is no longer able to provide catch estimates that are partially corrected for misreporting for the recent years 2003 and 2004. This is the reason for the change in assessment model, used since last year.

The overall trends in biomass and recruitment appear well-estimated and the perception of the stock from this year's assessment does not differ qualitatively from that obtained last year. The basis of the advice this year is the same as last year.

### 5.4.2 Cod in Divisions VIIe-k (Celtic Sea Cod)

State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in <br> relation to precautionary <br> limits | Fishing mortality in relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Reduced reproductive <br> capacity | Harvested unsustainably | Overexploited |  |

The current assessment indicates that the stock was well below $\mathbf{B}_{\text {lim }}$ since 2004 and is still declining. Fishing mortality has been very high since the mid-1980s, although it has declined slightly in recent years while remaining above $\mathbf{F}_{\mathrm{pa}}$. Recruitment since 2001 has been well below average.

## Management objectives

There are no specific management objectives or a management plan for this stock.

## Reference points

$\mathbf{B}_{\mathrm{lim}}$ and $\mathbf{B}_{\mathrm{pa}}$ were revised in 2004.

|  | ICES considers that: | ICES proposed that: |
| :---: | :---: | :---: |
| Precautionary Approach reference points | $\mathbf{B}_{\text {lim }}$ is 6300 t , the lowest observed spawning stock biomass. | $\mathbf{B}_{\text {pa }}$ be set at 8800 t . Biomass above this value affords a high probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the variability in the stock dynamics and the uncertainty in assessments. |
|  | $\mathbf{F}_{\text {lim }}$ is 0.90 , the fishing mortality estimated to lead to potential collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.68. This F is considered to have a high probability of avoiding $\mathbf{F}_{\text {lim }}$ and maintaining SSB above $\mathbf{B}_{\mathrm{pa}}$ in the medium term (assuming normal recruitment), taking into account the uncertainty assessments. |

Yield and spawning biomass per Recruit
F-reference points:

|  | Fish Mort <br> Ages 2-5 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| Average last 3 |  |  |  |
| years | 0.807 | 1.864 | 2.142 |
| $\mathbf{F}_{\text {max }}$ | 0.333 | 2.229 | 7.722 |
| $\mathbf{F}_{0.1}$ | 0.207 | 2.100 | 12.618 |
| $\mathbf{F}_{\text {med }}$ | 0.638 | 2.012 | 3.120 |

Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }} .(\mathrm{B} 76)$. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ based on historical response of the stock. | $\mathbf{F}_{\mathrm{pa}}=5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}$. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Fishing mortalities close to $\mathbf{F}_{\max }=0.33$ can be considered as candidate target reference points, which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential. The present fishing mortality ( 0.81 ) is above the candidate reference point.

## Exploitation boundaries in relation to precautionary limits

Given the low stock size, high fishing mortalities and recent poor recruitment, it is not possible to identify any non-zero catch which will be compatible with the Precautionary Approach. The forecast indicates that a zero catch in 2007 allows SSB to achieve $\mathbf{B}_{\text {lim }}$, but not $\mathbf{B}_{p \mathrm{a}}$ in 2008.

## Short-term implications

Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}($ age $3-5)=0.81 ; \mathrm{R}=\mathrm{GM} 2002-05=1.6$ million; $\operatorname{SSB}(2006)=4.48 \mathrm{kt}$ :
$\operatorname{SSB}(2007)=4.01 \mathrm{kt}$; landings $(2006)=3.54 \mathrm{kt}$.
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.68 .

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield)) is 0.33 .

| Rationale | $\begin{gathered} \hline \text { TAC(200 } \\ 7)^{1}{ }^{1} \\ \hline \end{gathered}$ | Basis | F(2007) | SSB(2008) | \%SSB change |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Zero catch | 0.00 | $\mathrm{F}=0$ | 0.00 | 7.67 | 92\% |
| Status quo | 3.23 | $\mathrm{F}_{\text {sa }}$ | 0.81 | 3.69 | -8\% |
| High long-term yield | 1.62 | F(long-term yield) | 0.33 | 5.65 | 41\% |
| Status quo | 1.59 | $\mathbf{F}_{\text {sa }} * 0.4$ | 0.32 | 5.69 | 42\% |
|  | 1.91 | $\mathbf{F}_{\mathrm{sa}} * 0.5$ | 0.41 | 5.29 | 32\% |
|  | 2.22 | $\mathbf{F s a}_{\text {sa }} * 0.6$ | 0.49 | 4.91 | 23\% |
|  | 2.50 | $\mathbf{F}_{\text {sa }} * 0.7$ | 0.57 | 4.57 | 14\% |
|  | 2.76 | $\mathbf{F}_{\text {sa }} * 0.8$ | 0.65 | 4.26 | 6\% |
|  | 3.00 | $\mathbf{F}_{\text {sa }} * 0.9$ | 0.73 | 3.96 | -1\% |

|  | 3.44 | $\mathbf{F}_{\text {sa }}$ * 1.1 | 0.89 | 3.45 | -14\% |
| Precautionary limits | 0.37 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 0.1$ | 0.07 | 7.20 | 80\% |
|  | 0.89 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{na}}\right) * 0.25$ | 0.17 | 6.55 | 64\% |
|  | 1.66 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 0.5$ | 0.34 | 5.60 | 40\% |
|  | 2.52 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{oa}}\right) * 0.842$ | 0.57 | 4.54 | 13\% |
|  | 2.65 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{na}}\right) * 0.9$ | 0.61 | 4.39 | 10\% |
|  | 2.86 | $\mathrm{F}_{\mathrm{pa}}=\mathrm{F}_{\mathrm{sq}} * 0.84$ | 0.68 | 4.13 | 3\% |
|  | 3.06 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ra}}\right) * 1.1$ | 0.75 | 3.89 | -3\% |
|  | 3.34 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{va}}\right) * 1.25$ | 0.85 | 3.56 | -11\% |
|  | 3.75 | $\mathrm{TAC}\left(\mathrm{F}_{\mathrm{ba}}\right) * 1.5$ | 1.02 | 3.08 | -23\% |
|  | 4.10 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.75$ | 1.19 | 2.67 | -33\% |
|  | 4.41 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{va}}\right) * 2$ | 1.36 | 2.32 | -42\% |
|  | 4.67 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{na}}\right) * 2.25$ | 1.53 | 2.03 | -49\% |
| Mixed Fisheries |  |  |  |  |  |

All weights in thousand tonnes.
${ }^{1}$ It is assumed that the TAC will be implemented and that the landings in 2007 therefore correspond to the TAC.
Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

Since the majority of the landings consist of 1- and 2-year-old fish, the catch forecast relies heavily on the incoming recruitment. Since 2001 the year classes of Celtic Sea cod have been very weak. At present there is no knowledge on the strength of the incoming year-class strength. Consequently ICES used the average of the recent weak year classes as input for the short-term forecast.

Long-term projections have been carried out to demonstrate the impact of a sustained period of poor recruitment. These projections indicate that the long-term yield is halved if the current low recruitment persists. The projections also show that the stock cannot sustain the current exploitation rate.

To assure that the current box closure in the Celtic Sea provides a reduction in fishing mortality, this regulation should be accompanied by measures to ensure that fishing effort and catches do not increase in other areas or in other periods.

Effort in the main fleet targeting cod has declined since 1999. There is some indication of recent reductions on fishing mortality, but not to sustainable levels. Further reductions of effective effort are needed to improve yields and reduce risks to the stock in the longer term.
There are also some indications of substantial underreporting of landings in some fleets.
The assessment area covers Divisions VIIe-k and the ICES advice applies to these areas only; however, the TAC is set for Divisions VIIb-k, Subareas VIII, IX, X, and CECAF 34.1.1. Within this larger area there is no control over where
the catches are taken. Current management measures for Divisions VIIe-k include cod in Divisions VIIbc and cod in Division VIId. Cod in Division VIId is assessed together with cod in the North Sea.

Cod in VIIe-k is caught in a range of fisheries including gadoid trawlers. Nephrops trawlers, otter trawlers. beam trawlers, and gillnetters. Other commercial species that are caught by these fisheries are haddock. whiting. Nephrops. plaice, sole, anglerfish, hake, megrim, and elasmobranchs.

## Ecosystem considerations

Cod in the Celtic Sea are at the southern limit of the range of the species in the Northeast Atlantic. It is known that at the southern limits of their range, recruitment tends to decrease in warmer waters (above $8.5^{\circ} \mathrm{C}$ ) and that cod are not found in waters warmer than $12^{\circ} \mathrm{C}$. It is at present unclear to what extent the recent poor recruitments are linked to increased water temperatures. The growth rates in the Celtic Sea are among the fastest observed for cod. Fishing mortality remains an important factor in the productivity of this stock.

Most cod spawning in the Celtic Sea occurs off northern Cornwall in mid- to late March. There is also some spawning off southeast Ireland and a little in the Western Channel.

Tagging studies have given no evidence of cod movement out of Division VIIe and into VIIfg, where there appears to be a simple inshore-offshore migration between deepwater wrecks and reefs in the summer and inshore spawning areas in the winter. Recent tagging work in the Irish Sea suggests that only a small component of cod landings from the Celtic Sea are fish which spawn in the Irish Sea. Furthermore, no cod tagged in the Celtic Sea were recaptured in the Irish Sea.

## Factors affecting the fisheries and the stock

Cod in Divisions VIIe- k are taken in mixed trawl fisheries. Landings are made mainly by French gadoid trawlers, which prior to 1980 were mainly fishing for hake in the Celtic Sea. Landings of cod by French Nephrops trawlers have fluctuated between $10 \%$ and $20 \%$ of the total French cod landings from this stock in recent years. Since 1988, Irish landings have accounted for on average $14 \%$ of the total, but in 2005 accounted for $28 \%$. UK and Belgium have contributed on average to $9 \%$ and $4 \%$, respectively. Landings occur throughout the year, but mainly in the winter months during November to April, with a peak in February-March.

## The effects of regulations

Council Regulation (EC) No. 27/2005. Annex III, part A 12 (b) and Council Regulation (EC) No. 51/2006. Annex III, part A 4.2 prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 during January-March 2005 and during February and March 2006. The direct impact of this closure on the status of cod is difficult to quantify. However, the effort of the main fleet fishing on cod, i.e. the French gadoid fleet, has decreased considerably since $1999(-37 \%)$. This fleet changed to other, mainly benthic metiers. Although the fleet still operates in the Celtic Sea and on other fishing grounds outside the Celtic Sea (mainly VIIe) this has resulted in a decreased fishing mortality on cod in most recent years. The impact on the fishing pressure on other species (including sensitive species such as elasmobranchs) is unclear.

VMS data for French, Belgian, and UK ( $\mathrm{E}+\mathrm{W}$ ) vessels has showed that overall the box closure has been respected by the fleets of these nations both in 2005 and in 2006. There has been some evidence of reduced LPUE for UK otter trawlers. but little evidence of a reduction of LPUE for UK beam trawlers and netters which together account for a substantial component of the UK cod catch.

Technical measures applied to this stock are: a minimum mesh size for beam and otter trawlers in Subarea VII and a minimum landing size (MLS) of 35 cm . For Belgian trawlers that land in Belgium the MLS is 40 cm . Minimum landing sizes do not prevent cod from being caught (and thrown back dead), but might prevent targeting juvenile cod. Recent sampling programmes in countries exploiting this stock indicate that discards account for between $40 \%$ and $60 \%$ by number of all fish caught. These discards are mainly under the MLS. Qualitative analysis of observations at sea in 2005 have shown that discarding practice is more important in Divisions VIIe and VII f.g than in VII h-k, where small fish are less abundant.

Management regulations, particularly effort control regimes in other areas (Division VIIa, Subareas VI \& IV), became increasingly restrictive since 2004 and should not be allowed to result in a displacement of effort into the Celtic Sea.

In 2003 and 2004 there has been a substantial behavioural change in the main fisheries with regard to discarding. Discarding occurred in the last quarter of 2002 as the French fishery was closed when the cod quota was exhausted. In 2003 and 2004 there was substantial high-grading of marketable cod in order to prevent a new early closure of the fishery. This high-grading practise was not continued in 2005.

## Scientific basis

## Data and methods

Analytical assessment has been carried out. The landings-at-age data which formerly were the basis of the assessment have been improved since 2003 to include estimates of misallocated landings and French high grading.

## Information from the fishing industry

Meetings with representatives of the fishing industry were held prior to this year's assessment in France and the UK. There was no major disagreement about the state of the stock or its assessment.

The industry has been cooperative in a number of scientific endeavours with regards to this stock. The fisheries science partnership conducted cooperatively between CEFAS and the UK industry has provided information on the relative age compositions, suggesting that the main year-class signals are captured by the assessment.

## Uncertainties in assessment and forecast

Although the change in high-grading practices has been partially corrected for in the current assessment data there are still some uncertainties about this. There is also substantial discarding of small fish by all fleets, which is not included in the assessment and forecast.

Although there are some small corrections for area misreporting in the current assessment there are still concerns about the accuracy of the reported landings statistics for some fleets exploiting this stock.

Most of the abundance estimates come from commercial fleets operating on different components of the stock (VIIe, VIIfgh, VII j). Only two fishery-independent surveys are available. Because of the low cod abundance, the calculated abundance indices for the UK and French surveys are based on very few cod. Nevertheless, both surveys give some indication of year-class strength, especially when a large year class comes through.

The forecast is highly dependent on the recruitment assumption used. In this case a reduced recruitment has been used in line with recent observations from the stock. This is considered the most likely scenario. If recruitment were to be at average levels then SSB could be rebuilt above $\mathbf{B}_{\mathrm{pa}}$ in one year if the fishing mortality is reduced by $50 \%$, corresponding to landings less than 2300 tonnes. Given the recent sustained weak recruitment this is an unlikely scenario.

Comparison with previous assessment and advice
In the past the assessment was only used to indicate trends, but this year the advice is based on a full analytical assessment and forecast. The assessment has been improved compared to last year's because estimates of misreporting and high grading have been included and the input data have been corrected. The changes in stock development in the new assessment are reasonably robust despite the assessment uncertainty discussed above. The advice this year is more restrictive than last year due to the now available estimates of low recruitment, lowest observed SSB , and high fishing mortality.

### 5.4.3 Haddock in Division VIIa (Irish Sea)

## State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in <br> relation to <br> precautionary limits | Fishing mortality in <br> relation to highest <br> yield | Fishing mortality <br> in relation to <br> agreed target | Comment <br> Undefined Overexploited |
| :--- | :--- | :--- | :--- | :--- |
| Not defined |  |  |  |  |

The assessment is indicative of trends in SSB and recruitment and is based on survey results. Mortality remains at a high level. SSB has been sustained by recent high recruitment. The SSB has increased since 2001 as a result of the stronger 1999 and 2001 year classes. Recruitment levels in the last 3 years appear to be above average and should result in increased SSB in the next years.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}$ is not defined. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.5. |
| Target reference points |  | Not defined. |

Yield and spawning biomass per Recruit (from 2004 Assessment)
F-reference points

|  | Fish Mort <br> Ages 2-6 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\max }$ | 0.35 | 0.511 | 1.232 |
| $\mathbf{F}_{0.1}$ | 0.19 | 0.469 | 2.009 |

Candidate reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

## Technical basis:

There is currently no biological basis for defining appropriate reference points, in view of the rapid expansion of the stock size over a short period and the inability to conduct a full analytical assessment. ICES proposed that $\mathbf{F}_{\mathrm{pa}}$ be set at 0.5 by association with other haddock stocks.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Although uncertain, recent estimates of total mortality are in excess of 1.0 which implies that F is above the $\mathbf{F}_{\mathrm{pa}}$ of 0.5 . Fishing at $\mathbf{F}_{\mathrm{pa}}$ requires a substantial reduction in effort and catches, but ICES cannot quantify the reduction.

## Management considerations

The EU Cod Recovery Plan implemented in the Irish Sea from 2004 will impinge upon the management measures for species caught in related fisheries, including haddock. The current directed fishery for haddock in the Irish Sea is likely to generate bycatches of cod in the same area.

Limited sampling schemes since the 1990s have shown high rates of discarding of haddock less than 3 years old, and variable discarding of 3 -year-olds in fisheries using $70-$ to $80-\mathrm{mm}$ mesh nets. Data for whitefish vessels since the introduction of $100+\mathrm{mm}$ mesh and other recent technical measures are too few to form a basis for evaluation of discards in that fleet. However, any measures to reduce discards will result in increased future yield.

There are strong indications that management control is not effective in limiting the catch, and that it has resulted in very uncertain data on the quantities of fish caught by the fleet.

## Factors affecting the fisheries and the stock

## The effects of regulations

Due to the bycatch of cod in the haddock fishery, the regulations affecting Division VIIa haddock remain linked to those implemented under the Irish Sea cod recovery plan. The regulations implemented for cod are detailed in the overview for the Irish Sea. The extent to which fishing mortality may have been reduced in 2005 by management measures such as effort limitation and decommissioning of vessels in 2003 could not be reliably evaluated.

## Scientific basis

## Data and methods

Landings data for this stock are uncertain because of species misreporting, which has been estimated from quayside observations in one country only. Restrictive quotas for some countries caused extensive misreporting during the 1990s prior to the introduction of a separate TAC allocation for the Irish Sea. Estimates of misreporting prior to 2003 have been included in the estimates of landings.

The present stock estimates are relatively uncertain due to a lack of access to port sampling in 2003 at several major ports and only limited access in 2004. A resumption of sampling took place in 2005 at these ports. There will continue to be uncertainties in the estimated stock status unless full sampling is maintained at all major ports.

The assessment of recent stock trends is based on survey data only, using the March survey data up to 2006.

## Uncertainties in assessment and forecast

Some discarding information is available, which indicates that discarding is substantial for younger age classes. Comparisons were made of relative trends in recruitment and SSB from this year's and last year's survey-based assessment. The methods indicate similar trends in SSB and recruitment estimates.

The survey-based assessment provides only relative trends in stock parameters.
Comparison with previous assessment and advice
The perception of the stock from this year's assessment does not differ qualitatively from that obtained last year, and the basis of the advice is the same as last year.

### 5.4.4 Haddock in Divisions VIIb-k (Irish Sea)

## State of the stock

The state of the stock is unknown in relation to precautionary reference points. Fishing mortality appears to be relatively stable on a high level. Recruitment is highly variable and there were strong 1995, 2001, and 2002 year classes. This has lead to an increase in spawning-stock biomass.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

No precautionary reference points have been established.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Because of the strong 2001 and 2002 year class SSB has increased, but ICES is unable to provide a reliable estimate of the current stock size. Future catches and SSB will be highly dependent on the strength of incoming year classes and their discard mortality. In this context the stock should be managed by ensuring that the effort is not allowed to increase, rather than by TAC management.

## Management considerations

Most of the haddock caught are discarded. Discards include both fish under the minimum landing size (MLS) and larger fish. Haddock are caught in mixed demersal fisheries in the Celtic Sea and management should take this into account. An increase in mesh size or other technical measures to reduce discarding would be of huge benefit to this stock and have a substantial impact on medium-term yield. Haddock is a relatively low value species and targeting practices in the fishery are highly dependent on availability and market demand.

## Factors affecting the fisheries and the stock

Haddock in Divisions VIIb-k are mainly taken in mixed trawl fisheries. These are mainly otter trawlers, including gadoid trawlers and Nephrops trawlers and to a lesser extent beam trawlers.

## The effects of regulations

The TAC for haddock is set for all of Subareas VII, VIII, IX, and X. Quotas in recent years have been based on average landings and as the strong 2002 year class recruited to the fishery underreporting, species misspecification in landings, and high grading are know to have increased. Technical measures applied to this stock include a minimum landing size ( $\geq 30$ cm ) and the minimum mesh sizes applicable to the mixed demersal fisheries. Given the observed discarding rates in some towed gears there is a mismatch between minimum mesh sizes in these mixed demersal fisheries and the MLS.

Within the large management area there is no control over where the catches are taken. Current management measures for Divisions VIIb-k include haddock in Division VIIa. Whatever management measures are implemented, they must be consistent with the assessment area.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in Divisions VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average national annual effort (calculated over the period 19982002).

Council Regulation (EC) No. 27/2005, Annex III, part A 12 (b) prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 during January-March 2005. The impact of this on the haddock stock is not yet known.

## Ecosystem considerations

Recruitment of haddock in this area has been increasing in recent years but as yet it has not been possible to link this to specific environmental drivers. The distribution of haddock varies with age; young haddock from Division VIIb move to deeper waters and possibly into Division VIaS as they grow, while migration patterns of haddock in Division VIIgj
are more variable. The spatial distribution of haddock and their length-at-age data suggest that Divisions VIIb and VIaS might be the same stock, and other biological parameters also do not show obvious spatial patterns.

## Scientific basis

## Data and methods

An exploratory assessment was carried out, but the available data were not considered sufficient to provide a reliable assessment. Work is in progress to include discards in the assessment. French survey information was available but requires further analysis, and the time-series of the Irish survey is still too short.

## Information from the fishing industry

Meetings with representatives of the fishing industry were held prior to the assessment group in Ireland and the UK. No specific issues were raised about the state of this stock or its assessment.

## Uncertainties in assessment and forecast

Only exploratory analyses of the data could be carried out for this stock.
The stock structure is uncertain. Stocks of haddock in Divisions VIa, VIIa, and VIIb-k have shown different growth rates and patterns of recruitment variation during the 1990s. This may reflect latitudinal variations in environmental conditions. Catches of haddock along the Atlantic seaboard of the British Isles are recorded more or less continuously between the west coast of Scotland and the Celtic Sea. Significant genetic differences have been found between samples collected at much smaller spatial scales than the entire west coast of the British Isles. The implications of this when evaluating the present stock management units remain unclear. Further investigation is needed to better define the biological stock units.

There are some concerns about the accuracy of the landings statistics in some fleets.
Comparison with previous assessment and advice
There have been some improvements in the data available to assess this stock, but as last year no reliable analytical assessment could be achieved.

The advice is consistent with last year's advice.

### 5.4.5 Whiting in Division VIIa (Irish Sea)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown, low SSB | Unknown | Unknown | Unknown |  |

Long-term information on the historical yield and catch composition all indicate that the present stock size is low. The assessment carried out in 2003 indicated a decrease in SSB by a factor 10 from the 1980s to the 1990s. Survey information indicates that the stock has remained at the low level.

## Management objectives

No explicit management objectives have been set for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\text {lim }}$ is 5000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 7000 t. |
|  | $\mathbf{F}_{\text {lim }}$ is 0.95. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.65. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not determined. |

## Technical basis:

$\mathbf{B}_{\text {lim }}$ : $\mathbf{B}_{\text {loss }}$. The lowest observed spawning stock biomass as estimated in previous assessment. There is no clear evidence of reduced recruitment at the lowest observed SSBs
$\mathbf{F}_{\text {lim }}$ : This is the fishing mortality estimated to lead to a potential stock collapse.
$\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }} * 1.4:$ This is considered to be the minimum SSB required to ensure a high probability of maintaining SSB above its lowest observed value, taking into account the uncertainty of assessments.
$\mathbf{F}_{\mathrm{pa}}$ : This F is considered to have a high probability of avoiding $\mathbf{F}_{\text {lim }}$ and is consistent with a high probability of remaining above $\mathbf{B}_{\mathrm{pa}}$ in the long run. It implies an equilibrium SSB of 10.6 kt , and a relatively low probability of SSB $<\mathbf{B}_{\mathrm{pa}}$ ( $=7 \mathrm{kt}$ ), and is within the range of historic Fs.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
On the basis of the stock status, ICES advises that catches of whiting in 2007 should be the lowest possible.

## Management considerations

Landings of whiting by all vessels as well as discards of whiting estimated for Nephrops fisheries have declined substantially since the 1990s, and whiting is now a relatively minor bycatch in the demersal fisheries. Due to the small catches and low value of the catch, a high proportion of whiting are discarded. Age profiles observed on these surveys are very steep, indicating either a continuing high mortality or some emigration effect. Fishing mortality cannot be managed by a TAC on whiting, and measures restricting landings alone will not be sufficient to allow recovery of the stock.

There are reports of significant non-reported landings and therefore the current implementation of the TAC system is not able to restrict fishing. Unless management measures are able to restrict the fishery within TAC limits they are not precautionary.

## Factors affecting the fisheries and the stock

## The effects of regulations

Various technical measures have been introduced in the past to mitigate bycatch of whiting in the Nephrops fishery, which operates on the whiting nursery grounds. It has proved difficult to evaluate the success of measures such as the mandatory use of square mesh panels in Nephrops trawls since 1994, as there have been very few direct observations of
size and age compositions of catches prior to discarding (much of the discards data are from fisher self-sampling schemes that do not record total catch). Experimentally these measures reduce substantially whiting discarding; however, monitoring programmes are needed to evaluate if these experimental benefits have been realised in the commercial fishery.

Due to the bycatch of cod in fisheries taking whiting, the regulations affecting Division VIIa whiting remain linked to those implemented under the Irish Sea cod recovery plan. The closure of the western Irish Sea to whitefish fishing from mid-February to the end of April, designed to protect cod, has been continued, though it is not clear to what extent these measures will protect whiting.

Similarly the extension of days-at-sea limitations into the Irish Sea in 2005 is not expected to result in a significant reduction in fishing mortality for whiting since the Nephrops fleet is still permitted to fish up to 21 days $/ \mathrm{month}$.

The minimum landing size (MLS) for whiting is 27 cm ; however, discard data shows that individuals in excess of that size are also discarded.

## Other factors

The stock structure of whiting in the Irish Sea is uncertain with differences in the population structure observed between the eastern and western components. However, individual whiting move between the western Irish Sea and other areas within the Irish Sea and this precludes treating different areas within the Irish Sea as containing functionally separate stocks.

It is not known if the severe decline of the population of adult whiting in the western Irish Sea represents a localised depletion of a more broadly distributed stock, or the depletion of a local sub-population. Survey catch-rates of whiting above the MLS of 27 cm have declined continuously in the western region since 1992, reflecting the rapid decline in commercial landings. Survey catch-rates in the eastern region above the MLS are much higher and the spring survey showed little or no trend over time up to 2003, but declined substantially in 2004-2006. The commercial fishery has become more concentrated in the western region in recent years as the English and Welsh fleets, which operate mainly in the east, have declined over time.

## Scientific basis

## Data and methods

Historically, the sampling of catch for length and age has been relatively poor for this stock. The unreliability of the catch numbers was also seen in 2004, due to a combination of low sampling levels and small landings (reported landings in 2004 were only 96.3 t , down from $\sim 11000 \mathrm{t}$ in the late 1980s). The issues with misreporting meant that a catch-based assessment would have been unreliable.

## Information from the fishing industry

Some information was available from the fishing industry. Ireland has established a trial self-sampling scheme (ECONEPH) in cooperation with the Nephrops fleet to augment discard sampling in the Nephrops fishery. The UK(NI) industry participated in an $a d h o c$ workshop on Irish Sea whiting in the spring of 2005 where their information on the fishery was used to inform on the perception of the stock structure.

## Uncertainties in assessment and forecast

The major deficiency is poor quality of the input data. An examination of the survey data indicates poor internal and external consistency at tracking year classes. In addition, the most recent estimates from different surveys give conflicting signals. Discard estimation and raising procedures are problematic and discard estimates may be imprecise. Comparison with previous assessment and advice

The last analytical assessment was undertaken in 2003 based on a catch-at-age analysis, using catch estimates and the western Irish Sea survey. There was no analytical assessment carried out for this stock in 2004 and again, no analytical assessment was possible this year. The advice this year is the same as last year.

### 5.4.6 Whiting in Divisions VIIe-k

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality in relation to <br> precautionary limits | Fishing mortality in relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Overexploited |  |

The available information is inadequate to evaluate the spawning stock in relation to precautionary approach reference points. The assessment is indicative of trends only. The stock is estimated to have declined in recent years as the strong 1999 year class passed through the fishery. There are some indications that recent recruitment has been low and stable. Fishing mortality was very high during the 1980s and decreased in the early 1990s; the estimates of recent fishing mortality are variable.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\text {lim }}$ is 15000 t, the lowest observed spawning <br> stock biomass. | $\mathbf{B}_{\mathrm{p}}$ be set at 21 000 t. Biomass <br> above this affords a high <br> probability of maintaining SSB <br> above $\mathbf{B}_{\text {lim }}$, taking into account <br> the uncertainty of the <br> assessment. |
|  | $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ not proposed. |

## Yield and spawning biomass per Recruit

F-reference points:

|  | Fish Mort <br> Ages 2-5 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |

| years | 0.533 | 0.185 | 0.538 |
| $\mathbf{F}_{\text {max }}$ | 1.360 | 0.188 | 0.338 |
| $\mathbf{F}_{0.1}$ | 0.160 | 0.157 | 1.001 |
| $\mathbf{F}_{\text {med }}$ | 0.734 | 0.187 | 0.456 |

## Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.4$. |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}$ not proposed. | $\mathbf{F}_{\mathrm{pa}}$ not proposed. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to management plan
There is no management plan for this stock.
Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Although uncertain it is likely that the current fishing mortality is above a fishing mortality that would lead to high long-term yields ( $\mathbf{F}_{01}$ ). Fishing at a lower mortality would lead to higher SSB and therefore lower the risk of bringing the stock outside precautionary limits.

## Exploitation boundaries in relation to precautionary limits

Although the current estimates of F and SSB are uncertain, F in recent years has been reduced and SSB is probably above $\mathbf{B}_{\mathrm{pa}}$. In this context the stock should be managed by ensuring that the effort is not allowed to increase.

## Management considerations

The assessment area covers Divisions VIIe- k and the ICES advice applies to these areas; however, this does not correspond to the TAC area. The TAC is set for Divisions VIlb-k. Within this larger area there is no control over where the catches are taken. Current management measures for Division VIIe-k include whiting in Division VIIbc and whiting in Division VIId. Whiting in Division VIId is assessed together with whiting in the North Sea (Subarea IV). Landings for VIlbc are given in Table 5.4.6.2.

A considerable part of the whiting catch is discarded. Any measure to reduce discarding and to improve the fishing pattern should be encouraged. Such measures might include increased cod-end mesh size, square mesh panels, separator trawls, and increased top sheet mesh in towed gears.

Whiting are taken in a mixed demersal trawl fishery with cod, haddock, plaice, and Nephrops, and management advice needs to be considered in that context.

Whiting are a relatively low-value species and targeting practices in the fishery are highly dependent on availability and market demand. In the past the TAC has been substantially higher than the realized catches and has not been restricting the fishery. There is some evidence that other species have been misreported as whiting in 2004 in some fleets.

## Ecosystem considerations

The main spawning areas of whiting in the Western Channel and Celtic Sea are off Start Point (VIIe), off Trevose Head (VIIf), and southeast of Ireland (VIIg).

Returns of adult whiting tagged in the Western Channel indicated more movement into the Celtic Sea than between the Western and Eastern Channel. Whiting released in the Bristol Channel moved south and west towards the two spawning grounds off Trevose Head and southeast of Ireland. There was no evidence of emigration out of the Celtic Sea area. Tagging experiments have indicated movement of whiting from the Irish Sea VIIa into the Celtic Sea.

## Factors affecting the fisheries and the stock

Celtic Sea whiting are taken in mixed species (cod, whiting, hake, Nephrops) fisheries. French trawlers account for about $60 \%$ of the total landings, Ireland takes about $30 \%$, and the UK (England and Wales) 7\%, while Belgian vessels take less than $1 \%$. The French Nephrops trawlers have for several years adopted a larger mesh, following bycatch restrictions and market demand for larger Nephrops.

The main Irish fleets in Divisions VIIf,g,h are inshore and offshore otter trawlers and seiners based in Dunmore East and Kilmore Quay. However, in recent years there has been an increase in the number of Irish beamers ( +6 vessels) offshore in Division VIIg, targeting anglerfish and megrim with whiting as bycatch. Irish landings of whiting from Division VIIj-k are taken in both a mixed fisheries ( $\mathrm{cod} /$ whiting/anglerfish/megrim and Nephrops) and in a directed fishery in the first quarter.

The main UK fisheries in Divisions VIIe-h are inshore between Newlyn and Salcombe and off the north Cornish coast, the bulk of the landings ( $>60 \%$ ) being made in the winter months between November and March. UK landings in the 1950s were $4-5$ times higher than at present. The main gears used in the Western Channel are otter trawls targeting a wide range of species, and beam trawls targeting sole, anglerfish, and plaice.

## The effects of regulations

The stock is managed by a TAC and technical measures. Technical measures applied to this stock are a minimum landing size ( $\geq 27 \mathrm{~cm}$ ) and the area-specific minimum mesh sizes applicable to the mixed demersal fisheries. There is substantial discarding above the minimum landing size due to economic or other factors.

Management regulations, particularly effort control regimes in other areas (VIIa, VI, \& IV), became increasingly restrictive in 2004 and 2005 and have resulted in a displacement of effort into the Celtic Sea.

Council Regulation (EC) No. 27/2005, Annex III, part A 12 (b) prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 during January-March 2005. This restriction did not apply to beam trawlers during March. The effect of the closure of the three rectangles during the fist quarter of 2005 cannot yet be quantified.

Council Regulation (EC) No. 51/2006, Annex III, part A 4.2 prohibited fishing in ICES rectangles 30E4, 31E4 and 32E3 during February-March 2006 for all vessels and gears (except within 6 nautical miles of the baseline).

Fishing effort for the French fleets operating in the three closed rectangles was mainly displaced to other fishing grounds outside the Celtic Sea and to areas within the Celtic Sea. The impact on whiting has not been evaluated. Some vessels have also switched to another métier, targeting anglerfish and megrim in the rest of the Celtic Sea.

The 2006 WGFTFB report identifies a number of issues in relation to the fleets fishing in the Celtic sea. Due to elevated fuel costs a number of fleets have changed their fishing practices, with some skippers steaming to and from fishing grounds at reduced speed as well as experimenting with gear designs to improve fuel efficiency. There has also been an Irish decommissioning scheme, whereby around 40 fishing vessels ( $\sim 6000 \mathrm{GT}, 18000 \mathrm{~kW}$ ) have been permanently withdrawn from the Irish fishing fleet and removed from the Register of Sea Fishing Vessels in 2005 and 2006.

## Scientific basis

## Data and methods

Analytical assessment based on catch-at-age (landings only) data, commercial CPUE, and survey data.

## Information from the fishing industry

Meetings with representatives of the fishing industry were held prior to WGSSDS2006 in Ireland and the UK. No specific concerns were raised about the state of this stock or its assessment. It has been noted by the FSP surveys that a relatively broad range of age classes of whiting has been present in both the eastern and western region of the Celtic Sea with fish up to six years of age being relatively abundant.

## Uncertainties in assessment and forecast

Discarding is considered to be significant and the assessment does not include discard information. Not including discards biases the recruit estimates. There are conflicting signals and considerable noise in the survey data as well as some concerns about the accuracy of the landings statistics in some fleets. These factors mean that no reliable assessment and forecast could be provided. The assessment can only be considered indicative of gross trends in stock productivity and exploitation.

## Comparison with previous assessment and advice

The current assessment was only indicative for stock trends and was rejected for current estimates because of conflicting signals in different tuning fleets. No reliable forecast could be presented this year.

The advice last year was based on $\mathbf{F}_{\mathrm{sq}}$ from a short-term forecast. The advice this year is based on no increase in effort, which is consistent with last year's advice.

### 5.4.7 Plaice in Division VIIa (Irish Sea)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably | Harvested <br> sustainably | Harvested <br> sustainably |  |

Based on the most recent estimate of SSB and fishing mortality, ICES classifies the stock as having full reproductive capacity and being harvested sustainably. The SSB in 2005 was above $\mathbf{B}_{\mathrm{pa}}$ and average fishing mortality in the last three years has been below $\mathbf{F}_{\mathrm{pa}}$. Fishing mortality on this stock has been maintained above $\mathbf{F}_{\mathrm{pa}}$ for much of the time-series, but declined through the 1990s. SSB has been above $\mathbf{B}_{\mathrm{pa}}$ throughout the period of assessment.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}$ be set at 3100 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.45. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not defined. |

Yield and spawning biomass per Recruit

## Technical basis

$\mathbf{B}_{\mathrm{lim}}$ : There is no biological basis for defining $\mathrm{B}_{\mathrm{lim}}$ as the $\quad \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }}$.
stock-recruitment data are uninformative.
$\mathbf{F}_{\text {lim }}$ : There is no biological basis for defining $\mathbf{F}_{\text {lim }}$ as $\quad \mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }}$ in a previous assessment, and in long-term
$\mathbf{F}_{\text {loss }}$ is poorly defined. considerations. This is considered to provide a high probability that SSB remains above $\mathbf{B}_{\text {loss }}$ in the long term

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Fishing mortality is estimated to be below $\mathbf{F}_{\max }(0.36)$ and to be close to $\mathbf{F}_{0.1}(0.13)$. There will be little gain to the longterm yield by increasing fishing mortalities above current levels. Fishing at $\mathbf{F}_{0.1}$ is expected to lead to landings of 2100 t in 2007.

## Exploitation boundaries in relation to precautionary limits

In order to harvest the stock within precautionary limits, fishing mortality should be kept below $\mathbf{F}_{\mathrm{pa}}(0.45)$. This corresponds to catches of less than 6500 t in 2007 and will lead to a reduction in SSB to 11900 t in 2008.

## Short-term implications

Outlook for 2007
Basis: $F(2006)=F_{\text {sq }}=$ mean $F(03-05)=0.126: \mathrm{R} 06-08=\mathrm{GM} 64-03=12630$ million: $\operatorname{SSB}(2006)=13940 \mathrm{t}$ : $\operatorname{SSB}(2007)=15100 \mathrm{t}$ : landings $(2006)=1990 \mathrm{t}$.

|  | 7430 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 1.2$ | 0.54 | 11022 |
|  | 8354 | $\operatorname{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 1.4$ | 0.63 | 10162 |
|  | 9196 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{Da}}\right) * 1.6$ | 0.72 | 9381 |
|  | 9956 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 1.8$ | 0.81 | 8681 |

Weights in t .
${ }^{1}$ It is assumed that landings in 2006 correspond to $\mathbf{F}_{\text {sq }}$.
Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

Average fishing mortality in the last three years has been below $\mathbf{F}_{\mathrm{pa}}$ and no long-term gains are obtained by increasing the current fishing mortality towards $\mathbf{F}_{\mathrm{pa}}$.

Plaice are taken in a mixed demersal fishery. The regulations affecting plaice and other demersal stocks in Division VIIa remain linked to those implemented under the Irish Sea cod recovery plan.

## Scientific basis

## Data and methods

The assessment is based on a catch-at-age analysis, using landings data and data from one age-disaggregated and two biomass surveys. Landings are at the lowest level in the time-series, but information on misreporting is not available. Discard levels are substantial in the fishery, but are not currently incorporated into the assessment.

## Uncertainties in assessment and forecast

There are conflicting signals in the survey and commercial tuning fleet indices. The commercial tuning fleet indices are not used in the assessment. The assessment may thus be biased, but it is not known to what extent. Surveys indicate a substantial increase in abundance of plaice in recent years that is not apparent from commercial catch data. The assessment is strongly influenced by survey trends and the resulting estimates of rapidly increasing stock biomass should be treated with some caution until the discrepancy between these two data sources can be better explained.

Discards are not currently incorporated into the assessment. The results of preliminary analyses indicate that the current perception of exploitation levels is not dramatically revised when estimates of discard levels are included. However, discard levels are substantial in this fishery and methods for estimating previous discard levels are still being investigated. Systematic collection of discard information is required for improved assessment and advice.

## Comparison with previous assessment and advice

This year's assessment is in line with last year's assessment and indicates an optimistic view of the status of the stock, suggesting $\mathbf{F}_{\mathrm{sq}}$ is at $\mathbf{F}_{0.1}$ and SSB is at the highest observed levels in the time-series. These trends are consistent with last year's assessment although F values for the final year have been revised upwards marginally. The basis of the advice is the same as last year.

### 5.4.8 Celtic Sea plaice (Divisions VIIf and g)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Reduced <br> reproductive <br> capacity | Unknown | Overexploited |  |

SSB peaked in 1988-1990, following a series of good year classes, then declined rapidly and has since 2000 remained around $\mathbf{B}_{\mathrm{lim}}$. No F reference points have been defined. Fishing mortality has fluctuated around an average level ( 0.60 ) for the entire time-series. Recruitment was relatively high in most years in the 1980s, but has been lower since then. Some very weak classes have occurred since the late 1990s.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 1100 t, the lowest observed spawning stock <br> biomass $\mathbf{B}_{\text {loss }}$. | $\mathbf{B}_{\text {pa }}$ be set at 1800 t . Biomass above this affords a high <br> probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into <br> account the uncertainty of assessments. |
| $\mathbf{F}_{\text {lim }}$ not defined. | $\mathbf{F}_{\mathrm{pa}}$ not defined. |

## Yield and spawning biomass per Recruit

$F$-reference points:

|  |  | Fish Mort <br> Ages 3-6 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: | :---: |
| Average last 3 |  |  |  |  |
| years |  | 0.501 | 0.241 | 0.516 |
| $\mathbf{F}_{\text {max }}$ |  | 0.315 | 0.247 | 0.853 |
| $\mathbf{F}_{0.1}$ |  | 0.153 | 0.226 | 1.665 |
| $\mathbf{F}_{\text {med }}$ |  | 0.533 | 0.240 | 0.483 |

Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss. }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} * 1.64$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Not defined. | $\mathbf{F}_{\mathrm{pa}}$ not defined. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Target reference points have not been agreed for this stock. A candidate for a target reference point which is consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}(0.15)$ and $\mathbf{F}_{\text {max }}(0.31)$. There is no gain in yield to have a target above this level. Current $F$ is estimated to be 0.35 .

## Exploitation boundaries in relation to precautionary considerations

A $50 \%$ reduction in $F$ is needed to increase SSB to around $\mathbf{B}_{\mathrm{pa}}$ in 2008. This corresponds to landings of less than 380 t in 2007.

If such a large reduction in $F$ is not achievable in the short term, ICES recommends that a recovery plan be developed. This plan should include a sustained reduction of fishing mortality to rebuild the stock above $\mathbf{B}_{\mathrm{pa}}$ in the medium term. Catch and effort reductions are required to promote such a reduction in fishing mortality.

## Short-term implications

Outlook for 2007
Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}(03-05)=0.5 ; \mathrm{R} 06-07=\mathrm{GM} 89-04=3.1$ million; $\operatorname{SSB}(2006)=1.28 \mathrm{kt}: \operatorname{SSB}(2007)=$ 1.41 kt ; landings $(2006)=0.63 \mathrm{kt}$.

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield) ) is 0.31 .

| Rationale | TAC(2007) (1) | Basis | F(2007) | SSB(2008) | \%SSB <br> change | \%TAC change |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Zero catch | 0.00 | $\mathrm{F}=0$ | 0.00 | 2.16 | 53\% | -100\% |
| Status quo | 0.69 | $\mathrm{F}_{\text {sq }}$ | 0.50 | 1.51 | 7\% | 44\% |
| $\begin{gathered} \text { High long-term } \\ \text { yield } \\ \hline \end{gathered}$ | 0.46 | $\begin{gathered} \text { F(long-term } \\ \text { yield) } \end{gathered}$ | 0.31 | 1.72 | 22\% | -4\% |
| Status quo | 0.08 | $\mathbf{F}_{\text {sq }} * 0.1$ | 0.05 | 2.08 | 47\% | -83\% |
|  | 0.24 | $\mathbf{F}_{\text {sq }} * 0.31$ | 0.16 | 1.93 | 36\% | -49\% |
|  | 0.38 | $\mathbf{F}_{\text {sq }} * 0.5$ | 0.25 | 1.80 | 27\% | -20\% |
|  | 0.54 | $\mathbf{F}_{\text {sq }} * 0.75$ | 0.38 | 1.64 | 16\% | 14\% |
|  | 0.63 | $\mathbf{F}_{\text {sq }} * 0.9$ | 0.45 | 1.56 | 10\% | 33\% |
|  | 0.69 | $\mathrm{F}_{\mathrm{sq}} * 1$ | 0.50 | 1.51 | 7\% | 44\% |
|  | 0.74 | $\mathbf{F}_{\text {sq }} * 1.1$ | 0.55 | 1.45 | 3\% | 56\% |
|  | 0.82 | $\mathbf{F}_{\text {sq }} * 1.25$ | 0.63 | 1.38 | -2\% | 72\% |

All weights in thousand tonnes.
(1) It is assumed that the TAC will be implemented and that the landings in 2007 therefore correspond to the TAC.

Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

The TACs have been gradually reduced over the last 20 years in line with ICES advice. Nevertheless, fishing mortality has remained stable and high. This could be caused by reduced recruitment or increased discarding of small fish. Improving the selection pattern in the fishery would be beneficial in both cases.

ICES has explored simulations with long-term target Fs below 0.65 for this stock. These indicate that when a HCR is developed for this stock, target fishing mortalities within the range of $\mathbf{F}_{0.1}(0.15)$ and $\mathbf{F}_{\max }(0.31)$ are predicted to result in the highest long-term yields, whilst posing little risk of being below $\mathbf{B}_{\text {lim }}$ in the long term. When such a HCR is developed interactions between the Celtic Sea plaice and sole stock should be considered.

The high level of discarding indicated in this mixed fishery would suggest a mis-match between the mesh size employed and the size of the fish landed. Increases in the mesh size of the gear should result in fewer discards and, ultimately, in increased yield from the fishery. The use of larger-mesh gear should be encouraged in this fishery in instances where mixed fishery issues allow for it.

## Ecosystem considerations

There is some evidence from tagging that plaice from the southern and western coasts of Wales move southwards to join the adult population off the north Cornish coast during spawning.

## Factors affecting the fisheries and the stock

In the 1970s, the plaice fishery in Divisions VIIf,g was mainly carried out by Belgian beam trawlers and Belgian and UK otter trawlers. Effort in the UK and Belgian beam-trawl fleets increased in the late 1980s, but has since declined. Recently, many otter trawlers have been replaced by beam trawlers targeting sole. Landings gradually increased until 1989, then declined rapidly in 1991. The main fishery occurs in the spawning area off the north Cornish coast, at depths greater than 40 m , about 20 to 25 miles offshore. Although plaice are taken throughout the year, the larger landings occur during February-March after the peak of spawning, and again in September.

## Regulations and their effects

Plaice in the Bristol Channel and Celtic Sea (ICES Divisions VIIf and VIIg) are managed by TAC and technical measures. Misreporting is known to occur as quotas become more restrictive.

Technical measures in force for this stock are minimum mesh sizes, minimum landing size, and restricted areas for certain classes of vessels. Technical regulations regarding allowable mesh sizes for specific target species, and associated minimum landing sizes, came into force on 1 January 2000. The minimum landing size for plaice in Divisions VIlf,g is 27 cm .

Council Regulation (EC) No. 27/2005, Annex III, part A 12 (b) prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 during January-March 2005 with the intention of reducing fishing mortality on cod. This restriction did not apply to beam trawlers during March 2005. Beam trawlers account for the vast majority of plaice landed by vessels in Divisions VIIf,g. The proportion of plaice taken from the closed area remained constant in 2005, but declined markedly in February and March 2006. Proportions taken in January and April, immediately before and after the closure, are higher than in previous years. CPUE of plaice in February and March is not dramatically reduced, reflecting the decrease in effort during this period and the fact that plaice can be caught in areas outside of the closed area. This probably had little impact on the fishing mortality on plaice.

## Scientific basis

## Data and methods

The analytical age-based assessment (XSA) is based on landings, one survey index, and two commercial CPUE series.

## Uncertainties in assessment and forecast

This assessment is conditional on the accuracy of the commercial CPUE and total catch data. Misreporting and underreporting of landings is suspected as quotas become more restrictive. Discards are substantial. Due to the short time-series discards are not included in the assessment.

There is a strong retrospective bias of overestimation of SSB and underestimation of fishing mortality. Recent forecasts for this stock have been overly optimistic, probably due to this bias problem. The GM assumptions of average recruitment in the most recent years contribute little to forecasted landings.

Comparison with previous assessment and advice
There has been little change in the perception of the state of the stock.
The advice for an F reduction to rebuild above $\mathbf{B}_{\mathrm{pa}}$ or to implement a recovery/management plan is consistent with last year's advice.

### 5.4.9 Plaice in Division VHe (Western Channel)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Increased risk | Increased risk | Overexploited |  |

The stock estimates are uncertain, but the assessment is indicative of trends. There are, however, strong indications that fishing mortality has been above $\mathbf{F}_{\mathrm{pa}}$ and SSB has been below $\mathbf{B}_{\mathrm{pa}}$ since the early 1990s. Recent recruitments seem to be weak.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 1300 t, the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 2 500 t. Biomass above this affords a high <br> probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into <br> account the uncertainty in assessments. |
| $\mathbf{F}_{\text {lim }}$ not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.45. |

Yield and spawning biomass per Recruit
F-reference points:

|  |  | Fish Mort <br> Ages 3-7 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: | :---: |
| Average | last | 3 |  |  |
| years |  | 0.70 | 0.28 | 0.38 |
| $\mathbf{F}_{\text {max }}$ |  | 0.23 | 0.30 | 1.14 |
| $\mathbf{F}_{0.1}$ |  | 0.10 | 0.27 | 2.26 |
| $\mathbf{F}_{\text {med }}$ |  | 0.52 | 0.29 | 0.51 |

Technical basis

| $\mathbf{B}_{\mathrm{lim}}=\mathbf{B}_{\text {loss }}$. | $\mathbf{B}_{\mathrm{pa}}=\mathrm{MBAL}$. |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}=$ Not defined. | $\mathbf{F}_{\mathrm{pa}}=0.45$ low probability that $\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Fishing mortalities between $\mathbf{F}_{0.1}=0.10$ and $\mathbf{F}_{\max }=0.23$ can be considered as candidate target reference points, which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential. The recent fishing mortality is clearly well above these potential fishing mortality targets.

## Exploitation boundaries in relation to precautionary limits

Given the low stock size, recent poor recruitment, high fishing mortality, the uncertainty in the assessment, and the inability to reliably forecast catch, ICES recommends a substantial reduction in catch until the estimate of SSB is above $\mathbf{B}_{\mathrm{pa}}$ or other strong evidence of rebuilding is observed.

## Short-term implications

Due to considerable uncertainty in current estimates of the stock and in recent recruitment estimates it is not possible to provide a short-term forecast.

## Management considerations

There are uncertainties in the stock definition of Channel plaice (Divisions VIId and VIe). If the present stock definition is valid the following needs to be considered. As the TAC for plaice in the Channel is set for Divisions VIId, e combined, the results from this assessment need to be considered along with those for the much larger Division VIId stock. Given that the Division VIId component dominates the TAC, a catch control does not guarantee that fishing mortality in Division VIIe is constrained. Management measures should be put in place to control fishing mortality even locally in the VIIe stock area.

Plaice are taken in a mixed demersal species otter trawl fishery, and as a bycatch in the sole beam trawl fishery. The major commercial species that interact with VHe plaice are VHe sole and VHe-k cod.

## Factors affecting the fisheries and the stock

The fisheries taking plaice in the Western Channel mainly involve vessels from the bordering countries: the total landings (2004) are split among UK vessels ( $80 \%$ ), France ( $16 \%$ ), and Belgium ( $4 \%$ ). Landings of plaice in the Western Channel were low and stable between 1950 and the mid-1970s, and increased rapidly during 1976 to 1988 as beam trawls began to replace otter trawls, although plaice are taken mainly as a bycatch in beam-trawling directed at sole and anglerfish. Estimated landings have been fairly stable since 1994. The main fishery is south and west of Start Point. Although plaice are taken throughout the year, the larger landings are made during February, March, October, and November.

## The effects of regulations

The catch of VIIe plaice is managed by a TAC applied to VIId (Eastern Channel) and VIIe combined. Consequently the TAC management does not control fishing mortality on the VIIe stock. There are also technical measures including mesh size and MLS ( 27 cm ) for this species. There is some discarding, in particular of fish below the MLS in the first two quarters.

Council Regulation EC No. 27/2005, Anmex IVc on 'Fishing effort for vessels in the context of the recovery of Western Channel sole stocks' limits the number of days at sea to 20 per month for beam trawlers with mesh size equal to or greater than 80 mm and for static demersal nets, including gillnets, trammel nets, and tangle nets. There is no obvious reduction in nominal effort in 2005 compared to 2004 for the main fleets.

## Scientific basis

## Data and methods

The analytical age-based assessment is based on landings, one survey, and three commercial CPUE series. Discard data are becoming available and indicate that discarding is variable, but lower compared to other plaice stocks.

## Information from the fishing industry

Misreporting of landings is thought to have occurred in the past, but industry comments indicate that in recent years this has not been a problem.

Fisheries science partnership surveys of the western Channel conducted cooperatively between CEFAS and the UK industry gave similar catch rates of plaice in 2003 and 2004 for all sizes of fish combined, although some small-scale spatial changes in distribution were observed. Lower catch rates were observed in the 2005 survey.

## Uncertainties in assessment and forecast

There is some uncertainty about the stock structure in VIIe plaice. Historical tagging information show that plaice may migrate from the VIIe into the VIId and the North Sea after spawning. A considerable proportion of the juvenile recruits in VIIe are thought to originate from VIId and the southern North Sea. There is also evidence of a resident stock in VIIe. Catch-at-age data have not been adjusted to take into account the impact of any migrations and it is unclear if these migrations persist.

This assessment is tuned using data from the commercial fishery as well as one survey. The accuracy of the assessment will depend on whether these commercial catch rates reflect changes in population abundance. The retrospective analysis indicates consistent downward revisions in the estimation of F in recent years. The cause of this retrospective pattern is unknown, but it leads to uncertainty and potential bias in the $F$, rendering a deterministic short-term forecast inaccurate.

The recruit estimates in the most recent 3-4 years are very uncertain, as shown by historical and retrospective assessments. Because of this and the uncertainty in current stock abundance no short-term forecast can be provided.

Comparison with previous assessment and advice
Recent recruitment estimates have been revised substantially. Results from this assessment indicate that historical SSB estimates are consistent, but the 2004 estimate of SSB has been revised downwards by $27 \%$. Fishing mortality has been revised downwards by the most recent assessment.

The advice is consistent with that provided last year.

### 5.4.10

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation to <br> highest yield | Comment |
| :---: | :---: | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The state of the stock is unknown. No assessment was performed, due to the short series of data and lack of reliable tuning indices.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

## No precautionary reference points have been established.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Catches in 2005 should be no more than the recent average (2003-2005) of around $196 t$, in order to avoid an expansion of the fishery until there is more information to facilitate an adequate assessment.

## Management considerations

Landings are substantially below the TAC and have been declining. The 2005 landings are the lowest observed in the time-series. The advice based on recent average landings may not be precautionary enough if this stock is in decline. Plaice are taken as part of a mixed demersal fishery by otter trawlers. Management options proposed for plaice should also take into consideration other demersal fish species taken in the fishery.

## Factors affecting the fisheries and the stock

## The effects of regulations

Plaice is managed through a precautionary TAC and technical conservation measures. The agreed TAC for plaice in 2004 and 2005 is 466 t , following a TAC of 582 t in 2003. The agreed TAC for 2006 is 396 t . Boat quota restrictions were imposed on Irish vessels for hake, cod, and anglerfish, and these are likely to have impacted the plaice landings.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in areas of Divisions VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 19982002).

## Changes in fishing technology and fishing patterns

Ireland, UK, and France are the major participants in this fishery. Plaice are predominantly caught within mixed species otter trawl fisheries in Division VIIj. Irish vessels operate from the ports of Castletownbere, Dingle, Union Hall, Baltimore, and Schull. Increasingly these Irish vessels target mainly hake, anglerfish, and megrim and not the more traditional inshore species (plaice, sole, whiting, and cod). Otter trawlers accounted for the majority, with beam trawlers and seiners taking smaller catches of plaice.

## Scientific basis

## Data and methods

Data update and screening methods only. No analytical assessment was performed.

### 5.4.11 Plaice West of Ireland (Division VIIb,c)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation to <br> highest yield | Comment |
| :---: | :---: | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The state of the stock is unknown, but landings show a declining trend in recent years. No assessment was performed, due to the short series of data and lack of reliable tuning indices.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

No precautionary reference points have been established.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Catches in 2005 should be no more than the recent average (2003-2005) of around 55 t , in order to avoid an expansion of the fishery until there is more information to facilitate an adequate assessment.

## Management considerations

Landings have been declining and 2005 landings are the lowest observed in the time-series. The advice based on recent average landings may not be precautionary enough if this stock is in decline. Plaice are taken as part of a mixed demersal fishery by otter trawlers. Management options proposed for plaice should also take into consideration other demersal fish species and Nephrops taken in the VIIb,c fishery.

## Factors affecting the fisheries and the stock

Ireland is the major participant in this fishery with around $90 \%$ of the international landings taken in 1993-2003. Plaice are normally caught in mixed species otter trawl fisheries in Division VIIb. These vessels mainly target other demersal fish species and Nephrops.

## The effects of regulations

Plaice is managed by a precautionary TAC and technical measures. The agreed TACs have been 160 t in 2003-2005 and 144 in 2006.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a biologically sensitive area' in areas of VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002).

## Scientific basis

## Data and methods

Data update and screening methods only. No analytical assessment was performed.

${ }^{1}$ See VIIg-k.
Table 5.4.11.1

### 5.4.12 Sole in Division VIIa (Irish Sea)

## State of the stock

| Spawning <br> biomass in <br> relation <br> precautionary <br> limits | to | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target |
| :--- | :--- | :--- | :--- | :--- |

Recent recruitment levels have been lower than earlier in the time-series. SSB has declined to low levels and is estimated to be close to the lowest observed level in 2005. Any rapid rise in SSB in the short term is unlikely given recent recruitment levels. Fishing mortality has been close to $\mathbf{F}_{\text {lim }}$ throughout the time-series. F status quo is estimated to be close to $\mathbf{F}_{\mathrm{pa}}$.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\text {lim }}$ is 2800 $t$, the lowest observed spawning <br> stock in an earlier assessment. | $\mathbf{B}_{\text {pa }}$ be set at 3800 $t$, which is <br> considered to be the minimum <br> SSB required to ensure a high <br> probability of maintaining SSB <br> above its lowest observed value, <br> taking into account the <br> uncertainty of assessments. |
|  | $\mathbf{F}_{\text {lim }}$ is 0.4. Although poorly defined, there is <br> evidence that fishing mortality in excess of <br> 0.4 has led to a general stock decline and is <br> only sustainable during periods of above- <br> average recruitment. | $\mathbf{F}_{\text {pa }}$ be set at 0.30. This F is <br> considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim. }}$. |
| Target reference points |  | Not defined. |

Yield and spawning biomass per Recruit from 2006 assessment
F-reference point:

|  |  | Fish Mort <br> Ages 4-7 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: | :---: |
| Average | last | 3 |  |  |
| years |  | 0.29 | 0.18 | 0.64 |
| Fmax |  | 0.43 | 0.19 | 0.39 |
| F0.1 |  | 0.21 | 0.17 | 0.95 |
| Fmed |  | 0.24 | 0.18 | 0.82 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{01}$.

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss. }}$. | $\mathbf{B}_{\mathrm{pa}} \sim \mathbf{B}_{\text {lim }} * 1.4$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ poorly defined; based on historical <br> considerations. | $\mathbf{F}_{\mathrm{pa}}=$ see above. |
|  |  |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield. low risk of depletion of production potential and considering ecosystem effects

Fishing mortality is estimated to be well above $\mathbf{F}_{0.1}(0.21)$. There will be little gain to the long-term yield by increasing fishing mortalities above $\mathbf{F}_{0.1}$.

## Exploitation boundaries in relation to precautionary limits

Given the low SSB and low recruitment since 2000 , it is not possible to identify any non-zero catch which will be compatible with the precautionary approach. However, a zero catch in 2007 should allow SSB to achieve $\mathbf{B}_{\mathrm{pa}}$ in 2008. If the implied $100 \%$ reduction is not possible then ICES recommends that a recovery plan be implemented which ensures a safe and rapid rebuilding of SSB to levels above $\mathbf{B}_{\mathrm{pa}}$.

## Short-term implications

Outlook for 2007
Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}(03-05)=0.290 ; \mathrm{R} 95-03=\mathrm{GM}=4.641$ million; $\mathrm{SSB}(2006)=3015 \mathrm{t}$; $\operatorname{SSB}(2007)=3.035 \mathrm{t}$; landings $(2006)=736 \mathrm{t}$.

| Rationale | TAC(2007) ( ${ }^{1}$ ) | Basis | F(2007) | SSB(2008) |

Weights in tonnes.
${ }^{1}$ It is assumed that landings in 2006 correspond to $\mathbf{F}_{\text {sq }}$.
Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

It is not possible for the stock to reach $\mathbf{B}_{\mathrm{pa}}$ in one year without a complete closure of the fishery. A management plan for effort reduction that can be phased in over a number of years and implemented in conjunction with technical conservation measures should be considered.

There are indications that area misreporting of sole occurs, and there are also indications that some fleets are not limiting their uptake to their quota. Such practices have the potential of masking the true stock trends for sole. Sole is caught in a mixed fishery with other flatfish as well as gadoids. Information on discards is very limited, but information from 2003 is indicative of discard ranges up to $5 \%$ in weight.

## Factors affecting the fisheries and the stock

## The effects of regulations

Technical measures in force are minimum mesh sizes and minimum landing size ( 24 cm ). Limited observations indicate that the rate of discarding of sole is relatively low.

The closures of cod spawning-grounds that have been in force since 2000 are unlikely to have had a big impact on the sole fishery. In 2000 the closure covered the Western and Eastern Irish Sea. Since then, closure has been mainly in the western part, whereas the main sole fishery has taken place in the eastern part of the Irish Sea.

## Scientific basis

## Uncertainties in assessment and forecast

Substantial revisions have been made to the catch-at-age data for 2003 and 2004. The assessment is tuned using two UK beam trawl survey series. The retrospective analysis indicates poor convergence of the assessment for both SSB and $\operatorname{Fbar}(4-7)$ but shows little evidence of substantial retrospective bias. The assessment indicates a change in exploitation pattern in the most recent years with a shift in the fishery towards younger fish.

Comparison with previous assessment and advice
The 2006 assessment is based on a revised catch-at-age and weight-at-age data set. Last year no analytical assessment was conducted because of concerns on the quality of these data and the advice was based on the average landings from 2002-04. This year an analytical assessment was the basis for the advice.

### 5.4.13 Sole in Division VIIf and g (Celtic Sea)

## State of the stock

| Spawning biomass in relation to <br> precautionary limits | Fishing mortality in <br> relation to <br> precautionary limits | Fishing mortality in <br> relation to highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Full reproductive capacity | Increased risk | Overexploited |  |

Based on the most recent estimates of SSB, ICES classifies the stock as having full reproductive capacity. The exceptional year class of 1998 has increased SSB to above the long-term average, but as the contribution of this year class on SSB wanes, SSB declines again. Based on the most recent estimates of fishing mortality, ICES classifies the stock as being at risk of being harvested unsustainably. Fishing mortality has been fluctuating around a high level exceeding $\mathbf{F}_{\mathrm{pa}}$ since the mid-1980s.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}$ be set at 2 200 t. There is no evidence of reduced <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ can <br> therefore be set equal to the lowest observed SSB. |
| $\mathbf{F}_{\text {lim }}$ is 0.52, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.37. This F is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim }}$ and maintaining SSB above <br> $\mathbf{B}_{\mathrm{pa}}$ in 10 years, taking into account the uncertainty of <br> assessments. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Target reference points have not been agreed for this stock. A candidate for a target reference point which is consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}(0.13)$ and $\mathbf{F}_{\text {max }}(0.27)$. There is no gain in yield having a target above this level. The risk to the stock at this level of fishing mortalities appears to be very low in the medium term.

## Exploitation boundaries in relation to precautionary limits

A $24 \%$ reduction in F is needed to reduce F below $\mathbf{F}_{\mathrm{pa}}$. This corresponds to landings of less than 840 tonnes in 2007.

Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}(03-05)=0.49 ; \mathrm{R} 71-03=\mathrm{GM}=4.9$ million; $\operatorname{SSB}(2006)=2.69 \mathrm{kt} ; \operatorname{SSB}(2007)=2.53$ kt ; landings $(2006)=1.1 \mathrm{kt}$.
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.37 .

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield)) is 0.27 .

| Rationale | TAC(2007) ${ }^{1}$ | Basis | F(2007) | SSB(2008) | \%SSB change | \%TAC <br> change |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | 0.84 | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {sq }} * 0.76$ | 0.37 | 2.67 | 5\% | -12\% |
|  | 0.91 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.1$ | 0.41 | 2.59 | 2\% | -5\% |
|  | 1.00 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.25$ | 0.46 | 2.48 | -2\% | 6\% |

All weights in thousand tonnes.
${ }^{1}$ It is assumed that the TAC will be implemented and that the landings in 2007 therefore correspond to the TAC.
Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

ICES has explored simulations with long term-target Fs below 0.59 for this stock. These show a range of fishing mortalities from 0.27 to 0.49 that are predicted to result in the highest long-term yields (around 950 t), whilst posing little risk of being below $\mathbf{B}_{\text {loss }}$ in the long term (Figure 4.3.18). Above F of 0.49 the risk of going below $\mathbf{B}_{\text {loss }}$ increases rapidly and as the estimation of this break point is sensitive to model assumptions a target fishing mortality should be chosen at the lower level within the range of $\mathbf{F}_{\text {max }}$. This would not lead to lower long-term yield. A Harvest Control Rule (HCR) should therefore be developed to reduce F to this type of target level in the medium term whilst minimizing the risk of SSB decreasing below $\mathbf{B}_{\text {loss }}$.

As sole is mainly taken in a beam-trawl fishery as part of a mixed demersal fishery, predominantly with plaice; a similar analysis for VIIf,g plaice was carried out, indicating a target $F$ range for plaice between 0.15 and 0.31 . A dialogue between managers and stakeholders will be required to define an appropriate management plan for this fishery.

In recent years, fishing mortality has been high. SSB declined until 1998; since then it has increased somewhat due to the contribution of some good year classes, particularly the 1998 year class. As the contribution of this year class
wanes, SSB declines again. At current levels of fishing mortality, there is a high probability that SSB will be below $\mathbf{B}_{\mathrm{pa}}$ in some years. SSB levels just above $\mathbf{B}_{\mathrm{pa}}$ are still low compared to the values observed in the past.

Effort restrictions are in place for many areas but not in the Celtic Sea, which makes the latter vulnerable to unrestricted increases in effort. This is undesirable where stocks are already overexploited. There was a substantial effort increase by the major fleet (Belgian fleet) in 2004 and 2005. However, preliminary results from 2006 indicate that the effort displacement into the Celtic Sea by Belgian beam trawl vessels is decreasing due to the non-effortlimitation in Subarea VIId in 2006.

## Factors affecting the fisheries and the stock

The fisheries for sole in the Celtic Sea and Bristol Channel involve vessels from Belgium, taking two thirds, the UK one quarter, and France and Ireland taking minimal amounts of the total landings. The sole fishery is concentrated on the north Cornish coast off Trevose Head and around Lands End.

Sole are taken mainly in a beam trawl fishery that started in the early 1960s and, to a lesser extent, in the longer established otter trawl fisheries. In the 1970s, the fishery was mainly carried out by Belgian beam trawlers and Belgian and UK otter trawlers. The use of beam trawls (to target sole and plaice) increased during the mid-1970s, and the Belgian otter trawlers have now been almost entirely replaced by beam trawlers. Effort in the Belgium beam-trawl fleet increased in the late 1980s as vessels normally operating in the North Sea were attracted to the west by improved fishing opportunities. Beam trawling by UK vessels increased substantially from 1986, reaching a peak in 1990 and decreasing thereafter. In the Celtic Sea, the beam and otter trawl fleets also take plaice, rays, brill, turbot, and anglerfish.

## Ecosystem considerations

The main spawning areas for sole in the Celtic Sea are in waters $40-$ to $75-\mathrm{m}$ deep, off Trevose Head, and spawning usually takes place between February and April. Juvenile sole are found in relatively high abundance in depths up to 40 m , and adult sole (fish aged 3 plus) are generally found in deeper water. Spawning and nursery grounds are well defined.

The results of recent tagging experiments suggest that there is only limited movement of sole between the Bristol Channel and adjacent areas.

## The effects of regulations

In 2004, effort limitations (due to e.g. recovery plans for cod in the Irish Sea and the Eastern Channel) on most fishing grounds where the Belgian fleet normally operates resulted in a concentration of the Belgian effort into the Celtic Sea, where no such effort restrictions were in place.

Council Regulation (EC) No. 27/2005, Annex III, part A 12 (b) prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 during January-March 2005. This restriction did not apply to beam trawlers in March. Council Regulation (EC) No 51/2006, Annex III, part A 4.2 prohibited fishing in ICES rectangles 30E4, 31E4, and 32E3 (except within 6 miles from the base line) during February and March 2006 for all vessels and gear.

There is evidence that the closure of rectangles $30 \mathrm{E} 4,31 \mathrm{E} 4$, and 32 E 3 have redistributed effort to other areas. Monthly sightings of beam trawlers and otter trawlers (vessels of all nationalities) in 2004 to 2006 show that, during the first months of the year, beam trawl effort is particularly concentrated in rectangle 30 E 4 except when the closure is in force. Otter trawl effort in Divisions VIIf,g is less concentrated during the first 3 months of the year and the spatial distribution of effort appears to be less affected by the closed area. VMS data for French, Belgian, and UK (E\&W) vessels show a similar overall picture, given that the French fleet consists mainly of otter trawlers whereas the Belgian fleet are beam trawlers.

Beam trawlers account for the vast majority of sole landed by UK (E\&W) vessels in Divisions VIIf,g. The proportion of sole taken from the closed area was significantly reduced in March 2006, but increased to previous levels in the months either side of the closure period. Overall effort levels were reduced in February and March 2006 but, as for plaice, CPUE levels did not decline.

## Changes in fishing technology and fishing patterns

There have not been any major shifts between fisheries. Beam trawlers still account for more than $93 \%$ of the Belgian fleet; however, due to high fuel prices; several vessels of this fleet segment have tested different methods in order to reduce their fuel costs. These include (a) reducing the weight of the beam trawl by decreasing the length of the beam
or reducing the weight of the shoes. There is also evidence of fishers from other countries beginning to experiment with gear designs to improve fuel efficiency.

Some large beam trawlers in the Belgium fleet $(\sim 1200 \mathrm{Kw})$ are currently testing two technical modifications for the beam trawl, including T90-codends in combination with a benthos release panel in the belly of the beam trawl. Indications are that the remaining fleet is considering a voluntary uptake of these modifications.

There is evidence from the Belgian beam trawl fleet sector, which had previously underreported their engine horsepower, have now re-aligned their engine horsepower upwards to increase their fishing entitlements, allocated under national management measures. Similar situations have arisen in a number of other countries.

There is evidence of a switch to targeting other species by the main beam trawl fleet in this area.

## Scientific basis

## Data and methods

The analytical age-based assessment is based on landings, two commercial CPUE series, and one survey index.

## Information from the fishing industry

A number of DEFRA-funded surveys (Fisheries Science Partnership) were conducted in 2003, 2004, 2005, and 2006, using chartered UK fishing vessels in order to obtain new information on the catch rates, length distributions, and discard rates of target species. Investigations conducted in the Western Channel, Eastern Celtic Sea, and Bristol Channel during 2003-2006 confirmed that catch rates were highest in the area off the coast of North Cornwall. There was a trend for sole to be larger in the catches near Cornwall than in the north of the survey region near Pembrokeshire. The bycatch of cod was very small.

There was little information from the Pre-WG industry briefing meetings on VIIf,g sole.

## Uncertainties in assessment and forecast

The catch numbers appear to be reasonably reliable though there is some variability in survey tuning data.
The contribution of recruitment of the incoming year class to the short-term forecast is low, and last year's forecast was close to the realized catches.

Comparison with previous assessment and advice
Results are very close to those of the previous assessment. The perception of the stock has not changed and the basis for the advice is similar.

### 5.4.14 Sole in Division VIIe (Western Channel)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Increased risk | Harvested <br> unsustainably | Overexploited |  |

Based on the most recent estimates of SSB, ICES classifies the stock as being at risk of reduced reproductive capacity.
SSB has declined since 1980 when fishing mortality increased and is close to a historic low in 2005. Based on the most recent estimates of fishing mortality, ICES classifies the stock as being harvested unsustainably. Fishing mortality has been above $\mathbf{F}_{\mathrm{pa}}$ since 1978, and mostly above $\mathbf{F}_{\text {lim }}$ since 1982.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

Precautionary Approach reference points (revised in 2001):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 2000 t , the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 2800 t. |
| $\mathbf{F}_{\text {lim }}$ is 0.28, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.2. |

Yield and spawning biomass per Recruit

| $\mathbf{F}_{\text {med }}$ | 0.251 | 0.210 |  |

## Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$. | $\mathbf{B}_{\text {pa }}:$ historical development: Biomass below this has <br> increased risk of reduced recruitment. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$. | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} * 0.72$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

There is no agreed management plan.
Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Fishing mortality around $\mathbf{F}_{0.1}=0.12$ can be considered as candidate target reference points, which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential. The present fishing mortality ( 0.41 ) is above the candidate reference point.

## Exploitation boundaries in relation to precautionary limits

Rebuilding the stock above $\mathbf{B}_{\mathrm{pa}}$ in just one year would require that fishing mortality to be reduced by at least $68 \%$. This would correspond to landings of around 350 tonnes in 2007. If this reduction is not possible then ICES recommends that a recovery plan be implemented which ensures a safe and rapid rebuilding of SSB to levels above $\mathbf{B}_{p a}$.

## Short-term implications

Outlook for 2007

Basis: $\mathrm{F}(2006)=\mathrm{F}_{\mathrm{sq}}=\operatorname{mean} \mathrm{F}(03-05)=0.41 ; \mathrm{R} 05-06=\mathrm{GM}=4.3$ million; $\operatorname{SSB}(2006)=2.33 \mathrm{kt} ; \operatorname{SSB}(2007)=2.28 \mathrm{kt}$; landings $(2006)=1.02 \mathrm{kt}$.
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.2 .

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield)) is around 0.12 .

| Rationale | TAC(2007) ${ }^{1}$ | Basis | F(2007) | SSB() | \%SSB change | \%TAC change |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Weights in ' 000 t .
${ }^{1}$ It is assumed that the TAC will be implemented and that the landings in 2007 therefore correspond to the TAC.
Shaded scenarios are not considered consistent with the Precautionary Approach.

## Management considerations

There is no obvious evidence of a reduction in fishing mortality despite recent changes in management.
Last year ICES explored simulations with long-term target Fs below 0.6 for this stock. These show a range of fishing mortalities from 0.1 to 0.3 that are predicted to result in the highest long-term yields, whilst posing little risk of being below Bilim in the long term. A Harvest Control Rule (HCR) should therefore be developed to reduce $F$ to this type of target level in the medium term, whilst minimizing the risk of SSB decreasing below Blim.

The long-term yield is predicted to be close to 900 t at $\mathbf{F}_{0.1}$, slightly higher than in the previous assessments due to a slight increase in recruitment and selection pattern.

Any harvest control rule developed for sole should also take into account plaice as these two species are strongly linked in the fishery.

The 2003 assessment and additional investigations undertaken since then do not suggest that the stock is in imminent danger of collapse. This assertion is confirmed by the 2006 assessment; however, it is clear that the SSB continues to decline at current levels of $F$.

Misallocated landings between VIId and VIIe has been a big problem and to remedy this situation the European Commission increased the TAC in VIIe in 2005 and 2006. Misallocation continued, but at a much reduced rate due to these increased TACs.

Although sole is the main target species in the beam trawl fishery, catches of cuttlefish, plaice, monkfish, and lemon sole are also important. Management measures applied to sole must take account of management measures applied to the other quota species, particularly VIIe plaice and to a lesser degree VIIe-k cod.

## Factors affecting the fisheries and the stock

In recent years, UK vessels have accounted for around $60 \%$ of the total landings, with France taking approximately a third and Belgian vessels the remainder. UK landings were low and stable between 1950 and the mid-1970s, but increased rapidly after 1978 due to the replacement of otter trawlers by beam trawlers. In recent years the WG estimates of landings indicate a slight increase in the percentage taken by French vessels. The principal gears used are otter trawls and beam trawls, and sole tends to be the target species of an offshore beam-trawl fleet, which is concentrated off the south Cornish coast, and also takes plaice and anglerfish and, at times, cuttlefish as part of a diverse mixed fishery.

## The effects of regulations

Management of this stock has been by TAC, applied to sole in Division VIIe (i.e. the same as the assessment area). Industry information and commercial landings data analysis indicate that TACs have always been overshot and therefore do not provide effective control of fishing mortality. The agreed TAC in 2004 was 300 t , and landings were 1001 t . The TAC has been set to 865 t for 2005 to tackle area misreporting and underreporting problems in conjunction with an effort control regime. However, the ICES estimate of landings was 1026 t in 2005. Since 2005 beam trawlers with mesh size equal to or greater than 80 mm , which are responsible for the majority of the landings of this stock, have been restricted to 20 days at sea. The same 20 days at sea limitation has been applied to the static demersal nets, including gillnets, trammel nets, and tangle nets (Council Regulation (EC) No. 27/2005). There is no obvious reduction in nominal effort in 2005 compared to 2004 for the main fleets, and the fishing mortality is increasing.

Technical measures applied to this stock include a minimum landing size ( 24 cm ) and minimum mesh size of 80 mm for beam trawlers. Local regulations restricting certain gear and vessel types are also in place.

## Changes in fishing technology and fishing patterns

Whilst industry information indicates that fewer beam trawlers may now be active in the fishery, the overall standardized effort statistics do not show a significant reduction in effort in recent years.

Effective effort may possibly be reduced due to displacement and licence amalgamation and retargeting to other species and areas. However, the boats, although fewer in number are now bigger on average than they have been in the past and this could result in increased effective effort.

In 2005 and 2006 the increased fuel prices are known to have had a negative impact on the profitability of beam trawl fleets. This might result in decreased effort and changes in fishing patterns, but no information is available yet for ICES to evaluate this. The issue and resulting consequences are discussed in the WGFTFB 2006 report. No specific comments regarding the fleets exploiting the western channel sole fishery were raised in this report.

## Other factors

In the Western Channel the peak spawning period of sole is April and May. The main spawning areas are to the west of the Isle of Wight and in the vicinity of Hurd Deep. The nurseries are in estuaries, tidal inlets, and shallow, sandy bays. Adult sole in the Western Channel may recruit from local nurseries and from those in the Eastern Channel, but there is no evidence of subsequent emigration from the Western Channel. Coupled with the localised spawning areas in the Western Channel, this suggests that adult sole in the Western Channel are largely isolated from those found in northern Biscay, the eastern Celtic Sea, and the Eastern Channel.

## Scientific basis

## Data and methods

The assessment is analytical, based on landings, one survey index, and 4 commercial CPUE series ( 2 of which are historic).

Variations in effort and fleet catchability may occur as vessels move in and out of the fishery. depending on the prevailing catch rates of sole.

Strategic misallocation and underreporting of landings from this stock have affected the assessment in the past. In 2002, the database was revised and now includes landings misreported to two rectangles in Division VIId since 1986.

## Information from the fishing industry

The industry has been cooperative in a number of scientific endeavours with regards to this stock:
The fisheries science partnership conducted cooperatively between CEFAS and the UK industry has provided some information on age structure and distribution of this stock (CEFAS Fisheries Science Partnership Report (www.cefas.co.uk/fsp.)

## Uncertainties in assessment and forecast

Substantial area misreporting of catches has been evident for a number of years and the catch statistics have been partially corrected for this. The extent of underreporting is unknown and the current stock assessment and forecast will be conditional on the accuracy of the landing statistics. Misallocation, mainly to Area VIId has continued in 2005, but at a much reduced rate due to the increase in the 2005 TAC . All sole landings into rectangles 28E8 and 29E8 have been reattributed to VIIe , for the purposes of the WG. Estimates of unreported landings are not available and so cannot be included in the assessment. Indications from this year's analysis are that levels of underreporting appear to have declined following high levels of misreporting in the early 1990s.

This assessment is tuned using data from the commercial fishery as well as from one survey. The accuracy of the assessment and forecast will depend on whether these commercial catch rates reflect changes in population abundance.

The evidence in the tuning data regarding the current level of fishing mortality is diverging, making the 2005 estimate uncertain. There are strong indications that fishing mortality has increased in recent years.

## Comparison with previous assessment and advice

The current assessment revises fishing mortality downwards (17\%) and SSB upwards (20\%) in recent years and also results in a reduction of the 2002 and 2003 year class which were previously considered relatively strong. Because of the uncertainty of the estimate of the incoming year-class abundance, the catch projections are based on an average for the years 1969-2003, discounted for natural mortality.

The basis for the advice is consistent with last year's advice, although the advised level of catch is higher than last year due to the upwards revision of SSB in the new assessment.

### 5.4.15 Irish Sea herring (Division VIIa)

## State of the stock

Based on the most recent estimates of SSB and fishing mortality ICES classifies the state of the stock as uncertain. It seems likely that the stock has been relatively stable for the last 10 years, and that the fishing mortality does not appear to be increasing above the recent average. There are no recruitment indices for this stock.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary <br> reference points$\quad$ Approach | $\mathbf{B}_{\mathrm{lim}}$ is 6000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 9500 t. |
|  | $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ is not defined. |
| Target reference points | Not defined. | Not defined. |

Technical basis

| $\mathbf{B}_{\text {lim }}:$ lowest observed SSB. | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{lim}} * 1.58$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ is not defined. |

## Single stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

The SSB is uncertain but stable at around $\mathbf{B}_{\mathrm{pa}}$, while F is uncertain but not increasing. Therefore the TAC of 4800 t which has been implemented in recent years is not expected to be detrimental to the stock.

## Management considerations

The catch data may not have been reliable in the recent past, but enforcement has improved in the past year.

## Ecosystem considerations

There are irregular cycles in the productivity of herring stocks (weights-at-age and recruitment). There are many hypotheses as to the cause of these changes in productivity, but in most cases it is thought that the environment plays an important role (through transport, prey, and predation). Coincident periods of high and low production have been seen in the herring in VIaN and Irish Sea herring. Exploitation and management strategies must account for the likelihood of productivity changing. Productivity changes may invalidate biomass-based reference points, but not those based on fishing mortality.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Areas closed to herring fishing were established around the east coast of Ireland and west coast of Britain to protect juveniles when an industrial fishery operated in the 1970s. A closed area exists to the east of the Isle of Man to protect the spawning aggregations.

## Other factors

The stock identity is complex as the juveniles mix with those of the Celtic Sea and the adults migrate from the Irish Sea after spawning. The stock identity is being reviewed by an EU-funded project and results are expected in 2007. During this year an additional smaller, mainly gillnet fishery of 11 vessels registered herring landings. The effort from these vessels was centred off the Northern Irish coastline, in the area of the collapsed Mourne fishery

## Scientific basis

## Data and methods

The exploratory assessment of the stock is based on survey data and catch-at-age data.

## Uncertainties in assessment and forecast

The assessment is not considered accurate with respect to recent $F$ and SSB. but it is indicative of trends and levels in the past. Estimates of recent recruitments are based on catch and survey information. The current estimate of high 2005 recruitment is not reliable. There is a retrospective pattern which shows an underestimate of fishing mortality and an overestimate of SSB.

## Source of information

### 5.4.16 Celtic Sea and Division VIIj herring

## State of stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Uncertain, but <br> likely at risk of <br> reduced <br> reproductive <br> capacity | unknown | unknown |  |  |

The stock size continues to be uncertain, but SSB may be below $\mathbf{B}_{\mathrm{pa}}$, and may even be below $\mathbf{B}_{\text {lim }}$. The fishery is heavily dependent on incoming cohorts, and older ages are almost absent in the stock. Recent recruitment has been relatively low. Current fishing mortality is very uncertain but may be very high.

## Management objectives

The Irish "Celtic Sea Herring Management Advisory Committee" was established to manage the Irish fishery for this herring stock. This Committee manages the Irish quota and implements measures in addition to the EU regulations. The committee has a series of objectives relating to the maintenance of high yield and a consideration to rebuild the stock if necessary to achieve this. ICES considers that now implementing these objectives should be in the form of a rebuilding plan.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary <br> reference points$\quad$ Approach | $\mathbf{B}_{\mathrm{lim}}$ is 26000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 44000 t. |
|  | $\mathbf{F}_{\mathrm{lim}}:$ not defined. | $\mathbf{F}_{\mathrm{pa}}:$ not defined. |

Technical basis

| $\mathbf{B}_{\text {lim }}:$ The lowest stock observed. | $\mathbf{B}_{\mathrm{pa}}:$ Low probability of low recruitment. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ not defined. | $\mathbf{F}_{\mathrm{pa}}:$ not defined. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

The current level of SSB is uncertain, but may be below $\mathbf{B}_{\mathrm{pa}}$ and possibly even below $\mathbf{B}_{\text {lim }}$. There is no short-term forecast on which to base catch advice for 2007. However, given the risk to the stock indicated by weak recent recruitment, no fishing should be allowed until a rebuilding plan is in place. Such a plan should include closed areas to protect recruitment and further reductions in the catches. ICES is prepared to participate in the evaluation of such a plan.

## Management considerations

Though the state of the stock is uncertain, SSB is considered to be at a low level, possibly as low as the size when the stock previously collapsed. Given the age structure of the population and the current uncertainty, ICES considers that there is a high risk for reduced stock productivity.

Celtic Sea and Division VIIj herring are assessed on a seasonal basis, the 1 April to 31 March, while TACs are set by the calendar year.

## Factors affecting the fisheries and the stock

The stock is exploited by two types of vessels, larger boats with Refrigerated Sea Water (RSW) storage, and smaller dry hold vessels. The smaller vessels are confined to the spawning grounds (VIIaS and VIIg) during the winter period. The RSW vessels target the stock inshore in winter and offshore during the summer feeding phase (VIIg). There has been little fishing in VIIj in recent seasons, and there is evidence that stock abundance in this area is currently low.

The area east of Mine Head was closed from 2001 to December 2003. This closure may have afforded protection to recruiting "first-time spawners" over this period. The strongest year class to enter the fishery in recent years was that which spawned for the first time in 2001/2002. This cohort was dominant in catches from the closed area, when this area was re-opened in 2003. It has subsequently dominated catches throughout the Celtic Sea (though not in Division VIIj).

The collapse of the market for herring roe means that there is no longer the same incentive to discard (slip) catches.
The number of vessels participating in the fishery has decreased in recent years. However, efficiency has increased, especially in the RSW vessels.

## The environment

In the Celtic Sea, herring is a key pelagic species. There are indications to suggest increasing salinity and temperature. Considering that Celtic Sea herring is at the extreme of the species range in Europe, in an area of warming sea surface water, productivity might be affected. Weight-at-age has steadily declined since the 1980s.

## Scientific basis

## Data and methods

The current management regime has resulted in catch data which are thought reasonably reliable. There is an acoustic survey; however, the results are considered uncertain. There is no quantitative information on recruitment. There is no quantitative assessment in 2006.

## Uncertainties in assessment and forecast

A tentative assessment was undertaken in 2006, but the results are uncertain. Hence, the levels of SSB and F in the most recent year are indicative of trends only. However, it is clear that there are low abundances of older fish both in the catches and the population. Also, it is clear that SSB has declined since the mid-1990s. In addition, the marked absence of 2-year-old fish is confirmed. In a fishery that is based on only a few age classes, this is a cause for concern as there may be a high risk to the reproductive capacity of the stock from such a series of events.

Comparison with previous assessment and advice
The perception of the stock status this year is similar to last year. There is confirmation that the 2001 year class is weak.

### 5.4.17 Herring in Divisions VIa (South) and VIIb,c

## State of stock/exploitation:

| Spawning biomass in to <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Uncertain | Uncertain | Unknown | No accepted assessment, but SSB likely to be below <br> $\mathbf{B}_{\text {lim }}$. |

The results of a tentative assessment suggest that the sharp decline in SSB may have stopped. The current level of SSB is uncertain, but likely to be below $\mathbf{B}_{\text {lim }}$. There is no evidence that large year classes have recruited to the stock in recent years. Fishing mortality appears to have been reduced due to the reduction in catch; however, $F$ is likely to be above $\mathbf{F}_{\mathrm{pa}}$ and may even be above $\mathbf{F}_{\text {lim }}$.

## Management objectives

The Irish Northwest Pelagic Management Committee manages the Irish fishery for this stock. Management appears to be effective at constraining catches to not exceed the TAC and providing reliable catch data, but it is uncertain if the catch limitations are sufficient to rebuild the stock.

## Precautionary Approach reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit and pa reference points | $\mathbf{B}_{\mathrm{lim}}$ is 81000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 110000 t. |
| Limit and pa reference points | $\mathbf{F}_{\mathrm{lim}}$ is 0.33. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.22. |
| Target reference points |  |  |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Lowest reliable estimated SSB. | $\mathbf{B}_{\mathrm{pa}}:$ Approximately $1.4 \mathbf{B}_{\mathrm{lim}}$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}$. | $\mathbf{F}_{\mathrm{pa}}:=\mathbf{F}_{\text {med }}(98)$. |

Exploitation boundaries in relation to precautionary limits
The current catch regime which has been in place since 2000 does not appear to be rebuilding the stock. No fishing should be allowed unless a rebuilding plan is in place. This rebuilding plan should be analyzed scientifically and ICES is prepared to participate in this process. One element of such a recovery plan should consider further reductions in the catch.

## Short-term implications

No final assessment was produced and no short-term predictions were possible.

## Management considerations

SSB may be stable at an historic low level or declining slightly, though the peak in SSB in the 1980s may have been an isolated event. Fishing mortality appears to have been substantially reduced since 1998. Recruitment since the late eighties has been below average and appears to have declined further since the late nineties.

In the past the quotas were not strictly enforced. Tight enforcement of catch quotas should be continued.
There are two fleets exploiting this stock; the smaller dryhold vessels tend to target the stock more than the larger boats. The main target species for these fleets is mackerel, and herring fishing is somewhat opportunistic in this area.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Changes to the management of this stock, including provisions of the management plan, have changed the way the fishery is prosecuted in space and time. Enforcement and regulation of the fishery has also improved in recent years.

The pattern of this fishery has changed over time. In the early part of the 20th Century the main spawning components were the winter spawners off the north coast, and this was where the main fishery took place. In the 1970s and 1980s the west of Ireland autumn-spawning components were dominant and the fishery was mainly distributed along the coasts of VIIbc and VIaS. More recently the northern grounds have become more important again with most of the catches from VIIb concentrated in the northwest, near to the boundary of VIa south.

Information from the fisheries suggests that the recent dominance of younger fish in the catches may be influenced by changes in targeting by components of the fleet. There is evidence to suggest that in recent years larger boats have prioritised their effort in favour of mackerel, horse mackerel, and blue whiting.

## Other factors

The fishery exploits a mixture of autumn- and winter/spring-spawning fish. The winter/spring-spawning component is distributed in the northern part of the area. The main decline in the overall stock appears to have taken place on the autumn-spawning component.

## Scientific basis

## Data and methods

The acoustic survey time-series was used for the first time this year in exploratory assessments. Exploratory runs showed similar trends in stock development over a range of assumptions.

## Uncertainties in assessment and forecast

The acoustic survey series used to tune the exploratory assessment is very short and this contributes to the uncertainty of the assessment. A longer time-series will be required to gain precision in the assessment results.

The perception of stock trends is consistent, even though the most recent estimates of SSB and F are uncertain.

## Environment conditions

Herring catch data were analysed in relation to oceanographic variation. Long-term trends in herring catches showed herring abundance decreasing with a warming of the sea surface temperature in the 1930s-1940s. Short-term fluctuations of catches are believed to reflect real fluctuations in herring abundance on a cycle of about 10 years and were correlated with:

- Salinity in western approaches especially in the two winter quarters at a lag period of 3 years;
- SST on the shelf and west off the shelf, especially November, December, and January with a lag period of 3-4 years. Although herring correlated negatively to temperature in the long term, short-term variations were positively correlated.

Comparison with previous assessment and advice
The perception of the state of the stock is not changed from last year. The advice this year is based on the continued lack of recovery of the stock and suggests that further reductions in catches must be considered as part of a recovery plan.

The assessment, although still exploratory for the first year now includes data from an acoustic survey. This is step forward towards a reliable assessment.

### 5.4.18 Sprat in Divisions VIId,e

## State of the stock

The state of the stock is not known as available data are insufficient to carry out an assessment.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

Reference points for this stock have not been defined.

## Management considerations

Sprat catches are very low and are mainly taken in the second half of the year by the Lyme Bay sprat fishery. The catch has decreased and was 836 t in 2004, being the lowest of the whole time-series.

## Ecosystem considerations

There are indications that there may be interactions between herring and sprat biomass. The current situation is unclear and is further complicated by the increasing presence of sardine and anchovy in the area.

## Scientific basis

Data and methods

Available data are insufficient to carry out an assessment.

### 5.4.19 Megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d

State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing ing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown | Unknown |  |

It has not been possible to fully quantify SSB, fishing mortality and recruitment for this stock. However, indications are that landings and SSB have been reasonably stable over the time-series. There are no indications of reduced recruitment.

## Management objectives

There are no specific management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\text {lim }}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}$ be set at 55000 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is 0.44. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ is not defined. |

Yield and spawning biomass per Recruit
$F$-reference points:

|  | Fish Mort <br> Ages 3-6 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\text {max }}$ | 0.269 | 0.060 | 0.292 |
| $\mathbf{F}_{0.1}$ | 0.161 | 0.056 | 0.473 |
| $\mathbf{F}_{\text {med }}$ | 0.316 | 0.060 | 0.246 |

Technical basis:

| $\mathbf{B}_{\text {lim }}=$ Not defined. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss. }}$. There is no evidence of reduced recruitment at <br> (he lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ was therefore set <br> equal to the lowest observed SSB. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$. | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }} ;$ this implies a less than $45 \%$ probability that <br> $\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality is uncertain and cannot be evaluated with respect to long-term yield and low risk to SSB.

## Exploitation boundaries in relation to precautionary limits

The current stock status is uncertain, but all indicators point to the stock and catches being stable. Therefore ICES recommends that the landings of L. whiffiagonis in 2007 should not exceed the average landings of 2003-2005. This corresponds to 14200 tonnes.

## Management considerations

Megrim is caught in a mixed demersal fishery on anglerfish, hake, and Nephrops, both as a targeted fishery and as a valuable bycatch.

Landings in 2004 and 2005 have been well below the agreed TACs. The 2006 TAC was set at 20425 t , including a 5\% contribution of $L$. boscii in the landings for which stock there is no assessment.

Discarding of smaller megrim even above the minimum landing size (MLS) of 20 cm is substantial. Improving the selection pattern should benefit the stock and result in a higher long-term yield.

## Factors affecting the fisheries and the stock

## The effects of regulations

The MLS of megrim was reduced from 25 to 20 cm length in 2000, to match the selection pattern of the gear. However, high-grading continues for market reasons.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in Subareas VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002). These measures appear not to have resulted in a decrease in fishing effort for fleets fishing for megrim.

## Changes in fishing technology and fishing patterns

No significant changes have been observed in recent years. There has been an Irish decommissioning scheme, whereby around 40 fishing vessels ( $\sim 6000 \mathrm{GT}, 18000 \mathrm{~kW}$ ) have been permanently withdrawn from the Irish fishing fleet and removed from the Register of Sea Fishing Vessels in 2005 and 2006.

## Other factors

French trawlers operating in the Celtic Sea and targeting demersal species catch megrim as a bycatch. Spanish fleets have a targeted fishery for megrim and also catch megrim in mixed fisheries for hake, anglerfish, Nephrops, and other species. Otter trawlers account for the majority of the Spanish landings from Subarea VII. Most UK landings of megrim are made by beam trawlers fishing in ICES Divisions VIIe,f,g,h. Irish megrim landings are taken largely by multipurpose vessels fishing in Divisions VIIb,c,g for gadoids, plaice, sole, and anglerfish.

## Scientific basis

## Data and methods

An age-based assessment was carried out using landings and discards data, calibrated by two commercial CPUE series and two surveys. However, the assessment was not considered to be robust and could not be used for the short-term forecast..

## Information from the fishing industry

The fishing industry and scientists met at the national level to discuss information that could be used in the assessments. Additional qualitative information has been provided by the industry in relation to catches and spatial distribution of the fleets.

## Uncertainties in assessment and forecast

There are large retrospective revisions in stock trends which cannot be fully explained and the analytical assessment was therefore not considered reliable. The input data for assessment show several deficiencies, including:

- Limited discards data are available in the time-series and filling in of the missing years is problematic because discarding practices in the fisheries are very variable over time;
- Conflicting trends in commercial tuning data;
- Limited survey information, particularly on the strength of the incoming year classes.

Comparison with previous assessment and advice
ICES was not able to provide an analytical assessment this year. This is due to conflicting signals in the commercial fleets used to tune the assessment, leading to large interannual changes in recent stock projections. The survey information does not give a good indication of incoming year-class strength and there are considerable retrospective revisions of recruitment in the stock, making forecasts unreliable.

Given the problems outlined above the basis of the advice has changed to recent average catches.

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably | Overexploited | Unknown |  |

Based on the most recent estimates of SSB and fishing mortality ICES classifies the stock as having full reproductive capacity and being harvested sustainably. SSB of both stocks decreased from 1986 until 1993, then increased up to 1995-1996. SSB of L. budegassa is at present stable above $\mathbf{B}_{\mathrm{pa}}$. SSB for L. piscatorius has been above $\mathbf{B}_{\mathrm{pa}}$ and increasing since the mid-90s. For both stocks, fishing mortality in most years has been above $\mathbf{F}_{\mathrm{pa}}$. In 2005 fishing mortality is estimated to be around $\mathbf{F}_{\mathrm{pa}}$ for L. budegassa and below $\mathbf{F}_{\mathrm{pa}}$ for L. piscatorius. For L. piscatorius, recent year classes (1999-2002) are above average while for L. budegassa the 1999 and 2000 year classes are below average, with 2000 being the lowest observed in the time-series.

## Management objectives

There are no explicit management objectives for these stocks.

## Reference points

## L. piscatorius:

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathbf{B}_{\text {lim }}$ is undefined. | $\mathbf{B}_{\mathrm{pa}}=31000 \mathrm{t}$. |
|  | $\mathbf{F}_{\text {lim }}$ is 0.33. | $\mathbf{F}_{\mathrm{pa}}=0.24$. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}:$ not defined. |

Yield and spawning biomass per Recruit
$F$-reference points:

|  |  | Fish Mort <br> Ages 3-8 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: | :---: |
| Average | last | 3 |  |  |
|  |  |  |  |  |
| years |  |  | 0.211 | 0.905 |
| $\mathbf{F}_{\text {max }}$ |  |  | 0.086 | 1.084 |
| $\mathbf{F}_{0.1}$ |  |  | 0.051 | 1.015 |
| $\mathbf{F}_{\text {med }}$ |  |  | 0.247 | 0.852 |

Candidates for target reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\max }$.

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Not defined. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }}$. There is no evidence of reduced recruitment <br> at the lowest biomass observed. $\mathbf{B}_{\mathrm{pa}}$ is equal to the lowest <br> observed SSB in 1993, as estimated in 2000. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}$, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} * 0.72$. This F is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim }}$, taking into account the <br> uncertainty in the assessment. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

For $L$. piscatorius the status quo fishing mortality is estimated at 0.21 , which is above fishing mortalities that would lead to high long-term yields and low risk of stock depletion $\left(\mathbf{F}_{0.1}=0.05\right.$ and $\left.\mathbf{F}_{\max }=0.09\right)$. For L. budegassa the status quo fishing mortality is estimated at 0.23 , which is above fishing mortalities that would lead to high long-term yields and low risk of stock depletion $\left(\mathbf{F}_{0.1}=0.09\right.$ and $\left.\mathbf{F}_{\text {max }}=0.15\right)$. This indicates that long-term yield is expected to increase at fishing mortalities below the historic values.

## Exploitation boundaries in relation to precautionary limits

In order to harvest the stock within precautionary limits fishing mortality should be kept below $\mathbf{F}_{\mathrm{pa}}$ and SSB should be above $\mathbf{B}_{\mathrm{pa}}$ for both species. Fishing at $\mathbf{F}_{\mathrm{pa}}$ for $L$. budegassa is equivalent to $\mathbf{F}_{\mathrm{sq}}$ and is expected to result in landings of 7600 t , leading to an SSB of 26800 t in 2008. Given the link between the two species, this corresponds to a fishing mortality of 0.21 for L. piscatorius, corresponding to landings of at most 28400 tin 2007 . The predicted SSBs are well above $\mathbf{B}_{\mathrm{pa}}$ in all scenarios.

## Short-term implications

Outlook for 2007
L. piscatorius: Basis: $\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}(03-05)=0.21$; R06-07 $=$ GM 1987-2003 = 22 millions; landings (2006) $=28.5$; $\operatorname{SSB}(2007)=84.1$.
L. budegassa: Basis: $\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}(03-05)=0.23 ; \mathrm{R} 06-07=\mathrm{GM} 1987-2002=15$ millions; landings $(2006)=7.4$; $\operatorname{SSB}(2006)=27.1$.

The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.24 (L. piscatorius), and 0.23 (L. budegassa).

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield) is 0.09 (L. piscatorius) and 0.16 (L. budegassa).

Note: F multipliers on F precautionary limits are not consistent between the two species.

## Management considerations

L. piscatorius and L. budegassa are both caught on the same grounds and by the same fleets and are usually not separated by species in landings, and the fishing mortalities are linked. Both species show similar trends in stock trajectories. So far the stocks have developed synchronously; if this changes in the future they should be managed separately.

Management measures for both species must be considered together and in conjunction with other species caught in these fisheries (sole, cod, rays, megrim, Nephrops, and hake).

There are two separate TACs for these stocks: in Subarea VII and in Divisions VIIIa,b,d,e. The assessment is carried out for a smaller area (Divisions VIIb-k and VIIIa,b) than the management area and will thus be a underestimate of the overall stock size. However, the assessment covers the majority of the area as recent landings in Division VIIa have been relatively small compared to the total TAC.

The majority of the anglerfish catch consists of young fish. An improvement of the selection pattern is expected to give a higher long-term yield.

## Factors affecting the fisheries and the stock

## The effects of regulations

There is no minimal landing size for anglerfish but an EU Council Regulation (No. 2406/96), laying down common marketing standards for certain fishery products fixes a minimum weight of 500 g for anglerfish. When the minimum landing size does not fit with the selective properties of the gears, this is expected to lead to discarding of undersized fish.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in Subareas VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002). These measures have not resulted in a decrease in fishing effort for fleets fishing for anglerfish.

The quota has been restrictive for some fleets and substantial underreporting of landings is known to have occurred. Information from the Irish fishery indicates that underreporting of total landings has been a problem in recent years due to restrictive individual vessel quotas. In 2005 specific anglerfish licences were introduced in Ireland to improve compliance. There has been an increased enforcement on anglerfish quotas in 2006.

## Changes in fishing technology and fishing patterns

No significant changes in recent years.

## The environment

The spawning of the Lophius species is very particular, with eggs extruded in a buoyant, gelatinous ribbon that may measure more than 10 m . This particular spawning pattern results in a highly clumped distribution of eggs and newly emerged larvae. Although this could result in recruitment being sensitive to environmental variations, this has not been observed.

## Other factors

Anglerfish are an important component of mixed fisheries taking hake, megrim, sole, cod, plaice, and Nephrops. A trawl fishery by Spanish and French vessels developed in the Celtic Sea and Bay of Biscay in the 1970s, and overall annual landings may have attained 35-40 000 t by the early 1980s. Landings decreased between 1981 and 1993; since 2000, landings have shown an increasing trend. France and Spain together still report more than $75 \%$ of the total landings of both species combined. The remainder is taken by the UK and Ireland (around $10 \%$ each) and Belgium (less than 5\%).

Otter-trawls (the main gear used by French, Spanish, and Irish vessels) currently take about $80 \%$ of the total landings of L. piscatorius, while around $60 \%$ of the UK landings are taken by beam trawlers and gillnetters. Over $95 \%$ of the total international landings of $L$. budegassa are taken by otter trawlers. There has been an expansion of the French gillnet fishery in the last decade in the Celtic Sea and in the north of the Bay of Biscay, mainly by vessels landing in Spain and fishing in medium to deep waters. Otter-trawling in medium and deep water in Subarea VII appears to have declined,
even though the increasing use of twin trawls by French vessels may have increased significantly the overall efficiency of the French fleet.

## Scientific basis

## Data and methods

Age-based (XSA) assessments for each species separately are based on landings, one survey, and four (L. piscatorius) or five (L. budegassa) commercial CPUE series.

## Information from the fishing industry

The fishing industry and scientists have met at the national level to discuss information that can be used in the assessments. Some CPUE time-series have been provided by the fishing industry. Qualitative information has also been provided and has contributed to the assessment process.

The UK Fisheries Science Partnership report on anglerfish was made available to the WG as a Working Document.

## Uncertainties in assessment and forecast

Retrospective patterns exist in the absolute estimates of SSB, recruitment, and F. For L. piscatorius there is a clear underestimation of SSB and overestimation of fishing mortality in recent years. For L. budegassa, the historical pattern is uncertain in the overall level of stock size. The recruitment estimates of the most recent years appear to be very uncertain.

The main factors contributing to the uncertainties for these stocks are:

- Stock definition is problematic.
- Discards are not included in the assessment; discards are known to be partly dependent on market conditions and TAC restrictions and not just a proportion of the catch.
- The catch information has not been corrected for the substantial underreporting of landings.
- There are conflicting signals in the commercial CPUE series which could be caused by different targeting behaviour (changes in spatial and temporal fishing patterns).

## Comparison with previous assessment and advice

For L. piscatorius fishing mortality and recent recruitments are revised downward and SSB upward, and for $L$. budegassa the usual downward revision of recent recruitment has been reversed for the year classes 2001 and 2002, while F and SSB trends are similar.

### 5.4.21 Cod in Division VIa (West of Scotland)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Reduced <br> reproductive <br> capacity | Harvested <br> unsustainably | Overexploited | Not defined | SSB is estimated to be at an historical <br> low level. The level of fishing mortality <br> is estimated to be high and probably <br> above $\mathbf{F}_{\text {lim. }}$ |

The spawning stock biomass is at an all time low, but the rate of exploitation is uncertain and probably high. The survey SSB estimates indicate that the stock has been declining and is presently at an historical low. Recruitment estimates indicate a decline in recruitment in the last decade, correlated with a decline in the spawning stock to the lowest levels observed. Recruitment since 2003 has been the weakest in the time-series.

## Management objectives

The European Commission has enacted a Council Regulation ((EC) No. 423/2004) which establishes measures for the recovery of cod stocks:

For stocks above $\mathbf{B}_{\mathrm{lim}}$, the harvest control rule ( HCR ) requires:

1) setting a TAC that achieves a $30 \%$ increase in the SSB from one year to the next,
2) limiting annual changes in TAC to $\pm 15 \%$ (except in the first year of application), and,
3) a rate of fishing mortality that does not exceed $\boldsymbol{F}_{p a}$

For stocks below $\boldsymbol{B}_{\text {lim }}$ the Regulation specifies that:

1) conditions 1-3 will apply when they are expected to result in an increase in $\operatorname{SSB}$ above $\boldsymbol{B}_{\text {lim }}$ in the year of application,
2) a TAC will be set lower than that calculated under conditions 1-3 when the application of conditions 1-3 is not expected to result in an increase in $S S B$ above $\boldsymbol{B}_{\text {lim }}$ in the year of application.

ICES has previously concluded that a precautionary recovery plan must include an adaptive element implying that fisheries for cod remain closed until an initial recovery of the cod SSB has been proven. An initial 3-year closure would be required to increase SSB above $\mathbf{B}_{\text {lim }}$ with high probability. Such an element of zero catch is not included in the existing plan. ICES therefore considers the recovery plan not to be consistent with the precautionary approach.

## Reference points

|  | ICES considers that: | ICES proposes that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is 14000 t. | $\mathbf{B}_{\mathrm{a}}$ be set at 22000 t. |
|  | $\mathbf{F}_{\mathrm{l} \text { lim }}$ is 0.8. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.6. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not determined. |

Yield and spawning biomass per Recruit (from 2004 Assessment, assuming the selection pattern at that time)
$F$-reference points:

|  | Fish Mort <br> Ages 2-5 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\max }$ | 0.191 | 1.138 | 8.637 |
| $\mathbf{F}_{0.1}$ | 0.132 | 1.088 | 11.440 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{011}-\mathbf{F}_{\text {max }}$.

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss, }}$, the lowest observed spawning stock <br> estimated in previous assessments. | $\mathbf{B}_{\text {pa }}:$ This is considered to be the minimum SSB required to <br> ensure a high probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, <br> taking into account the uncertainty of assessments. This |
| :--- | :--- |
| also corresponds with the lowest range of SSB during the |  |
| earlier, more productive historical period. |  |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to existing management plans
Due to the uncertainty in the level of fishing mortality, ICES is not in a position to give quantitative forecasts. In addition the management plan is not explicit about the level of reduction in the catch when the stock is below $\mathbf{B}_{\mathrm{lim}}$. Simulations show that fishing should be closed for 3 years in order to bring SSB above $\mathbf{B}_{\mathrm{lim}}$.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

There will be no gain in the long-term yield by having fishing mortalities above $\mathbf{F}_{\text {max }}$ (0.19). Fishing at such lower mortalities would lead to higher SSB and, therefore, lower risks of fishing outside precautionary limits.

## Exploitation boundaries in relation to precautionary limits

Given the very low SSB estimates, the high fishing mortalities and low recruitment in this stock, ICES advises zero catch of cod in 2007.

## Conclusion on exploitation boundaries

As the recovery plan for this stock is considered to be consistent with the precautionary approach only when the fishery is closed for an initial period, and as this is congruent with the advice in relation to precautionary limits, ICES advises a zero catch of cod in 2007.

## Management considerations

Management of cod fisheries must deal with the combined effects of assessment bias (of which unreliable catch data are a major contributing factor) and the inability of management to control catch. As long as these two interrelated conditions persist and substantial effort is permitted for fisheries catching cod, rebuilding cannot be achieved. Survey information shows that the total removal of cod in Division VIa may have been underestimated in the past decade relative to earlier periods. In an attempt to remove bias in the assessment a catch-at-age model was used that ignored landings and discard data from 1995 onwards, relying on survey data for this later period. It is, however, considered that mortality estimates arising from an assessment heavily or wholly based on survey data are poorly estimated and therefore noisy and sensitive to survey catchability. In contrast, historical trends in spawning biomass and recruitment appear to be robust measures of stock dynamics.

The advised measures are required if the cod stock is to reach a level where it can regain historic productivity.
As cod is taken in mixed demersal fisheries, following the advice will likely result in having to greatly reduce harvesting of other stocks, particularly haddock, whiting, and Nephrops. Management needs to take this into account.

Effort data 1998-2005 from UK vessels (one of the main countries fishing in the area) suggests that overall, effort has declined in recent years in Area VIa, and that declines in particular categories have not been compensated for by rises in other categories. Larger-meshed whitefish demersal trawls were the most important gears in Division Vla prior to 2002, but since then there has been a marked decline in KW-days by this category. This is principally explained by the recent, significant decommissioning schemes in the UK. Single-rig Nephrops trawls in the $70-$ to $99-\mathrm{mm}$ mesh category are the other major gears in use and effort by these seems to have been maintained at a fairly stable level throughout the timeseries. Numerous other gears generally make small contributions to the overall effort, and the pattern in most of these has either been a downward trend (e.g. seine nets and midwater trawls) or fluctuation without trend (e.g. fixed nets).

Time and area closures for particular fisheries may be tools for rebuilding this stock. The consequence of displacing effort, caused by the closures, needs to be considered in determining the role of such measures in the recovery plan.

## Management plan evaluations

The management plan was evaluated and SSB recovery to above $\mathbf{B}_{\mathrm{pa}}$ is expected to occur by about 2015. The result of the evaluation depends on a large number of assumptions, e.g. fishing mortality at zero implemented without errors. However, there are reports of significant non-reported landings, and as a consequence the current implementation of the TAC system is not able to regulate fishing mortality. Unless recovery measures are able to restrict the fishery they cannot be considered precautionary.

The plan depends primarily on annual estimates of SSB in relation to $\mathbf{B}_{\mathrm{pa}}$ but also on estimates of fishing mortality relative to $\mathbf{F}_{\mathrm{pa}}$. While SSB appears to be estimated well by this assessment, the fishing mortality is less well known and aspects of the management plan relating to maximum fishing mortality levels may be difficult to implement.

## Factors affecting the fisheries and the stock

## The effects of regulations

The fishery is managed by a TAC that does not seem to be restricting catches.
Several regulations have been introduced for West of Scotland in recent years. These regulations and their impact on the fisheries have been discussed in detail in the overview. Emergency EU measures were established in the first half of 2001 and led to short-term area closures in the north of the Division and, on a smaller scale, in the Clyde Sea area. These closures were intended to allow as many cod as possible to spawn. The Clyde closure has continued in all subsequent years under national UK legislation. Various derogations were introduced for gears not targeting cod. A new closed area was implemented west of Scotland in 2004 (EC Reg. No. 2287/2003).

The proportion of discarded fish has been high. In 2002 and 2003 regulations were implemented to improve the exploitation pattern of cod. It is not clear if it is possible to evaluate potential impacts of these measures to the stock and fishery.

Increases in cod-end mesh sizes have been introduced into the fishery to improve selectivity. The increase in minimum mesh size from 100 to 120 mm in 2001/2002 (before the introduction of effort regulation 27/2005) partly caused a shift to $80-\mathrm{mm}$ mesh sizes in the mixed fishery trawls, due to the loss of valuable Nephrops catch. Catch composition regulations for this mesh size may have resulted in increased discarding and high grading.

The regulation is complemented by a system of fishing effort limitation. This is done by adjustment to the number of fishing days for various vessel categories deploying gears with various mesh sizes. The introduction of effort regulation has effectively further encouraged vessel operators to reduce mesh size and shift to other fisheries, particularly Nephrops trawling, in order to gain more days at sea. It is not possible to evaluate whether the mesh size changes and effort limitations may have benefited cod without information on the level of adherence to catch composition regulations required when using smaller mesh sizes.

However, the continued decline in the stock indicates that these measures alone have not proven sufficient to rebuild the stock to precautionary levels. Detailed analysis of the impact of such regulations is not possible until data of sufficient quality become available.

## Changes in fishing technology and fishing patterns

From mid-September 2003 to mid-July 2004 the Irish trawl fishery off Greencastle, Co. Donegal that traditionally targets juvenile cod was closed. The closure was instigated by the local fishing industry to allow an assessment of seasonal closure as a potential management measure. The fishing industry again called for and received a statutory instrument closing the fishery from November 2004 until mid-February 2005 and again November 2005 until midFebruary 2006. Most of the cod catch is normally taken in the fourth quarter. During 2000-2002 50\% of the Irish catch weight of cod in Division VIa ( $61 \%$ by number) was taken in the fourth quarter. The closure is expected to have reduced the Irish fishing mortality on cod that would otherwise have occurred in 2003, 2004, and 2005.

## Scientific basis

## Data and methods

A catch-at-age model using catch data up to 1994 tuned by survey data and utilizing survey information alone from 1995 onward was used to evaluate trends in spawning stock biomass and recruitment. Trends in SSB are similar to results from a model based on survey data alone.

Some changes have been made to the survey design in the past, but surveys are considered to provide an indicator of long-term stock trends.

Comparison with previous assessment and advice
The last analytical assessment was undertaken in 2003 based on a catch-at-age model using estimates of landings-atage, discards-at-age, and survey CPUE data. No analytical assessment was carried out for this stock in 2004 or 2005. This year's assessment is based on a catch-at-age model using catch data up to 1994 tuned by survey data and survey information alone from 1995 onwards. Because of large uncertainties in mean F estimates no attempt was made to generate forecasts from this model. The perception of the state of the stock remains unchanged compared to 2003 and subsequent years. The advice this year is the same as last year.

* Preliminary.

State of the stock
There have been no investigations and no catches in 2005.

### 5.4.23 Haddock in Division VIa (West of Scotland)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Risk of being <br> harvested <br> unsustainably | Overexploited | Not defined |  |

Based on the most recent estimate of SSB and fishing mortality ICES classifies the stock as having full reproductive capacity. The estimate of fishing mortality is uncertain, but is estimated above $\mathbf{F}_{\mathrm{pa}}$ in most years since 1987. F has declined in recent years. SSB varied around $\mathbf{B}_{p a}$ during the 1990s. The very strong 1999 year class has caused SSB to increase from a level near the historic low in 2000 to above $\mathbf{B}_{p \mathrm{a}}$ since 2001. More recent year classes, 2003 to 2005 year classes, are estimated to be low.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposes that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is 22000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 30000 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.5. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not determined. |

Yield and spawning biomass per Recruit
$F$-reference points:

|  |  | Fish Mort <br> Ages 2-6 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: | :---: |
| Average | last 3 |  |  |  |
| years |  | 0.493 | 0.076 | 0.342 |
| $\mathbf{F}_{\text {max }}$ |  | 0.176 | 0.110 | 0.919 |
| $\mathbf{F}_{0.1}$ |  | 0.118 | 0.105 | 1.210 |
| $\mathbf{F}_{\text {med }}$ |  | 0.425 | 0.084 | 0.402 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss, }}$ the lowest observed spawning stock <br> estimated in previous assessments. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} * 1.4$. This is considered to be the minimum <br> SSB required to have a high probability of maintaining |
| :--- | :--- |
| SSB above $\mathbf{B}_{\mathrm{lim}}$, taking into account the uncertainty of |  |
| assessments. |  |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current estimated fishing mortality is uncertain, but is likely to be well above $\mathbf{F}_{\text {max }}$. There will be no gain to the long-term yield by having fishing mortalities above $\mathbf{F}_{\text {max }}(0.29)$. Fishing at such lower mortalities would lead to higher SSB and, therefore, lower risks of fishing outside precautionary limits.

Exploitation boundaries in relation to precautionary limits
In order to maintain SSB above $\mathbf{B}_{\mathrm{pa}}$ in 2008, ICES recommends a reduction in fishing mortality to less than 0.44. This corresponds to landings less than 7200 t in 2007.

## Short-term implications

Outlook for 2007
Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=$ mean $\mathrm{F}($ age $3-5)=0.49 ; \mathrm{R}(1978-2005) \mathrm{GM}=108.5 \mathrm{million} ; \operatorname{SSB}(2007)=29.3 \mathrm{kt}$; $\operatorname{SSB}(2008)=28.7 \mathrm{kt}$; landings $(2006)=9.3 \mathrm{kt}$.

The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.5 .

The fishing mortality which is consistent with taking high long-term yield and achieving low risk of depleting the productive potential of the stock ( F (long-term yield)) is not defined.

| Rationale | TAC(2007) ${ }^{\mathbf{1}} \mathrm{kt}$ | Basis | F(2007) | SSB(2008) kt | $\%$ \%SSB change ${ }^{2}$ | \%TAC <br> change ${ }^{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Zero catch |  | $\mathrm{F}=0$ | 0 |  |  |  |
| Status quo | 7.79 | $\mathrm{F}_{\mathrm{s} \text { a }}$ | 0.49 | 28.7 | -2 | 0 |
| High longterm yield | 5.3 | F(long-term yield) | 0.295 | 33.7 | 15 | -32 |
| Status quo | 3.58 | $\mathbf{F}_{\text {sa }} * 0.4$ | 0.20 | 36.8 | 26 | -54 |
|  | 5.12 | $\mathbf{F}_{\text {so }} * 0.6$ | 0.30 | 33.8 | 15 | -34 |
|  | 6.52 | $\mathbf{F}_{\text {sa }} * 0.8$ | 0.39 | 31.1 | 6 | -17 |
|  | 7.79 | $\mathrm{F}_{\mathrm{so}} * 1$ | 0.49 | 28.7 | -2 | 0 |
|  | 8.93 | $\mathbf{F}_{\text {sa }} * 1.2$ | 0.59 | 26.4 | -10 | 14 |
| Precautionarylimits | 1.9 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 0.2$ | 0.10 | 39.9 | 36 | -76 |
|  | 3.7 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 0.4$ | 0.20 | 36.6 | 25 | -53 |
|  | 5.3 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 0.6$ | 0.30 | 33.7 | 15 | -32 |
|  | 6.7 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 0.8$ | 0.40 | 30.9 | 5 | -14 |
|  | 7.2 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{ba}}\right) * 0.87$ | 0.436 | 30.0 | 2 | -8 |
|  | 8.0 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.0$ | 0.50 | 28.7 | -2 | 2 |
|  | 8.1 | $\mathbf{F}_{\mathrm{sq}}=\mathbf{F}_{\mathrm{pa}} * 1.014$ | 0.507 | 28.3 | -3 | 4 |
|  | 9.2 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.2$ | 0.60 | 26.1 | -11 | 18 |
|  | 10.2 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{pa}}\right) * 1.4$ | 0.70 | 24.1 | -18 | 31 |

All weights in thousand tonnes.
${ }^{1}$ It is assumed that the TAC will be implemented and that the landings in 2006 therefore correspond to the TAC.
${ }^{2}$ SSB 2008 relative to SSB 2007.
${ }^{3}$ TAC 2007 relative to TAC 2006.
Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

There have been several technical conservation measures introduced in the demersal fishery in Division VIa in recent years. These will have affected selectivity for haddock. There have also been a number of decommissioning rounds in the Scottish fleet, which will have reduced effective effort. The effect of recent effort regulations also still needs to be ascertained. Management for haddock will be strongly linked to that for cod for which a recovery plan is currently in force.

In 2005, Ireland introduced a decommissioning scheme aimed at removing around $6000 \mathrm{GT} / 18000 \mathrm{~kW}$ from the Irish fleet. This stems from the two Whitefish Renewal Schemes, which introduced around 32 new vessels into the Irish fleet. The decommissioning scheme is targeted at demersal and scallop vessels over 18 m . The scheme is split into three rounds, with around 8 vessels already scrapped as part of the first phase and a total of 44 vessels due to be scrapped by the end of 2006. These changes in fleet structure are likely to have an impact on CPUE in this component of the data.

Special attention needs to be given to considering the sporadic nature of the haddock recruitment and how to manage periods of low recruitment interspersed with large, occasional pulses. In recent years over $50 \%$ of the total catch in weight has been discarded, so restricting landings alone may not achieve the necessary increase in SSB. Recent recruitment has been poor.

There are reports of significant non-reported landings and therefore a TAC system may not be able to restrict fishing. The conflicting signals in the survey and the catch-at-age information indicate that there is unaccounted removal from the system. The problem does not appear to be as severe as for whiting and cod, but this has not been fully evaluated.

## Factors affecting the fisheries and the stock

## The effects of regulations

The fishery is regulated by a TAC that does not, however, seem to be restricting catches.
The increase in minimum mesh size from 100 to 120 mm in 2001/2002 (before the introduction of effort regulation $27 / 2005$ ) partly caused a shift to $80-\mathrm{mm}$ mesh sizes in the mixed fishery trawls due to the loss of valuable Nephrops catch. Poorer selectivity at this mesh size may have resulted in increased discarding and high grading.

With the introduction of effort regulation, vessel operators have effectively been further encouraged to reduce mesh size and shift to other fisheries, particularly Nephrops trawling, in order to gain more days at sea. It is not possible to evaluate whether the mesh size changes and effort limitations may have benefited haddock without information on the level of adherence to catch composition regulations required when using smaller mesh sizes.

## Changes in fishing technology and fishing patterns

Haddock in Division VIa are caught mainly by Scottish trawlers. Since 1976, Scottish heavy trawl and seine effort has declined, whilst that of light trawlers (shorter than 90 feet) has generally increased.

## Other factors

Haddock in Division VIa are fully exploited from age group 3, and also reach full maturity at that age. Immature fish are subject to comparatively high fishing mortality, and comprise a large fraction of the discarded catch. High fishing mortality on immature haddock increases the susceptibility of the stock to overexploitation.

## Scientific basis

## Data and methods

The analytical age-based assessment is based on landings-at-age data, discard-at-age data, and indices from research vessel surveys. Due to uncertainties in landings quantity, catch data 1995-2005 were not used in the assessment.

## Uncertainties in assessment and forecast

Survey information indicates an increase in unaccounted removal from this stock. Absolute biomass estimation may thus be biased, but it is not known to what extent. The relatively high SSB in recent years implies that the unaccounted catches have not caused harm to the stock in recent years.

Since effort data are unreliable (due to effort reporting not being mandatory in logbooks) commercial CPUE data are not used as tuning inputs.

Weights-at-age have shown a declining trend in this stock. The predictions conducted here provide guidance on the likely trajectories of stock biomass under various mortality scenarios. The shape of these trajectories also depends on the input weights-at-age. In the predictions carried out here the weights-at-age in 2006 were predicted from a simple linear model applied to the weight-at-age of each year class. Although other more complex options (e.g. the von Bertalanffy model) might also be contemplated, the simple linear models seem to fit the data reasonably well for the age ranges considered.

The perception of the state of the stock from this year's assessment does not differ from that obtained last year, and the basis for the single-stock fishery advice is the same as last year.

## Source of information

Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, 9-18 May 2006 (ICES CM 2006/ACFM:30).

### 5.4.24 Haddock in Division VIb (Rockall)

## State of the stock

| Spawning biomass in to <br> relation <br> precautionary limits | Fishing mortality <br> is relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably | Overexploited | Not defined |  |

Spawning biomass levels have increased in recent years as a result of the 2000 and 2001 year classes. SSB in 2005 is estimated to be above $\mathbf{B}_{\mathrm{pa}}$. Fishing mortality has been high throughout the available time-series, but appears to have declined in 2005.

## Management objectives

In consultation with the Russian Federation, a recovery plan has been proposed by the EC. However, now that the stock has recovered to $\mathbf{B}_{\mathrm{pa}}$, a management plan should be proposed and evaluated for this stock.

## Reference points

|  | ICES considers that: | ICES proposes that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is 6000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 9000 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. |

Yield and spawning biomass per Recruit
$F$-reference points:

|  |  | Fish Mort <br> Ages 2-5 | Yield/R | SSB/R |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Average | last | 3 |  |  |  |
| years |  |  | 0.65 | 0.17 | 0.23 |
| $\mathbf{F}_{0.1}$ |  |  | 0.18 | 0.15 | 0.75 |
| $\mathbf{F}_{\text {med }}$ |  |  | 0.43 | 0.17 | 0.35 |

A candidate for target reference point which is consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be around $\mathbf{F}_{0.1}(0.18) . \mathbf{F}_{\max }$ is undefined due to a flat-topped Y/R.

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$, the lowest observed spawning stock <br> estimated in previous assessments. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} *$ 1.4. This is considered to be the minimum SSB <br> required to have a high probability of maintaining SSB <br> above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of <br> assessments. |
| :--- | :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is not defined due to uninformative stock <br> recruitment data. | $\mathbf{F}_{\mathrm{pa}}$ This F is adopted by analogy with other haddock stocks <br> as the F that provides a small probability that SSB will fall <br> below $\mathbf{B}_{\mathrm{pa}}$ in the long term. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Target reference points have not been agreed for this stock. There is no gain in yield by having a target above $\mathbf{F}_{0.1}$ (0.18).

## Exploitation boundaries in relation to precautionary limits

Fishing mortality should be less than $\mathbf{F}_{\mathrm{pa}}$, corresponding to catches less than 7100 t in 2007.

## Short-term implications

Outlook for 2007
Basis: $\mathrm{F}(2006)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(05)=0.39 ; \mathrm{R}=\mathrm{GM} 91-03=70385$ million; $\operatorname{SSB}(2006)=16840 \mathrm{t}: \operatorname{SSB}(2007)=15680 \mathrm{t}$ : catch (2006) $=6765 \mathrm{t}$.

| Rationale | TAC(2007) | Basis | F(2007) | SSB(2008) |
| :---: | :---: | :---: | :---: | :---: |
| Zero catch | 0 | $\mathrm{F}=0$ | 0 | 29500 |
| High long-term yield | 3514 | $\mathrm{F}(0.1)$ | 0.18 | 25741 |
|  | 1585 | $\mathbf{F}_{\text {sa }} * 0.2$ | 0.078 | 27789 |
|  | 3062 | $\mathbf{F}_{\text {sa }} * 0.4$ | 0.155 | 26220 |
|  | 4439 | $\mathbf{F}_{\text {sa }} * 0.6$ | 0.233 | 24766 |
|  | 5726 | $\mathbf{F}_{\text {sa }} * 0.8$ | 0.310 | 23415 |
|  | 6929 | $\mathrm{F}_{\mathrm{s} 0}$ | 0.388 | 22159 |
|  | 7110 | $\mathbf{F}_{\mathrm{pa}}$ | 0.40 | 21968 |
|  | 8055 | $\mathrm{F}_{\mathrm{sa}} * 1.2$ | 0.465 | 20990 |
|  | 9112 | $\mathrm{F}_{\mathrm{sa}} * 1.4$ | 0.543 | 19901 |
|  | 10103 | $\mathrm{F}_{\text {sa }} * 1.6$ | 0.620 | 18886 |
|  | 11036 | $\mathbf{F}_{\text {sa }} * 1.8$ | 0.698 | 17938 |

Shaded scenarios are not considered consistent with the precautionary approach.

## Management considerations

An international TAC applicable only to Division VIb, including international waters, would improve prospects for sustainability in the fishery in Division VIb. Previous to 2004, the EU TAC was set as a total for Division VI, with a limit on how much of the catch could be taken in Division VIa. Since 2004, TACs have set a specific limit for the EU fleets operating in Division VIb. In addition, part of Division VIb has since 1999 been in international waters where non-EU vessels are not subject to TAC. This allows for an unregulated fishery in the Rockall area.

However, the application of TACs implies that there is a simple relationship between recorded landings and effort exerted, and TACs are therefore likely to be effective only if the fishery strictly adheres to them. Such assumptions are unlikely to be true for Rockall haddock, especially when coupled with ways of evading TACs (e.g. misreporting). Also, the catches are not closely linked to the TACs because of high grading and discarding. Control is difficult because the fishery takes place in remote areas and some fleets process catches at sea. Therefore, effort regulation should be considered as a means of controlling fishing mortality on Rockall haddock.

Haddock is taken in a mixed fishery that currently includes substantial catches of blue whiting and non-assessed species such as grey gurnard.

There is a need for an internationally agreed management plan. Such a plan should involve extensive collaboration between stakeholders, scientists, and management authorities in both the design and the monitoring of conservation measures.

## Factors affecting the fisheries and the stock

## The effects of regulations

Following the NEAFC agreement in March 2001, an area of the NEAFC zone around Rockall was closed to fishing. Effort in the rectangle containing the closure declined following the closure coming into effect. There was also a decline in UK effort across the bank as a whole at this time, but an increase of effort in other areas of Division VIb. The most recent assessment of the stock shows an upturn in spawning biomass, but it is difficult to determine what contribution has been made by the efforts to protect juveniles in the closed area.

## Scientific basis

## Data and methods

Information about age composition in the landings is incomplete. The total catch composition has been estimated, but it is not possible to validate these estimates. Survey estimates are available from 1988-2003. In 2004-2005 new data on
biology and distribution were obtained, a trawl acoustic survey was carried out, and the biomass of haddock from the Rockall Bank was estimated.

## Uncertainties in assessment and forecast

The survey covers only part of the currently known distributional area of haddock. The survey index may thus in part reflect changes in the distributional pattern, and not only in stock dynamics. An annual survey covering the whole of the distributional area may improve assessment of the stock status.

There is an urgent requirement for well-designed scientific monitoring programmes capable of delivering accurate data on trends in abundance and composition of the fish fauna throughout the area, in a form that can support the development and implementation of a management plan for Rockall Bank.

## Comparison with previous assessment and advice

Last year, the assessment was only indicative of trends. The improved quality and documentation of the input data (especially the catch data) allowed an analytical assessment this year, although the assessment is still considered to be uncertain. The strong 2001 year class was not fully taken into account in the advice last year due to uncertainty about its strength. Data for 2005 confirm that the 2001 year class is strong and that it now contributes significantly to SSB. This, in combination with a decrease in fishing mortality in 2005, has changed the perception of the stock substantially and resulted in an increase in recommended catch.

### 5.4.25 Whiting in Division VIa (West of Scotland)

State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown | Not defined | The state of the stock is unknown, but <br> all indicators point towards the stock <br> being at an historical low. |

Long-term information on the historical yield and catch composition all indicate that the present stock size is low. A survey-based assessment covering the more recent period indicates that the stock is at its lowest level over this time period. Total mortality is at the highest level over the time period.

## Management objectives

There are no explicit management objectives for this stock.
Reference points

|  | ICES considers that: | ICES proposes that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\mathrm{lim}}$ is 16000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 22000 t. |
|  | $\mathbf{F}_{\text {lim }}$ is 1.0. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.6. |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not defined. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}(1998)$, the lowest observed spawning stock <br> estimated in previous assessments. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} * 1.4$. This is considered to be the minimum <br> SSB required to have a high probability of maintaining |
| :--- | :--- |
| SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of |  |
| assessments. |  |

The advice is based on information from abundance surveys. In the past the reference points have been estimated using a different basis such that they cannot be compared.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Given that SSB is estimated at the lowest observed level and total mortality at the highest level over the time period, catches in 2007 should be reduced to the lowest possible level.

## Management considerations

There are strong indications that management control is not effective in limiting the catch. Survey information shows that the total removal of whiting in Division VIa may be underestimated in the past decade relative to earlier periods. The effect of the fishery on the stock has therefore been evaluated in relative terms, and advice on absolute levels of future catches is not possible.

The proportion of fish discarded is very high and appears to have increased in recent years. Approximately half of the annual catch weight comprises undersized or low-value whiting which are discarded. Measures to reduce discards and to improve the exploitation pattern would be beneficial to the stock and to the fishery.

Effort data 1998-2005 from UK vessels (one of the main countries fishing in the area) suggests that overall, effort has declined in recent years in Area VIa, and that declines in particular categories have not been compensated for by rises in other categories. Larger-meshed whitefish demersal trawls were the most important gears in Vla prior to 2002, but since then there has been a marked decline in KW days by this category. This is principally explained by the recent, significant decommissioning schemes in the UK. Single-rig Nephrops trawls in the $70-$ to $99-\mathrm{mm}$ mesh category are the other major gears in use and effort by these seems to have been maintained at a fairly stable level throughout the time-
series. Numerous other gears make generally small contributions to the overall effort and the pattern in most of these has either been a downward trend (e.g. seine nets and midwater trawls) or fluctuation without trend (e.g. fixed nets).

The last accepted assessment in 2003 indicated a decrease in SSB by a factor 5 from the 1980s to the 1990s.

## Factors affecting the fisheries and the stock

## The effects of regulations

The fishery is regulated by a TAC that does not, however, seem to restrict catches.
The more widespread use of $110-\mathrm{mm}$ mesh nets in 2002 as well as the requirement to fit square mesh panels to certain towed gears since late 2000 , may have temporarily improved the selection pattern for whiting. However, the increase in minimum mesh size from 100 to 120 mm in 2001/2002 (before the introduction of effort regulation $27 / 2005$ ) partly caused a shift to $80-\mathrm{mm}$ mesh sizes in the mixed fishery trawls, due to the loss of valuable Nephrops catches. Poorer selectivity at this mesh size may have resulted in increased discarding and high grading.

With the introduction of effort regulation, vessel operators have effectively been further encouraged to reduce mesh size and shift to other fisheries, particularly Nephrops trawling, in order to gain more days at sea. It is not possible to evaluate whether the mesh size changes and effort limitations may have benefited whiting without information on the level of adherence to catch composition regulations required when using smaller mesh sizes.

The continued decline in the stock indicates that these measures alone have not proven sufficient to rebuild the stock to precautionary levels. Detailed analysis of the impact of the regulations will not be possible until data of sufficient quality become available.

## Changes in fishing technology and fishing patterns

Whiting in Division VIa are caught mainly by Scottish trawlers. There has been a reduction in trawl and seine effort, but with a more moderate reduction by Nephrops trawlers. At present a higher proportion of the overall effort is by relatively small-meshed trawls. There has been a tendency to shift from the use of heavy groundgear (like rockhopper) to lighter groundgear.

## Scientific basis

## Data and methods

A survey-based assessment was used to evaluate trends in SSB and recruitment.

## Uncertainties in assessment and forecast

Some changes have been made to the survey design in the past, but surveys are considered to be a reasonable indicator of long-term stock trend. Jumps in survey indices are observed in occasional years. Survey information indicates an increase in unaccounted removal from this stock. Absolute biomass estimates from landings may thus be biased, but it is not known to what extent. Thus, an analytical catch-at-age assessment is not acceptable as a basis for management advice. Advice has therefore been conditioned to the survey-based assessment patterns. The decrease in survey biomass in recent years implies that the unaccounted catch is causing harm to the stock.

## Comparison with previous assessment and advice

The assessment and advice are based on survey information and are consistent with last year's advice.

## Source of information

[^21]State of the stock
Landings of whiting from Division VIb are negligible. No assessment has been carried out on this stock.

## Source of information

Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, 9-18 May 2006 (ICES CM 2006/ACFM:30).

### 5.4.27 Saithe in Subarea VI (West of Scotland and Rockall)

This stock has now been combined with Saithe in Subarea IV (North Sea), Division IIIa (Skagerrak), and Subarea VI (West of Scotland and Rockall) and can be found in Volume 6-6.4.12.

### 5.4.28 Megrim in Subarea VI (West of Scotland and Rockall)

State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> Agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown. Landings show a declining trend since 1996.

## Management objectives

No explicit management objectives have been set for this stock.

## Reference points

No precautionary reference points have been defined for this stock.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Catches in 2007 should be no more than the recent (2002-2004) landings of about 2100 t . This includes landings in Division VIa and VIb and unallocated landings in Subarea IV.

## Management considerations

Although the international megrim landings in recent years have been below the precautionary TAC, some national quotas are restrictive and this may have led to underreporting of catches.

Area misreporting has been prevalent as megrim catches were misreported from Subarea VI into Subarea IV, due to restrictive quotas for anglerfish (i.e. vessels targeting anglerfish misreported all landings including megrim from Subarea VI into Subarea IV). In order to avoid misreporting by area, the TAC should include Subarea IV.

In the past, management of the megrim stock has been linked to that for anglerfish on the assumption that landings were correlated in the fishery. It was assumed that the anglerfish management would also constrain fishing mortality on megrim. This may no longer be true. Due to recent changes in the fishing pattern; the dynamics of the species are probably not linked.

The minimum landing size (MLS) of megrim was reduced in January 2000 to 20 cm (EC Regulation No. 850/98). The catch is routinely high graded and large numbers of fish continue to be discarded above this MLS.

## Factors affecting the fisheries and the stock

## The effects of regulations

New effort regulations provided an incentive for some vessels previously using $>100-\mathrm{mm}$ mesh in otter trawls to switch to smaller-mesh gears to obtain the right to more days-at-sea. This would also require these vessels to be targeting either Nephrops or anglerfish, megrim, and whiting with various catch and bycatch composition limits according to EC Regulation No. 850/98. No detailed information was available to quantify how many vessels have switched to using smaller meshes as a result of effort regulation as this information is not reliably recorded in logbook information for some countries.

## Changes in fishing technology and fishing patterns

There have been recent changes to the UK Scottish fleets with decommissioning schemes removing 96 of the 298 demersal trawlers (mesh sizes $>=100 \mathrm{~mm}$ ) between 2001 and 2004. This will have affected the effort, but due to uncertainty in the effort statistics it is not known to what extent effort has been reduced. The Irish fleet in Division VIa has also been reduced substantially and now the majority of the reported landings are made by only 12 vessels. In the case of the Irish fleet a large number of older vessels have been replaced by fewer modern whitefish vessels as part of a
national whitefish renewal scheme. There has also been an Irish decommissioning scheme, whereby around 40 fishing vessels ( $\sim 6000 \mathrm{GT}, 18000 \mathrm{~kW}$ ) have been permanently withdrawn from the Irish fishing fleet and removed from the Register of Sea Fishing Vessels in 2005 and 2006.

No information is available on changes in the French and Spanish fleets operating in this area.

## Scientific basis

## Data and methods

The stock was evaluated using information on landing compositions provided by Scotland and catch compositions provided by Ireland.

The quality of the available landings data, specifically the area misreporting and lack of effort and CPUE data for the main fleet in the fishery, severely hampers the ability of ICES to carry out an assessment for this stock. For stocks like megrim and anglerfish on the northern shelf, there is a general need for improved spatio-temporal resolution of commercial catch and effort data.

At the moment no survey series adequately covers this stock. Scottish and Irish groundfish surveys catch low numbers of megrim due to unsuitable gear and survey design. In addition, the Irish GFS survey series consists of only two years.

## Uncertainties in assessment and forecast

The quality of the landing statistics is unknown, and discard information and CPUEs from the main fleet are lacking. The surveys only cover a limited range of the known distribution of the stock and are not suitable for a survey-based assessment/forecast approach.

Comparison with previous assessment and advice
This year and last year there was no analytical assessment for this stock and the management advice was based on average landings. ICES has serious concerns about the accuracy of the landings data which are area misreported and underreported for this stock, but the advice is still based on maintaining recent landings.

### 5.4.29 Anglerfish in Division IIa (Norwegian Sea), Division IIIa (Kattegat and Skagerrak), Subarea IV (North Sea), and Subarea VI (West of Scotland and Rockall) (Lophius piscatorius and L. budegassa)

Two species occur in these areas, Lophius piscatorius and L. budegassa, although catches are almost exclusively of the former

## State of the stock

| Spawning biomass in to <br> relation <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

There are major uncertainties about catch and effort data for anglerfish, as well as limited knowledge about population dynamics and distribution. The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk. Official landings have declined substantially since the mid-1990s. The development of commercial CPUE from a logbook and observer data study in Subarea IV and Division VIa have shown that the stock is not in decline in recent years. The mean size of landed anglerfish from trawl landings from Division Vla shows no trend over the last ten years, while a decrease in mean size was evident for the gillnet landings from Division IIa in the most recent years.

## Management objectives

There are no explicit management objectives for this stock; the European Community and Norway are currently discussing the joint management of this shared stock.

## Reference points

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| There is currently no biological basis for defining $\mathbf{B}_{\text {lim }}$ or <br> $\mathbf{F}_{\text {lim. }}$ | $\mathbf{F}_{35 \% \mathrm{SPR}}=0.30$ be chosen as $\mathbf{F}_{\mathrm{pa}}$. This fishing mortality <br> corresponds to $35 \%$ of the unfished $\mathrm{SSB} / \mathrm{R}$. It is <br> considered to be an approximation of $\mathbf{F}_{\mathrm{MSY}}$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

The available information is inadequate to evaluate spawning stock or fishing mortality relative to precautionary reference points. The effort in fisheries that catch anglerfish should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data on both target and bycatch fish.

## Management considerations

## Recent TAC history

For a number of years, anglerfish in Subareas VI, XII, XIV and Division Vb (EU zone) were subjected to a precautionary TAC ( 8600 t ) based on average landings in earlier years. In 2002 the TAC was set at 4770 t and was further reduced to 3180 t in 2003 and 2004. The TAC for 2005 has been increased to 4686 t .

No TAC was set in Subarea IV prior to 1998. Landings in excess of the TAC in other areas were likely to be misreported into the North Sea. A precautionary TAC for North Sea anglerfish was introduced in 1999 in line with recent catch levels from the North Sea which included a substantial amount misreported from Subarea VI.

In light of the significant amount of non-reported landings the official statistics for 2003-2005 are considered to be not representative of actual landings. There is also significant area misreporting from West of Scotland and Skagerrak into the North Sea.

Estimates which account for area misreporting indicate that the percentage of the catch taken in Division IIIa and Subarea IV, and in Divisions VIa \& VIb in the years 1993-2002 average $60 \%$ and $40 \%$, respectively. In previous years,
these proportions have been used to allocate TAC between these areas. However, given the concerns about the veracity of the recent reported landings data, such proportionate splitting may no longer be appropriate.

## Mixed fishery considerations

Recent attempts at actually defining anglerfish fisheries have shown that the vast majority of the catch of anglerfish stems from mixed fisheries, catching sole, saithe, plaice, megrim, Nephrops, haddock, and cod, amongst others, with the landings of anglerfish actually being a relatively low percentage of the total. Optional effort restrictions aiming at a recovery of these other species will have a side-effect for the anglerfish too, but a shift from anglerfish-poor areas to anglerfish-rich areas might annihilate this effect. However, the statistical analysis of Scottish observer data did not show evidence for such shifts in the recent past.

Ghost fishing and discarding of fish not suitable for consumption due to long soaking times are known to be problems within some offshore gillnetting carried out by "flag-vessels" targeting anglerfish in Subareas VI and VII.

## Actions required

ACFM suggested in 2005 that a TAC regulation, such as that currently implemented, is not adequate to regulate fishing mortality within sustainable limits. Furthermore, it was implicit in the inadequate landings and effort data that a reliable estimation of $\mathbf{F}_{\mathrm{sq}}$ would also be impossible, as such a TAC would continue to result in misreporting. ICES considers that the most productive way forward would be a two-stage approach.

The first stage would be to substantially improve the quality and quantity of data collected on the fishery while maintaining exploitation at its current level. This was the basis of ICES recommendation in 2004 to allow the fishery to continue with the current effort (inasmuch as this can be determined - see above). This process was begun with the implementation of a Scottish tally book scheme. The programme also included the development of a targeted, industry collaboration trawl survey which started in 2005, and which will be repeated in 2006. This first stage of data collection is expected to take at least five years to establish useable time-series of fisheries-dependent and -independent data.

The second stage would then be launched to use these data to examine alternative management approaches and harvest control rules appropriate to this fishery in a fashion similar to that used elsewhere. Should evidence appear of a decline in the state of the stock during this period of data collection appropriate management measures may be initiated.

In the context of the two-stage approach, ICES recommended

- A detailed and stringent programme, including the mandatory reporting of both catch and effort data in logbooks should be established in all countries fishing for anglerfish to ensure high quality effort and landings data.
- Small-sized anglerfish are known to be discarded. Routine sampling schemes should be implemented in order to estimate levels of discarding.
- Female anglerfish reach $50 \%$ maturity at a length of about 90 cm . A high proportion of anglerfish catches consist of small anglerfish. Technical measures improving the selectivity of gears used in these fisheries should be implemented.

It is not yet clear to what extent these measures have been put in place.

## Factors affecting the fisheries and the stock

Until the mid-1980s, anglerfish was taken mainly as a by-catch in bottom trawl groundfish fisheries. Restrictive TACs for other species in Division VIa led to increased fishing pressure on anglerfish in that area, where they are now caught in a targeted anglerfish fishery and as a by-catch in other demersal fisheries, including roundfish fisheries in Division VIa, the haddock fishery on Rockall Bank, Nephrops fisheries, and fisheries in deeper waters. In the North Sea, anglerfish are caught as a by-catch in demersal fisheries, Nephrops and Pandalus fisheries in the northern and eastern parts of the North Sea, the Fladen Ground, and the Norwegian Deeps. In the Norwegian Deeps anglerfish has also been targeted by some demersal trawlers. A Norwegian large-mesh gillnet fishery targeting fish above $60-65 \mathrm{~cm}$ has been developed along the Norwegian coast since the early 1990s.

The fishery has expanded into deeper waters, areas believed to have been a refuge for adult anglerfish, and this new fishery therefore increases the vulnerability of the stock to overexploitation. Immature fish are subjected to exploitation for a number of years prior to first maturity.

## The effects of regulations

In 2005 the TAC was raised to take misreporting practices into account, but it is not known to what extent this has resolved the misreporting problems in this fishery. Legislation that came into action at the start of 2006 on registration of buyers and sellers in Scotland should make it more difficult to make unreported landings of this (and other) species. This is unlikely to have any major impact on area misreporting.

In 2005 specific anglerfish licenses were introduced in Ireland aiming to improve compliance. There has been an increased enforcement on anglerfish quotas in 2006.

## Other factors

The key features of the species' life history in relation to its exploitation are the location of the main spawning areas in relation to the exploited areas, and whether or not there is any systematic migration of younger fish back into the deeper waters to spawn. At present, despite the large increase in catches, there is no apparent contraction in distribution; fish are still recruiting to relatively inshore areas such as the Moray Firth and along the Norwegian coast in the northern North Sea. The fact that spawning appears to occur largely in deep water off the edge of the continental shelf may offer the stocks some degree of refuge. It is therefore likely that the current expansion of the fisheries into deeper water will have a negative effect on the stocks.

The distribution of anglerfish in the North Sea, Kattegat, and Skagerrak is associated with the distribution to the West of Scotland (Divisions VIa and VIb). It is likely that catches from these areas come from the same biological stock. Genetic studies have found no evidence of separate stocks and particle-tracking studies have indicated interchange of larvae between areas.

## Scientific basis

## Data and methods

Information on catch-at-length distribution is available from Scottish market sampling covering Divisions VTa, VIb, and IVa. Irish length-frequency data are also available for the West of Scotland (Division VIa). Danish length samples of landings covering mainly Division IVa are available from 2002. The Norwegian sampling-at-sea by the coast guard began in 2003 and covers also the eastern part of Division IVa. Catch and corresponding effort data based on official Danish logbook records covering the fisheries where anglerfish are caught were presented to ICES from 2005. It is hoped that together with UK data they could provide useful information on stock development. Logbook information from the Norwegian or French fisheries is not yet available.

## Information from the fishing industry

Personal logbook information from Scottish vessels was made available to scientists during 2004 and 2005 but could not be incorporated in the assessment because data mostly covered only a short time period. These logbooks also showed contradictions in the trends, particularly in recent years. A new tallybook scheme has been implemented as part of a long-term process to provide detailed information on the temporal and spatial distribution of catch rates in the Scottish fishery. An analysis of observer data presented this year indicated increasing LPUE.

## Uncertainties in assessments and forecasts

Although historical catches for the combined area are believed to have been adequately estimated there is uncertainty in the recent level of landings due to misreporting; these data can therefore not be used as the basis for stock assessment. There are inconsistencies in the survey data and traditional groundfish surveys do not appear to be useful indicators of anglerfish stock abundance. The weakness in the recruitment index and the problems in landings data would suggest that previous assessments may also be unreliable.

A targeted survey has begun in 2005 and will be continued. So far it has not been possible to fully include the results into the assessment.

There is considerable uncertainty in the biology and stock structure of anglerfish.
Comparison with previous assessment and advice
Analytical assessments have not been made since 2003. This year's advice is similar to last years.

### 5.4.30a Herring in Division VIa (North)

## State of the stock

The state of the stock is uncertain. Exploratory assessments this year confirm earlier perceptions of a lightly exploited stock ( $\mathrm{F}<=0.2$ ), but the level of the current biomass is uncertain. There appears to be no recent strong year classes since 2001.

## Management objectives

There are no explicit management objectives for this stock.
Reference points -defined in 2004

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary <br> reference points$\quad$ Approach | $\mathbf{B}_{\mathrm{lim}}$ is at 50000 t. | $\mathbf{B}_{\mathrm{pa}}$ is at 75000 t. |
|  | $\mathbf{F}_{\text {lim }}$ not defined. | $\mathbf{F}_{\mathrm{pa}}$ not defined. |

Yield and spawning biomass per Recruit
$F$-reference points

| Reference point | F <br> multiplier | Absolute <br> F |
| :--- | :---: | :---: |
| $\bar{F}_{(3-6)(2002-2004)}$ | 1.00 | 0.19 |
| $\mathbf{F}_{0.1}$ | 0.85 | 0.16 |
| $\mathbf{F}_{35 \% \text { SPR }}$ | 0.90 | 0.17 |
| $\mathbf{F}_{\text {low }}$ | 0.33 | 0.06 |
| $\mathbf{F}_{\text {med }}$ | 1.48 | 0.27 |

In the absence of defined PA reference points for fishing mortality, candidates for target reference points are between $\mathbf{F}_{0.1}$ and $\mathbf{F}_{\text {med }}$. The Yield-per-Recruit curve rises slowly above $\mathbf{F}_{0.1}$ and there is a $12 \%$ gain in long-term yield by fishing at the higher fishing mortality of $\mathbf{F}_{\text {med }}$.

Technical basis

| $\mathbf{B}_{\mathrm{lim}}:$ lowest reliable estimate of SSB. | $\mathbf{B}_{\mathrm{pa}}:$ Approximately $1.5 \mathbf{B}_{\mathrm{lim}}$. |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ is not defined. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

The recent level of fishing mortality is low and decreasing. The SSB, although uncertain is around $\mathbf{B}_{\mathrm{pa}}$. Given that the perception of the stock is the same as last year, the 2006 TAC should be applicable in 2007 also.
Management considerations
A catch forecast was not made in 2006 for technical reasons (described below). Thus, the current advice is based on the perception that the stock status is stable and lightly exploited. This perception should be confirmed by the next acoustic survey which will be available by September 2006. There appear to have been no strong year classes since 2001.

## Ecosystem considerations

Herring in this area is an important food source for seabirds, sea mammals, and many piscivorous fish.

## Factors affecting the fisheries and the stock

## Changes in fishing technology and fishing patterns

Historically, catches have been taken from this area by three fisheries:
i) A Scottish domestic pair trawl fleet and the Northern Irish fleet operating in shallower, coastal areas, principally fishing in the Minches and around the Island of Barra in the south; younger herring are found in these areas. This fleet has reduced in recent years.
ii ) The Scottish single-boat trawl and purse seine fleets, with refrigerated seawater tanks, targeting herring mostly in the northern North Sea, but also operating in the northern part of Division VIa (N). This fleet now operates mostly with trawls, but many vessels can deploy either gear.
iii ) An international freezer-trawler fishery has historically operated in deeper water near the shelf edge where older fish are distributed. These vessels are mostly registered in the Netherlands, Germany, France, and England, but most are Dutch owned.

In recent years the catch of these last two fleets has become more similar and has been dominated by younger adults, due to increased recruitment into the stock from the stronger 2000 and 2001 year classes.

In 2005, the Scottish trawl fleet fished in areas similar to the freezer trawler fishery, and not in the coastal areas in the southern part of Division VIa (N). The Northern Irish fleet fished in both the north and the south of Division VIa (N).

As a result of perceived problems of area-misreporting of catch from IVa into VIa (N), Scotland introduced a fishery regulation in 1997 with the aim to improve reporting accuracy. Under this regulation, Scottish vessels fishing for herring were required to hold a license either to fish in the North Sea or in the west of Scotland area (VIa (N)). Only one licensed option could be held at any one time. However in 2004, the requirement to carry only a single license was rescinded. Area-misreporting of catch taken in area IVa into area VIa (N) then increased in 2004 and continued in 2005. It is possible, therefore, that the relaxation of this single area license has contributed to resurgence in area-misreporting. Reinstating the single-area license requirement should be considered as it appears to be helpful in the management of this area. It is also important that all nations with reported official catch in VIa (North) investigate the accuracy of the catch area reported.

## Other factors

The stock identity is uncertain and is being reviewed by an ongoing EU-funded project.

## Scientific basis

## Uncertainties in assessment and forecast

A potential year effect is apparent in the 2005 acoustic survey; causing a problem with the scaling of the SSB in the most recent years. The assessment is sensitive to the inclusion of the most recent acoustic estimate (Figure 5.4.30.1). Estimates of fishing mortality are still consistent and low.

Catch estimates from observer programmes indicate that misreporting of the catches has decreased until 2003 and risen again in 2004 and 2005. The figure for misreporting used for 2005 is 14000 tonnes. Better information on the catches had been obtained and biological sampling of catches had improved over the last 4-5 years, but it declined both in 2004 and 2005.

## Comparison with previous assessment and advice

Even though the SSB estimate in the current assessment is uncertain, the perception of trends in fishing mortality is unchanged from last year. The 2007 SSB estimate needs to be confirmed through the July survey as noted above.

### 5.4.30.b Herring in Division VIa (North) - update

## Background

In the June 2006 advice for this stock, ICES noted that "a potential year effect is apparent in the 2005 acoustic survey; causing a problem with the scaling of the SSB in the most recent years. The assessment is sensitive to the inclusion of the most recent acoustic estimate (Figure 5.4.30.1). Estimates of fishing mortality are still consistent and low." and that "The 2007 SSB estimate needs to be confirmed through the July [acoustic] survey as noted above".

This section provides an update of the advice for Herring in Division VIa (North) based on the new survey information that has become available in September 2006.

## State of the stock

The state of the stock is unchanged compared to the June 2006 advice and remains uncertain. The new exploratory assessment confirms earlier perceptions of a lightly exploited stock with a relatively stable biomass. The absolute level of the current biomass is uncertain. The new survey information of 2006 confirms the impression of a relatively stable stock. (figure 5.4.30.b.1).

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
The recent level of fishing mortality appears to be low. The SSB is uncertain appears to be relatively stable. Given that the perception of abundance is similar to recent years, there is no basis to change the advice of June 2006.

## Scientific basis

## Data and methods

The exploratory assessment is based on catch-at-age data (1976-2005) and acoustic survey data (1987-2006). The assessment is indicative of trends only.

## Uncertainties in assessment and forecast

A potential year effect was apparent in the 2005 acoustic survey which caused a problem with the scaling of the SSB in the most recent years. The surveys is noisy which is evident from the lack of correspondence between the exploratory assessment and the individual survey points (figure 5.4.30.b.1)

## Comparison with previous assessment and advice

In 2005 ICES based the advice on an assessment that estimated the stock to be stable just above Bpa. The SSB estimate in this exploratory assessment is similar to the trend that was estimated in June 2006 which indicates a small decrease in stock size in 2002-2005. However, the survey in 2006 indicates that the stock is likely to be at the same level as in the previous years. This is interpreted that the stock is still in a stable condition. The advice is reiterated from June 2006.

## Source of information

Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N} 14-23$ March 2006 (ICES CM 2006/ACFM:20).

### 5.4.31 Norway pout in Division VIa (West of Scotland)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown. The size of the stock is unknown.

## Management considerations

The fishery is a small-mesh trawl fishery operated by Danish vessels.

## Scientific basis

## Uncertainties in assessment and forecast

Catches are highly variable. The only data available are official landings statistics. There is no information available on which to base scientific advice.

## Ecosystem considerations

Bycatches in this fishery should be quantified and made available to ICES.

## Source of information

### 5.4.32 Sandeel in Division VIa (West of Scotland)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown. There is no current information on which to evaluate the state of the stock.

## Management objectives

There are no explicit management objectives for this stock.

## Single-stock exploitation boundaries

The stock was last assessed in 1996 and a new assessment has not been made. At that time it was considered to be within safe biological limits.

## Reference points

No reference points have been defined for this stock.

## Management considerations

The current management regime uses a multi-annual TAC of 12000 t per year with the fishery closed from 31 July. Access is limited to vessels with a track record. These arrangements took effect in 1998 for a period of three years and were renewed in 2001 for another three years.

## Ecosystem considerations

Fishing grounds are close inshore and often adjacent to large colonies of seabirds for which the sandeel population is an important food supply, especially during the breeding season.

### 5.4.33 Nephrops in Division VIa (Nephrops Area C)

There are three Functional Units in Division VIa: a) North Minch (FU 11), b) South Minch (FU 12), and c) Clyde (FU 13).

## State of the stock

| Spawning biomass in to <br> relation <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The uncertain quality of fishery information, particularly landings, is inadequate to use analytical methods relying on accurate catch statistics to evaluate spawning stock or exploitation rate relative to risk. Results from TV surveys, and trends in mean size, however, suggest that the stocks comprising this Division VIa appear to be exploited at a sustainable level.
a. North Minch: The TV survey estimate of abundance for Nephrops in the North Minch suggests that the population remained relatively stable between 1994 and 2001, but increased sharply between 2001 and 2003. The higher level of abundance observed in 2003 is maintained in the latest (2005) survey. The increase in abundance observed between 2001 and 2003 coincides with the increases in CPUE observed in the catch data, particularly for the smaller size category, interpreted as increase in recruitment. The mean size of larger Nephrops ( $>35 \mathrm{~mm}$ carapace length) in the landings has been stable throughout the time-series.
b. South Minch: The TV survey estimate of abundance for Nephrops in the South Minch suggests that the population fluctuated without trend between 1995 and 2000 , but remained more stable and at a slightly higher level from 2001 to 2003. A further increase in abundance in 2004 has been maintained in the latest (2005) survey. The increase to the more stable level of abundance observed after 2001 coincides with the increase in CPUE and reduction in mean size observed in the catch data, particularly for the smaller size category, interpreted as an increase in the recruitment. The mean size in larger Nephrops ( $>35 \mathrm{~mm}$ carapace length) in the landings has been stable throughout the time-series.
c. Clyde: Two TV surveys are conducted in the area. The TV survey estimate of abundance for Nephrops in the Firth of Clyde suggests that the population has increased steadily since 1999, with the latest estimate (2005) being the highest in the series. Reductions in the mean size in catches of small animals ( $<35 \mathrm{~mm}$ carapace length) coincide with increases in CPUE. The increase to the more stable level of abundance observed after 2001 likewise coincides with the increase in CPUE, suggesting strong recruitments in 1995, 1998, and 2003. A series of good recruitments would be consistent with the increase in abundance observed from the TV surveys. The higher levels of discarding observed in recent years are associated with the increase in CPUE of smaller individuals. The mean size in larger Nephrops ( $>35 \mathrm{~mm}$ carapace length) in the landings has declined very slightly throughout the time-series. The less detailed TV survey in the Sound of Jura is of shorter duration and suggests that the population has been fairly stable over the last 5 years.
d. Nephrops are also caught outside these areas. TV surveys in deep water suggest widespread distribution at low density, and surveys at Stanton Bank and in sea lochs (where important creel fisheries occur), suggest widespread distribution there also.

## Management objectives

No specific management objectives have been set for this fishery.

## Reference points

Precautionary reference points relating to stock biomass and fishing mortality rate have not been determined for Nephrops.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
The effort in this fishery should not be allowed to increase relative to the past three years. In addition to the ceiling on effort ICES advises that the exploitation ratio in this stock should be no more than $15 \%$, until such time that more
reliable catch information becomes available. This corresponds to landings of less than 3200 t for North Minch, 7200 t for the South Minch, and 3800 t for the Firth of Clyde stock. Landings from other areas in Division VIa should be below the average of 2003-2005, corresponding to landings of 2100 t .

## Short-term implications

Outlook for 2007
A range of candidate harvest ratios were applied to the TV abundance estimates (average of last 3 years) and adjusted to the landed weight equivalent to provide predictions of landings in 2007 under the different options as follows:

| Harvest ratio | North Minch | South Minch | Firth of Clyde | Total |
| :--- | :---: | :---: | :---: | :---: |
| $\mathbf{1 5 \%}$ | $\mathbf{3 2 1 3}$ | $\mathbf{7 2 2 6}$ | $\mathbf{3 7 6 5}$ | $\mathbf{1 4 2 0 4}$ |
| $20 \%$ | 4284 | 9634 | 5020 | $\mathbf{1 8 9 3 8}$ |
| $25 \%$ | 5355 | 12043 | 6275 | 23673 |

Note: These are predicted landings for the three Functional Units only and, in the case of the Clyde this only includes the Firth of Clyde component, not the Sound of Jura component.

Additional allowance needs to be made for Nephrops in areas that are outside the main FUs but still part of the VIa TAC area (Management C). Some of these areas are now being surveyed by TV, but the data series is short. A predicted landing based on recent landings provides a short-term solution which should be replaced as soon as more reliable data become available. Figures below should be added to the predicted landings figure adopted:

Creeling areas: average creel landings 2003-2005
Sound of Jura: average landings 2003-2005
$=1673$ tonnes
Other areas in Management Area C: 2003-2005
$=35$ tonnes

Management considerations
Landings divided by survey biomass indices is a proxy of the exploitation ratio. Available information indicates that landings in recent years are most likely an underestimate of actual landings. The landings reported in the 1990s are considered to be more accurate. The lower bound of the exploitation ratio for the stocks during that period was around $15 \%$. The general increase in Nephrops abundance in recent years indicates that using a $15 \%$ exploitation ratio as a basis for setting a TAC will probably not have a detrimental effect on the stocks.

The TAC in 2006 was increased substantially in this area to allow catches to be reported. This higher TAC was based on a harvest ratio of $20 \%$ without additional allocation for stocks not assessed by TV surveys. It is not clear as yet if this harvest ratio of $20 \%$ will be sustainable in the longer term; therefore ICES maintains the advice given last year of using a $15 \%$ harvest ratio. When more reliable catch and effort data become available, the $15 \%$ harvest ratio can be reevaluated. ICES considers that the harvest ratio could be adaptively adjusted over time in the fishery to ensure that the stock is exploited at a sustainable ratio. Implicit in this approach is that catch and effort are reported accurately and the fishery is managed at an appropriate geographic scale (i.e. Functional Unit).

The Nephrops trawl fisheries take bycatches of other species, especially haddock and whiting but also cod, megrim, and anglerfish. The management of these fisheries should be seen in the context of mixed fisheries.

A recent investigation suggests that bycatches of cod are generally low (as is the cod stock) in Division VIa in the Nephrops fisheries. Nevertheless, young cod are known to occur in inshore areas and any future emerging year classes should not be subjected to mortality as bycatch in smaller-mesh fisheries. The use of $70-\mathrm{mm}$ mesh continues in a number of the VIa Nephrops fisheries. Every effort should be made to eliminate bycatches of cod in Nephrops fisheries.

## Factors affecting the fisheries and the stock

## The effects of regulations

The minimum landing size for Nephrops is 20 mm carapace length (CL), and less than $0.5 \%$ of the animals are landed under size. Discarding takes place at sea. The main bycatch species is haddock, although whiting, Norway pout, and flatfish also feature significantly in discards.

The introduction of 'Buyers and Sellers' legislation to this area and the higher TACs in 2006 are expected to lead to major improvements in the quality of fishery data over the next few years.

## Scientific basis

## Data and methods

There is considerable uncertainty about landings. discard, and effort data for these stocks and assessments based on quantitative fishery data are considered unreliable at the present time. TV surveys of the main Functional Units have been carried out for over 10 years now and provide estimates of abundance and variance. Recent TV surveys indicate higher stock abundance than in recent years and have remained consistently high in this period. Though subject to continuous refinement the method is considered to give more reliable indications of abundance than other approaches.

Comparison with previous assessment and advice
The assessment and advice is consistent with last year's advice which was also based on a no effort increase and a harvest ratio of $15 \%$.

### 5.4.34 Nephrops in Division VIIa, North of $53^{\circ} \mathrm{N}$ FU $14 \& 15$ (Area J)

## There are two Functional Units in this area: a) Irish Sea East (FU 14) and b) Irish Sea West (FU 15).

## State of the stock

| Spawning biomass in to <br> relation <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The uncertainty in the fishery information, particularly landings, makes such information inadequate for use by analytical methods and the status of spawning stock or exploitation rate cannot be evaluated relative to risk. Results from TV surveys and trends in biological characteristics, however, suggest that the stocks in Division VIIa are exploited at a sustainable level.
a) Irish Sea East: Annual LPUEs have been fluctuating, but were generally lower in the 1990s and 2000s than in the late 1970s and early 1980s. Landings have been fairly stable since the mid-1980s.
b) Irish Sea West: TV survey estimates of abundance for Nephrops in Irish Sea West are available only since 2003. They show that the stock has declined in 2004 and 2005 from the 2003 level. Indices of abundance from the August trawl survey are available for a longer period. They show the stock to have reached its highest abundance in 2003 and also indicate a decline from this level in 2004 and 2005. The 2005 trawl survey index of abundance is close to the long-term (1994-2004) mean abundance estimates. Mean size in the catches and in trawl surveys has been stable over time.

## Management objectives

Nephrops in Division VIIa are managed through a total TAC for Subarea VII. There are no specific management objectives set for this fishery.

## Reference points

No reference points have been determined for Nephrops.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
Given the uncertainties surrounding the landings for this stock it is not possible to provide advice on catches in 2007. The stocks in this area appear to be in good condition and have sustained current levels of effort for many years. Therefore ICES advises that effort in this fishery should not be allowed to increase compared to 2003-2005 levels.

## Management considerations

The advice implies maintaining fishing effort in Nephrops-directed fleets at recent levels of around 4.4 million kW days. This is based on the 2003-2005 average effort by Nephrops single- and twin-rig trawls as estimated by STECF for 2003 and 2004 and updated by ICES for 2005. If effort can be effectively controlled, this fishery can be managed without a TAC.

If the true landings can be established ICES considers that the harvest ratio based on the TV surveys could be adjusted over time in the fishery to ensure that the stock is exploited at a sustainable rate in the long term. Implicit in this approach is that catch and effort are reported accurately and that the fishery is managed at an appropriate geographic scale (i.e. Functional Unit).

The Nephrops trawl fisheries take bycatches of other species such as cod and particularly juvenile whiting. The management of these fisheries should be seen in the context of mixed fisheries.

## Factors affecting the fisheries and the stock

## The effects of regulations

The minimum landing size for Nephrops is 20 mm carapace length (CL), which is appropriate for the gears used in this area. Almost all of the discarded catch are above the minimum landing size and discard sampling indicates that Nephrops over 25 mm CL are mainly retained.

Separator trawls were introduced in the Irish fishery in 2000 in an attempt to reduce cod bycatches. The uptake of separator trawls has increased in recent years (to around $80 \%$ of the vessels in 2002).

## Scientific basis

## Data and methods

There is considerable uncertainty in landings data for these stocks and assessments that rely on quantitative fishery data are considered unreliable at the present time. Size distribution of catches in the fishery and surveys is available for a longer period and these data are considered reliable. The time-series of underwater TV surveys is very short and the 2006 estimate is not yet available; however, the abundance estimates in recent years are consistent with the August trawl survey which has a longer series. Although subject to continuing refinement the UWTV method is considered to provide more reliable indications of stock status than other approaches.

Comparison with previous assessment and advice
The assessment is similar to last year. The advice is similar to last year, effort information is now available for the Nephrops fleets and a reference period has been given.

### 5.4.35 Nephrops in Divisions VIIb,c,j,k

There are 4 Functional Units in this Divisions VIIb,c.j,k: a) Porcupine Bank (FU 16), b) Aran Grounds (FU 17), c) Ireland SW and SE Coast (FU 19), and d) Ireland NW Coast (FU 18).

The TAC area applies to the whole of Area VII, including VIIa (Section 5.4.34).

## State of the stock

No quantitative assessment of this stock is available.
For FU 16 (Porcupine bank) landings have been variable over time. Maximum landings of more than 4000 t were observed in the early 1980s before declining to less than 1000 t in the early 2000s. Landings increased in 2005 to over 2000 t . For most fleets, landings and LPUEs were at low levels in the early 2000s. Landings and LPUEs seem to have increased for some fleets recently.

For FU 17 (Aran Grounds) the maximum landings of 1400 t were reported in 1998. Since then the reported landings have shown a decline. The LPUEs have fluctuated without trends around $37 \mathrm{~kg} / \mathrm{hr}$ over the time-series. A recent UWTV survey series shows increased burrow density and estimated biomass from 2002-2004 before declining slightly in 2005.

For FU 19 (Ireland SW and SE coast) landings have been variable throughout the time-series, reaching the highest observed levels in 2002-2004. Landings declined sharply in 2005. The LPUEs have fluctuated considerably over the short time-series.

Landings FU 18 (Ireland NW coast) have been negligible in recent years and there are no major Nephrops fishery in this area.

## Management objectives

No management objectives have been set for this fishery.

## Reference points

There are no reference points and no yield-per-recruit table for this fishery.

## Single-stock exploitation boundaries

There are no exploitation boundaries for this stock. Although the total reported landings appear relative stable for FUs $16,17,18$, and 19 combined ( $\sim 3500 \mathrm{t}$ ), there have been large changes in fishing effort and landings for individual stocks. Furthermore, landings may be unreliable for some countries. This may lead to unbalanced exploitation of stocks and overfishing. ICES herefore advises that these Nephrops fisheries should be constrained to recent levels of effort at an appropriate geographical scale (FU).

## Management considerations

The FU populations are distinct populations and management should be matched to these FUs. Currently the TAC is set for Subarea VII. Therefore there is a risk that inappropriate levels of effort may occur for these stocks due to effort shifts from other areas.

Fishing effort directed at Nephrops will have implications for the hake stock in the mixed fisheries unless species and size selectivity of gears can be improved.

## Factors affecting the fisheries and the stock

Changes in fishing technology and fishing patterns
In FU 16 (Porcupine bank) landings effort and LPUEs indicate increased targeting of Nephrops over the last two years by all countries involved in the fishery.

In FU 17 (Aran Grounds) the typical vessel length is $13-38 \mathrm{~m}$ compared to $15-25 \mathrm{~m}$ in 2003, while engine power ranges from $120-870 \mathrm{~kW}$ compared to $150-550 \mathrm{~kW}$ in 2003 . The most recent change in the fishery is the proportion of twin-rig vessels, which has increased to over $90 \%$ of the fleet in the past eight years. There have also been changes to the fleet structure which implies that nominal fishing effort is not an appropriate indicator of effective fishing effort.

In FU 19 (Ireland SW and SE coast) there has been a shift of effort to Nephrops by Irish vessels due to a combination of factors. There has been increasing enforcement of the anglerfish quota, leading to detention of a number of Irish vessels. As a result several vessels in the $20-$ to $24-\mathrm{m}$ category based in the southwest of Ireland have converted to Nephrops. Due to the low price of whitefish species during 2004 and in early 2005 a number of Irish seine net vessels have also switched to Nephrops.

## Scientific basis

## Data and methods

There are some length-structured data available, but growth rates cannot be well determined. There are concerns about the accuracy of the landings statistics in some fleets. Analytical assessments are not feasible at present.

For FU 16 (Porcupine bank) annual landings length compositions for males and females are available from Spain (1986-2005), France (1995-2005), and Ireland (1995-2005). LPUE and effort data are available for the Spanish (SPCORUTR7), French (FR-PORCUPINE), and Irish fleets (Figure 5.4.35.2).

For FU 17 (Aran Grounds) landings length compositions by sex are available for 1995-2000. Since 2001 a catch and discard sampling programme has been in place which shows the discarding of smaller individuals. An effort and LPUE data set for Irish trawlers from 1995-2005 is available (Figure 5.4.35.3). Results of the TV survey for this stock are shown in Table 5.4.35.1.

For FU 19 (Ireland SW and SE coast) length-frequency data of the landings were collected on an irregular basis in the years 1996-1997, 1999, and 2002 to 2005. Spatial and temporal coverage is problematic because landings from FU 19 originate from several discrete grounds. In 2005 length-frequency data were only available for quarters 2 and 3. Since 2001 a catch and discard sampling programme has been in place which shows the discarding of smaller individuals. Effort and LPUE data are available for the Irish Nephrops fleet in FU 19 from 1995-2005 (Figure 5.4.35.1).

For FU 18 (Ireland NW coast) only landing data are available.

## Comparison with previous assessment and advice

The advice last year was based on average landings. As there are serious doubts about the quality of the landings data, the advice is now presented in terms of no increase in effort.

| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

In the absence of reference points, the state of the stock cannot be evaluated in this regard. Landings have fluctuated around 4500 t since the mid-1990s. The landings per unit effort (LPUE) series for the French Nephrops trawlers increased between 1999 and 2002 and then stabilised at this level. The Irish LPUE seems to have a slight downward trend but with large variations from year to year.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

No reference points have been established.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary considerations
Landings have been relatively stable at around 4600 t in recent years and there are no other specific concerns about recent stock development. Therefore, ICES advises that Nephrops fisheries in this area should be constrained at recent levels of effort.

The landings from all FUs in this TAC area is presented in Section 5.4.36 (Nephrops in Division VIIa).

## Management considerations

Management for Nephrops stocks should be conducted at an appropriate geographic scale (e.g. Functional Unit). Currently the TAC is set for Subarea VII, and this may allow unrestricted catches for stocks under excessive fishing pressure where catches should be limited.

Nephrops in these functional units are known to occur in several areas of muddy sediment and the stock structure is uncertain. The Nephrops fisheries target different areas, and Nephrops catches and landings show very different size structures. These fisheries also have differences in non-Nephrops bycatch composition. Cod, whiting, and to a lesser extent haddock are the main bycatch species.

Discarding of small Nephrops is substantial. Because of the heterogeneity of FUs 20-22 and of divergence in the exploitation pattern of the main fleets, the discard rate seems to have notably fluctuated between fleets or years. This shows that trawls currently used to target Nephrops are not technically adapted to select marketable Nephrops. Discarding of other fish species is also a problem in Nephrops fishery.

There are no specific concerns of underreporting in this area.

## Ecosystem considerations

Nephrops occur in discrete patches where the sediment is suitable for them to construct their burrows. There is a larval phase where there may be some mixing with Nephrops from other areas depending on the oceanographic conditions, but the mechanisms for this in the Celtic Sea are not currently known.

Cod has been identified as a predator of Nephrops in some areas, and the generally low level of the cod stock is likely to have resulted in reduced predation on Nephrops.

## Factors affecting the fisheries and the stock

Landings from this stock are reported by France, the Republic of Ireland, and the UK. The contribution of the French landings to the total quantity gradually decreased from $80-90 \%$ at the end of the 1980 s to $50-60 \%$ at the beginning of the 2000s. There has been a considerable increase in Irish landings, from around 500 t to more than 2000 t in 15 years. There has also been increasing effort by Irish vessels targeting Nephrops in the Celtic Sea in recent years.

## The effects of regulations

The minimum EU landing size (MLS) for Nephrops in this area is 8.5 cm of total size ( 25 mm CL ), whereas French Producers' Organizations adopted a specific regulation of 11.5 cm of total size ( 35 mm CL ). There has been strong discarding above this EU 8.5 cm MLS by the French fleet, but some recent indications point out that the discard rate of French trawlers may have decreased. The decrease must be substantial to determine whether this decrease is induced by the gradual adoption of new mesh regulations or by a recruitment decline.

## Changes in fishing technology and fishing patterns

There has been increasing diversification into different Nephrops fisheries within this area by the Irish fleet. Several old fishing units of the French fleet were replaced by more recent ones, but the contribution of this change to the fishing pattern remains unknown. A fishing power analysis has not yet been carried out.

## Scientific basis

## Data and methods

The basic source of information is landings and LPUE together with some information on the length distributions of the landings. There are some concerns about increasing efficiency of the French fleet. Discarding is substantial, but varies between fleets and areas.

There is limited fishery-independent survey data for this stock and none of the current surveys in this area specifically target Nephrops. There was an UWTV survey for this stock for the first time in 2006, but the results are not yet available.

French discard data are available for some years only (1985, 1991, and 1997; only 1997 is entirely useful for compilations). Some methodological investigations on discard derivation for missing years improved quantitative information on actual catches. It is expected that the new Irish catch sampling programme implemented under EU DCR will improve the quality of the series for future assessment. More frequent discard samplings of the French fleet would greatly improve the quality of the length-frequency data.

## Information from the fishing industry

Prior to the assessment, meetings were held with the Irish and French industry. The French industry underlined that the increase of LPUE series since the end of the 90s may be caused by the change of the global fishing efficiency of the fleet because some old vessels were replaced by more recent ones.

Comparison with previous assessment and advice
It was not possible to carry out a reliable analytical assessment for this stock, as was the case last year as well. The advice is based on recent average landings and indicators as LPUE and CPUE.

## Source of information

Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, 27 June-6 July 2006 (ICES CM 2006/ACFM:33).

Figure 5.4.36.1 Nephrops in VIIgh. LPUE and fishing effort series for French (top) and Irish fleet (bottom). The CPUE indices are calculated by including discard sampling on-board and, failing that, by a derivation method.

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The state of the stock is unknown. No assessment was performed, due to the short series of data and lack of reliable tuning indices.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

## No precautionary reference points have been established.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Catches in 2007 should be no more than the recent average (2003-2005) of around 287 t , in order to avoid an expansion of the fishery until there is more information to facilitate an adequate assessment.

## Short-term implications

No forecast.

## Management considerations

Sole are taken as part of a mixed demersal fishery by otter trawlers. Management options proposed for sole should also take into consideration other demersal fish species taken in the fishery.

Area misreporting from VIIf,g into VIIhjk is known to be a problem in some fleets, but landings data have not been corrected for this. The extent of other misreporting is not known.

## Factors affecting the fisheries and the stock

Sole are predominantly caught in mixed-species otter trawl fisheries in Division VIIj. These vessels target mainly hake, anglerfish, and megrim. Sole are also caught in flatfish-directed beam trawler fisheries. Seiners generally take a lesser catch of sole. Ireland and Belgium are the major participants in this fishery.

## The effects of regulations

Sole is managed through TAC and technical conservation measures. Boat quota restrictions were imposed on Irish vessels for hake, cod, and anglerfish, and these are likely to have impacted the sole landings.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in Divisions VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002).

## Changes in fishing technology and fishing patterns

Ireland, UK, and France are the major participants in this fishery. Sole were predominantly caught by Irish otter trawl vessels in Division VIIj, within a mixed-species fishery. Irish otter trawl vessels operate from the ports of Castletownbere, Dingle, Union Hall, Baltimore, and Schull. Increasingly these Irish vessels target mainly hake, anglerfish, and megrim and not the more traditional inshore species (plaice, sole, whiting, and cod). The Irish beam trawlers and seiners generally take a lesser catch of sole. Other international fleets operating in this area are the UK, French otter trawl, and Belgian beam trawl fleets.

## Scientific basis

## Data and methods

Data update and screening methods only. No analytical assessment was performed.

### 5.4.38 Sole West of Ireland (Division VIIb,c)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The state of the stock is unknown. No assessment was performed, due to the short series of data and lack of reliable tuning indices.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

## No precautionary reference points have been established.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Recent catches have been close to the TAC of 65 t . Catches should not be allowed to increase unless it can be shown that an expansion of the fishery is sustainable.

## Short-term implications

No forecast.

## Management considerations

The recent average catches (2002-2004) were 64 t . Sole are taken as part of a mixed demersal fishery by otter trawlers. Management options proposed for sole should also take into consideration other demersal fish species and Nephrops taken in the VIIb,c fishery.

## Factors affecting the fisheries and the stock

Ireland is the major participant in this fishery with around $75 \%$ of the international landings in recent years. Sole are normally caught in a mixed species otter trawl fisheries in Division VIIb. These vessels mainly target other demersal fish species and Nephrops.

## The effects of regulations

Sole is managed by a precautionary TAC and technical measures. The agreed TAC for 2004 and 2005 was 65 t , which is a decrease from the previous TAC of 80 t for 2001-2003.

Council Regulation (EC) No. 1954/2003 established measures for the management of fishing effort in a 'biologically sensitive area' in Divisions VIIb, VIIj, VIIg, and VIIh. Effort exerted within the 'biologically sensitive area' by the vessels of each EU Member State may not exceed their average annual effort (calculated over the period 1998-2002).

## Changes in fishing technology and fishing patterns

Sole are opportunistically exploited in otter trawl fisheries in this area and there is no known change in fishing technology and fishing patterns in this area.

## Scientific basis

## Data and methods

Data update and screening methods only. No analytical assessment was performed.

## Source of information

Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, 27 June- 6 July 2006 (ICES CM 2006/ACFM:33).

| Year | ICES <br> Advice | Single-stock exploitation boundaries | Predicted catch corresp. to advice |  | Agreed TAC | ACFM landings |

[^0]:    Weights in ' 000 t .
    ${ }^{1}$ TAC covers Subareas VII (except Division VIIa) and VIII. ${ }^{2}$ For the VIIf +g stock component. ${ }^{3}$ For the VIIf-h stock component. ${ }^{4}$ For the VIIe-h stock component. ${ }^{5}$ For the VIIe-k stock component. ${ }^{6}$ ACFM landings for the period 19882002 revised.

[^1]:    Weights in ' 000 t .
    ${ }^{1}$ Precautionary TAC for VII, VIII, IX, and X.
    ${ }^{2}$ VIIa allocation of precautionary TAC.
    ${ }^{3}$ Incomplete data.
    ${ }^{4}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.
    $\mathrm{n} / \mathrm{a}=$ not available .

[^2]:    *Preliminary

[^3]:    Weights in ' 000 t .
    ${ }^{1}$ Not including discards from the Nephrops fishery.
    ${ }^{2}$ From the Nephrops fishery.
    ${ }^{3}$ Including estimates of misreporting.
    ${ }^{4}$ Landings only, no discards included.
    $\mathrm{n} / \mathrm{a}=$ not available.

[^4]:    a: Preliminary
    b: Preliminary. Reported as VIIb-k.
    c: As available from Eurostat in June 2005 (http://www.europa,eu.int/comm/eurostat).

[^5]:    ${ }^{1}$ See VIIg-k.

[^6]:    ${ }^{2}$ Single-stock boundary, the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.

[^7]:    Weights in ' 000 t .
    ${ }^{1}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.
    (Official landings figures have been corrected following the discovery of errors in the time-series).

[^8]:    Weights in '000 t.
    ${ }^{1}$ TACs for Divisions VIId,e.
    ${ }^{2}$ For Division VIIe only.
    ${ }^{3}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.

[^9]:    ${ }^{1}$ Estimated by the Working Group.
    ${ }^{2}$ Divisions VIId, $\mathrm{e}=4,739 \mathrm{t}$
    ${ }^{3}$ Included in Division VIId
    ${ }^{4}$ Preliminary

[^10]:    Weights in t .
    ${ }^{1}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.

[^11]:    Weights in $t$.
    ${ }^{1}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.

[^12]:    Weights in ' 000 t .
    ${ }^{1}$ Catch at status quo F .
    ${ }^{2}$ Not including misreporting.
    ${ }^{3}$ Revised in 1990 to 1.5 .
    ${ }^{4}$ Single-stock boundary; the exploitation of this stock should be conducted in the context of mixed fisheries.

[^13]:    * Preliminary
    ${ }^{1} 1989$ onwards: N. Ireland inoluded with England \& Wales

[^14]:    Weights in '000 t.
    ${ }^{1}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.

[^15]:    ${ }^{1}$ Preliminary.

    * Including VIIg-k.

[^16]:    Weights in ' 000 t .

[^17]:    Weights in ‘ 000 t .
    ${ }^{1}$ Includes $L$. boscii.

[^18]:    ${ }^{1}$ Preliminary.
    ${ }^{2}$ Includes Divisions $\mathrm{Vb}(\mathrm{EC})$ and VIb .
    ${ }^{3}$ 1989-2002 N. Ireland included with England and Wales. $\mathrm{n} / \mathrm{a}=$ Not available.

[^19]:    ${ }^{1}$ Preliminary
    ${ }^{2}$ Included in Division VIa.
    ${ }^{3}$ Includes UK England, Wales and NI landings. ${ }_{5}^{4}$ Includes the total Russian catch.
    ${ }^{5}$ Nonofficial.
    $\mathrm{n} / \mathrm{a}=$ Not available.

[^20]:    Weights in ' 000 t .
    ${ }^{1}$ TAC is set for Divisions VIa and VIb combined.
    ${ }^{2}$ Single-stock boundary and the exploitation of this stock should be conducted in the context of mixed fisheries protecting stocks outside safe biological limits.
    $\mathrm{n} / \mathrm{a}=$ not available .

[^21]:    ${ }^{1}$ Preliminary.
    ${ }^{2}$ Includes Divisions Vb (EC) and VIb.
