GLOSSARY

BIS	Dredging Information System used in the Lower Sea Scheldt
d	Density of dredged sediment [kg/dm ³]
DGD	Deurganckdok
HCBS	High Concentration Benthic Suspensions
M	mass of dry solids [ton]
ρ_s	density of the solid minerals [kg/dm ³]
ρ_w	density of clear water [kg/dm ³]
t _{0d}	Reference situation for densimetric analysis (empty dock)
t _{0e}	Reference situation for volumetric analysis (24 March 2006)
TDS	Ton of dry solids [ton]
V	volume of dredged sediment [m ³]

1. INTRODUCTION

1.1. The assignment

This report is part of the set of reports describing the results of the long-term measurements conducted in Deurganckdok aiming at the monitoring and analysis of silt accretion. This measurement campaign is an extension of the study "Extension of the study about density currents in the Beneden Zeeschelde" as part of the Long Term Vision for the Scheldt estuary. It is complementary to the study 'Field measurements high-concentration benthic suspensions (HCBS 2)'.

The terms of reference for this study were prepared by the 'Departement Mobiliteit en Openbare Werken van de Vlaamse Overheid, Afdeling Waterbouwkundig Laboratorium' (16EB/05/04). The repetition of this study was awarded to International Marine and Dredging Consultants NV in association with WL|Delft Hydraulics and Gems International on 10/01/2006. The project term was prolonged with an extra year from April 2007 till March 2008, 'Opvolging aanslibbing Deurganckdok'.

Waterbouwkundig Laboratorium– Cel Hydrometrie Schelde provided data on discharge, tide, salinity and turbidity along the river Scheldt and provided survey vessels for the long term and through tide measurements. Afdeling Maritieme Toegang provided maintenance dredging data. Agentschap voor Maritieme Dienstverlening en Kust – Afdeling Kust and Port of Antwerp provided depth sounding measurements.

The execution of the study involves a twofold assignment:

- Part 1: Setting up a sediment balance of Deurganckdok covering a period of one year, i.e. 04/2007 – 03/2008
- Part 2: An analysis of the parameters contributing to siltation in Deurganckdok

1.2. Purpose of the study

The Lower Sea Scheldt (Beneden Zeeschelde) is the stretch of the Scheldt estuary between the Belgium-Dutch border and Rupelmonde, where the entrance channels to the Antwerp sea locks are located. The navigation channel has a sandy bed, whereas the shallower areas (intertidal areas, mud flats, salt marshes) consist of sandy clay or even pure mud sometimes. This part of the Scheldt is characterized by large horizontal salinity gradients and the presence of a turbidity maximum with depth-averaged concentrations ranging from 50 to 500 mg/l at grain sizes of 60 - 100 μm . The salinity gradients generate significant density currents between the river and the entrance channels to the locks, causing large siltation rates. It is to be expected that in the near future also the Deurganckdok will suffer from such large siltation rates, which may double the amount of dredging material to be dumped in the Lower Sea Scheldt.

Results from the study may be interpreted by comparison with results from the HCBS and HCBS2 studies covering the whole Lower Sea Scheldt. These studies included through-tide measurement campaigns in the vicinity of Deurganckdok and long term measurements of turbidity and salinity in and near Deurganckdok.

The first part of the study focuses on obtaining a sediment balance of Deurganckdok. Aside from natural sedimentation, the sediment balance is influenced by the maintenance and capital dredging works. This involves sediment influx from capital dredging works in the Deurganckdok, and internal relocation and removal of sediment by maintenance dredging works. To compute a sediment

balance an inventory of bathymetric data (depth soundings), density measurements of the deposited material and detailed information of capital and maintenance dredging works will be made up.

The second part of the study is to gain insight in the mechanisms causing siltation in Deurganckdok, it is important to follow the evolution of the parameters involved, and this on a long and short term basis (long term & through-tide measurements). Previous research has shown the importance of water exchange at the entrance of Deurganckdok is essential for understanding sediment transport between the dock and the Scheldt river.

1.3. Overview of the reports

1.3.1. Reports

Reports of the project 'Opvolging aanslibbing Deurganckdok 2' for the period April 2007 – March 2008 are summarized in Table 1-1. A list of the delivered reports for the period April 2006 – March 2007 can be found in IMDC (2007).

Table 1-1: Overview of Deurganckdok Reports March 2006 –March 2007

Report	Description
Sediment Balance: Bathymetry surveys, Density measurements, Maintenance and construction dredging activities	
1.1	Sediment Balance: Three monthly report 1/4/2006 – 30/06/2006 (I/RA/11283/06.113/MSA)
1.2	Sediment Balance: Three monthly report 1/7/2006 – 30/09/2006 (I/RA/11283/06.114/MSA)
1.3	Sediment Balance: Three monthly report 1/10/2006 – 31/12/2006 (I/RA/11283/06.115/MSA)

3.13	Boundary conditions: Three monthly report 1/1/2008 – 31/03/2008 (I/RA/11283/07.100/MSA)
3.14	Boundary conditions: Annual report (I/RA/11283/07.101/MSA)
Analysis	
4.1	Analysis of Siltation Processes and Factors (I/RA/11283/06.129/MSA)
4.2	Analysis of Siltation Processes and Factors (I/RA/11283/07.102/MSA)

1.3.2. Measurement actions

Following measurements have been carried out during the course of this project:

1. Monitoring upstream discharge in the Scheldt river
2. Monitoring Salt and sediment concentration in the Lower Sea Scheldt taken from on permanent data acquisition sites at Lillo, Oosterweel and up- and downstream of the Deurganckdok.
3. Long term measurement of salt distribution in Deurganckdok.
4. Long term measurement of sediment concentration in Deurganckdok
5. Monitoring near-bed processes in the central trench in the dock, near the entrance as well as near the landward end: near-bed turbidity, near-bed current velocity and bed elevation variations are measured from a fixed frame placed on the dock's bed.
6. Measurement of current, salt and sediment transport at the entrance of Deurganckdok for which ADCP backscatter intensity over a full cross section are calibrated with the Sediview procedure and vertical sediment and salt profiles are recorded with the SiltProfiler equipment
7. Through tide measurements of vertical sediment concentration profiles -including near bed highly concentrated suspensions- with the SiltProfiler equipment. Executed over a grid of points near the entrance of Deurganckdok.
8. Monitoring dredging activities at entrance channels towards the Kallo, Zandvliet and Berendrecht locks
9. Monitoring dredging and dumping activities in the Lower Sea Scheldt

In situ calibrations were conducted on several dates (15 March 2006; 14/04/2006; 23/06/2006; 18/09/2006) to calibrate all turbidity and conductivity sensors (IMDC, 2006f & IMDC, 2007l).

1.4. Structure of the report

This report is the sediment balance of the Deurganckdok for the period of 01/04/2007 to 31/06/2007. The first chapter comprises an introduction. The second chapter describes the project. Chapter 3 describes the methodology. The measurement results and processed data are presented in Chapter 4, whereas chapter 5 gives a preliminary analysis of the data.

2. SEDIMENTATION IN DEURGANCKDOK

2.1. Project Area: Deurganckdok

Deurganckdok is a tidal dock situated at the left bank in the Lower Sea Scheldt, between Liefkenshoek and Doel. Deurganckdok has the following characteristics:

1. The dock has a total length of 2750 m and is 450 m wide at the Scheldt end and 400 m wide at the inward end of the dock
2. The bottom of Deurganckdok is provided at a depth of -17 m TAW in the transition zones between the quay walls and the central trench. The bottom in the central trench is designed at -19 m TAW .
3. The quay walls reach up to $+9\text{ m TAW}$

Figure 2-1: Overview of Deurganckdok

The dredging of the dock is performed in 3 phases. On 18 February 2005 the dike between the Scheldt and the Deurganckdok was breached. On 6 July 2005 Deurganckdok was officially opened. The second dredging phase was finalized a few weeks later. The first terminal operations have started since. In February 2007, the third dredging phase started and is planned to be finalised in 12 months time (by February 2008).

2.2. Overview of the studied parameters

The first part of the study aims at determining a sediment balance of Deurganckdok and the net influx of sediment. The sediment balance comprises a number of sediment transport modes: deposition, influx from capital dredging works, internal replacement and removal of sediments due to maintenance dredging (Figure 2-2).

Figure 2-2: Elements of the sediment balance

A net deposition can be calculated from a comparison with a chosen initial condition t_0 (Figure 2-3). The mass of deposited sediment is determined from the integration of bed density profiles recorded at grid points covering the dock. Subtracting bed sediment mass at t_0 leads to the change in mass of sediments present in the dock (mass growth). Adding cumulated dry matter mass of dredged material removed since t_0 and subtracting any sediment influx due to capital dredging works leads to the total cumulated mass entered from the Scheldt river since t_0 .

Figure 2-3: Determining a sediment balance

The main purpose of the second part of the study is to gain insight in the mechanisms causing siltation in Deurganckdok. The following mechanisms will be aimed at in this part of the study:

- Tidal prism, i.e. the extra volume in a water body due to high tide
- Vortex patterns due to passing tidal current
- Density currents due to salt gradient between the Scheldt river and the dock
- Density currents due to highly concentrated benthic suspensions

Figure 2-4: Transport mechanisms

These aspects of hydrodynamics and sediment transport have been landmark in determining the parameters to be measured during the project. Measurements will be focused on three types of timescales: one tidal cycle, one neap-spring cycle and seasonal variation within one year.

Following data are being collected to understand these mechanisms:

- Monitoring upstream discharge in the Scheldt river.
- Monitoring Salt and sediment concentration in the Lower Sea Scheldt at permanent measurement locations at Oosterweel, up- and downstream of the Deurganckdok.
- Long term measurement of salt and suspended sediment distribution in Deurganckdok.
- Monitoring near-bed processes (current velocity, turbidity, and bed elevation variations) in the central trench in the dock, near the entrance as well as near the current deflecting wall location.
- Dynamic measurements of current, salt and sediment transport at the entrance of Deurganckdok.
- Through tide measurements of vertical sediment concentration profiles -including near bed high concentrated benthic suspensions.
- Monitoring dredging activities at entrance channels towards the Kallo, Zandvliet and Berendrecht locks as well as dredging and dumping activities in the Lower Sea Scheldt.
- In situ calibrations were conducted on several dates to calibrate all turbidity and conductivity sensors.

3. MEASUREMENTS

3.1. Depth soundings

The client executes dual-frequency echo-sounder measurements every week to every three weeks. F. De Cock (Agentschap voor Maritieme Dienstverlening en Kust – Afdeling Kust) communicated that these measurements are carried out with a 210-33 kC Echo sounder using Qinsy software. The depth sounding measurements are executed in a grid configuration, consisting of sections perpendicular and parallel to the quay wall.

Table 3-1: Overview of the available depth soundings suitable for analysis 01/01/2007 – 31/03/2007

date	type of measurement	signal	Source
24/03/2006*	dual frequency 210-33 kHz	210	Afdeling Kust
27/04/2007	dual frequency 210-33 kHz	210	Afdeling Kust
23/05/2007	dual frequency 210-33 kHz	210	Afdeling Kust
22/06/2007	dual frequency 210-33 kHz	210	Afdeling Kust

*= reference situation depth soundings: t_{0e}

To calculate a sediment balance it is necessary to analyse the measurements in stationary situation, with no alteration in boundary conditions being dredging operations. Every period is characterized by a depth sounding measurement before ('inpeiling') and one after ('uitpeiling').

A number of analyses were done using the depth soundings in Table 3-1. The raw depth sounding data was processed in ESRI ArcGIS. Only the 210 kC signal is used in the following analyses as it gives an indication of the water-bed interface.

A reference level was chosen from all depth sounding measurements, effectively the earliest most complete measurement. This turned out to be the measurement on 24 March 2006. This will be considered as a reference situation, initial condition t_{0e} .

A number of analyses were performed in ArcGIS 9 and a Matlab environment to produce maps, figures and tables with relevant information concerning elevation, elevation changes and volumetric growth (§4.2 to §4.4).

3.2. Density measurements

Navitracker was used to perform density measurements. Density measurements are necessary to calculate a sediment balance of dry weight of sediment per surface unit.

The Navitracker is a patented system to measure the density of fluid mud suspensions, by means of a gamma-density meter. It has been used by the Flemish authorities over 20 years to determine the nautical bed for the port of Zeebrugge.

The Navitracker system can be operated by a computer controlled winch to tow it through the mud (horizontal mode). The Navitracker is equipped with the following sensors:

- The Gamma ray density sensor, mounted on a fork-like tow fish, gives density information.
- The depth sensor gives information of the depth of the sensor.
- The position of the fish is calculated out of the length of the winch cable. Together with the position of the tow fish, following the density level, a dual frequency echo sounder is used to map the hard bottom and the top of the mud. With a speed of 2 to 3 knots, large areas can be covered.

For these measurements the Navitracker was used in a vertical profiling mode, with the probe in vertical position in order to penetrate the soft bottom. The vertical density profiler is used to measure density in thick mud layers with high densities.

Figure 3-1: Navitracker

The Navitracker was calibrated in the laboratory for measuring high densities, formed by very dense water-mud mixtures. For this reason the Navitracker did not detect subtle variations in density caused by changes in salinity. The density deviated from 1.000 ton/m³ only in the presence of a high concentration of sediments.

The Navitracker has a sampling frequency of 10 measurements per second.

As a reference situation the empty dock will be used at the design depth. The design depths for the different zones are shown in Table 3-2. The different zones are described in §4.1.

Table 3-2: Reference Situation Density Measurements (t_{0d})

Zone	Design Depth (mTAW)
Central trench	-19
Berthing zones and transition zones to central trench	-17
Sill	-13.5
Transition sill to navigation channel	Not applicable

The resulting profiles were processed in a Matlab environment and visualized in Matlab and ESRI ArcGIS. Equal density layers were computed. Volume and density information was used to calculate masses of silt. All masses are given in ton of dry solids (TDS) characterized by a density of 2.65 kg/dm³. The water-bed interface is defined as the layer with a density of 1.03 kg/dm³.

There were no density measurements performed during this 3-month period.

3.3. Maintenance Dredging Data

All maintenance dredging (except sweep beam) activities in Deurganckdok were collected in the BIS-system. This system gives a standardised output per week, that states the weight, volume and

V^1 removed/dumped in every 5*5m grid cell in the area. In case the density of the dredged sediment in the hopper bin is larger or equal to 1.6 kg/dm³, V' is equal to the volume in the bin. In case the density is smaller than 1.6 kg/dm³, V' is equal to the reduced volume which is defined as the volume the dredged sediment would have in case the density would be equal to 2 kg/dm³ (AWZ 2000). These dredged volumes are important to have an overall view on the sediment balance.

The available data on sweep beam activity is not collected in the BIS-system. However the mode of operation of the sweep beam is explained:

- On the sill (zone 1 & 2): the sediment is swept into the Lower Sea Scheldt
- Inside the dock: the sweep beam sweeps the berthing zones next to the quay walls and moves sediment into the central trench

Therefore an overview is given of where and when sweep beam dredger was working in Deurganckdok (DGD) or on the sill of Deurganckdok (sill DGD).

Table 3-3: Sweep beam Maintenance dredging activities in Deurganckdok and on the sill of Deurganckdok between April 2007 and June 2007 (source: Afdeling Maritieme Toegang)

An overview of the total dredged mass in all zones (BIS data) is provided in APPENDIX D. The sweep beam tracks are shown in APPENDIX E for the following dates: 26-27 April, 5 and 24 May, 14, 18 and 23 June 2007. No data is available of the other sweep beam activities. The loggings of the sweep beam tracks show the position and depth of the rake. From the up-down position of the rake and the ship's direction, it is possible to identify whether the ship is sweeping sediment into the Scheldt or not. A thorough analysis of the obtained data revealed some problems though (IMDC, 2007d). For these reasons, the tracks will not be applied as such in this study. Only the sweep beam locations will be utilised in a qualitative way.

3.4. Capital Dredging Data

In February 2007, the 3rd phase of the capital dredging works was initiated. Topographic measurements on a regular grid were supplied by the contractor in order to follow up the capital dredging progress. For the period 01/04/2007 till 30/06/2007 progress data is available for the

¹ V' = Reduced Volume

following dates: 3 April, 2 May, 8 May, 21 May, 6 June and 18 June 2007 and are shown in APPENDIX F. Note that the design depth of the first half of the dock is presented and not the actual bathymetry.

These data allow studying the progress of the dredging works. In reference to 14 February 2007, i.e. before capital dredging started, the volume of removed sediment is calculated. In order to calculate the tide prism, the decadal tide data at Liefkenshoek was used, which resulted in a yearly averaged high and low tide level of 5.19 and 0.05 m TAW respectively.

4. SEDIMENT BALANCE ANALYSES

4.1. Project Area: (Sub)Zones and Sections

To calculate volumes and masses for the sediment balance of Deurganckdok it is necessary to subdivide it into 5 zones:

- Zone 1: Between the sill and the navigation channel in the Lower Sea Scheldt.
- Zone 2: Sill at entrance DGD designed at -13.5 m TAW.
- Zone 3: Central trench in DGD with a design depth at -19 m TAW (including slope to -17 m TAW)
- Zone 4: Transition between central trench and berthing zones with a design depth at -17.00 m TAW: on both (North (N) and South (Z)) sides of DGD (55 m wide).
- Zone 5: Berthing zones next to quay walls on both (North (N) and South (Z)) sides of DGD (40 m wide)

Zones 3, 4 and 5 are subdivided into subzones A, B, C, D and E. This is shown in Figure 4-1.

Figure 4-1: Deurganckdok: Zones and Subzones

Sections are defined for this whole area (Figure 4-2):

- D sections are oriented perpendicular to the quay walls inside the dock and parallel to the navigation channel outside the dock (sill and Scheldt). The origin of the sections is taken on the quay wall at the left bank (West side) looking outwards.
- L Sections are oriented along the centerline of the dock and run from the navigation channel towards the inland end of the dock, in anticipation of the realisation of the third phase of Deurganckdok. The origin is situated on the intersection between each L section and section D10.

Figure 4-2: Deurganckdok: D and L Sections

The coordinates of these sections are given in Table 4-1.

Table 4-1: Coordinates of Sections [UTM ED50]

Name	Origin		End	
	Easting	Northing	Easting	Northing
D Sections				
D1	587773	5683253	588123	5683037

L3	588901	5684410	587409	5682007

4.2. Depth of the water-bed interface (210 kC)

This is shown as a GIS grid map generated directly from the depth sounding data and is shown in APPENDIX A. An example is shown in Figure 4-3.

Figure 4-3: Example of a map showing depth of water-bed interface (210 kC) for 23/05/07 and 22/06/07

4.3. Evolution of water-bed interface (210 kC)

GIS grid maps show the difference charts for every depth sounding in relation to the reference situation (t_{0e}) and to the previous depth sounding (right). An example is shown in Figure 4-4.

The difference in depth between subsequent depth soundings for 210 kC measurements is also shown for all predefined sections. Graphs show a colour plot with Time in the X-axis, Distance to origin of section in the Y-axis and the depth of the top layer [m TAW] as a colour plot.

The origin for the D sections is the northern quay wall. The origin of the L sections is the intersection between the L section with the Scheldt edge of zone 1. An example for sections is shown in Figure 4-5. The description of the sections is given in § 4.1.

Maps and graphs are shown in APPENDIX B.

Figure 4-4: Difference charts of the depth sounding on 23/05/07: in reference to t_{0e} (left), and to the previous measurement (right) on 27/04/07

Figure 4-5: Graph of Evolution of the water-bed interface (210 kC) for section D5

4.4. Volumetric siltation rates [cm/day] in different zones and sections

A table with monthly average siltation rates for all (sub)zones is also given in APPENDIX C.

Graphs in APPENDIX C show two parameters:

- Average siltation rates [cm/day]: The average siltation rate is the difference in the depth of the water-bed interface and is calculated only for those zones and subzones that have at least a 50% surface area overlap between two subsequent depth soundings. This is done for all successive depth soundings. For each month an average siltation rate is calculated this way. It is shown in the plots as a bar and is positive for sedimentation and negative for erosion or removal.
- Cumulative bed level change [m]: an initial situation (t_0) is used as baseline. Starting from this reference level the evolution of the average bed level elevation is shown for the particular (sub)zone.

Dredging events from the BIS system are marked on each of these graphs. This is computed for all zones, subzones, sections and Deurganckdok as a whole. As an example we show siltation rate and cumulative bed level change for zone 3a in Figure 4-6.

Figure 4-6: Volumetric siltation rate for zone 3a

4.5. Capital dredging works

Capital dredging data is used to compute the time evolution of the volume of dredged sediment. The volumetric change has been calculated in reference to 14 February 2007.

To compute the tide prism, it is necessary to have an idea about the total dock volume available for water storage during high and low tide. Therefore, the decadal tide data at Liefkenshoek was used and resulted in a yearly averaged high and low tide level of 5.19 and 0.05 m TAW respectively (AMT, 2003). In the operational part of the Deurganckdok (see Figure 4-7), the volume of exchanged water remains constant, and does not contribute to any change in tide prism, during the

capital dredging works. For the remainder of the dock, topographic measurements were applied for the necessary calculations. An example of such a data set is shown in Figure 4-8.

Figure 4-7: Operational part of Deurganckdok at the start of the 3rd phase of capital dredging works (Feb. 2007)

Figure 4-8: Depth of capital dredging (and design depth) on 8/05/2007

5. PRELIMINARY ANALYSIS OF THE DATA

Depth sounding data is processed to show the evolution of the average sediment volume per unit of surface, i.e. the average evolution of bed level as detected by a 210kHz sounder. If more than 50% of the area of a (sub)zone is covered, an average siltation rate is calculated. For the period of April – June 2007, depth soundings were performed on 27 April, 23 May and 22 June. During these measurements, an adequate coverage was obtained during depth soundings, except for zone 1 and zones 5A-Z, 5B-Z, 5C-Z, 4B-N, 4C-N, and all subzones of D and E. As a result, these newly defined zones (D and E) are not yet included in the calculations although depth soundings had been performed in zones 4D-N, 4D-Z and 3D.

BIS data revealed that hopper maintenance dredging occurred twice in April and lasted two consecutive weeks: 81% of the total amount of dredged solids of $95 \cdot 10^3$ TDS was dredged in the week of 9 April. The maintenance dredging mainly occurred in zone 3B with more than 46% of the total dredged mass in this period of investigation. Instead, zones 3A and 3C contributed each for around 25% to the dredged solids' mass. All other zones were dredged less than 0.5% of the total dredged mass.

Sweep beam maintenance dredging occurred both on the sill and at the commercial berths. The commercial berths were dredged on 26-27 April and 24-25 May. Whereas the southern berth is only dredged at the end of May, sweep beam dredging occurred at the northern berth in both April and May. Note that the sweep beam actions are not followed by any hopper maintenance dredging to remove the solids in the central trench (being moved there by the sweep beam).

The bathymetric measurements show that the bed elevation on the sill is higher in comparison to the last observation of the previous report, i.e. March 9, 2007. Instead, zones 4B-N and 5B-N have a lower bed elevation. Interesting to note is the slope in zone 3C at the side where the capital dredging occurred. This may be the result of local sedimentation of resuspended sediments during the capital dredging operations.

From the maintenance dredging operation files, sediment removal from the central dock trench happened in the month of April. Despite this large amount, no large discrepancies can be seen between the bathymetric maps of March and April. The cause of this may be twofold. Firstly, the depth sounding was executed immediately after the sweep beam actions at both the northern and southern quays and, therefore, may explain the absence of the deepened central trench. The accumulated sediments near the quays are indeed moved to the central part of the dock during the sweep beam operations. Secondly, removing highly concentrated sediments by the hopper does not necessarily lead to a change in the water-bed interface (as measured by the 210 kHz sounding); only the sediment density below this interface is possibly altered. Note that this depends on the sediment properties too.

From the bathymetric maps, and the calculated siltation rates too, the month of June is characterised by local bed deepening although no maintenance dredging is reported. The sill showed a bed deepening of almost 60 cm. From the corresponding depth map of the water-bed interface in APPENDIX A it is observed that the bed elevation decrease is located at the northern part of the sill, which is to be related to the sweep beam operations prior to the depth sounding on 22 June 2007.

It is also clearly observed from the bathymetric maps that zones 4A-N and 5A-N are silted between April and June due to the specific hydrodynamic flow pattern at the dock entrance. One indeed can see that the siltation rate increases in time until the bed level evolves to such a height that the siltation slows down again.

Interesting to note is the fact that zones 3B and 3C have areas where the bed lowers despite that no maintenance dredging was reported. Zone 3C, nevertheless, shows a positive siltation rate due

to the strong bed elevation increase near the site of capital dredging. A cause for these local bed decreases is not straightforward on the basis of the available dataset though.

Averaged over zones A, B and C (see Figure 5-1), the order of magnitude of the observed undisturbed siltation rates (for the months of May and June) is around 0.5 cm/day.

A table with siltation rates per month and for all cross sections, longitudinal sections and subzones is given in a table in APPENDIX C.

Figure 5-1: Monthly averaged siltation rate for the present measurement period (April - June 2007)(BOTTOM) (t_{0e} : 24/03/2006)

Capital dredging started in February 2007 in order to deepen the remainder of the Deurganckdok to its design depth. In this respect, Table 5-1 summarizes the time evolution of removed sediment by capital dredging. From the table, it is clear that more than 0.8 million m^3 sediment/month is dredged.

Whereas the period February-March led to a tide prism increase of $1041 \cdot 10^3 m^3$, the period of April until June 2007 only resulted in an increase of $375.4 \cdot 10^3 m^3$ (Table 5-2). The main reason for this discrepancy is the preliminary capital dredging work on land near the berths at the end of the dock (see Figure 5-2). After breaching in February 2007, a large volume for water exchange became immediately available, which explains the large initial increase of tide prism.

Note however that 8 May is characterised by a larger dredged volume in comparison with 21 May, in reference to 14 February 2007. Obviously, this observation seems doubtful because it reflects an accumulation of sediment volume instead of dredging. However, when investigating the bathymetry of the capital dredging area it becomes clear that some areas show a lower bed level

in comparison to 21 May (see APPENDIX F). These rather deep spots, also in comparison to the operational part of the dock, are expected to be rapidly filled up with sediments resulting in the artificially lower dredged volume on 21 May in Table 5-1.

Table 5-1: Calculated volume removed by capital dredging in reference to 14 February 2007

Date	Dredged volume from capital dredging works (reference time: 14 Feb. 2007) ($10^3 m^3$)

C.2 Water-bed interface evolution for ali zones

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 1
t0 = 24-Mar-2006

Gross siltation zone 2
t0 = 24-Mar-2006

Siltation rate
x 210kHz Bed El. change
 Dredging

Reference level: depth sounding 24-Mar-2006

Data Processed by:

In association with :

I/RA/11283/07.081/MSA

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 3a
t0 = 24-Mar-2006

Gross siltation zone 3b
t0 = 24-Mar-2006

Siltation rate
 210kHz Bed El. change
 Dredging

Reference level: depth sounding 24-Mar-2006

Data Processed by:

In association with:

I/RA/11283/07.081/MSA

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 3c
t0 = 24-Mar-2006

Gross siltation zone 3d
t0 = 24-Mar-2006

Siltation rate
x 210kHz Bed El. change
Dredging

Reference level: depth sounding 24-Mar-2006

Data Processed by:

In association with:

I/RA/11283/07.081/MSA

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 3e
t0 = 24-Mar-2006

Gross siltation zone 4Na
t0 = 24-Mar-2006

Siltation rate

 210kHz Bed El. change
 Dredging

Reference level: depth sounding 24-Mar-2006

Data Processed by:

In association with:

I/RA/11283/07.081/MSA

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 4Nb
t0 = 24-Mar-2006

Gross siltation zone 4Nc
t0 = 24-Mar-2006

Siltation rate
—x—
210kHz Bed El. change
■
Dredging

Reference level: depth sounding 24-Mar-2006

Data Processed by:

In association with :

I/RA/11283/07.081/MSA

Long-term monitoring siltation Deurganckdok

Siltation height / monthly gross siltation rate

Equipment(s):

210kHz depth sounder

Location:

DGD

Gross siltation zone 4Nd
t0 = 24-Mar-2006

Gross siltation zone 4Ne
t0 = 24-Mar-2006
