1.4.30 Nephrops in Division IVb,c, east of $1^{\circ} \mathrm{E}$, excluding Rectangles 43 F5-F7 (Management Area H) ..... 265
1.4.31 Demersal elasmobranchs in the North Sea, Skagerrak, and eastern English Channel ..... 271

### 1.1 Ecosystem overview

### 1.1.1 Ecosystem components

## Sea bed topography and substrates

The topography of the North Sea can broadly be described as a gradual slope from shallow ( $<50 \mathrm{~m}$ ) in the south to deeper ( $100-150 \mathrm{~m}$ ) in the north. The other main feature is the Norwegian Trench in the northeastern North Sea along the Norwegian coast into the Skagerrak with depths greater than 200 m . The shallow area is found south of a line drawn from $53^{\circ} \mathrm{N}$ on the UK coast to $57^{\circ} \mathrm{N}$ on the Danish coast. The $100-\mathrm{m}$ contour runs approximately east to west at around $58^{\circ} \mathrm{N}$. The remainder, up to $62^{\circ} \mathrm{N}$, is between 100 and 200 m deep in the west and up to 500 m deep in the Norwegian Trench area in the east. Further to the southeast, the Kattegat east of Denmark is also a marked shallow watershed. The substrates are dominated by fine muds and sands in the main part of the North Sea, and the general trend is towards coarse sands and gravels in patches to the east and west. The area around and to the west of the Orkney/Shetland archipelago is dominated by coarse sand and gravel. The deep areas of the Norwegian trench are mostly fine mud; however, some of the slopes have rocky bottoms and several underwater canyons extend further towards the coasts of Norway and Sweden. A number of sand banks across the North Sea qualify for protection under the EU habitats directive, mainly along the UK coast, the eastern Channel, and the approaches to the Skagerrak. Extensive biogenic reefs of Lophelia have recently been mapped in the Norwegian part of the eastern Skagerrak.

Figure 1.1.1 Bathymetry of the North Sea.

## Circulation patterns

Circulation in the North Sea is classically presented as an anticlockwise gyre driven mainly by wind forcing. However, modelling and some empirical observations suggest that this may be reversed some of the time as a result of wind forcing, and may also split into two gyres in the north and south. Circulation may even cease for limited times (Kauker and von Storch, 2000). Empirically, it seems likely that these changes and their timings may be important for fish stocks, e.g. the transport of larval herring to nursery areas in the southeastern North Sea. However, no precise data on these changes have been found. The main inflows are of warm and more saline North Atlantic water along the shelf break into the Norwegian Trench, and also around the Shetland Islands. The strength of these inflows has been linked to zooplankton and fish distributions. Atlantic water also enters into the southern North Sea, via the Channel (Hughes and Lavin, 2004). The eastern Skagerrak and the Kattegat are strongly influenced by the brackish surface water entering from the Baltic, following the Swedish coast and turning west along southern Norway. However, the bottom water layer, which runs below the brackish water layer in the opposite direction, is of oceanic origin, giving rise to similar bottom fauna components as commonly found in the North Sea proper. There are a number of known frontal systems in the North Sea (e.g. Fair Isle, Flamborough, and Skagerrak). Changes in these frontal systems would be expected to be important for several fish species and would merit monitoring.

## Physical and chemical oceanography

North Sea oceanographic conditions are determined mainly by the inflow of saline Atlantic water through the northern entrances, and to a lesser degree through the Channel. This mixes with river runoff and lower-salinity Baltic outflow along the Norwegian coast. The temperature of the North Sea is largely controlled by local solar heating and atmospheric heat exchange. The salinity and the temperature of the North Sea generally reflect the influence of the North Atlantic Oscillation (NAO) on the movement of Atlantic water into the North Sea and the ocean-atmosphere heat exchange. Numerical model simulations show strong differences in the North Sea circulation, depending on the state of the NAO. A balance of tidal mixing and local heating forces the development of a seasonal stratification from April/May to September in most parts of the North Sea. This stratification is absent in the southern part of the North Sea (up to 100 km from the Dutch/German coast) throughout the summer. The extent and duration of this mixed area is probably an important environmental factor for fish in this area. Recently, the NAO index (Hurrell winter index) was weak after having been strongly negative in 2001. The ICES Annual Ocean Climate Status Summary (IAOCSS) for $2003 / 04$ suggests that it may have been negative in the winter of $2003 / 04$. A negative NAO would suggest colder and drier weather conditions in the North Sea (Hughes and Lavin, 2004).

Figure 1.1.2 Temperature and salinity anomalies in the Fair Isle Current (FIC) entering the North Sea from the North Atlantic.

Both 2003 and 2004 were unusually warm years, particularly in August and September. The inflowing Atlantic water was also warmer than the long-term mean. The temperature anomalies can be overstated, however. While August in 2003 was the warmest on record since 1968, the pattern was closer to average from December 2002 to May 2003. The increased temperature was evident in deeper waters as well as at the surface. Surface salinity levels have also risen in the recent years, but from a recent low value to close to the long-term average. Initial indications from a coastal monitoring site in the north western North Sea suggest that summer temperatures in 2004 did not quite reach the extremes of 2003; however, Norwegian stations suggest similar or higher summer temperatures, at least in the Atlantic inflow (www.marlab.ac.uk/FRS.web/Delivery/display_standalone.aspx?contentid=1166).

There is perceived to be considerable eutrophication in some areas of the North Sea, particularly in the Wadden Sea area, the southern part of the Kattegat and coastal part of the Skagerrak, and shallow waters and estuaries along the UK and the European mainland coast. Below the halocline decomposition of organic matter may occasionally cause oxygen deficiency during late summer/autumn. This phenomenon may be linked to enhanced primary productivity but can be a natural process, especially in enclosed inshore areas such as the Kattegat, fjords, and estuaries. The problem is accelerated by large-scale eutrophication of the coastal waters (Karlsson et al., 2002).

## Major climatic and oceanographic features

See the general text on this topic in the separate section on the Northeast Atlantic (see Volume 1 section 2.1)

## Phytoplankton

Primary productivity in the North Sea is dominated by diatoms and dinoflagellates. Up to the 1970s this was classically seen as following a spring/autumn bloom pattern. This is borne out by Continuous Plankton Recorder (CPR) "greenness" values. Since the 1970 s this separation has become increasingly blurred and primary production has been continuous over much of the year. This longer and less bipolar productivity has led to a much greater primary production in all recent years. At the same time this production has involved a reduction in diatom production and an increase in dinoflagellates. Both trends appear to be continuing in the most recent years in the North Sea. Theoretically this should provide more food at the base of the food web (SAHFOS, 2003). After the recent changes the primary productivity in the North Sea can be considered as stronger and lasting longer than in adjacent Atlantic waters.

## Zooplankton

Zooplankton production in the North Sea is dominated by copepods and euphausids, both important food items for many key commercial fish stocks. Zooplankton change in the North Sea has been linked to Atlantic inflow patterns across the twentieth century (Reid et al., 2003). CPR and other data sources show that the abundance of copepods (particularly Calanus finmarchicus) has declined dramatically in the last 10 years (Heath et al., 1999, and www.marlab.ac.uk/ FRS.web/Uploads/Documents/Zooplankton.pdf). This decline shows a strong link to the NAO and can be linked to spring wind patterns and the volume of cold bottom water in the Faroe-Shetland Channel rather than to conditions in the North Sea per se. At the same time the relative proportions of C. finmarchicus to C. helgolandicus have changed markedly. Up to the 1970s C. finmarchicus was dominant, representing around $70 \%$ of the zooplankton biomass. In recent years (since 1995) the copepod abundance has been dominated by C. helgolandicus. Additionally, C. helgolandicus is generally a smaller and less valuable prey than C. finmarchicus. C. finmarchicus is seen as a coldwater species, while C. helgolandicus is generally considered a more warmwater species. The CPR data also show a reduction in euphausid availability. This trend appears to be continuing, and links have been made with cod and flatfish recruitment (Beaugrand et al., 2003; Beaugrand, 2004) as well as with herring growth and migration patterns. It seems likely that if both cod and herring life histories are linked to zooplankton availability, there may also be implications for other demersal and pelagic species.

Figure 1.1.3 Top plot: long-term monthly changes (1958-1999) in the Beaugrand et al. (2003) plankton index. A negative anomaly in the index indicates a low value for Calanus finmarchicus, euphausiids, and mean size of calanoid copepods, with the exception of C. helgolandicus (opposite pattern) and Pseudocalanus spp. (no relationship). A positive anomaly indicates a high abundance of prey (and prey of suitable size). The lower plot shows cod recruitment in the North Sea. The period of the

Gadoid Outburst is also indicated. Source: SAHFOS (2003) - modified, from Beaugrand et al. (2003).

## Benthos and larger invertebrates

The $50-\mathrm{m}, 100-\mathrm{m}$, and $200-\mathrm{m}$ depth contours broadly define the boundaries between the main benthic communities in the North Sea, with local community structure further modified by sediment type (Künitzer et al., 1992; Callaway et al., 2002). Descriptions of the spatial distribution of infaunal and epifaunal invertebrates show that the diversity of infauna and epifauna is lower in the southern North Sea than in the central and northern North Sea. However, large spatial scale gradients in biomass are not so pronounced. Bottom temperature, sediment type, and beam trawling intensity have been identified as the main environmental variables affecting community structure, but the relationships are not necessarily causal. Epifaunal communities are dominated by free-living species in the south and sessile species in the North.

In areas with periodical oxygen deficiency e.g. in the Kattegat, benthic fauna are affected by mortality and reduced growth (Diaz and Rosenberg, 1995). This may in turn cause shortage of food for demersal fish.

Directed fisheries exist for Nephrops norvegicus, Pandalus borealis, and brown shrimp Crangon crangon.

## Fish community

## Dominant species

The pelagic component of the North Sea fish community is throughout the year dominated by herring and to some extent sprat. Mackerel and horse mackerel are mainly present in the summer half year when they enter the North Sea from the south and from the northwest. Dominating gadoid species are cod, haddock, whiting, and saithe, whereas the main flatfish species are dab, long rough dab, plaice, sole, and lemon sole. The major forage fish species in the North Sea are sandeels, herring, sprat, and Norway pout. The total biomass of North Sea fish is in the order of 10 million tonnes.

The late 1960s and early 1970s were characterised by a sudden and yet unexplained increase in the abundance of a number of gadoid species, the 'gadoid outburst'. In this period the gadoids: cod, haddock, whiting, and saithe, all produced a series of strong year classes. Since the early 1980s, however, the stocks of these species have been decreasing and especially cod is at the lowest level observed over the last century. North Sea herring was heavily overfished in the 1960s and 1970s. After a closure of the fishery in the late 1970s the stock has increased again and is now above precautionary levels.

Over the last decade a number of so-called 'southern' species have increased in abundance, which is probably a response to the raise in water temperatures (Beare et al., 2004).

## Size spectrum

On the basis of three trawl surveys Daan et al. (2005) have shown that abundance of small fish (all species) as well as abundance of species with a low maximum length (demersal species only) have steadily and significantly increased in absolute numbers over large parts of the North Sea during the last 30 years (for comparison along the Swedish Skagerrak coast see Svedäng, 2003). At the same time the abundance of the larger fish species decreased.

## Biomass/abundance of crucial species in the food chain

Landings of Norway pout in recent years were the lowest of the past two decades. Spawning biomass of sandeel was at the lowest level ever observed in 2004. Sandeel are an essential component of the diet of most piscivorous fish species as well as birds and marine mammals and their low abundance is therefore expected to have severe implications for the whole North Sea ecosystem.

## Status of vulnerable species

Certain species that have been fairly common in the North Sea have disappeared completely (e.g. tuna) or have become very rare (e.g. halibut). Recently, species like hake and pollack in the Skagerrak and Kattegat are decreasing.

The stocks of most elasmobranchs are at low levels. The spurdog (Squalus acanthias) was once the most common shark species but is now considered to be depleted to approximately $5 \%$ of its virgin biomass in the whole Northeast Atlantic (Hammond and Ellis, 2005). Species such as porbeagle and tope have become rare. Most ray species are at low levels and have disappeared from large parts of the North Sea (Walker and Heessen, 1996).

## Fish population structure

There is generally an apparent lack of information about the population structure of many important fish species such as cod in the North Sea, Skagerrak, and Kattegat, both in a genetic sense and with regards to spatial distribution of spawning aggregations. For instance, due to the disappearance of local spawning subpopulations in the last 20 years, the North Sea spawning stock has become increasingly more important for the recruitment of cod in the Kattegat-Skagerrak area (Svedäng, 2003; Cardinale and Svedäng, 2004).

Notwithstanding uncertainties concerning the cod meta-population structure in the North Sea region, historic spawning aggregations are well known from various parts of the area, and it may be argued that such aggregations are important aspects of the cod meta-population structure. Remaining cod spawning aggregations may thus not necessarily give a reassurance of a readily recovery of the stock biomass in the Kattegat or in the North Sea, even if the fishing intensity is substantially reduced.

## Birds

About 2.5 million pairs of seabirds breed around the coasts of the North Sea. The seasonal distributions, current and historical, of these populations are quite well known. Some progress was made in tabulating the current status (i.e., size) and trends of seabird populations in some parts of the North Sea. The seabird fauna is dominated by seagulls (blackheaded gull, mew gull, lesser black-backed gull, herring gull) kittiwakes, fulmars, terns, common guillemots, and puffins. There is an observed increase in the number of cormorants in coastal areas in the southern North Sea and in the Kattegat. Certain fisheries activities disturb various species such as marine birds and mammals. Recent restrictions to the North Sea sandeel fishery in order to safeguard food for birds and mammals and the driftnet ban to protect sea mammals are examples where environmental problems were the origin of fisheries management actions. Seal population trends have by ICES been recommended as useful EcoQ elements. Similarly, trends in individual colonies of kittiwakes might serve as an index of seabird community health.

## Mammals

Seven marine mammal species occur regularly and frequently in the North Sea, others occur in low numbers or in small parts of the area (e.g., orca whale, Risso's dolphin, sperm whale). The cetacean species that occur regularly are: harbour porpoise (Phocoena phocoena), white-beaked dolphin (Lagenorhynchus albirostris), Atlantic white-sided dolphin (Lagenorhynchus acutus), bottlenose dolphin (Tursiops truncatus), and minke whale (Balaenoptera acutorostrata). The seal species are the harbour seal (Phoca vitulina) and the grey seal (Halichoerus grypus). The only abundance estimate in the North Sea for harbour porpoises is 262,540 individuals. This estimate was made in 1994 (Hammond et al., 2002) and included the whole North Sea and the Channel. The Kattegat and part of the Skagerrak had an additional estimate of 36,046 harbour porpoises.

### 1.1.2 Major environmental influences on ecosystem dynamics

No specific environmental signals were identified specifically to be considered in assessment or management in this area in 2005.

### 1.1.3 Fishery effects on benthos and fish communities

Large-scale discarding is known to occur in the mixed demersal trawl fisheries in the North Sea. In the roundfish fishery (cod, haddock) discards will mainly consist of small-sized specimens of the target species, or of unwanted bycatch of landable size. In the flatfish (plaice, sole) and the Nephrops norvegicus fishery there is also discarding of a variety of macrobenthos species.

Bottom trawling modifies the biomass, production, size structure, and diversity of benthic communities, with the intensity and patchiness of bottom trawling disturbance determining the aggregate impacts (ICES, 1999). One recent estimate suggests that beam trawling in the southern and central North Sea beam trawl fleets reduces total benthic biomass by $39 \%$ and benthic production by $15 \%$ relative to the unfished state (Hiddink et al., in press), but similar estimates are not available for most other fleets. Historically, trawling effort has been greatly concentrated in preferred fishing grounds. Cumulative trawling impacts would increase if trawling effort were spread more homogeneously or relocated, particularly to more vulnerable habitats, because the first impacts of trawling on a previously untrawled community are greater than subsequent effects (Duplisea et al., 2002). For example, the cod box closure of 2001 led to the beam trawl vessels fishing in previously unimpacted areas (Rijnsdorp et al., 2001), and led to a greater reduction in the total productivity of benthic communities (Dinmore et al., 2003).

Many management actions could result in effort redistribution that could increase fishery impacts on benthic communities and habitats. Fisheries management should consider this factor, and seek to implement measures which do not provide incentives for the industry to relocate effort to new areas.

The principal effects of fishing on the size and species composition of the North Sea fish community has been that as fishing mortality rose, the mean size of individuals in the community fell, and species with larger body sizes formed a smaller proportion of community biomass (Gislason and Sinclair, 2000). This is reflected in the steeper slopes of size spectra (Rice and Gislason, 1996), reductions in the abundance of large species, such as many elasmobranchs, with low intrinsic rates of increase (Walker and Heessen, 1996; Walker and Hislop, 1998), increases in abundance of many smaller species (Greenstreet and Hall, 1996; Heessen and Daan, 1996; Greenstreet et al., 1998; Daan et al., 2003; 2005). The changes in size composition of the community redistribute predation mortality among species and sizes of fish, and these changes are taken into account in the natural mortality values used in assessments. Changes in size composition of species and communities due to overfishing can also affect population fecundity both directly (reduction of larger, more fecund spawners), and indirectly (earlier maturation at smaller sizes). These changes are considered when setting reference points as well as when providing management advice to protect the productivity of the exploited resources.

The long-term effects of an eroded population structure must be considered. The differences between the various subpopulations may be behavioural or genetic, but go unobserved by both the fishers and by regulators who believe there is a gradual decline in one big stock while in fact they are witnessing the successive disappearance of a series of sub-populations. Fishing also has differential effects on species with contrasting life histories (Jennings et al., 1999), with many large and vulnerable species subject to unsustainable mortality rates when taken as bycatch in mixed fisheries. Management should take account of the status of these species, and ensure that fishing mortality on bycatch species does not exceed estimates of sustainable mortality for vulnerable species (e.g. Pope et al., 2000).

### 1.1.4 Important topics for further research

Many of the issues which arise in the North Sea, and for which additional research is necessary for improved scientific advice, are also issues in the other ecological areas. However, because of the greater availability of data and information for the North Sea, and the focused scientific effort historically and currently through for example REGNS, it may be appropriate to highlight the research needs for this area. Progress in this area should be viewed with regard to implications for other areas, however, and opportunities for collaborative and integrative work should be sought:

- Community ecology: what are the ecological effects of a diminishing size spectrum and a dominance of prey species like herring? Can these changes be readily reversed through management?
- Temperature preferences, i.e. what are the effects of climate change on reproduction, egg mortality, growth, and the implications for changes in stock population dynamics and distributions?
- What are the consequences of the loss of meta-population structure and erosion of spawning aggregations in depleted populations?
- There should be better estimations of population fecundity, i.e. better understanding of reproduction biology, including better estimates of maturity ogives, variation in maturation rates, and the linkage between maturation, growth, and temperature, for a more realistic view of stock productivity.

Using this information, it is important to investigate and test management strategies which would be sustainable in the face of these dynamic ecological conditions: how to preserve the productivity of the seas and have some revenues from fishing at the same time.

### 1.1.5 Synthesis

The presently observed low abundance of species that play an important role in the North Sea food web (Calanus, sandeels, and Norway pout) is expected to have considerable impact on growth, maturation, and possibly recruitment of a range of fish species and on the breeding success of seabirds.

Many North Sea fish stocks are presently seriously depleted (e.g. cod). Recruitment of commercially important gadoids is at a low level and the ecosystem may be changing in an irreversible direction. Another phenomenon worth mentioning is the apparent increase in the presence of a number of southern species. In the case of red mullet Mullus surmuletus the increase is so significant that a new fishery is developing.

### 1.2 The human use of the ecosystem

### 1.2.1 Overall impacts

### 1.2.2 Fisheries

The fisheries in the North Sea can be grouped into demersal and pelagic human consumption fisheries and into industrial fisheries, which land their catch for industrial purposes. Demersal human consumption fisheries usually target a mixture of roundfish species (cod, haddock, whiting), or a mixture of flatfish species (plaice and sole) with a bycatch of roundfish or Nephrops generally taken in a multi-species fishery. A fishery directed at saithe exists along the shelf edge. The catch of these fisheries is landed for human consumption. The pelagic fisheries mainly target herring, mackerel, and horse mackerel. Although most of the landings of these species may be landed for human consumption purposes, part of the landings is used for fishmeal and fish oil. The catch of the industrial fisheries mainly consists of sandeel, Norway pout, and sprat. The industrial catches also contain bycatches of other species, including herring, haddock, and whiting. In addition to the finfish fisheries, smaller fleets exist which fish for crustaceans, including Nephrops, Pandalus, and brown shrimp (Crangon crangon), both of which are associated with medium to high by-catch and/or discard rates of commercially important species (Madsen and Hansen, 2001; Graham, 2003; Anon, 2004).

Each fishery uses a variety of gears. Demersal fisheries: otter trawls, pair trawls, twin trawls, seines, gillnets, and beam trawls. Pelagic fisheries: pelagic trawls and purse seines. Industrial fisheries: small-meshed otter trawls, pelagic trawls, and purse seines.

Some major technological developments changed the fisheries in the North Sea during and after the 1960s such as the development of the beam trawl fishery for flatfish, purse seines in the pelagic fishery, and large pelagic trawls to replace driftnets. In recent years multiple twin trawls have been introduced in the fishery for flatfish, roundfish, and the mixed fish/Nephrops fishery. The introduction of power blocks in the 1960s has enormously increased the possibilities for the purse seiners. Right up to the present time further development of electronic equipment such as satellite navigation, fish finders, and sonar as well as advances in vessel design has increased the fishing efficiency of the fleets.

The trends in landings or catch of the most important species targeted by these fleets since 1970, together with the total international landings or catch, are shown in Table 1.2.2.2 and in Figure 1.2.2.1. The demersal landings have steadily declined over the period. The pelagic catches, dominated by herring, decreased to a minimum in the late 1970s, when the fishery for herring was closed, but increased again up to over 1 million $t$ in the period 1987-1995. In 1996 they were reduced by about half and have again slightly increased since 2002. The landings in the industrial fisheries increased to approximately 1.5 million $t$ in the mid-1970s, and have fluctuated around 1 million $t$ from 1980 onwards. These landings show the largest annual variations, due to the short life span of the species. The industrial landings have suddenly dropped to below 400 thousand tonnes in 2003 . Total landings from the North Sea reached 3 million $t$ in the.

Landings by fleet segment in the North Sea and Skagerrak demersal fisheries in 2003 and 2004 are shown in Table 1.2.2.3 and figure 1.2.2.2. The table and figure allow comparisons between different fleet segments. Some discard estimates are included in the table, but in many cases the estimates of discards are based on extrapolations from very limited sampling and should only be considered as indicative of the potential amount of discards.
Most commercial species are managed by TAC/quota regulations that apply to Subarea IV, or to a combination of Subarea IV with an adjacent area. The national management measures with regard to the implementation of the quota in the fisheries differ between species and countries. The industrial fisheries are subject to regulations for the bycatches of protected species.

Fishing effort by demersal fleet segment between 2000 and 2004 are shown in Table 1.2.2.4 and figure 1.2.2.3. A longer time series of effort from selected countries (for which data was available) is shown in figures 1.2.2.5 and 1.2.2.6. Effort by demersal fishing fleets in the North Sea and Skagerrak has decreased in recent years. The strongest decrease was observed after 2000 in the demersal trawl fishery with mesh size over 100 mm . Some of the effort that was removed from that fishery has been used to increase the fishing effort in the demersal trawl fishery with $70-99 \mathrm{~mm}$ (Nephrops fishery, twintrawl fishery). Fishing effort in the beamtrawl fleets has decreased over a longer period but the decline after 2000 is less pronounced.

## Stock status

In the past 10 years the state of the stock for most roundfish and flatfish species in the North has further deteriorated. Some of these stocks have reached a historical low within this period. One of the major causes of this deterioration is the continuous very high level of exploitation. This exploitation has lead to a reduction in the number of age groups in the stocks and fishing opportunities have consequently become more dependent on the success of recruitment. Recruitment for most stocks is very variable. For a number of species (cod, plaice) recruitment in the recent decade has been lower than in previous decades. At the same time it is observed that a number of species (cod, haddock, whiting, sole, and plaice) simultaneously show a reduction of growth. Southern species like sea bass and red mullet have increased in the North Sea and have sometimes attracted a new fishery. There is considerable speculation on the reasons for the observed changes. The reduction in recruitment can be explained by a reduction in the production of eggs by the reduced spawning stocks, but it cannot be excluded that changes in the environment play a role. In the last 10 years the climate has changed not only on land but also in the sea, and mean temperatures in the sea have increased. Changes in the sea currents have also been observed. The changes in environmental conditions may also be responsible for changes in the distribution and abundance of the different species.

All roundfish and flatfish stocks in the North Sea have been exposed to high levels of exploitation. The present assessments indicate that the fishing mortality in recent years has been reduced for haddock, saithe, sole, and plaice (human consumption fishing mortality only). This coincides with an overall decrease in fishing effort (see above). The total catches (landings and discards) of cod, haddock, saithe, whiting, sole, and plaice peaked in the late 1960s and early 1970s around 1.5 million t per year (Figure 1.2.2.1). Since then the catches have gradually decreased to less than 0.4 million $t$ in 2004. The aggregate fishing mortality has been above the aggregate $\mathbf{F}_{\mathrm{pa}}$ since 1974 , but has decreased to below in the most recent three years.

Mean F

Index of recruitment

SSB

Figure 1.2.2.1 Aggregate historical stock development for North Sea cod, haddock, saithe, whiting, sole, and plaice.

Multispecies assessments have shown that there are indications of changes in natural mortality for a number of North Sea stocks. For haddock and cod these changes entail a reduction in natural mortality on the youngest ages due to a reduction in fish-predator abundances, and an increase in natural mortality on older ages due to increased abundance of grey seals. The single-species assessments models are only moderately affected by incorporating time-varying estimates in natural mortality and the assessments put forward by ICES do not include time-varying natural mortality.

Several technical measures have been implemented in the mixed demersal fisheries in the North Sea in 2001 and onwards. If implemented effectively, these measures are likely to impact the exploitation patterns for roundfish, and to a lesser extent flatfish. The effects of the new technical measures have so far been observed to a limited extent in changes in selection patterns or in weights-at-age in the landings. However, this may be confounded by shifts towards smaller mesh mixed Nephrops fisheries due to higher effort allocations in comparison to the $120-\mathrm{mm}$ fleet segment.

The herring stock in the North Sea collapsed in the mid-1970s due to heavy exploitation, but has recovered after a closure of the fisheries between 1977 and 1981. In the mid-1990s it declined again. In 1996, effective management measures have been implemented to reduce the catches in both human consumption and industrial fisheries. These measures resulted in a considerable reduction in the fishing mortality in 1996-2001. Additionally, the North Sea autumn-spawning herring showed a very high recruitment over a number of years. The stock has been below $\mathbf{B}_{\mathrm{pa}}$ until 2002, but has now recovered and is expected to remain at this level in the short term. Recruitment of the 2001 and 2002 year classes is well above average. However, the year classes from 2003 to 2005 appear to be low, and catch opportunities will be reduced in the medium term. Catches in the human consumption and industrial fisheries in the North Sea have increased from 450000 t in 2003 to 550000 t in 2004 (IV and VIId), following an increase of the TAC in recent years. The herring stock is exploited in the North Sea and the Channel (Downs herring) by human consumption fisheries. Bycatches of juvenile North Sea herring are taken in the industrial fishery for sprat in the North Sea and Division IIIa (Skagerrak/Kattegat).

The sprat stock fluctuates considerably between years. The actual state of the sprat stock is not precisely known, but the biomass is thought to be high at present. Landings in 2004 increased to 194000 t .

The North Sea component of the Northeast Atlantic mackerel stock collapsed in the early 1970s. The 2002 and 2005 egg surveys in the North Sea with limited spatial and temporal coverage both indicate a higher egg production in the North Sea area than in 1999. However, this component is still considered to be severely depleted. Most of the mackerel catches taken in the northern North Sea in recent years originate from the western component. The total catch recorded from the North Sea in 2004 was about 297000 t , which is 34000 t less than the catches in 2003 . There had been a trend of increasing catches in this area since 1996, but this trend has reversed in the last two years with a decline in catches since 2002. Misreporting of catches taken in this area into VIa has decreased by more than $50 \%$ of levels from previous years to 18000 t . This component of the catch is highly variable and depends on the availability of mackerel to the fleet.

The present state of the North Sea horse mackerel stock is not known. In 2004 the catch was 35154 tonnes, which is almost 3000 tonnes more than in 2003. Roughly one third of the catch is used for industrial purposes. Both the industrial and the human consumption fishery increasingly exploit younger fish in the southern North Sea and the Eastern Channel in the $1^{\text {st }}$ and $4^{\text {th }}$ quarter.

The estimated yield (landings and discards) for cod in Subarea IV and Divisions IIIa and VIId was the lowest in the historical time-series ( 34500 t ). Estimates of mortality in 2004 were extremely sensitive to sparse data from researchvessel surveys. Although the current level of fishing mortality is not precisely estimated, all data sources consistently indicate that SSB and recruitment were very low in 2004. Preliminary indications from the Scottish Q3 survey are that in the northern North Sea the abundance of the 0 -group cod is higher than in recent years, but this perception is very uncertain and will need to be confirmed by subsequent surveys.

The strong 1999 year class again dominated the catches of haddock in Subarea IV and Division IIIa in 2004 (66 500 t). However, the contribution of this year class to the fishery appears to be drawing to a close, and this estimated yield was the lowest in the historical time-series. Recruitment following the 1999 year class has been low, and SSB will decline further in the short term. All sources of information agree that fishing mortality has declined rapidly in this fishery to at or near an historical minimum. Indications from the third-quarter Scottish groundfish survey are that the 2005 year class may be stronger than those in recent years. Haddock is known to produce strong recruitment only every 7-8 years.

Catches of whiting in Subarea IV and Division VIId have continued to decline, and are now at their lowest observed level (29000 t). Recent information from both commercial fleets and research-vessel surveys indicate similar trends in mortality, biomass, and recruitment for the last 10 years, with all three being at their lowest observed levels.

The estimated SSB for saithe in Subareas IV and VI and Division IIIa is above $\mathbf{B}_{\mathrm{pa}}$ and is apparently increasing. Fishing mortality is at or near the historic low, and recruitment remains just below the long-term mean. Considerable
annual revisions of the saithe assessment are a direct consequence of the lack of survey or fishery information for younger age-groups. Reported landings for $2004(104000 \mathrm{t})$ were around the recent mean.

Landings of sole in Subarea IV in 2004 (17000 t) were at a similar level as in recent years. SSB has fluctuated around a moderate level for several years and for 2004 was estimated to be above $\mathbf{B}_{\mathrm{pa}}$. Fishing mortality appears to have declined rapidly in 2004 and, although uncertain, is now estimated to be below $\mathbf{F}_{\mathrm{pa}}$. After the strong 2001 year class, recruitment has fallen back down to near the mean of the full time-series.

The yield of sole in Division VIId in 2004 was at or near the historic maximum. Fishing mortality is estimated to be around $\mathbf{F}_{\mathrm{pa}}$. SSB is above $\mathbf{B}_{\mathrm{pa}}(8000 \mathrm{t})$ following improved recruitment in recent years, particularly of the year classes 1998 to 2000 and 2003.

As last year, the assessment for plaice in Subarea IV included discards (based on sampling after 1999, growth modelling before 1999). Although reported landings for 2004 are at the lowest observed level ( 61500 t ), estimated total catches ( 120000 t ) are around the recent average. SSB is estimated to be stable, but low and fluctuating between $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{B}_{\text {lim }}$. Fishing mortality is fluctuating around the proposed Fpa. Recent recruitment appears to be below average.

Plaice landings in Division IIIa have remained stable since 1997 with landings of 9000 tonnes in 2004. Historically, the TAC has not been restrictive for this stock. About $82 \%$ of the landings were taken in Skagerrak. The stock status is uncertain.

Landings of plaice in Division VIId were below the recent mean, and near the historical minimum. Discrepancies between catch-at-age based analyses and survey-based analyses has prevented ICES from assessing the state of this stock.

Landings in 2004 for sandeel in Subarea IV (359 000 t) remained at or near the same low level as in 2003. Landings in 2005 have continued this trend. Following the implementation of a real-time management plan, the fishery was closed in July 2005. Estimated SSB is at its lowest observed level. Fishing mortality has declined in recent years but is still high in comparison with the historical estimates, while recruitment remains low.

Landings for Norway pout in Subarea IV in 2004 (13 500 t) were the lowest observed. The directed Norway pout fishery remained closed during 2005, and only very limited bycatch was observed in other fisheries. Estimated SSB for this stock in 2004 was very near to $\mathbf{B}_{\text {lim }}$, fishing mortality was the lowest in the historical time-series, and recruitment was at or near the historical minimum.

The yields for stocks of Nephrops are fairly stable from year to year. Reported landings for Functional Unit 3 (Skagerrak, 2200 t), FU 4 (Kattegat, 1600 t), FU 5 (Botney Gut, 1100 t), FU 6 (Farne Deeps, 2200 t), FU 8 (Firth of Forth, 1100 t), FU 9 (Moray Firth, 1300 t), FU 10 (Noup, 230 t), and FU 32 (Norwegian Deeps, 900 t) are all at or near the respective recent averages. Both FU 7 (Fladen, 8700 t) and FU 33 (Off Horn Reef) are at their highest observed levels. Indications from TV surveys for FUs $6,7,8$, and 9 are that stock densities are fluctuating about a long-term mean and are currently at high levels in FUs 6, 8 and 9.

The stock of Pandalus borealis in Division IVa (Norwegian Deep) and Division IIIa appears to be stable to sustain current fishing pressure. The state of the stocks in Division IVa (Fladen Ground) and Division IVb (Farn Deep) is not known, as data for assessments were insufficient. The fishery in the latter two areas is opportunistic, strongly influenced by stock abundance and market prices. Landings in 2004 were about 15200 t .

The state of individual stocks is presented in more detail in the stock sections.

### 1.3 Assessments and advice

### 1.3.1 Assessments and advice regarding fisheries

## Effects of fishing on the ecosystem

## Sandeel and Norway pout

The ecosystem effects of industrial fisheries are discussed in the Report of the ICES Advisory Committee on Ecosystems, June 2003, Section 11 (ICES CRR 262). The direct effects of industrial fishing that have been identified on other species fished for human consumption, e.g. haddock and whiting, are relatively small in comparison to the effects of directed fisheries for human consumption species. Sandeel are important prey species for many marine predators. However, there is still relatively scant information on the effects of fisheries targeting these stocks (sandeel, Norway pout, sprat), and further analysis of the ecological impacts of these fisheries is required. The effects of variation in the sizes of most industrial stocks on their predators are also poorly known. The importance of these species in the food-web and the potential indirect effects of fishing are discussed in Section 1.1.

## North Sea skates and rays

Elasmobranchs have been shown to generally have life history traits which result in them being able to sustain only low and some species of skates and rays are widely thought to have relatively high catchabilities in fishing gears. Taken together the vulnerability to capture and low rates of sustainable mortality have been proposed as major factors in the severe decline in the common skate from the Irish Sea and trends in a variety of other skates and rays. In 1998 ICES (WGECO) reported life history-based estimates of the maximum total mortality rate that were sustainable for 5 species of rays (common skate Dipturus batis -0.38 , thornback ray Raja clavata -0.5 , spotted ray Raja montagui -0.54 , cuckoo ray Raja naevus -0.58 , and starry ray Raja radiata -0.87 ). In that report, ICES also reported that recent estimates of total mortality from survey catch data were greater than the theoretical sustainable mortality rates for three of the five species, and could not be estimated for a fourth, because this species was reduced to such a low abundance that current mortality rates could not be estimated. ICES (1997) advised some specified areas of the North Sea be closed to gears with a high by-catch of these species.

Recently ICES has developed and implemented analytical methods for estimating at least relative catchability of different fish species to different fishing gears (WGFE 2004). ICES is also in the process of changing the form of advice to advise on fleet-based effort levels consistent with the single-species catch boundaries of the suite of species taken by the fishery. When the methods of estimating catchability have been applied to skates and rays, the combination of fleet-based effort advice and gear-specific catchabilities will allow estimates of the maximum fleet-specific effort levels that can be exerted without exceeding the sustainable mortality rates for skates and rays. Then it will be possible to integrate the fishery- and fleet-based catch advice with the need to ensure that impacts on non-target species are also sustainable.

## Mixed fisheries and fisheries interactions

Demersal fisheries in the area are mixed fisheries, with many stocks exploited together in various combinations in different fisheries. In these cases management advice must consider both the state of individual stocks and their simultaneous exploitation in demersal fisheries. Stocks in the poorest condition, particularly those outside safe biological limits, become the overriding concern for the management of mixed fisheries, where these stocks are exploited either as a targeted species or as a by-catch.

The exploitation of sole and plaice are closely connected as they are caught together in fisheries mainly targeting sole, which are more valuable. This means that the minimum mesh size is decided on the basis of the more valuable species, resulting in substantive discards of undersized plaice. The mixed fisheries for flatfish is dominated by a mixed beam trawl fishery using $80-\mathrm{mm}$ mesh in the southern North Sea where up to $80 \%$ in number of all plaice caught are being discarded. Measures to reduce discarding in the mixed beam trawl fishery would greatly benefit the plaice stock and future yields. In order to improve the selection pattern, mesh size increases or configuration changes (i.e. square mesh), would help reduce the discards. However, this would result in a short term loss of marketable sole. Readjustment of minimum landing sizes corresponding to an improved selection pattern could be considered.

Roundfish are caught in otter trawl and seine fisheries, with a $120-\mathrm{mm}$ minimum mesh size. This is a mixed demersal fisheries with more specific targeting of individual species in some areas and/or seasons. Cod, haddock, and whiting form the predominant roundfish catch in the mixed fisheries, although there can be important bycatches of other species, notably saithe and anglerfish in the northern and eastern North Sea and of Nephrops in the more offshore Nephrops grounds. Cod and whiting also comprise a bycatch in the beam trawl fisheries. Static gear fisheries with mesh
sizes generally in excess of 140 mm are also used to target cod. Saithe in the North Sea are mainly taken in a directed trawl fishery in deeper water near the northern shelf edge and the Norwegian Deeps. There is little bycatch of other demersal species associated with the directed fishery.

For mixed demersal fisheries improvements to gear selectivity, such as increased mesh size or the inclusion of square mesh panels, would contribute to a reduction in discards and better exploitation patterns. Commission regulation (EC) No. 2056/2001 and several UK unilateral measures were evaluated by an EU expert meeting in April 2003 (Anon., 2003). The actual uptake of these measures is still unknown. However, in the case of full uptake it was shown that discards are substantially reduced over both the short and the medium term. While there for cod and haddock would be mediumterm gains in yield, for whiting the effects of the gear regulations alone result in immediate and short term (ca. 2-3 years) losses in consumption landings that do not revert to gains in the medium term (ca. 10 years). A phased, stepped increase in mesh size over a period of years is likely to reduce discards significantly, and be more acceptable to industry due to the reduction of short term losses.

Nephrops fisheries take place in discrete areas that comprise an appropriate muddy sea bed sediment. Targeted Nephrops fisheries on these grounds are taken predominantly in trawls with mesh sizes of between 70 mm and 100 mm using single or multiple-rig trawls. UK legislation prohibits the use of meshes less than 100 mm in most of its twin trawl Nephrops fishery, particularly in the offshore areas. Nephrops fishing grounds vary from small, localised inshore grounds to more offshore large areas such as the Fladen Ground in the northern North Sea, and while there is bycatch and discarding of other demersal species associated with Nephrops, the general nature of these fisheries and their bycatch can vary widely. Prior to the increase in minimum mesh size (MMS) in 2003/2003, a significant proportion of the vessels reporting Nephrops also recorded significant catches of other whitefish species. These vessels used $100-\mathrm{mm}$ mesh in order to avoid catch composition regulations. However, following the mesh size increases almost all these vessels switched to $80-\mathrm{mm}$ mesh to avoid losses of Nephrops. This is likely to have resulted in increased discards because of lower selection and high grading due to catch composition regulations associated with the mesh size. There is a desperate need to obtain selection patterns similar to a $120-\mathrm{mm}$ mesh codend while still retaining Nephrops (Graham and Ferro, 2004). Solutions could, e.g., include modifications to the square mesh panel construction and location.

Small-mesh industrial fisheries for sandeel and Norway pout occur separately in the North Sea. Sandeel fisheries take place throughout the North Sea in areas defined by the appropriate sandy sea bed sediment. These fisheries have a low bycatch rate of important demersal species. Fishing for Norway pout takes place in the northern and northeastern North Sea and has higher bycatch rates of other species such as haddock and whiting.

The available national log-book data suggest that landed bycatch of fish for human consumption from the Pandalus fisheries in Skagerrak and the Norwegian deep amounts to $10-15 \%$ of landed shrimp. In the Fladen Ground fishery for Pandalus (Danish log-book records) this bycatch varies from $8 \%$ to $20 \%$ relative to shrimp landings.

## Single-stock exploitation boundaries and critical stocks

The state and the limits to exploitation of the individual stocks are presented in the stock sections. The state of stocks and single-stock exploitation boundaries are summarised in the table below.

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single-stock exploitation boundary for agreed management plan or in relation to precautionary limits. Tonnes or effort in 2006 and $\%$ reduction in $F$. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spawning <br> biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high longterm yield | In relation to agreed management plan | in relation to high long term yield | in relation to precautionary limits |  |
| Cod in the North Sea, Eastern Channel and Skagerrak | Reduced reproductive capacity | Uncertain | Overexploite d | Due to the lack of a short term forecast the exploitation boundaries in relation to existing management plans cannot be calculated. |  | Given the low stock size, recent poor recruitment, it is not possible to identify any non-zero catch which will be compatible to the precautionary approach | Zero TAC |
| Cod in Kattegat | Reduced reproductive capacity | Harvested unsustainably | Overexploite d | Even with no landings in 2006 the SSB in 2007 is likely to be below $\mathbf{B}_{\text {lim }}$. In this case, the management plan would set a TAC consistent with F below 0.6 and a more than $30 \%$ increase in SSB; however, there is no estimate of the stock size on which to calculate this. | Yield-per-recruit analysis suggests that $\mathrm{F}=0.2-0.3$ is a reasonable exploitation boundary. | Taking into account the current state of the stock, fishing at any level will involve a risk for further depletion of the stock. There should therefore be no fishing on this stock in 2006 | Zero TAC |
| Haddock in the North Sea and Division IIIa | Full reproductive capacity | Harvested sustainably | Close to target | Following the agreed management plan ( $\mathrm{F}=0.3$ ) would imply human consumption landings of 39 400 t in 2006 which is expected to lead to an SSB of 225800 t in 2007. |  |  | TAC 39400 t |
| Whiting in the North Sea and Eastern Channel | unknown | unknown | unknown | Unknown | Unknown | The stock status cannot be assessed with reference to precautionary reference points. However, in the light of the low estimate of stock size in combination with the low recent landings with indication of current low exploitation rates, ICES recommends that the human consumption landings in 2006 should not be allowed to increase above the recent (2002-2004) average of 17300 t for Subarea IV and Division VIId. | TAC $<17300 \mathrm{t}$ |
| Saithe in the North Sea, Division IIIa and Subarea VI | Full reproductive capacity | Harvested sustainably | Appropriate | At the present SSB level, F should be below 0.3 to be in accordance with the management plan. This corresponds to catches of less than 108.7 kt in 2006. Unless paragraph 6 is invoked the management plan limits the annual deviation of the TAC to $15 \%$ which would correspond to catches of 136 kt . |  |  | TAC <136 000 t . |

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single-stock exploitation boundary for agreed management plan or in relation to precautionary limits. Tonnes or effort in 2006 and $\%$ reduction in $F$. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high longterm yield | In relation to agreed management plan | in relation to high long term yield | in relation to precautionary limits |  |
| Angleffish in Division IIIa, Subareas IV and VI | unknown | unknown | unknown | No management plan. | Unknown | The effort in this fishery should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data on both target and bycaught fish. | No effort increase |
| Plaice in the North Sea | At risk of reduced reproductive capacity | Harvested sustainably | Overexploite <br> d | The management agreement has not been renewed for 2005. Therefore, advice is only presented in the context of precautionary boundaries. | The current fishing mortality is estimated as 0.58 , which is above rates which are expected to lead to high long-term yields ( $\mathrm{F}_{\text {max }}$ on human consumption $=0.17$ ). | The exploitation boundaries in relation to precautionary limits imply human consumption landings of less than 48 000 t in 2006, which is expected to rebuild SSB to the proposed Bpa ( $=230000 \mathrm{t})$ in 2007. | TAC $<48000$ t. |
| Plaice in the Eastern Channel | Unknown | Unknown | Unknown | No management plan. | No long-term reference points are available | No short-term forecasts can be provided. There is conflicting information; some information suggests that the stock is stable and some information suggests that the stock is declining and as a minimum measure there should be no increase in effort. | No effort increase |
| Plaice in Division IIIa | Unknown | Unknown | Unknown | No management plan | Unknown | There is no basis for an analytical forecast. Given the possible increase in stock size in recent years in combination with an unknown exploitation rate, fishing mortality in 2006 should not be allowed to increase. This may be achieved by allowing landings of less than 9600 t in 2006 , which is the average of landings of the last four years. | TAC $<9600 \mathrm{t}$. |
| Sole in Division IIIa | Full reproductive capacity | Likely sustainably exploited | Unknown |  |  | Given the uncertainties in the assessment regarding non-reporting and discarding in recent years, ICES advises a TAC for 2006 not higher than the TAC for 2005, even though SSB is estimated much higher than $\mathrm{B}_{\mathrm{pa}}$. The estimate of present (status quo) fishing mortality is uncertain but status quo fishing mortality is probably at or below $\mathbf{F}_{\mathrm{pa}}$. It is thus not considered precautionary to increase the fishing mortality above status quo irrespective of the actual estimate. | TAC $<900 \mathrm{t}$ |

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single stock exploitation boundary for agreed management plan or in relation to precautionary limits. Tonnes or effort in 2006 and $\%$ reduction in F . |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high longterm yield | In relation to agreed management plan | in relation to high long term yield | in relation to precautionary limits |  |
| Sole in the North Sea | Full reproductive capacity | Harvested sustainably | Overexploite d | No management plan | The current fishing mortality $\left(\mathbf{F}_{\mathrm{sq}}\right)$ is estimated as 0.35 , which is above the rate that would lead to high long-term yields. $\mathbf{F}_{\text {max }}$ is not well defined and $\mathbf{F}_{0,1}$ is 0.13 . Fishing at $\mathbf{F}_{0,1}$ is expected to lead to landings in 2006 of 5600 t and SSB in 2007 of around 41300 t . | The exploitation boundaries in relation to precautionary limits imply human consumption landings of less than 11 900 t in 2006, which is expected to lead to an SSB equal to $\mathbf{B}_{\mathrm{pa}}(=35000 \mathrm{t})$ in 2007. | TAC $<11900 \mathrm{t}$. |
| Sole Eastern Channel | Full reproductive capacity | At risk of being harvest unsustainably | Overexploite d | No management plan | Target reference points have not been agreed for this stock. The current fishing mortality ( $\mathbf{F}_{\text {sq }}$ ) is estimated as 0.42 , which is above the rate that would lead to high long-term yields ( $\mathrm{F} 0.1=0.13$ ). $\mathrm{F}_{\text {max }}$ is not well defined. Fishing at $\mathbf{F}_{0.1}$ is expected to lead to landings in 2006 of 2100 t and SSB in 2007 of around 15500 t . | The exploitation within the precautionary limits would imply landings of less then $5720 t$ in 2006 which is expected to lead to a $12 \%$ decrease in SSB in 2007. | TAC $<5720 \mathrm{t}$. |
| Sandeel North Sea | Reduced reproductive capacity | Freference points are not defined | Unknown | No management plan | Management of fisheries should try to prevent local depletion of sandeel aggregations, particularly in areas where predators congregate. | The fishery should remain closed until information is available which assures that the stock can be rebuilt to $\mathbf{B}_{\mathrm{pa}}$ by 2007. The information on which this could be based includes a survey in December 2005 and exploratory fishing in April 2006. | In-year considerations |
| Norway pout North Sea | Reduced reproductive capacity | F reference points are not defined | F reference points are not defined | No management plan. | Unknown | ICES recommends that the fishery should remain closed. Re-opening the fishery should only be considered if the IBTS survey in January-February 2006 demonstrates a strong 2005 year class and only if it can be assured that the SSB in 2007 will be above $\mathbf{B}_{\text {pa }}$. | In-year considerations |
| Nephrops in Division IIIa (Management Area E) | Unknown | Unknown | Unknown | No management plan | Unknown | Given the apparent stability of the stocks, current levels of exploitation appear to be sustainable. <br> Due to uncertainty in the available data ICES is not able to reliably forecast catch. Therefore ICES recommends that fishing effort for fleets targeting Nephrops should not. be allowed to increase. | No increase in effort |
| Nephrops in Division IVa, East of $2^{\circ} \mathrm{E}+$ rectangles $43 \mathrm{~F} 5-\mathrm{F} 7$ (Management Area S) | Unknown | Unknown | Unknown | No management plan | Unknown | Given the apparent stability of the stocks, current levels of exploitation appear to be sustainable. Therefore, ICES recommends that fishing effort for fleets targeting Nephrops should not be allowed to increase. | No increase in effort |

| Stock | State of the stock |  |  | ICES considerations in relation to single-stock exploitation boundaries |  |  | Upper limit corresponding to single -stock exploitation boundary for agreed management plan or in relation to precautionary limits. |  |  | Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to high longterm yield | In relation to agreed management plan | in relation to high long-term yield | in relation to precautionary limits |  |
|  | Horse Mackerel in the North Sea | Unknown | Unknown | Unknown |  |  | ICES reiterates the recommendation made in 2004 to limit the catches to be below the 1982-1997 average of 18000 t , in order to constrain the fishery until there is more information about the structure of horse mackerel stocks, and sufficient information to show that higher exploitation rates are sustainable. | TAC $<18000$ t |
|  | Rays and skates in the North Sea | Unknown | Unknown | Unknown |  |  | The stocks of common skate and thornback rays are depleted. Target fisheries should not be permitted, and by-catch in mixed fisheries should be reduced to the lowest possible level. <br> If the fisheries for rays continue to be managed with a common TAC for all ray species, this TAC should be set at zero for 2006. | Minimal bycatch. Zero TAC. |
|  | Spurdog | Unknown | Unknown | Unknown |  |  | Target fisheries should not be permitted to continue, and by-catch in mixed fisheries should be reduced to the lowest possible level. A TAC should cover all areas where spurdog are caught in the northeast Atlantic. This TAC should be set at zero for 2006. | Low bycatch. Zero TAC. |

## Identification of critical stocks

The above table identifies the stocks where spawning stock biomass is at reduced reproductive capacity (cod in the North Sea, Eastern Channel and Skagerrak, cod in Kattegat, sandeel in the North Sea) and/or where fishing mortality indicates unsustainable harvesting of the stock (cod in the North Sea, Eastern Channel and Skagerrak, cod in Kattegat). Norway pout is also being considered as a critical stock because the spawning stock is around $\mathbf{B}_{\text {lim }}$ and recent recruitments of this shortliving species have been very low. These stocks are the overriding concerns in the management of all demersal fisheries:

- For cod in the North Sea, Eastern Channel and Skagerrak, for cod in Division IIIa, North Sea and Eastern Channel and for cod in Kattegat, it is not possible to identify any non-zero catch which will be compatible to the precautionary approach. ICES therefore recommends a zero catch;
- for sandeel and Norway pout in the North Sea ICES recommends that the fishery should remain closed until information is available which assures that the stock can be rebuilt to $\mathbf{B}_{\mathrm{pa}}$ by 2007. For sandeel the information on which this could be based includes a survey in December 2005 and exploratory fishing in April 2006. For Norway pout the IBTS survey in February 2006 will provide the information.

There are also concern about the stocks of spurdog, porbeagle, and some rays species taken as bycatch in fisheries directed towards other species.

## Advice for fisheries management

Fisheries in Division IIIa (Skagerrak-Kattegat), in Subarea IV (North Sea) and in Division VIId (Eastern Channel) should in 2006 be managed according to the following rules, which should be applied simultaneously:

## Demersal fisheries

- with minimal bycatch or discards of cod;
- Implement TACs or other restrictions that will curtail fishing mortality for those stocks mentioned above for which reduction in fishing pressure is advised;
- within the precautionary exploitation limits for all other stocks (see text table above);
- Where stocks extent beyond this area, e.g. into Division VI (saithe and anglerfish) or are widely migratory (Northern hake), taking into account the exploitation of the stocks in these areas so that the overall exploitation remains within precautionary limits.
- With minimum by-catch of spurdog (see Volume 9, section 1.4.6), porbeagle and thornback ray and skate.

Pelagic fisheries exploiting herring (western Baltic spring-spawning and North Sea autumn-spawning stocks) mackerel and horse mackerel

- with minimal bycatch or discards of cod;
- with minimal catch of North Sea mackerel, respecting the closed season;
- within the precautionary exploitation limits for the herring stocks taking into account the exploitation of herring in the western Baltic (Subdivisions 22-24);
- Where stocks extend beyond this area, e.g. widely migratory species (NEA mackerel and blue whiting), taking into account the exploitation of the stocks in these areas so that the overall exploitation remains within precautionary limits.

Fisheries with small meshed gears for industrial purposes

- with minimal bycatch of cod and other fish used for human consumption;
- without fishing for Norway pout or sandeel except if the fisheries are reopened on basis of information that they will rebuild to $B_{p a}$;
- within the single-stock exploitation limits for all other stocks (see text table above).

## Management considerations

ICES notes that this advice presents a strong incentive to fisheries to avoid catching species that are identified as critical stocks. Industry-initiated programmes to pursue such incentives should be encouraged, but must include a high rate of independent observer coverage, or other fully transparent methods for ensuring that their catches of critical stocks are fully and credibly reported. Such programmes could be considered in the management of these fisheries.

Reductions in fishing mortalities have been advised for several demersal stocks in the North Sea. Fishing mortality is generally high but for some stocks there are now indications that fishing mortality is decreasing in recent years. This is
consistent with the observed decrease in fishing effort due to days at sea regulations and decommissioning in the major fleets. ICES reiterates that required reductions in fishing mortality can only be achieved if significant reductions in effort are included in management, and effective deterrents to discarding are implemented. Extensive discarding occurs in most fisheries on roundfish, flatfish, and Nephrops in the North Sea. These discards are largely small and juvenile fish. They always result in foregone potential yield, and for depleted stocks they are a serious impediment to rebuilding.

## Short-term implications

The catch options that would apply if single stocks could be exploited independently of others are summarized in the table above. However, many stocks are exploited in mixed fisheries. Mixed fisheries management options should be based on the expected catch in specific combinations of effort in the various fisheries taking into consideration the advice given above. The distributions of effort across fisheries should be responsive to objectives set by managers, which is also the basis for the scientific advice presented above.

The information on the mix of demersal species in 2003 has been compiled by ICES (Tables 3.4.1.3-5). However, ICES is not yet in a position to present scenarios of the effects of various combinations of fleet effort, because the methodology to calculate these scenarios has not been agreed.

The extent to which the stocks are taken in the same fisheries has not been quantified on basis of available data. The existing information suggest that the stocks are caught together to a high (H), medium (M), low (L) extent, or not at all $(0)$, as indicated in the table below. The information in the table relates to catches and the linkage is thus indicated as high, also in cases where the catches of most of one stock taken in a fishery with another stock is discarded.

## Regulations in force and their effects

An emergency measure (Council Regulation (EC) 259/2001) involving the closure of a large area of the North Sea was implemented from 14 February to 30 April 2001 to all fishing vessels using gears likely to catch cod. Analysis of the effectiveness of the emergency measures indicated that the closure had an insignificant effect upon the spawning potential for cod in 2001. The redistribution of the fishery, especially along the edges of the box coupled to the increases in proportional landings from January and February appeared to have been able to negate the potential benefits of the box. The conclusion from the study was that the box would have to be extended in both space and time to be more effective (see: ICES 2004). The emergency measure has not been adopted after 2001.

EU technical regulations in force in 2003 and 2004 are contained in Council Regulation (EC) 850/98 and its amendments. The regulation prescribes the minimum target species' composition for different mesh size ranges. In 2001, haddock in the whole of NEAFC region 2 were a legitimate target species for towed gears with a minimum codend mesh size of 100 mm . As part of the cod recovery measures, the EU and Norway introduced additional technical measures from 1 January 2002 (EC 2056/2001). The basic minimum mesh size for towed gears for cod from 2002 was 120 mm , although in a transitional arrangement until 31 December 2002, vessels were allowed to exploit cod with 110mm codends provided that the trawl was fitted with a $90-\mathrm{mm}$ square mesh panel and the catch composition of cod retained on board is not greater than $30 \%$ by weight of the total catch. From 1 January 2003, the basic minimum mesh size for towed gears for cod was 120 mm . The minimum mesh size for vessels targeting haddock in Norwegian waters is also 120 mm . There is some indication of the effect of mesh size regulations in the sudden increase in weight-at-age in the human consumption component for age 2 haddock. However, a shift in exploitation pattern at the early ages has not been observed. This may be confounded by the shift to smaller mesh fisheries ( $80-\mathrm{mm}$ mixed Nephrops) by some fleet segments that previously fished for a mix of fish and Nephrops using 100 mm . This shift was also encouraged by the differences in effort allocation between the $80-$ and $120-\mathrm{mm}$ fleets, where the smaller mesh fishery was awarded a higher proportion of days per month. It is likely that this may have increased discarding due to the lower selectivity and high grading to comply with catch composition regulations.

Minimum landings sizes are in effect for several North Sea species. The minimum landing size for cod in Subarea IV and Divisions IIla and VIId is 35 cm ; in Denmark it is 40 cm . In addition, size restrictions occur in flatfish fisheries. The minimum landing size of North Sea plaice is 27 cm . This minimum landing size results in high discard rates in the mixed flatfish fishery with beam trawls using $80-\mathrm{mm}$ mesh size. The minimum landing size of North Sea sole is 24 cm .

Effort restrictions in the EC were introduced in 2003 (EC 2341/2002, Annex XVII, amended in EC 671/2003). Effort restriction measures were revised for 2004 (EC 2287/2003, Annex V). Preliminary analysis of fishing effort trends in the major fleets exploiting demersal stocks indicates that fishing effort in those fleets has been decreasing since the mid1990s due to a combination of decommissioning and days-at-sea regulations. The decrease in effort is most pronounced in the years 2002 and beyond. However, effort restrictions combined with higher fuel costs has resulted in effort being shifted towards coastal fisheries. It is likely that this will increase discard rates because of the presence of small plaice in these areas.

A cod protection area has been implemented for 2004 only (EC 2287/2003, amended in EC $867 / 2004$ ) which defined the conditions under which certain stocks, including haddock, could be caught in Community waters. A maximum of $35 \%$ of the haddock TAC in 2004 could be taken from within the cod protection area. For UK a special permit was introduced that was needed to fish for haddock in the cod protection area. Although this management scheme was proposed to permit additional haddock to be caught in 2004, the uptake of the special permit has been relatively low.

In 2004 agreement was reached within the EU on a formal cod recovery plan that will be operational during the TAC and management decision processes of 2004, effectively rendering the plan operational in 2005. Details of it are given in Council Regulation (EC) 423/2004. Technical measures applicable to the flatfish fishery in the North Sea included mesh size regulations, minimum landing size, gear restrictions, and a closed area (the plaice box). Mesh size regulations for towed gears require that vessels fishing North of $55^{\circ} \mathrm{N}$ (or $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$, since January 2000) should have a minimum mesh size of 100 mm , while to the south of this limit, where the majority of the plaice fishery takes place, an $80-\mathrm{mm}$ mesh is allowed. In the fishery with fixed gears a minimum mesh size of 100 mm is required. Mesh enlargement would reduce the catch of undersized plaice and cod, but would also result in loss of marketable sole. An increase in the minimum landing size of sole could provide an incentive to fish with larger mesh sizes and therefore a reduction in the discarding of plaice and juvenile cod.

In addition to this, since 2002 a small part of the North Sea plaice fishery is affected by the additional cod recovery plan (EU regulation 2056/2001) that prohibits trawl fisheries with a mesh size $<120 \mathrm{~mm}$ in the area to the north of $56^{\circ} \mathrm{N}$. The aggregated beam length of beam trawls is limited to 24 m . In the 12 nautical mile zone the maximum aggregated beamlength is 9 m in the plaice box. The plaice box has been enforced since 1989, and the area was closed in all quarters since 1995. The closed area applies to vessels using towed gears, but vessels smaller than 300 HP , including the small
mesh fishery for Crangon, are exempted from the regulation. The effectiveness of the plaice box has been evaluated by an expert group in 2004, but the report of that group was not yet available to ICES.

Previous MAGP programmes have induced changes in fleet compositions in the flatfish fishery. The Dutch beam trawl fleet has reduced in number of vessels and shifted towards two categories of vessels: 2000 HP (the maximum engine power allowed) and 300 HP (the maximum engine power for vessels that are allowed to fish within the 12 -mile coastal zone and the plaice box). A substantial part of the decommissioned vessels have been replaced by vessels in other countries (England, Scotland, Germany, Belgium). Overall capacity and effort of North Sea beam trawl vessels appears to have decreased since 1995. A management plan has been implemented in 1999 for the North Sea herring fishery. The management plan consists of restraining fishing mortality and keeping the stock above threshold levels. Simulations indicate that the current management strategy maintains this stock within precautionary limits. The likelihood of exceeding precautionary limits depends on the accuracy of the assessment and the compliance of the fishery with the regulations. Thus, overfishing the TAC by $20 \%$, combined with an overestimation of the stock in assessment by $10 \%$ on average, would lead to a near $50 \%$ risk that SSB drops below $\mathbf{B}_{\mathrm{pa}}$ and a $4 \%$ risk that it falls below $\mathbf{B}_{\text {lim }}$.

## Information from the fishing industry

ICES held consultations with North Sea Commission Fisheries Partnership in Copenhagen, October 3-4 2005, during which meeting the participants and two invited experts reviewed four stocks: cod, whiting, plaice, and sole. Plaice and cod were also reviewed in 2002, 2003, and 2004 and various recommendations were made as a part of that review and have been implemented by the relevant assessment working group.

## Quality of assessments and uncertainties

The level of biological sampling of the commercial landings of roundfish, flatfish, herring, and mackerel is relatively good and has been maintained. However, a major drawback in the available data is that they mostly refer to the landed component of the catch for most species. Discard data have traditionally only been used directly in assessments for haddock and whiting, with the majority of whiting discards based on a historical series only for one country. Several countries now collect discard data on a recurrent basis. This year, discards data have been included in the assessments of North Sea cod and plaice. It is noted that the inclusion of discards appears to reduce potential biases but may increase the uncertainties in the assessment (noise), because discards sampling is often rather scanty. In order to be able to include discards into an assessment, when discards have only been sampled in recent years, assumptions have to be made about the historical part of the time-series. These assumptions could compromise the reliability of the assessment that is based on them.

Data on catch and effort are available for many fisheries, but it is uncertain how reliably these data reflect trends in effective effort, i.e. nominal effort after corrections for technological improvements or changes in efficiency. Restrictive management measures (TACs) have also resulted in changes in the fishing practice of some fleets and redirected their effort to other species. In a number of cases this has lead to abandoning the use of time-series of commercial CPUE data in the assessments (cod, haddock, whiting, plaice), although the time-series of CPUE are still presented in the working group reports. In some recent years there was misreporting of roundfish landings associated with restrictive quotas. Substantial underreporting of cod landings is estimated to have occurred in between 1993 and 2003. Additionally, misreporting where fish are caught may have created problems for species groups such as those in the Eastern Channel. The consequence of the reporting problems in landings may have led to retrospective problems in analytical assessments. These retrospective problems lead to further uncertainty in short-term forecasts.

Several series of research vessel survey indices are available for most species. Quarterly data were available from the International Bottom Trawl Survey for a period of 6 years (1991-1996) and these were used in the assessment of some stocks. This survey has covered quarters 1 and 3 since then. For herring and mackerel the spawning stock sizes are estimated by annual larvae and acoustic surveys (herring) or intermittent egg surveys (mackerel). Lack of any fisheriesindependent surveys for sandeels has resulted in analytical problems with potential auto-correlation between catch and fisheries-dependent indices in the model. Changes in English and Scottish surveys in the time-series has resulted in the use of a split time-series for several species (e.g. haddock), which has improved the residual patterns in the assessment.

Multispecies considerations are incorporated in the assessments and the forecasts for the North Sea stocks of cod, haddock, whiting, herring, sprat, sandeel, and Norway pout. In those cases average natural mortalities estimated by multispecies assessments were incorporated in the assessments. Incorporation of time variable natural mortalities from a multispecies assessment model into the single-species assessments has been carried out as a sensitivity analysis of the assessments.

### 1.3.2 Special requests

### 1.3.2.1 Long-term Management Advice (DG Fish with Norway)

ICES has received a request from the European Community and Norway:

## 'Background

The Community and Norway have developed work on long-term management modelling of shared stocks through work reported in "Multi-Annual management plans for stocks shared by EU and Norway, Brussels, 14 to 18 June 2004" and "Evaluation of Harvest Control Rules for North Sea Cod. Report of a two-day Meeting of Scientists from Norway and the Community.Brussels, 18th. and 19th. March 2002 ". These two documents are forwarded to ICES under separate cover.

The Community and Norway wish three additional issues to be addressed in the context of ICES Iong-term management advice:
a). Appropriate Iong-term management of the North Sea cod stock in any eventual post-recovery situation;
b). An updating of the simulation studies for North Sea plaice to take account of new data and perceptions of discarding.
c). Management strategies for western horse mackerel, sandeel, Norway pout and anglerfish.

## The detailed request is as follows:

1) ICES is requested to evaluate a range of harvest rules for the North Sea cod (from a starting point of SSB=Bpa) and North Sea plaice (from a starting point based on the ICES assessment made in 2004) with respect to medium and long term yields, stability of yield and effort; stock status with respect to safe biological limits. Evaluations shall at a first instance be made on a single species basis, but the experts shall, to the extent possible, quantify mutual compatibility of the rules for cod with those for other stocks that are exploited in mixed fisheries.

- The types of harvest rules to be considered should include
- Harvest rules where TACs and/or fishing effort are derived according to a target fishing mortality, supplemented with a rule for reducing the mortality if the spawning stock biomass is below a trigger level, to ensure avoiding a limit value for the spawning biomass.
- Harvest rules as above, but with an additional constraint on the year to year variation of the TAC including a $+/-15 \%$ limit on TAC variation.
- Evaluate alternative approaches to limit year-to-year changes in TAC. The current simulated harvest control rule uses a fixed target $F\left(F_{L T}\right)$ above a trigger biomass $\left(B_{\text {trig }}\right)$. Increased stability can be achieved by replacing $F_{L T}$ with a $F$ rule that implies reducing $F$ with increasing stock size. One candidate is the rule corresponding to a fixed TAC for stock sizes above $B_{\text {tuig. }}$.
- Alternative rules if feasible.

2) The rules shall be evaluated through simulations taking into account inter alia:

- Alternative scenarios for future recruitments, weights and maturities at age, assessment error, discarding and other unaccounted mortality.
- Changes in fishing practice (i.e. selection at age).
- Feedback between stock assessment and fisheries management.

3) The performance of the rules shall be evaluated both with respect to the perceived state of the stock and to the state of the underlying operating model population. The performance criteria shall include:

- Compatibility with the precautionary approach and relevant international standards and agreements.
- Probability distributions of TACs, yield, spawning stock biomass and fishing mortality.
- Year to year variation in TACs, yield and fishing mortality.
- The risk of entering rebuilding situations ( $B<B_{\text {trig }}$ ) in simulations without the year-to-year limitations in TAC change.

4) Evaluations shall show:

- The robustness of the harvest rules in assuring stock recovery and maintaining stocks within safe biological limits, considering a plausible range of scenarios as outlined in 3 and a range of alternative parameters as outlined in 2 .

## Request concerning western horse mackerel, anglerfish, sandeels and Norway pout:

1. Advise on appropriate management systems including management strategies, objectives and ecosystem considerations for western horse mackerel, anglerfish, sandeels and Norway pout.'

## ICES comments:

The present response deals specifically with the request concerning North Sea cod and plaice, and anglerfish. For sandeel, Norway pout, and western horse mackerel work has been initiated within the ICES community that will enable a response to be delivered by October 2005.

The Ad hoc Group on Long-Term Advice [AGLTA] met at ICES Headquarters, Copenhagen from 12-13 April 2005 to discuss and agree the technical basis for the ICES advisory response to this joint request from EC and Norway. The results of their evaluations and simulations are summarised in this response, but their report should be consulted for full technical details (ICES CM 2005/ACFM:25).

## Evaluation framework

Based on the request, the objectives of the management strategies to be evaluated are in all cases assumed to be high medium- and long-term yields and good stock status with respect to safe biological limits (reflected by a low risk of SSB falling below a conservation limit). The hierarchy is assumed to be that high long-term yield will be conditioned by simultaneous low risk to SSB, which has overall priority. Important performance criteria are taken to be stability of yield and robustness to both assumptions concerning stock productivity (reflected in assumptions about a stockrecruitment relationship) and the precision and bias of stock assessments.

Note that for brevity, the phrase low risk to reproduction is used within the text of this response to replace low risk of SSB falling below a conservation limit.

The evaluations for North Sea cod and plaice are based on simulations of stochastic medium-term projections over a 10year period, taking into account uncertainty in initial stock numbers-at-age, future recruitments, and individual weights and maturities. The robustness of the simulated outcomes to uncertainty and bias in future assessments, assumptions about the recruitment regime and implementation error have been evaluated though sensitivity tests (ICES CM 2005/ACFM:25). Implementation error in this document is understood as including both failure to make decisions according to the management plan and failure to enforce management decisions. The evaluations of management strategies have been undertaken within the common framework presented next.

The management strategies evaluated included a harvest control rule (HCR) with three parameters - a target $F\left(F_{t}\right)$, a limit spawning stock biomass ( $\mathbf{B}_{\text {lim }}$ ), and a trigger spawning stock biomass ( $\mathbf{B}_{\text {trig }}$ ). Pictorially, depicted by:

The figure represents the decision rule and not the realised fishing mortality. The actual fishing mortality will be different due to assessment and implementation error. In the simulations, which have been part of the evaluation, such errors have been included. A small fishing mortality below $\mathbf{B}_{\text {lim }}$ has also been included to simulate a small unavoidable mortality which must be assumed to exist even if management decisions for closure of targeting and important mixed fisheries catching the species in question have been made.

In this framework values of $\mathbf{F}_{\mathrm{t}}$ and $\mathbf{B}_{\text {trig }}$ are estimated which achieve objectives regarding low risk to SSB and high future yields whilst satisfying relevant performance criteria.
$\mathbf{F}_{t}$ and $\mathbf{B}_{\text {trig }}$ are conceptually different from the reference points $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{pa}}$ used in an earlier framework. $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{pa}}$ are signposts regarding the state of the stock and the fisheries within the Precautionary Approach where the concern is the need to maintain low risk that the actual spawning stock falls below the biomass level below which there is increased risk of impaired recruitment, $\mathbf{B}_{\mathrm{lim}}$. Even though $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{pa}}$ are parameters of the state of the stock they have in practice been used as parameters in a decision rule which implicitly has had avoidance of risk to SSB as its sole objective. The new framework distinguishes between state of the stock parameters ( $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{F}_{\mathrm{pa}}$ ) and management plan decision rule parameters ( $\mathbf{F}_{\mathrm{t}}$ and $\mathbf{B}_{\text {trig }}$ ). The management decision rule parameters should be selected such that all objectives and performance criteria are satisfied or balanced simultaneously. As low risk to SSB is a prioritised objective the normal assumption will be that $\mathbf{F}_{\mathrm{t}}$ will be lower than $\mathbf{F}_{\mathrm{pa}}$ and that $\mathbf{B}_{\text {trig }}$ will be higher than $\mathbf{B}_{\mathrm{pa}}$.

An alternative set of strategies was evaluated, based on a fixed TAC ( $\mathrm{TAC}_{f}$ ) and the biomass parameters $\mathbf{B}_{\text {lim }}$ and $\mathbf{B}_{\text {trigg }}$. Pictorially,

## TAC

Other variants, such as a TAC slope below $\mathrm{B}_{\text {trig }}$ or more than one intermediate TAC level below $\mathbf{B}_{\text {trig }}$, are conceivable, but due to practical limitations of the simulation software a harvest control rule with one plateau of $\mathrm{TAC}_{\mathrm{f}} / 2$ was used between $\mathbf{B}_{\text {lim }}$ and $\mathbf{B}_{\text {trig }}$.

The assumed benefits of a fixed TAC approach relative to a target F approach are stability in fishing opportunities and that management becomes less dependent on the precision of annual stock assessments as long as the stock is well above $\mathbf{B}_{\text {trig. }}$. The possible losses in terms of yield, risk to reproduction and performance are evaluated below.

While $\mathbf{B}_{\mathrm{lim}}$ is supposed to be an estimate of a property of nature (namely, the spawning stock biomass below which reproduction is at risk of being impaired) both $\mathbf{B}_{\text {trig }}$ and $\mathbf{F}_{\mathrm{t}}$ (or in the fixed TAC rule $\mathrm{TAC}_{f}$ ) are only parameters of the decision rule. These parameters can be decided entirely on the basis of the desired objectives and performance of the management strategy.

In some cases with fishing mortalities far below what has been observed in several decades, the simulated long-term spawning stock levels of both cod and plaice grow well beyond what has been observed historically. It is emphasised that simulations which do not take biological interactions and density-dependent growth/maturity into account will not produce results which are reliable in an absolute quantitative sense. The results should therefore only be taken as indicative of the direction of change when simulations are well beyond the historical range of fishing mortalities. For that reason alone, this response does not include the quantitative graphical outputs of the simulations undertaken by ICES and reported in ICES CM 2005/ACFM:25.

For the present, this response deals only with the request concerning North Sea cod and plaice, and anglerfish.

- For sandeel and Norway pout the management strategy will be based on in-year information from either an initial fishery (sandeel) or surveys (Norway pout). The currently available software does not enable simulation for these stocks, but a process has been proposed by which simulations and advice will be produced during 2005 (ICES CM 2005/ACFM:25). The response to this part of the request will thus be available in October 2005.
- For western horse mackerel, the spasmodic nature of spawning indicates that a dual management regime is needed with different management rules for the cases where a large year class either is, or is not, present. The conditions for such a regime have been discussed within ICES and a process devised through which proposals for a management strategy will be produced (ICES CM 2005/ACFM:25). The response to this part of the request will be available in October 2005.
- For anglerfish there is insufficient catch data, no survey information and important aspects of the biology are unknown. This response therefore includes a proposal for a two-step adaptive approach that will enable better information to be produced, after which management measures could be adapted.

## Overall conclusions

Some overall conclusions regarding management strategies may be drawn across the stocks studied. These conclusions are based on the stocks for which simulations were made:

- At low target Fs (considerably lower than the present F), low risk to reproduction and high long-term yields are achieved simultaneously. The general pattern is that there is no conflict between the two objectives. A low $\mathbf{F}_{t}$ will lead to high yield simultaneously with a low risk to reproduction that is lower than the $5-10 \%$ risk which has generally been considered acceptable by managers.
- Once stocks have recovered and fishing mortality is around a low $F$ target, the outcomes are insensitive to $\mathbf{B}_{\text {trig }}$. Criteria for the selection of $\mathbf{B}_{\text {trig }}$ in this situation are discussed below.
- Fixed TAC regimes are feasible, but result in lower long-term yield for the same risk to reproduction.
- At low target Fs there is low sensitivity to recruitment assumptions (recruitment model used in simulations).
- Implementation errors above $10-20 \%$ disrupt achievement of low risk to reproduction and high long-term yield.

The selection of $\mathbf{F}_{\mathrm{t}}$ and $\mathbf{B}_{\text {trig }}$ is evaluated by simulated outcomes of management strategies in terms of the achievement of objectives and performance criteria. While the simulations provide clear indications of the relevant ranges of $\mathbf{F}_{\mathrm{t}}$, the outcomes may be insensitive to choices of $\mathbf{B}_{\text {trig }}$ once low Fs have been achieved. Some general supplementary considerations in the choice of $\mathbf{B}_{\text {trig }}$ are:

- As low risk to SSB is a prioritised objective the normal assumption will be that $\mathbf{F}_{\mathrm{t}}$ will be lower than $\mathbf{F}_{\mathrm{pa}}$ and that $B_{\text {trig }}$ will be higher than $B_{p a}$.
- The main role of having a $\mathbf{B}_{\text {trig }}$ is to have an early response to a declining SSB. A high $\mathbf{B}_{\text {trig }}$ is more robust to implementation and assessment error and poor recruitment.
- As a rule-of-thumb, $\boldsymbol{B}_{\text {trig }}$ should be chosen to be well above $\mathbf{B}_{\text {lim }}$ and take into account the uncertainty in the annual SSB estimate.
- A low $\mathbf{B}_{\text {trig }}$ is expected to result in large interannual variations in the Fs prescribed by the decision rule. This will result when the variance in the biomass estimates results in estimates of SSB changing from one year to the next from being above $\mathbf{B}_{\text {trig }}$ to being below or close to $\mathbf{B}_{\text {lim }}$, and vice versa.
- A high $\mathbf{B}_{\text {trig }}$ will result in faster response and thus more proactive action in worst case situations of consecutive years with low recruitment.

## North Sea cod summary

The evaluation of the probability of recovery to $\boldsymbol{B}_{\mathrm{pa}}$ was not part of the request. However, in order to derive a starting population for a recovered North Sea cod stock at $B_{p \mathrm{a}}$, ICES has evaluated several scenarios by which the recovery might be achieved and has concluded that:

- recovery is unlikely unless $F$ can be substantially reduced from current levels;
- implementation bias over $10 \%$ seriously reduces the likelihood of the cod recovery; and
- recovery time and probability are dependent on the continued influx of at least moderate recruitment.

The last point is critical and cannot be predicted as the stock presently is in a state where future reproduction is unknown. For this reason, ICES in 2003 concluded that a precautionary recovery plan must include an adaptive element implying that the fisheries for cod remains closed until an initial recovery of the cod SSB has been proven.

In relation to the joint request, the evaluations of harvest control rules for North Sea cod have demonstrated the following:

- target fishing mortalities (covering all catches) below 0.4 (ages 2-4) result in a low risk of SSB falling below the conservation limit $\mathbf{B}_{\mathrm{lim}}$ and high long-term yields. With fishing mortalities below 0.4 the following conclusions can be drawn:
- a low risk to reproduction when a constraint on year-to-year variation in TAC (down to $\pm 5 \%$ ) is used;
- a constraint to year-to-year variation in TAC of less than $\pm 20 \%$ results in reductions in long-term yields;
- implementation error above $10 \%$ results in significant increases in risk to $\mathbf{B}_{\text {lim }}$.

However, a word of caution is necessary. In the simulations with low fishing mortalities, the absolute stock sizes projected are very high and well outside of the historically observed ranges. It is unknown whether such high stock sizes can actually be achieved given the constraints within the natural system and what effects this would have on the dynamics of the stock. However, the numerical results of the simulations in terms of risk to reproduction and expected yield are conditional on these large stock sizes. The conclusions regarding the general direction required are not sensitive to density-dependent effects - i.e. significant reductions in fishing mortality to achieve simultaneously a low risk to reproduction and high long-term yield. It is therefore suggested that an implementation of long-term management plans is based on an adaptive approach whereby the development of the stock is monitored as the effects of the reduced fishing mortality are developing, and the specific numerical values within the management plan may then be modified on the basis of the outcome of the fishing mortality reductions.

## North Sea plaice summary

The starting population for the simulations on North Sea plaice was taken from the last ICES assessment made in 2004 (ICES CM 2005/ACFM:07) which included simulated discards (1957-1998) and estimated discards (1999-2003). The exploitation pattern used is thus based on assessments including landings and discards.

In relation to the joint request, the evaluations of harvest control rules for plaice have demonstrated, under the assumption of the current exploitation pattern, that target fishing mortalities (covering all catches) in the range 0.3-0.4 (ages 2-6) result in a low risk to reproduction and high long-term yields. The performance of a long-term management plan with target Fs below 0.4 is not sensitive to choices of $\mathbf{B}_{\text {trig }}$. A major improvement to the stock development and to the landings is expected if an additional (i.e. more than proportional) reduction of juvenile mortality could be achieved, in which case the target mortality could be reconsidered. A constraint on annual TAC variations is expected to improve the performance both in terms of minimising short-term landings variation and in terms of making the system less sensitive to the noise in annual assessments. For $\mathbf{F}_{\mathrm{t}}$ in the range of 0.3 to 0.4 , the likelihood of meeting objectives and performance criteria is relatively insensitive to assumptions regarding stock productivity and assessment error and bias.

A fixed TAC regime with TAC below 80000 t is expected to produce the same results in terms of low risk to reproduction, but will result in considerably lower average landings in the longer term.

The simulations investigated have neither taken biological interactions nor density dependent growth/maturity into account and are thus merely indicative of the direction of outcomes from the management strategies prescribed in the joint request. However, the conclusions regarding the general direction required are not sensitive to density-dependent effects - i.e. significant reductions in fishing mortality to achieve simultaneously a low risk to reproduction and high long-term yield. It is therefore suggested that an implementation of long-term management plans is based on an adaptive approach whereby the development of the stock is monitored as the effects of the reduced fishing mortality are developing, and the specific numerical values within the management plan may then be modified on the basis of the outcome of the fishing mortality reductions.

## Anglerfish approach

There are major uncertainties about catch and effort data for anglerfish, as well as limited knowledge about population dynamics and distribution. In addition, existing surveys have not proven useful in describing the population. For these reasons, simulations of management plans would have to be so generic that they would tell little about the expected outcomes.

In this situation the most productive way forward would be a two-stage approach. The first stage would be to substantially improve the quality and quantity of data collected on the fishery while maintaining exploitation at its current level. This was the basis of ICES recommendation (ACFM 2004) to allow the fishery to continue with the current effort (inasmuch as this can be determined). This was to be accompanied by a detailed and stringent monitoring programme, including the mandatory reporting of both catch and effort data in logbooks, as well as the use of VMS data. The programme would also include the development of a targeted, industry collaboration trawl survey to start in 2005.

A key point in this recommendation was that the restrictive TAC in 2004 and previous years had led to extensive misreporting. Management aimed at maintaining effort at or below that of 2004, but without a specific TAC, would have allowed the accurate reporting of catch and effort. In the event, a TAC-based regime was retained, although at an increased level. To date it is not clear if this has improved the quality of the landings data, however, the TAC is still perceived as restrictive by the industry. The existing tally book scheme is to be continued and extended, and observers will be placed on as many vessels as is feasible. The targeted survey is planned to go ahead in the autumn of 2005 and analysis of VMS data at approximately the same time. More robust management measures to control the targeted fishery have been proposed in the UK.

This first stage of data collection would be expected to take at least five years to establish useable time-series of fisheries-dependent and -independent data. The second stage could then be launched to use these data to examine alternative management approaches and harvest control rules appropriate to this fishery in a fashion similar to that used elsewhere within this response; e.g. North Sea cod and plaice. Should evidence appear of a decline in the stock size during this period of data collection, the management of this stock should be revisited and appropriate management measures initiated.

## Sources of information

ACFM(2004).
Report of the Ad hoc Group on Long-Term Advice, 12-13 April 2005 (ICES CM 2005/ACFM:25).
Report on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 7-16 September 2004 (ICES CM 2005/ACFM:07).

### 1.3.2.2 $\quad$ Sole in Division IIIa (DG FISH)

The EC DG FISH has by 21 January 2005, requested non-recurrent advice from ICES on sole in Division IIIa. The EC asked ICES:

- when "...significant new information would be collected to allow a meaningful reassessment of this stock";
- if ICES could "...assess this new information and provide a review of its advice for 2005 ".

ICES has now done this and the outcome is presented below as an ICES Advice (including Management considerations), taking into account the mixed fishery aspect of the Division IIIa sole fishery, and as a single-stock summary text.

## ICES Advice

Fisheries of sole in Division IIIa (Skagerrak-Kattegat) should in 2005 be managed according to the following rules, which should be applied simultaneously:

- with minimal bycatch or discards of cod;
- within the precautionary exploitation limits for sole (see attached single-stock summary text).

## Management considerations

ICES notes that this advice presents a strong incentive to fisheries to avoid catching cod that are identified as critical stocks. Industry-initiated programmes to pursue such incentives should be encouraged, but must include a high rate of independent observer coverage, or other fully transparent methods for ensuring that their catches of critical stocks are fully and credibly reported. Such programmes could be considered in the management of these fisheries.

## Single-Stock Summary

Sole in Division IIIa (Skagerrak and Kattegat).
State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing mortality in <br> relation to <br> precautionary limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |  |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Likely sustainably <br> exploited | unknown |  |  |

Based on the most recent estimates of SSB, ICES classifies the stock as having full reproductive capacity. The assessment is uncertain due to substantial discarding and non-reporting in the most recent years. While the SSB estimate is relatively robust against this, the fishing mortality estimate in the most recent year is more uncertain, but available information indicates sustainable exploitation.

## Management objectives

There are no management objectives for this stock. However, for any management criteria to meet the proposed precautionary criteria $F$ should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and the $S S B$ should be maintained above the proposed $\mathbf{B}_{\mathrm{pa}}$

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\text {lim }}$ is 770 t. | $\mathrm{B}_{\mathrm{pa}}$ be set at 1060 t. |
|  | $\mathbf{F}_{\mathrm{lim}}$ is 0.47. | $\mathrm{~F}_{\mathrm{pa}}$ be set at 0.30. |
| Target reference points |  | $\mathrm{N} / \mathrm{A}$ |

The assessment has revised the level of SSB considerably for the last 5 years. Because of this, previously defined biomass-related reference points need to be re-evaluated.

## Technical basis:

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Given the uncertainties regarding non-reporting and discarding in recent years, ICES advises a fishing mortality not higher than the status quo fishing mortality to be applied in setting the final TAC for 2005. ICES will on the basis of the decision by the EU commission on the fishing in 2005 advise on the fishing options for 2006 in October 2005. The predicted catches in 2005 at various fishing mortalities are very sensitive to assumptions regarding non-reporting and discarding in recent years, which cannot be estimated precisely. The catch option table for 2005 is therefore provided in relative terms and gives the change of catch relative to the total catch in 2004 , i.e. reported landings and unreported/discarded catches in the order of $100 \%$ as well as corresponding changes in SSB in 2006 relative to 2005 .

## Short-term implications

Outlook for 2006
Basis: $\mathrm{F}(2004)=\mathbf{F}_{\mathrm{sa}} ; \operatorname{SSB}(2005)=4621 \mathrm{t}$, $\operatorname{catch}(2004)=784^{1)} \mathrm{t}$.

| Rationale | Basis | \% Catch change $^{2{ }^{2)}}$ | \% SSB change $^{\text {4) }}$ |
| :---: | :---: | ---: | ---: |
| Zero catch | $\mathrm{F}=0$ |  | $\mathbf{1 4 . 2}$ |
| Status quo | $\mathbf{F}_{\mathrm{sq}}$ | 2.6 | -3.3 |
|  | $\mathbf{F}_{\mathrm{sq}}{ }^{*} 0.5$ | -46.0 | 5.0 |
|  | $\mathbf{F}_{\mathrm{sq}} * 0.6$ | -36.0 | 3.3 |
|  | $\mathbf{F}_{\mathrm{sq}} * 0.7$ | -26.0 | 1.6 |
|  | $\mathbf{F}_{\mathrm{sq}} * 0.8$ | -16.3 | 0 |
|  | $\mathbf{F}_{\mathrm{sq}} * 0.9$ | -6.8 | -1.7 |
|  | $\mathbf{F}_{\mathrm{sq}} * 1.1$ | 11.1 | -4.8 |
|  | $\mathbf{F}_{\mathrm{sq}} * 1.2$ | 20.8 | -6.4 |
|  | $\mathbf{F}_{\mathrm{sq}} * 1.3$ | 29.6 | -7.9 |
|  | $\mathbf{F}_{\mathrm{sq}} * 1.4$ | 38.1 | -9.4 |

Weights in tonnes.
Shaded scenarios are not considered consistent with the precautionary approach. The estimate of present (status quo) fishing mortality is uncertain, but status quo fishing mortality is probably at or below $\mathbf{F}_{\mathrm{pa}}$. It is thus not considered precautionary to increase the fishing mortality above status quo irrespective of the actual estimate.
${ }^{1)}$ Catch includes reported landings plus an overall estimate of non-reporting and discarding of legal sized sole of $100 \%$ in 2004. This estimate is uncertain and the forecast is therefore provided on a relative basis.
${ }^{2)}$ Catch includes reported landings plus non-reporting and discarding due to quota restrictions.
${ }^{3)}$ Catch 2005 relative to catch 2004.
${ }^{4)}$ SSB 2006 relative to SSB 2005.

## Management considerations

Due to considerable non-reporting, discarding of fish above minimum landing size caused by restrictive quotas since 2002 and to a lesser extent misreporting to other species in recent years, the assessment is considered uncertain in relation to the estimate of $F$ in the final year. The forecast presented is based on the best available information from the industry and inspection regarding non-reporting and discards in 2002, 2003, and 2004, but this information is by its nature uncertain. The sensitivity of the assessment and the forecasts to assumptions regarding non-reporting and discarding has been evaluated for a range of likely scenarios. SSB estimates are more stable against such assumptions, but estimates of recent $F$ and thus the projected catches in future years are not. The short-term forecast has therefore been provided as changes relative to the assumed catches in 2004.

The estimate of present $F$ may be an underestimate, but the present $F$ is likely to be at or below $F_{p a}$. In order to avoid fishing at a fishing mortality above $\mathbf{F}_{\mathrm{pa}}$ ICES therefore advises that single-stock boundaries for fishing mortality should be below status quo fishing mortality in 2005.

The change in total catch provided in the forecast refers to the sum of reported and non-reported landings and discards of legal-sized sole.

Cod is taken as a bycatch in the sole fishery, thus the TAC for sole in 2005 should be set taking into account the status of the Kattegat cod stock, i.e. advice of no fishery in 2005.

## Management plan evaluations

There is no management plan in place.

## Regulations and their effects

The Danish fishery is regulated by half-monthly rations that depend on vessel length and vary over the year. The rations have been reduced since 2002, reflecting the decline in the agreed TAC and the Danish sole fishery was entirely closed late in the years 2002 to 2004 .

For the period 1991-1993 the official catch statistics are disputable with a significant amount of sole assumed landed without being properly recorded. For Kattegat where most of the sole catches in 1994-2000 were taken under an effort regime, the official statistics are assumed fairly accurate. Considerable misreporting by areas in 2000 and 2001 was corrected, i.e. North Sea sole reported as caught in Division IIIa.

Analyses of private logbooks, survey data, and observer data indicate that there was considerable economic incentive to non-report landings in 2002-2004 as the entire two-week ration in many cases could be taken in just a few hauls. However, it is not known to what extent these catches are discarded or landed as black landings (i.e. excluding both catch and effort data from the official statistics), or distributed to and landed by vessels not having caught their rations. Thus, this information could not be used to quantify discarding and/or non-reporting.

Based on information from the industry non-reporting and discarding is believed to be in the order of magnitude of 50$100 \%$ in 2002 and $100-200 \%$ in 2003 and 2004. Although the advice on the stock status is robust to the assumptions, unreported catches in this order of magnitude have a severe impact on the quality of the stock assessment through the estimate of status quo F and needs to be quantified properly.

There is a mis-match between the assessment area that is Division IIIa and the management area that includes Division IIIa plus the Western Baltic (Subdivisions 22-24). Danish vessel rations cover the management area and there are therefore no incentives for misreporting IIIa sole into the Western Baltic. However, the low TAC creates incentives for non-reporting for this stock.

## Ecosystem considerations

Sole is taken in a directed trawl fishery with bycatch of Nephrops and cod. Sole itself is taken as bycatch in the Nephrops trawl fishery. Gillnet catches are mainly taken in directed fisheries.

## Factors affecting the fisheries and the stock

## Changes in fishing technology and fishing pattern

Sole are caught with both gillnet and trawl. The peak season for trawl is from October to January. On average more than $75 \%$ of the annual sole catches with trawl are caught in this 4 -month season. However, September and February are important months for the sole fishery also, but the percentage of sole in the catches is significantly less, indicating that there might be other target species also in these periods. The season for sole gillnet fishery is from April to September.

## The environment

The stock is probably influenced by both temperature and salinity because it is located near the species' physiological limits for both of these factors. Large variations in either factor will therefore influence stock productivity.

The large increase in landings in the early 1990s compared to long-term historical levels (1950s-1980s) may represent both changes in environmental conditions and fishery developments (e. g., increased effort), but the relative importance of the two factors is not known.

The Kattegat has also been eutrophicated over the past 50 years, but the specific effects of eutrophication on sole have not been investigated.

## Scientific basis

## Data and methods

The assessment includes CPUE data from seven new commercial CPUE series and one CPUE series from a scientific trawl survey with Havfisken in quarter 4. Four of the commercial series were based on data from private logbooks ( 6 trawlers and 3 gillnetters and 2 area combinations) and three of the series on official logbooks from fisheries outside the main sole fishing seasons when rations were not restrictive (small and large trawlers as well as gillnetters). Assessment results were robust to various combinations of CPUE fleets. As in previous years, the 1st quarter IBTS Argos and Havfisken surveys were not used in the assessment, due to their low signal-to-noise ratio. This is consistent with the practice in the assessment of the North Sea sole, where IBTS indices are similarly not used in the assessment.

The available data from discard sampling is insufficient to be used directly in the assessment. Overall estimates of nonreporting and discarding have been used in the assessment based on information from the industry and the inspection, see section on management considerations above and information from the industry below.

The assessment is considered highly uncertain in relation to the estimates of $F$ in the final year, while SSB estimates are more stable to assumed levels of unreported catches.

Due to a closure in the fisheries in the 4th quarter of 2002 to 2004 , the commercial data matrix is biased in not reflecting the strength of the incoming recruitment at the end of the year.

## Information from the fishing industry

Collaboration between the Danish Fishermen's Organisation and DIFRES was initiated in 2004 to establish a database with data from private logbooks. Data from 6 trawlers and 3 gillnetters covering the time period 1987 to 2004 were available for the assessment.

The industry provided information on the likely order of magnitude of discarding and non-reporting in 2002-2004.

## Comparison with previous assessment and advice

New data (CPUE series based on private and official logbooks and estimates of non-reporting and discards of legalsized sole in recent years) have been compiled to supplement the data formerly available for the assessment. Utilising the new CPUE series from private and official logbooks and catch data including an estimate of discard and nonreporting revises the perception of the stock in the most recent years. This new perspective indicates an increasing trend in SSB and decreasing F since the late 1990s. Previous advice was based on a perception of the stock, which was close to $\mathbf{B}_{\mathrm{pa}}$ and fished around $\mathbf{F}_{\mathrm{pa}}$.

### 1.4.1 Cod in the Kattegat

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Reduced <br> reproductive <br> capacity | Harvested <br> unsustainably | Overexploited | Unsustainable | The stock is depleted with low <br> SSB and very low recruitment in <br> the last 5 years. The recent stock <br> size is not precisely known, but is <br> indicated to be well below $\mathbf{B}_{\text {lim. }}$ |

Based on the all available evidence on SSB and fishing mortality ICES classifies the stock as having reduced reproductive capacity. Given the low stock size, the present fishing mortality is high and the stock is harvested unsustainably. The estimated SSB in 2004 is considerably below $\mathbf{B}_{\mathrm{lim}}$.

The spawning stock declined steadily from about 35000 t in the early 1970 s to about 10000 t in the 1990 s , with a concurrent drop in recruitment from $20-30$ millions in the 1970 s, to around 10 millions in the 1990 s and less than 1 million in the recent years. The fishing mortality exceeded 1.0 during most of the 1980 s and 1990 s , and has continued to do so in the last decade. In the present state the stock is highly dependent on the strength of incoming year classes only.

The present assessment indicates that recruitment has been well below average since the late 1990s. Available information indicates that recruitment in the last five years is very low.

## Management objectives

In 2004 agreement was reached within the EU on a formal recovery plan that will be operational during the TAC and management decision processes of 2004, effectively rendering the plan operational in 2005. Details of it are given in Council Regulation (EC) 423/2004:

## Article 1

This Regulation establishes a recovery plan for the following cod stocks (hereinafter referred to as 'depleted cod stocks'):
(a) cod in the Kattegat;
(b) cod in the North Sea, in the Skagerrak and the eastern Channel;
(c) cod to the west of Scotland;
(d) cod in the Irish Sea.

Article 3 - Purpose of the recovery plan
The recovery plan referred to in Article 1 shall aim to increase the quantities of mature fish to values equal to or greater than the target levels specified in the following table: (Stock Target levels in tones)
Cod in the Kattegat 10500
Cod in the North Sea, Skagerrak and eastern Channel 150000
Cod to the west of Scotland 22000
Cod in the Irish Sea 10000
Article 4 - Reaching of target levels
Where the Commission finds, on the basis of advice from ICES and following agreement on that advice by the Scientific Technical and Economic Committee for Fisheries (STECF), that for two consecutive years the target level for any cod stock concerned has been reached, the Council shall decide by qualified majority on a proposal from the Commission to remove that stock from the scope of this Regulation and to establish a management plan for that stock in accordance with Article 6 of Regulation (EC) No 2371/2002.

Article 5 - Setting of TACs
A TAC shall be set in accordance with Article 6 where the quantities of mature cod have been estimated by the STECF, in the light of the most recent report of ICES, to be equal to or above the minimum levels specified in the following table (Stock Minimum levels in tones)
Cod in the Kattegat 6400
Cod in the North Sea, Skagerrak and eastern Channel 70000
Cod to the west of Scotland 14000
Cod in the Irish Sea 6000
Article 6 - Procedure for setting TACs

1. Each year, the Council shall decide by qualified majority, on the basis of a proposal from the commission, on a TAC for the following year for each of the depleted cod stocks.
2. The TACs shall not exceed a level of catches which a scientific evaluation, carried out by the STECF in the light of the most recent report of the ICES, has indicated will result in an increase of $30 \%$ in the quantities of mature fish in the sea at the end of the year of their application, compared to the quantities estimated to have been in the sea at the start of that year.
3. The Council shall not adopt a TAC whose capture is predicted by the STECF, in the light of the most recent report of the ICES, to generate in its year of application a fishing mortality rate greater than the following values: Concerned fish stock Fishing mortality rate

Cod in the Kattegat 0,60
Cod in the North Sea, Skagerrak and eastern Channel 0,65
Cod to the west of Scotland 0,60
Cod in the Irish Sea 0,72
4. Where it is expected that application of paragraph 2 will result in a quantity of mature fish at the end of the year of application of the TAC in excess of the quantity indicated in Article 3, the Commission shall carry out a review of the recovery plan and propose any adjustments necessary on the basis of the latest scientific evaluations. Such a review shall in any event be carried out by 16 March 2007.
5. Except for the first year of application of this Article:
(a) where the rules provided for in paragraphs 2 or 4 would lead to a TAC which exceeds the TAC of the preceding year by more than $15 \%$, the Council shall adopt a TAC which shall not be more than $15 \%$ greater than the TAC of that year; or
(b) where the rules provided for in paragraphs 2 or 4 would lead to a TAC which is more than $15 \%$ less than the TAC of the preceding year, the Council shall adopt a TAC which is not more than $15 \%$ less than the TAC of that year.
6. Paragraphs 4 or 5 shall not apply when their application would entail an exceeding of the values laid down in paragraph 3.

Article 7 - Setting TACs in exceptional circumstances
Where the quantities of mature fish of any of the cod stocks concerned have been estimated by the STECF, in the light of the most recent report of the ICES, to be less than the quantities set out in Article 5, the following rules shall apply:
(a) Article 6 shall apply where its application is expected to result in an increase in the quantities of mature fish at the end of the year of application of the TAC to a quantity equal to or greater than the quantity indicated in Article 5;
(b) where the application of Article 6 is not expected to result in an increase in the quantities of mature fish at the end of the year of application of the TAC to a quantity equal to or greater than the quantity indicated in Article 5, the Council shall decide by a qualified majority, on a proposal from the Commission, on a TAC for the following year that is lower than the TAC resulting from the application of the method described in Article 6.

Article 8 - Fishing effort limitations and associated conditions

1. The TACs referred to in Chapter III shall be complemented by a system of fishing effort limitation based on the geographical areas and groupings of fishing gear, and the associated conditions for the use of these fishing opportunities specified in Annex V to Council Regulation (EC) No 2287/ 2003 of 19 December 2003 fixing for 2004 the fishing
opportunities and associated conditions for certain fish stocks and groups of fish stocks, applicable in Community waters and, for Community vessels, in waters where catch limitations are required (1).
2. Each year, the Council shall decide by a qualified majority, on the basis of a proposal from the Commission, on adjustments to the number of fishing days for vessels deploying gear of mesh size equal to or greater than 100 mm in direct proportion to the annual adjustments in fishing mortality that are estimated by ICES and STECF as being consistent with the application of the TACs established according to the method described in Article 6.
3. The Council may decide by a qualified majority, on a proposal from the Commission, on alternative arrangements for fishing effort limitations to be applied under the recovery plan in order to manage fishing effort consistently with the TACs established according to the method described in Article 6.

This management plan has not been evaluated by ICES, and because article 7 clause (b) opens for unspecified actions ICES cannot evaluate it precisely. In such an evaluation it would have to be assumed that decisions made in accordance with article 7 clause (b) would imply reductions in the TAC as needed to ensure the required increase in the SSB.

## Single stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

Even with no landings in 2006 the SSB in 2007 is likely to be below $\mathbf{B}_{\text {lim }}$. In this case, the management plan would set a TAC consistent with F below 0.6 and a more than $30 \%$ increase in SSB; however, there is no estimate of the stock size on which to calculate this.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Yield-per-recruit analysis suggests that $\mathrm{F}=0.2-0.3$ is a reasonable exploitation boundary.

## Exploitation boundaries in relation to precautionary limits

Taking into account the current state of the stock, fishing at any level will involve a risk for further depletion of the stock. There should therefore be no fishing on this stock in 2006.

## Short-term implications

Outlook for 2006
Even with no fishing in 2006 it is likely that the stock will remain below $\mathbf{B}_{\text {lim }}$.

## Environment conditions

The productivity of the fish community in the area during the last 20 years seems to depend mainly on fishing mortality, with a decrease of most of the commercial stocks and an increase of several other species, including scavenger and other small-sized fish as an effect of predation release.

## Management considerations

The stock is at such a low level that any fishing at any level will involve a risk for further depletion of the stock. Therefore, there should be no fishing on this stock in 2006. However, no fishing on cod implies a closure of all demersal fisheries in the Kattegat. If this is not possible then the reductions should be concentrated to the period where cod is most available to capture, i.e. the first and fourth quarters. Implementation of proven technical measures to avoid catching cod could also be considered.

There is evidence of misreporting from the Kattegat to the western Baltic, indicating that the effort and TAC restriction are not sufficient to limit the catches at the intended level.

## Management plan evaluations

ICES considers the management plan to be not consistent with the precautionary approach when the stock is below $\mathbf{B}_{\text {lim }}$.

## Ecosystem considerations

SSB of cod in Kattegat has declined steadily from around 35000 tonnes in the 1970 s to around 5000-6000 tonnes in the 1990s. This decline seems associated with the disappearance of separate spawning aggregations/subpopulations in the Kattegat area.

## Factors affecting the fisheries and the stock

## Regulations and their effects

The TAC is implemented by period rations for individual vessels. Ration sizes have been low in recent years and may have created incentives to discard in order to high-grade the landing. At the same time, because ration sizes were higher in the Western Baltic there might also have been misreporting of Kattegat catches into the Western Baltic. The recovery plan, agreed in 2004, stipulate strict rules for carrying and landing cod in Kattegat.

## Changes in fishing technology and fishing patterns

An effort regulation system is now in place for the mixed fisheries. A separator grid has been introduced in the Nephrops trawl fishery.

## The environment

Recent analysis of the possible effect of environment and climate on this stock has shown that fishing mortality has been the major driver on the long-term dynamics of the stock. A possible influence of wind-temperature conditions on recruitment together with inflow of larvae from the adjacent North Sea stock has been demonstrated.

## Information from the fishing industry

The fishing industry reported that there were relatively high catch rates of cod in the northern Kattegat since 2004. ACFM considers that such catches are possibly a spill-over effect from Skagerrak.

## Scientific basis

## Data and methods

This assessment does not include discard data. There is discarding, but this has not yet been quantified. The assessment is age-based (XSA) with research survey tuning indices. This assessment is indicative of trends although estimates of F and SSB in the most recent year are uncertain due to the noise in the survey indices and uncertain catch data. The commercial effort data indicate a significant reduction for most fleets; however, it has not been possible to evaluate the effect of this reduction in terms of fishing mortality.

Uncertainties in assessment and forecast
Restrictive TACs may have resulted in misreporting, e.g. reporting catches taken in the Kattegat to the western Baltic (Subdivisions 22-24). However, misreporting has not been quantified yet and thus catch data are uncertain. Recruitment estimates as derived from XSA are unreliable since there is a mix between age 1 individuals from the North Sea stock and Kattegat cod in the area, and the proportion of the Kattegat component is unknown.

Comparison with previous assessment and advice
The perception of the state of the stock and the exploitation and therefore the advice, are similar to last year. Tagging information supports the estimated high F in 2004. The perception of the overall state of the stock and the fishing mortality is robust to the level of assumed misreporting.

${ }^{1}$ Recruitment is the geometric mean of the last five years

## State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Reduced reproductive <br> capacity | Uncertain | Overexploited |  |

The assessment is indicative of trends in SSB and recruitment and is based on survey results. Recent trends in fishing mortality are uncertain. Based on this assessment of SSB ICES classifies the stock as suffering reduced reproductive capacity. SSB is well below the $\mathbf{B}_{\text {lim }}$ of 70000 t . The 2001-2004 year classes are all estimated to be well below average.

## Management objectives

In 1999 the EU and Norway have "agreed to implement a long-term management plan for the cod stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $70000 t\left(\boldsymbol{B}_{l i m}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality rate of 0.65 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $150000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 150000 t .
4. In order to reduce discarding and to enhance the spawning biomass of cod, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

The recovery plan adopted by the EU Council in 2004, is still to be fully implemented. Details of it are given in Council Regulation (EC) 423/2004:

Article 3. Purpose of the recovery plan: The recovery plan (..) shall aim to increase the quantities of mature fish to values equal to or greater than 150000 (Cod in the North Sea, Skagerrak and eastern Channel)

Article 4: Reaching of target levels. Where the Commission finds, on the basis of advice (..), that for two consecutive years the target level for any cod stock concerned has been reached, the Council shall decide by (..) to remove that stock from the scope of this Regulation (...)

Article 5: Setting of TACs. A TAC shall be set in accordance with Article 6 where the quantities of mature cod have been estimated by the STECF, in the light of the most recent report of ICES, to be equal to or above the minimum level of 70000 t (Cod in the North Sea, Skagerrak and eastern Channel).

Article 6: Procedure for setting TACs. (1.) Each year, the Council shall decide (..) on a TAC for the following year for each of the depleted cod stocks. (2.) The TACs shall not exceed a level of catches which a scientific evaluation ( ..) has indicated will result in an increase of $30 \%$ in the quantities of mature fish in the sea at the end of the year of their application, compared to the quantities estimated to have been in the sea at the start of that year. (3.) The Council shall not adopt a TAC whose capture is predicted (..) to generate in its year of application a fishing mortality rate greater than 0.65 (Cod in the North Sea, Skagerrak and eastern Channel). (4.) (...) (5.) Except for the first year of application of this Article: (a) where the rules provided for in paragraphs 2 or 4 would lead to a TAC which exceeds the TAC of the preceding year by more than $15 \%$, the Council shall adopt a TAC which shall not be more than $15 \%$ greater than the TAC of that year; or (b) where the rules provided for in paragraphs 2 or 4 would lead to a TAC which is more than 15 $\%$ less than the TAC of the preceding year, the Council shall adopt a TAC which is not more than $15 \%$ less than the TAC of that year.

Article 7: Setting TACs in exceptional circumstances. Where the quantities of mature fish of any of the cod stocks concerned have been estimated by the STECF, in the light of the most recent report of the ICES, to be less than the quantities set out in Article 5, the following rules shall apply: (a) Article 6 shall apply where its application is expected to result in an increase in the quantities of mature fish at the end of the year of application of the TAC to a quantity equal to or greater than the quantity indicated in Article 5; (b) where the application of Article 6 is not expected to result in an increase in the quantities of mature fish at the end of the year of application of the TAC to a quantity equal to or greater than the quantity indicated in Article 5, the Council shall decide (..) on a TAC for the following year that is lower than the TAC resulting from the application of the method described in Article 6 .

Article 8. Fishing effort limitations and associated conditions. (1.) The TACs referred to in Chapter III shall be complemented by a system of fishing effort limitation based on the geographical areas and groupings of fishing gear, and the associated conditions for the use of these fishing opportunities specified in Annex V to Council Regulation (EC) No 2287/2003 of 19 December 2003 fixing for 2004 the fishing opportunities and associated conditions for certain fish stocks and groups of fish stocks, applicable in Community waters and, for Community vessels, in waters where catch limitations are required. (2.) Each year, the Council shall decide by a qualified majority, on the basis of a proposal from the Commission, on adjustments to the number of fishing days for vessels deploying gear of mesh size equal to or greater than 100 mm in direct proportion to the annual adjustments in fishing mortality that are estimated by ICES and STECF as being consistent with the application of the TACs established according to the method described in Article 6 .

ICES has not evaluated the current cod recovery plan. In response to a request from the European Community and Norway ICES has evaluated a range of harvest rules for the North Sea cod (from a starting point of a stock recovered to $\mathbf{B}_{\mathrm{pa}}$ ) with respect to medium- and long-term yields, stability of yield and effort and stock status with respect to safe biological limits (see section on evaluation of management plans).

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathrm{B}_{\lim }$ is 70000 t | $\mathrm{B}_{\mathrm{pa}}$ be set at 150000 t |
|  | $\mathrm{F}_{\lim }$ is 0.86 | $\mathrm{~F}_{\mathrm{pa}}$ be set at 0.65 |
| Target reference points |  | Not Defined |

Yield and spawning biomass per Recruit (from ACFM 2004).
$\underline{F-r e f e r e n c e ~ p o i n t s ~}$

|  | Fish Mort <br> Ages 2-4 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\text {max }}$ | 0.201 | 0.628 | 2.767 |
| $\mathbf{F}_{0.1}$ | 0.132 | 0.595 | 4.095 |
| $\mathbf{F}_{\text {med }}$ | 0.791 | 0.355 | 0.292 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\max }$.

Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}(\sim \mathbf{1 9 9 5})=70000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=$ Previous MBAL and signs of impaired recruitment <br> below 150000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.86$ | $\mathbf{F}_{\mathrm{pa}}=$ Approx. $5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}$ and implies an <br> equilibrium biomass $>\mathbf{B}_{\mathrm{pa}}$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

Due to the lack of a short-term forecast the exploitation boundaries in relation to existing management plans cannot be calculated.

## Exploitation boundaries in relation to precautionary limits

Given the low stock size and recent poor recruitment, it is not possible to identify any non-zero catch which will be compatible with the Precautionary Approach. Rebuilding can only be achieved if fishing mortality is significantly reduced on a longer term.

## Short-term implications

## Outlook for 2006

With zero catch in 2006 in all fisheries, SSB in 2007 could be around $\mathbf{B}_{\text {lim }}$.

## Management considerations

There is a continued substantial removal from this stock. The officially reported landings in 2004 were 27200 t and the estimated discards from these landings in 2004 were 6400 t , giving a total of 33600 t . However, the surveys indicate that the year classes are depleted faster than one would expect from these estimated catches. The source of this apparent additional mortality cannot be determined precisely.

Cod are taken by towed gears in mixed demersal fisheries, which include haddock, whiting, Nephrops, plaice, and sole. They are also taken in directed fisheries using fixed gears. Mixed fishery advice is further elaborated in Section 1.3.

Although the current SSB and fishing mortality are uncertain, it is clear that the stock has been reduced to a level at which productivity is impaired and the biological dynamics of the stock are difficult to predict. All assessments indicate that the stock is below $\mathbf{B}_{\text {lim._ }}$ During 2002 to $2004,90 \%, 80 \%$, and $75 \%$ of the international landings in number were accounted for by juvenile cod aged $1-3$.

Assessment estimates and reports from some fisheries indicate that quota restrictions have not been effective in controlling the catch of cod. Since 1992, TACs were set by managers to substantially reduce $F$, and were accompanied by an increasing number of technical measures and effort limitation (since 2003) imposed on the fisheries targeting cod. These measures were intended to reduce F and discarding. However, effort restrictions in the smaller mesh size fisheries, which have significant discards, have been less stringent. Missing catch components (discards and unrecorded landings) between $35 \%$ and $50 \%$ of official landings were estimated by the assessment model. Management of cod fisheries must deal with the combined effects of unreliable catch data and the inability of management to control catch. As long as these two interrelated conditions persist for fisheries which catch North Sea cod, rebuilding cannot be achieved.

Cod catch in Division VIId is managed by a TAC for Divisions VIIb-k,VIII, IX, X and CECAF 34.1.1, (i.e. the TAC covers a small proportion of the North Sea cod stock together with cod in Divisions VIIe-k). Cod taken in Division VIId should be included with the North Sea cod TAC.

## Management plan evaluations

In response to a request from the European Community and Norway, ICES has evaluated a range of harvest rules for the North Sea cod (see Section 1.3.3.1 and the ICES AGLTA report Section 3.6). The starting population for the simulations on North Sea cod was taken as the $\mathbf{B}_{\mathrm{pa}}$ value. Results indicated that target fishing mortalities (covering all catches and ages 2-4) below 0.4 were expected to result in a low risk to reproduction and high long-term yields unless the constraint on year-to-year variation in TAC is less than $\pm 20 \%$. The performance of a long-term management plan with target Fs below 0.4 was not sensitive to choices of $\mathbf{B}_{\text {trig }}$ (the biomass where management measures were triggered). A constraint on annual TAC variations was expected to improve the performance both in terms of minimizing shortterm landings variation and in terms of making the system less sensitive to the noise in annual assessments. It should be noted that the simulations have not taken biological interactions or density-dependent growth and maturity into account, therefore the numerical results of these simulations are only indicative of trends.

## Factors affecting the fisheries and the stock

See Section 1.4 on mixed fisheries.

## The effects of regulations

An emergency measure (Council Regulation (EC) 259/2001) involving the closure of a large area of the North Sea was implemented from 14 February to 30 April 2001 to all fishing vessels using gears likely to catch cod. Analysis of the effectiveness of the emergency measures indicated that the closure had an insignificant effect upon the spawning
potential for cod in 2001. The redistribution of the fishery, especially along the edges of the box coupled to the increases in proportional landings from January and February appeared to have been able to negate the potential benefits of the box. The box would have to be extended in both space and time to be more effective (see: ICES 2004). This emergency measure has not been adopted after 2001.

EU technical regulations in force in 2003 and 2004 are contained in Council Regulation (EC) 850/98 and its amendments. The regulation prescribes the minimum target species composition for different mesh size ranges. In 2001, cod in the whole of NEAFC region 2 was a legitimate target species for towed gears with a minimum codend mesh size of 100 mm . As part of the cod recovery measures, the EU and Norway introduced additional technical measures from 1 January 2002 (EC 2056/2001). The basic minimum mesh size for towed gears for cod from 2002 was 120 mm , although in a transitional arrangement until 31 December 2002, vessels were allowed to exploit cod with 110 mm codends provided that the trawl was fitted with a 90 mm square mesh panel and the catch composition of cod retained on board was not greater than $30 \%$ by weight of the total catch. From 1 January 2003, the basic minimum mesh size for towed gears for cod was 120 mm . The minimum mesh size for vessels targeting cod in Norwegian waters is also 120 mm .

Effort restrictions in the EC were introduced in 2003 (EC 2341/2002, Annex XVII, amended in EC 671/2003). Effort restriction measures were revised for 2004 (EC 2287/2003, Annex V). Preliminary analysis of fishing effort trends in the major fleets exploiting North Sea cod indicates that fishing effort in those fleets has been decreasing since the mid1990s due to a combination of decommissioning and days-at-sea regulations. The decrease in effort is most pronounced in the years 2002 and beyond.

A cod protection area has been implemented in 2004 (EC 2287/2003, amended in EC 867/2004) which defined the conditions under which certain stocks, including haddock, could be caught in Community waters (see Figure 4.4.1.a.1). A maximum of $35 \%$ of the haddock TAC in 2004 could be taken from within the cod protection area. For UK a special permit was introduced that was needed to fish for haddock in the cod protection area. Although this management scheme was proposed to permit additional haddock to be caught in 2004, the uptake of the special permit has been relatively low. This cod protection area was only in force in 2004.

In 2004 agreement was reached within the EU on a formal recovery plan that will operate during the TAC and management decision processes of 2004, effectively rendering the plan operational in 2005 (EC 423/2004). Details of the recovery plan are presented above.

The minimum landing size for cod in Subarea IV and Divisions IIIa and VIId is 35 cm ; in Denmark it is 40 cm .

## Changes in fishing technology and fishing patterns

The expected benefits from the increase in mesh size to 120 mm are not apparent from the available data. The effect of this is confounded by the transfer of effort from the fleets fishing with meshes ( $>120 \mathrm{~mm}$ ) to fleets fishing with ( $70-99$ mm ). Fishing with the smaller mesh allowed more days at sea than fishing with larger meshes.

Information presented to ICES indicated that the UK large mesh, demersal trawl fleet category ( $>100 \mathrm{~mm}, 4 \mathrm{~A}$ ) has been reduced by decommissioning and days-at-sea regulations to $40 \%$ of the levels recorded in the EU reference year of 2001. There was a movement into the $70-90 \mathrm{~mm}$ sector to increase days at sea in 2002 and 2003, but the level of effort stabilised in 2004.

## Scientific basis

## Data and methods

The assessment model (ADAPT) used reported landings and estimated discards, calibrated with three survey indices. Two implementations were used: the first used all surveys and data up to 2005 and estimated missing catch components, assuming that they have the same age composition as reported landings and estimated discards; the second using the same inputs except the Scottish survey data in 2005. Discards were included in the assessment for the North Sea only.

Discards were estimated from the Scottish discards sampling program, raised to the total international fleet.
A commercial CPUE series was available for the Scottish fleet, but was not a reliable index of abundance because of problems in estimating effort.

## Information from the fishing industry

The fishermen's survey was evaluated. Signals from the survey suggest little change in fishable biomass in most areas,
confirming the perception from the assessment model.

## Uncertainties in assessment and forecast

Estimating and projecting missing catch components is difficult and imposes considerable uncertainty in the assessment and forecasts. However, the different data sets and models all indicate that SSB and recruitment are very low.

Different datasets and model formulations give considerably different perceptions of fishing mortality levels and trends since 2003, with more certainty for SSB and recruitment. The catch data indicate a continued decline in F to an historic low, while the combined survey data also indicate a decline although to a lesser extent. When considered separately, the English and Scottish Q3 surveys indicate a substantial increase in F in 2004, which is not apparent from the IBTS Q1 series and is not in agreement with effort trends in the fishery since 2003.

## Comparison with previous assessment and advice

No full analytical assessment is presented this year, due to the uncertainties in the status of the landings data and the discrepancies between the surveys. The assessment is now only presented as indicative of trends in SSB and recruitment. Last year the assessment was presented as an absolute indication of stock size and of unaccounted removals.

The advice is consistent with last year.

Figure 1.4.2.1 Cod in Subarea IV and Divisions IIIa (Skagerrak) and VIId. ADAPT estimates of average fishing mortality, estimated removals and spawning stock biomass from model fits to individual survey series (IBTS, EGFS (Eng), SGFS (Sco)) and without misreporting (called "Exact" in the figures). Removals means reported plus unreported catches under the assumption that natural mortality are correctly reflected in the models.

Figure 1.4.2.2 Cod in Subarea IV and Divisions IIIa (Skagerrak) and VIId. ADAPT estimates of recruitment from model fits to individual survey series (IBTS, EGFS, SGFS) and without misreporting (called "Exact" in the figures).

## State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> management <br> target | Comment |
| :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably | Close to target |  |

Based on the most recent estimate of SSB and fishing mortality, ICES classifies the stock as having full reproductive capacity and being harvested sustainably. SSB in 2004 is estimated at 289000 t and is estimated to have decreased to around 266000 t in 2005 . SSB is well above the $\mathbf{B}_{\mathrm{pa}}$ of 140000 t . The 2001-2004 year classes are all estimated to be well below average. Indications from surveys and industry are that the 2005 year class will be above the long-term geometric mean. Fishing mortality in 2004 is estimated at 0.31 , which is well below $\mathbf{F}_{\mathrm{pa}}=0.7$.

## Management objectives

In 1999 the EU and Norway have "agreed to implement a long-term management plan for the haddock stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield.". The agreement was updated in November 2004:
"The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of Spawning Stock Biomass (SSB) greater than 100,000 tonnes (Blim).
2. For 2005 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality rate of no more than 0.30 for appropriate age groups.
3. Should the SSB fall below a reference point of 140,000 tonnes (Bpa), the fishing mortality rate referred to under paragraph 2, shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 140,000 tonnes.
4. In order to reduce discarding and to enhance the spawning biomass of haddock, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from inter alia ICES.
5. A review of this arrangement shall take place no later than 31 December 2006.
6. This arrangement enters into force on 1 January 2005.

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as lower boundaries on SSB, and not as targets.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\lim }$ is 100000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 140000 t |
|  | $\mathbf{F}_{\text {lim }}$ is 1.0 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.7 |
| Target reference points | Target F according to the management plan <br> is 0.3 |  |

Yield and spawning biomass per Recruit (from the 2004 assessment)
F-reference points

|  | Fish Mort <br> Ages 2-4 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\text {max }}$ | 0.321 | 0.004 | 0.016 |
| $\mathbf{F}_{0.1}$ | 0.202 | 0.004 | 0.024 |
| $\mathbf{F}_{\text {med }}$ | 0.498 | 0.004 | 0.010 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

## Technical basis

| $\mathbf{B}_{\text {lim }}:$ Smoothed $\mathbf{B}_{\text {loss. }}$ | $\mathbf{B}_{\mathrm{pa}}: 1.4^{*} \mathbf{B}_{\text {lim } .}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: 1.4^{*} \mathbf{F}_{\mathrm{pa}}$ | $\mathbf{F}_{\mathrm{pa} a}$ implies a long-term biomass $>\mathbf{B}_{\mathrm{pa}}$ and a less than |
|  | $10 \%$ probability that $\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

Following the agreed management plan ( $\mathrm{F}=0.3$ ) would imply human consumption landings of 39400 t in 2006, which is expected to lead to an SSB of 225800 t in 2007.

## Short-term implications

Outlook for 2006 :
Basis: $F(2005)=$ scaled mean $F(2002-2004)$. F (ages 2-5) $=0.32$, $\operatorname{SSB}(2006)=232$, HC landings (2005) $=51$, Discards $(2005)=13$, Industrial bycatch $(2005)=5$.

Weights in ' 000 t .
Shaded scenarios are considered inconsistent with the Precautionary Approach.

## Management considerations

The stock and fishery is dominated by the 1999 year class with a sequence of poor recruitments following it. The sustainable catch from this stock is expected to decline in the future unless new strong year classes emerge.

Information on fishing effort indicates significant reductions in the fleet sectors which take the largest proportion of haddock.

## Management plan evaluations

In June 2004 an EU-Norway expert group met in Brussels to evaluate harvest control rules (HCRs) for different stocks, among which was North Sea haddock. The report of this meeting is available, but has not been evaluated by ICES so far.

## Factors affecting the fisheries and the stock

Haddock are generally caught in mixed fisheries along with cod and whiting.
The effects of regulations
EU technical regulations in force are contained in Council Regulation (EC) 850/98 and its amendments. The regulation prescribes the minimum target species composition for different mesh size ranges. In 2001, haddock in the whole of NEAFC region 2 were a legitimate target species for towed gears with a minimum codend mesh size of 100 mm . As part of the cod recovery measures, the EU and Norway introduced additional technical measures from 1 January 2002 (EC 2056/2001). The basic minimum mesh size for towed gears for cod from 2002 was 120 mm , although in a transitional arrangement running until 31 December 2002 vessels were allowed to exploit cod with $110-\mathrm{mm}$ codends provided that the trawl was fitted with a $90-\mathrm{mm}$ square mesh panel and the catch composition of cod retained on board was not greater than $30 \%$ by weight of the total catch. From 1 January 2003, the basic minimum mesh size for towed gears for cod was 120 mm . The minimum mesh size for vessels targeting haddock in Norwegian waters is also 120 mm .

Effort restrictions in the EC were introduced in 2003 (EC 2341/2002, Annex XVII, amended in EC 671/2003). Effort restriction measures were revised for 2005 (EC 27/2005, Annex IV). Preliminary analysis of fishing effort trends in the major fleets exploiting North Sea cod indicates that fishing effort in those fleets has been decreasing since the mid1990s due to a combination of decommissioning and days-at-sea regulations. The decrease in effort is most pronounced in the years 2002 and beyond.

## Changes in fishing technology and fishing patterns

The change in mesh size might be expected to shift exploitation patterns to older ages and increase the weight-at-age for retained fish from younger age classes. Improvements in the exploitation pattern have not been observed. It was not possible to examine if this is due to confounding effects from other fleet segments. Information presented to ICES noted that the UK large mesh, demersal trawl fleet category ( $>100 \mathrm{~mm}, 4 \mathrm{~A}$ ) has been reduced by decommissioning and days-at-sea regulations to $40 \%$ of the levels recorded in the EU reference year of 2001. There was a movement into the 70-90 mm sector to increase days at sea in 2002 and 2003, but the level of effort stabilised in 2004. The effort of the combined trawl gears has shown a continued decrease of $36 \%$ overall, from the EU reference year of 2001.

## Scientific basis

## Data and methods

The assessment model is XSA calibrated with five survey indices. Alternative methods were evaluated, and all confirmed the indications from the final assessment of F in 2004 around the lowest estimated level since 1963. Discards and industrial bycatch were included in the assessment for the North Sea only. Discards were estimated from the Scottish discards sampling program, raised to the total international fleet. The strong 1999 year class is slow-growing and is forecast to have a relatively low mean weight in the future.

## Information from the fishing industry

The fishermen's survey was evaluated and shows a stabilisation or decline of fishable biomass in most areas, confirming the perception from the assessment.

## Uncertainties in assessment and forecast

Stock dynamics estimated using several different sources of information were consistent. Retrospective bias could not be evaluated. The very different F pattern of the 1999 year class compared to other year classes may indicate that this year class is overestimated. The assessment and forecast are largely influenced by the strong 1999 year class. The weight and exploitation pattern of the 1999 year class were taken into account in projections. Estimated recruitment of the 2005 year class was derived from the Q3 Scottish groundfish survey (1998-2005).

In this assessment the 1999 year class is estimated to be less strong, and accordingly the estimate of SSB in 2003 was also revised significantly downwards.

Since the management plan has been revised in 2004 the single-stock exploitation boundary is now given on that basis.

### 1.4.4 Whiting in IIIa (Skagerrak - Kattegat)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield |  |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate spawning stock or fishing mortality. It is likely that this stock is linked to the North Sea stock.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

There are no reference points defined for the stock.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
The landings in 2005 should be less than 1500 t as a precautionary value to restrict the potential for re-expansion of the fishery and misreporting from other regions.

## Management considerations

The major part of the catch is taken as a bycatch in small-mesh fisheries. The landings value advised for 2006 is consistent with ICES advice provided in 2005, and is based on the average of the catch during 1996-1998.

## Source of information

### 1.4.5

## State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate the spawning stock in relation to precautionary approach reference points. The assessment is indicative of trends only. The stock is estimated at or near the lowest observed level (see Figure 1.4.5.1). Landings are at an historical low, and fishing mortality as well.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

The assessment is only regarded as indicative of trends for the most recent $10-15$ years. Without a reliable assessment for the whole time period, no revised reference points can be proposed. The present indicative assessment cannot be compared to the previous defined reference points.

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 225000 t , the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 315000 t . This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. Below this value the <br> probability of below-average recruitment increases. |
| $\mathbf{F}_{\text {lim }}$ is 0.90 , the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.65. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathbf{F}_{\text {lim }}$, <br> into account the uncertaing of the assessment. |

Yield and spawning biomass per Recruit
F-reference points:

| F-reference points: |  |  |  |
| :--- | :---: | :---: | :---: |
|  | Fish Mort <br> Ages 2-6 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| $\mathbf{F}_{\max }$ | $\mathrm{N} / \mathrm{A}$ |  |  |
| $\mathbf{F}_{0.1}$ | 0.268 | 0.022 | 0.158 |
| $\mathbf{F}_{\text {med }}$ | 0.373 | $\mathbf{0 . 0 2 3}$ | 0.132 |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=225000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4^{*} \mathbf{B}_{\text {lim }}$, apparent impaired recruitment below this <br> value: 315000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.9$. | $\mathbf{F}_{\mathrm{pa}}-0.7 \mathbf{F}_{\text {lim }}=0.65$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

The stock status cannot be assessed with reference to precautionary reference points. However, in the light of the low estimate of stock size in combination with the low recent landings with indication of current low exploitation rates, ICES recommends that the human consumption landings in 2006 should not be allowed to increase above the recent (2002-2004) average of 17300 t for Subarea IV and Division VIId.

## Management considerations

The minimum mesh size increased to 120 mm in the northern area in 2002 and this may have contributed to the substantial decrease in reported landings. However, research vessel and fisher surveys both indicate a decline in the northern component. Landings in the southern area (which uses a smaller mesh) have remained stable, and now represent the principal fishery for whiting. Fisher surveys indicate that the southern component is either stable or increasing. Therefore management actions appropriate for one area may not be suitable for the other.

Whiting is taken in mixed fisheries together with other roundfish and Nephrops.

## Factors affecting the fisheries and the stock

## The effects of regulations

The EU technical regulations in force in 2004 and 2005 are contained in Council Regulation (EC) 850/98 and its amendments. The minimum mesh size for vessels fishing for cod in the mixed demersal fishery in EC Zones 1 and 2 (West of Scotland and North Sea, excluding Skagerrak) was changed from 100 mm to 120 mm from the start of 2002 under EU regulations regarding the cod recovery plan (Commission Regulation EC 2056/2001), with a one-year derogation of 110 mm for vessels targeting other species such as whiting. This derogation was not extended beyond the end of 2002. The UK implemented a national regulation in mid-2000, requiring the mandatory fitting of a $90-\mathrm{mm}$ square mesh panel (SSI 227/2000), predominantly to reduce discarding of the large 1999 year class of haddock. Further unilateral legislation in 2001 (SSI 250/2001) banned the use of lifting bags in the Scottish fleet. The minimum landing size for whiting in the North Sea is 27 cm .

Restrictions on fishing effort were introduced in 2003 and details of its implementation in 2004 can be found in Annex V of Council Regulation (EC) no. 2287/2003, and for 2005 in Annex IVa of Council Regulation (EC) no. 27/2005.

Vessel decommissioning in several fleets has been underway since 2002. Effort reductions for much of the international fleet to 15 days at sea per month have been imposed since February 2003 (EU 2003/0090).

Given the uncertainties in the fishing mortality estimates it is not possible to determine regulatory effects on the stock.

## Scientific basis

## Data and methods

Commercial catch-at-age data were disaggregated into human consumption, discards, and industrial bycatch components. This could not be done on an area basis. Discards were estimated based on the Scottish discards sampling program and raised to the total international fleet.

Three survey CPUE series are available: English groundfish survey (EngGFS), Scottish groundfish survey (ScoGFS), and IBTS Q1. Due to non-mandatory reporting of effort (in terms of hours fished), commercial CPUE series were not considered reliable and were not included in the exploratory analyses.

Several assessment approaches (XSA, TSA, ICA, CSA, SURBA) were explored.

## Information from the fishing industry

Spatial information on landings (based on $70 \%$ of the total in 2002) suggests three distinct areas of major catch: a northern zone, an area off the eastern English coast, and a southern area extending into the Channel (with the largest catches, and prosecuted predominantly by French vessels). The southern whiting fishery uses $80-\mathrm{mm}$ nets, whereas the other fisheries are prosecuted by vessels using larger mesh nets. Northern catches have declined whilst southern landings have been maintained. In the northern zone the reduction in landings may have taken place because of changes in mesh (increases, square mesh panels, etc.).

The fishers' North Sea Stock Survey indicated different stock trends in different roundfish areas of the North Sea. These stock trend perceptions were in broad agreement with IBTS Q1 survey indices aggregated by roundfish area. The fishers' survey suggests a decreasing stock in the north, but increasing further south.

## Uncertainties in assessment and forecast

There are considerable discrepancies in the historical stock trends between the survey time-series and the assessment based on commercial catch data. The main discrepancies occur prior to 1990 (see Figure 1.4.5.1). This could be related to indications from research vessel surveys of different stock trends in different areas (Figure 1.4.5.2). This is confirmed by fisher surveys.

Discard estimates are based on the Scottish sampling program, which is mainly in the northern area. Extrapolation of this to the entire area is a source of uncertainty because the fishery in the southern area is mostly carried out with different gears and smaller mesh sizes.

Comparison with previous assessment and advice
No analytical assessment of whiting has been provided in the recent years due to the discrepancies between survey information and the catch data. The assessment that is the basis for the current advice covers a short time-series of catch data and survey information where this discrepancy does not occur. The assessment is only considered indicative of trends and does not form the basis for a short-term forecast.

Compared to the situation last year, both the assessment based on the commercial catch and the research vessel data indicate a low stock size this year. Therefore, the catch advice this time is lower than last year.

### 1.4.6 Plaice in Division IIIa (Skagerrak - Kattegat)

## State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation <br> to highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The assessment is indicative of trends only. In the absence of a reliable assessment, the state of the stock cannot be evaluated in relation to the Precautionary Approach. Indices from both surveys and the commercial fishery suggest a substantial increase in biomass in recent years. Survey indices indicate that recruitment of the year classes 1999 and onwards have been high, and these year classes might have contributed to an increase in SSB in recent years.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathbf{B}_{\text {lim }}$ cannot be accurately defined. | $\mathbf{B}_{\mathrm{pa}}=24000 \mathrm{t}$. |
|  | $\mathrm{F}_{\text {lim }}$ cannot be accurately defined. | $\mathrm{F}_{\mathrm{pa}}=0.73$. |
| Target reference points |  | $\mathrm{F}_{\mathrm{y}}$ undefined |

Technical basis

|  | $\mathbf{B}_{\mathrm{pa}}=$ smoothed $\mathbf{B}_{\text {loss }}$ (no sign of impairment). |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }}$. |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

There is no basis for an analytical forecast. Given the possible increase in stock size in recent years in combination with an unknown exploitation rate, fishing mortality in 2006 should not be allowed to increase. This may be achieved by allowing landings of less than 9600 t in 2006, which is the average of landings of the last four years.

## Short-term implications

The assessment is very uncertain and is characterized by large annual revisions in population estimates, hence no shortterm forecasts were performed (see Uncertainties in assessment and forecast).

## Management considerations

Plaice is taken both in a directed fishery and as an important bycatch in a mixed cod-plaice fishery. The stock area for North Sea cod includes the Skagerrak (Division IIIaN). Both North Sea cod and Kattegat (Division IIIa South) cod are well below $\mathbf{B}_{\text {lim }}$. Thus, monitoring of bycatches and discards of cod should be continued.

## Ecosystem considerations

The large-scale circulation pattern in the northern Kattegat depends mainly on the interaction between Baltic runoffs and local variations due to wind stress. Nielsen et al. (1998) demonstrated that the abundance of settled 0-group plaice along the Danish coast of the Kattegat depends on transport from the Skagerrak. The 0 -group abundance measured in July-August was significantly higher in years when wind conditions during the larval development period (MarchApril) were moderate to strong. This might imply that larval plaice are food-limited in years when calm conditions prevail during the larval drift period (Nielsen et al., 1998).

It was recognized long ago that the stock boundaries are arbitrary and drawn more to suit management purposes than for biological stock separation. Electrophoresis and meristic character indicated that the plaice in IIIa is a mixed population of the Kattegat and the Skagerrak component, which is dominating, and a Belt Sea component. Some additional work has been started in 2004 about the biological links between the Kattegat and the Western Baltic (ICES Area 22) and the potential extension of the stock beyond its current assessment area. Preliminary results concluded that there is good evidence for mixing sub-populations in both areas. There may also be linkages with the North Sea plaice stock. Migrations of plaice outside and/or inside the assessment area are one of the factors that could explain the large and likely unrealistic fluctuations in the estimated fishing mortality.

## Factors affecting the fisheries and the stock

## The effects of regulations

The use of beam trawl is prohibited in the Kattegat, but allowed in the Skagerrak. Minimum mesh size is 90 mm for towed gears, and 100 mm for fixed gears. The minimum landing size is 27 cm . Danish fleets are prohibited to land female plaice from Division IIIa from January 15th to April 30th.

## Scientific basis

The quality of input data or model assumptions used in the exploratory assessments is generally poor. There are indications that misreporting from the North Sea to the Skagerrak and from the Belt Sea (ICES area 22) could have occurred repeatedly in the rectangles being shared between those areas.

## Data and methods

The exploratory assessments are based on catch data calibrated with three commercial and four survey indices (XSA, SMS) and also based on survey data (SURBA) only.

## Information from the fishing industry

The fishing industry has provided information which has been included in considerations of assessments. Such information has contributed to the understanding of the fisheries, also in cases where information has not been in a form which enables direct inclusion in quantitative assessments.

## Uncertainties in assessment and forecast

The assessment is very uncertain, and is characterized by large annual revisions in population estimates. Fishing mortality displays excessive fluctuations between years, and point estimates are very uncertain. Principal inconsistencies between catch and survey data lead to different perceptions of the stock status. This inconsistency could partly be due to increasing migration patterns to outside the assessment area, or to discard and misreporting practices. Current commercial tuning series are considered questionable when used as measures for stock abundance. More accurate tuning fleet definitions should be considered. Under these conditions the assessment is only considered to be indicative of trends.

## Comparison with previous assessment and advice

Poor performances of the analytical assessment lead to rejection of the final assessment. Several exploratory analyses were attempted, but principal inconsistencies between survey and catch data impedes any firm conclusions. Catch data suggest a strong 2001 year class while surveys suggest several strong year classes since 1999.

### 1.4.7 Plaice in Subarea IV (North Sea)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| At risk of reduced <br> reproductive <br> capacity | Harvested <br> sustainably | Overexploited | Above |  |

Based on the most recent estimate of SSB and fishing mortality, ICES classifies the stock as being at risk of reduced reproductive capacity and as being harvested sustainably. SSB in 2004 was estimated at around 170000 t and is expected to have increased to just above 200000 t in 2005. SSB is below the $\mathbf{B}_{\mathrm{pa}}$ of 230000 t . Fishing mortality in 2004 is estimated to be at or near $\mathbf{F}_{\mathrm{pa}}$. Fishing mortality has been disaggregated into human consumption ( $\mathbf{F}_{\mathrm{hc}}$ ) and discards ( $\mathbf{F}_{\text {disc }}$ ) components, and the former appears to be decreasing while the latter is increasing. Recent recruitment has been below average.

## Management objectives

In 1999, the EU and Norway have "agreed to implement a long-term management plan for the plaice stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of $S S B$ greater than $210000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality of 0.3 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $300000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 300000 t .
4. In order to reduce discarding and to enhance the spawning biomass of plaice, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

The management agreement was not renewed for 2005. A new management plan for North Sea plaice is under development. The current plan does not refer to the reference points changed in 2004. In response to a request from the European Community and Norway, ICES has evaluated a range of harvest rules for the North Sea plaice (from a starting point based on the ICES assessment made in 2004) with respect to medium- and long-term yields, stability of yield and effort, and stock status with respect to safe biological limits (see section on evaluation of management plans).

## Reference points (as changed in 2004)

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathrm{B}_{\mathrm{lim}}$ is 160000 t. | $\mathrm{B}_{\mathrm{pa}}$ be set at 230000 t |
|  | $\mathrm{F}_{\text {lim }}$ is 0.74 | $\mathrm{~F}_{\mathrm{pa}}$ be set at 0.60. |
| Target reference points | Target F according to the management plan <br> is 0.3 |  |

Yield and spawning biomass per Recruit (from ACFM 2004)
$\underline{F \text {-reference points }}$

|  | Fish Mort <br> Ages 2-6 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{F}_{\text {max }}$ | 0.167 | 0.142 | 1.503 |
| $\mathbf{F}_{0.1}$ | 0.117 | 0.136 | 2.107 |
| $\mathbf{F}_{\text {med }}$ | 0.473 | 0.093 | 0.340 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

Technical basis

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=160000 t$, the lowest observed biomass in <br> 1997 as assessed in 2004 | $\mathbf{B}_{\mathbf{p a}}=$ Approximately $1.4 \mathbf{B}_{\text {lim }}$. |
| :--- | :--- |
| $\mathbf{F}_{\text {limm }}=\mathbf{F}_{\text {loss }}=0.74$ (ages 2-6). | $\mathbf{F}_{\mathbf{p a}}=5$ th percentile of $\mathbf{F}_{\text {loss }}(0.6)$ and implies that <br> $\mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}{ }^{1)}$ and a $50 \%$ probability that $\left.\mathbf{S S B} \mathbf{B}_{\mathrm{MT}} \sim \mathbf{B}_{\mathrm{pa}} .2\right)$ |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

The management agreement has not been renewed for 2005 . Therefore, advice is only presented in the context of precautionary boundaries.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality is estimated at 0.58 , which is above the rate expected to lead to high long-term yields ( $\mathrm{F}_{\max }$ on human consumption=0.17).

## Exploitation boundaries in relation to precautionary limits

The exploitation boundaries in relation to precautionary limits imply human consumption landings of less than 48000 t in 2006, which is expected to rebuild SSB to the proposed Bpa $(=230000 \mathrm{t})$ in 2007.

## Management considerations

Because the assessment now incorporates discards, ICES has proposed to change the value of Fpa so that it refers to the overall fishing mortality (landings and discards). Managers should reconsider the value of $\mathrm{F}=0.3$ as it was stated in the management agreement between the EC and Norway.

Due to a range of factors such as TAC constraints on plaice, effort limitations and increases in fuel prices, the fishing effort of the major fleets has concentrated in the southern part of the North Sea. This is the area where a large part of the juvenile fish of e.g. plaice in the North Sea are found. In addition, juvenile plaice has shown a more off-shore distribution in recent years. The combination of a change in fishing pattern and the spatial distribution of juvenile plaice has lead to an apparent increase in discarding of plaice.

Technical measures applicable to the mixed flatfish fishery will affect both sole and plaice. The minimum mesh size of 80 mm in the beam trawl fishery selects sole at the minimum landing size. However, this mesh size generates catches of plaice from 17 cm , while the minimum landing size is 27 cm , leading to a high discard rate. Mesh enlargement would reduce the catch of undersized plaice, but would also result in short-term loss of marketable sole. An increase in the minimum landing size of sole could provide an incentive to fish with larger mesh sizes and therefore mean a reduction in the discarding of plaice.

## Management plan evaluations

In response to a request from the European Community and Norway ICES has evaluated a range of harvest rules for the North Sea plaice (see Section 1.3.3.1 and the ICES AGLTA report Section 4.7). The starting population for the simulations on North Sea plaice was taken from the 2004 ICES assessment (ICES CM 2005/ACFM:07) which included landings and discards. Results indicated that target fishing mortalities (covering all catches and ages 2-6) in the range of
$0.3-0.4$ were expected to have a low risk to reproduction and high long-term yields. The performance of a long-term management plan with target Fs below 0.4 was not sensitive to choices of $B_{\text {trig }}$ (the biomass where management measures were triggered). A constraint on annual TAC variations was expected to improve the performance both in terms of minimizing short-term landings variation and in terms of making the system less sensitive to the noise in annual assessments. A fixed TAC regime with a TAC below 80000 t was expected to produce the same results in terms of low risk to reproduction, but would result in considerably lower average landings in the longer term. It should be noted that the simulations have not taken biological interactions or density-dependent growth and maturity into account; the numerical results of these simulations are therefore only indicative of trends.

## Factors affecting the fisheries and the stock

## The effects of regulations

The TACs for plaice are likely to have been respected.
Previous MAGP programs have induced changes in fleet compositions. The Dutch beam trawl fleet has reduced the number of vessels and shifted towards two categories of vessels: 2000 HP (the maximum engine power allowed) and 300 HP (the maximum engine power for vessels that are allowed to fish within the 12 -nautical mile coastal zone and in the plaice box). A substantial part of the decommissioned vessels have been replaced by vessels in other countries (England, Scotland, Germany, Belgium). Overall capacity and effort of North Sea beam trawl vessels appears to have decreased since 1995.

The minimum landing size of North Sea plaice is 27 cm . This minimum landing size results in high discarding levels in the mixed flatfish fishery with beam trawls using $80-\mathrm{mm}$ mesh size.

The plaice box is a closed area along the continental coast that has been introduced in 1989. The area was closed in all quarters since 1995. The closed area applies to vessels using towed gears, but vessels smaller than 300 HP are exempted from the regulation. The closed area applies to vessels using towed gears, but vessels smaller than 300 HP are exempted from the regulation. An evaluation of the plaice box (Grift et al, 2004) has indicated that: "From trends observed it was inferred that the Plaice Box has likely had a positive effect on the recruitment of plaice but that its overall effect has decreased since it was established. There are two reasons to assume that the Plaice Box has a positive effect on the recruitment of plaice: 1) at present, the Plaice Box still protects the majority of undersized Plaice. Approximately $70 \%$ of the undersized Plaice are found in the Plaice Box and Wadden Sea, and despite the changed distribution, densities of juvenile Plaice inside the Box are still higher than outside; 2) In the 80 mm fishery, discard percentages in the Box are higher than outside. Because more than $90 \%$ of the Plaice caught in the 80 mm fishery in the Box are discarded, any reduction in this fishery would reduce discard mortality. There is, however, no proof of a direct relationship between total discard mortality and recruitment."

## Changes in fishing technology and fishing patterns

The Dutch beam trawl fleet, one of the major operators in the mixed flatfish fishery in the North Sea, has shifted towards more inshore fishing grounds and a reduction in fishing effort in the more northern areas. This shift may be caused by a number of factors, such as the implementation of fishing effort restrictions, the recent increase in fuel prices, and different changes in the TACs for the two main target species plaice and sole. However, the contribution of each of these factors is yet unknown.

## The environment

Adult North Sea plaice have an annual migration cycle between spawning and feeding grounds. The spawning grounds are located in the central and Southern North Sea, overlapping with the distribution area of sole. The feeding grounds are located more northerly than the sole distribution areas.

Juvenile stages are concentrated in shallow inshore waters and move gradually offshore as they become larger. The nursery areas on the eastern side of the North Sea contribute most of the total recruitment. Sub-populations have strong homing behavior to specified spawning grounds and rather low mixing rate with other sub-populations during the feeding season. Genetically, North Sea and Irish Sea plaice are weakly distinguishable from Norway, Baltic, and Bay of Biscay stocks using mitochondrial DNA.

Juvenile plaice have been distributed more offshore in recent years. Surveys in the Wadden Sea have shown that 1group plaice is almost absent from the area where it was very abundant in earlier years. This could be linked to environmental changes in the productivity or changes in the temperature of the southern North Sea, but these links have not been shown conclusively.

## Scientific basis

## Data and methods

The stock assessment is based on an XSA of landings and estimated discards, calibrated with three survey indices. Commercial CPUE series are not included in the assessment model but they are used as general indicators of stock development.

Discards were included in a dual approach. For the years 1999-2004, sampled Dutch and UK discard numbers were raised by effort ratio. The weighted average of these numbers was calculated, and then raised to the total international landings. This approach was used as it incorporates all available discard data from observer sampling programmes. For the years prior to 1999 , discards were reconstructed based on a model-based analysis of growth, selectivity of the 80mm beam trawl gear, and the availability of undersized plaice on the fishing grounds.

## Information from the fishing industry

The fishers' survey report was available and has been evaluated. Signals from the fishers' survey indicate that in the southern and southeastern North Sea, plaice is becoming more available. The assessment indicates that the plaice stock has more or less remained at a low level since the mid-1990s. Although the exact magnitude of the increase is difficult to derive from the fishers' survey, there does seem to be a difference in perception between the fishermen and the assessment.

## Uncertainties in assessment and forecast

The assessment is considered to be uncertain. Estimates of discards are based on a few observations of two dominant fleets since 1999, and by using a reconstruction model for the years prior to 1999. The inclusion of discard estimates appears to contribute to a reduction in the retrospective bias that was previously observed in this assessment. However, the apparent reduction in bias has probably been accompanied by decreased precision.

Different trends are observed in different areas of the North Sea. Commercial CPUE series and a survey in the central part of the North Sea appear to indicate an increase in the plaice stock, whereas surveys in the southern North Sea indicate that the stock has remained at a low level.

Available tagging information suggests that Nursery grounds in the North Sea contribute around $40 \%$ to the recruits in VIId. Movements of adult plaice are also reported. Some similarities between trends in F, SSB and R between VIId and North Sea Plaice stocks suggest that the mixing between Eastern Channel and North Sea may be important for this species.

## Comparison with previous assessment and advice

This year's assessment is consistent with the assessment carried out in 2004. The assessment cannot be directly compared to assessments prior to 2004 because the inclusion of discards has a large influence on both the estimates of recruitment and the mean fishing mortality.

In 2003, ICES recommended a recovery plan for plaice because the stock was perceived to be well below $\mathbf{B}_{\text {lim }}$. Recent assessments including discards have changed the perception of the stock dynamics and in 2004 ICES therefore proposed a change in the biological reference points to accommodate this perception.

2) 2005 recruitment: GM 1957-2002

### 1.4.8 Plaice in Division VIId (Eastern Channel)

## State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation <br> to highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown | Divergent perception <br> between catch-at-age based <br> and survey-based analyses |

The state of the stock cannot be assessed due to discrepancies in the available data. The most recent estimates have shown a divergent perception of the historical trends between the catch-at-age based analyses and the survey-based analyses. This divergence seriously affects the trends of the last 5 years, leading to an uncertain assessment of the state of the stock. Possible stock identification problems may contribute to divergence between catch and survey data.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathbf{p a}}=5$ th percentile of $\mathbf{F}_{\text {loss }} ;$ long-term SSB $>\mathbf{B}_{\mathrm{pa}}$ <br> and $\mathrm{P}\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<\mathbf{1 0} \%$ |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

No short-term forecasts can be provided. There is conflicting information; some information suggests that the stock is stable and some information suggests that the stock is declining; as a minimum measure there should be no increase in effort.

## Management considerations

The plaice stock in VIId is mostly harvested in a mixed fishery with sole. Even if there exists a directed fishery on plaice that occurs in a limited period at the beginning of the year on the spawning grounds, plaice is mainly taken as bycatch by the demersal fisheries, especially targeting sole.

Due to the minimum mesh size ( 80 mm ) in the mixed beam trawl fishery, a large number of undersized plaice are discarded. The $80-\mathrm{mm}$ mesh size is not matched to the minimum landing size of plaice ( 27 cm ). Measures taken specifically to sole fisheries will impact the plaice fisheries.

## Factors affecting the fisheries and the stock

## The effects of regulations

The minimum landing size for plaice is 27 cm . Demersal gears permitted to catch plaice are 80 mm for beam trawling and otter trawling. Fixed nets are required to use $100-\mathrm{mm}$ mesh since 2002 although an exemption to permit 90 mm has been in force since that time.

An EU regulation that was enforced in 2004 is a limit of 22 days at sea per month for trawlers with mesh size less than $99 \mathrm{~mm}, 14$ days at sea for beam trawlers, and gillnetters have a derogation of 20 days at sea in the Eastern Channel provided that their mesh size is less than 110 mm .

## Scientific basis

## Data and methods

The assessment is based on reported landings data, three commercial CPUE indices, and three survey indices. Time-series of discard data are not available, but French observations from 2003 indicate that discards are high.

## Information from the fishing industry

The fishing industry has provided information which has been included in considerations of assessments. Such information has contributed to the understanding of the fisheries, also in cases where information has not been in a form which enables direct inclusion in quantitative assessments.

Uncertainties in assessment and forecast
The updated formulation as used in the 2004 assessment exhibited patterns in the residuals, trends in the index-specific catchabilities, and a retrospective problem. These may be associated with a lack of discarding information, use of commercial catch rate indices, and stock identification problems.

There is some uncertainty about the stock structure in VIId Plaice. Historical tagging information show that around 40\% of the juvenile plaice in VIId come from nursery grounds in the North Sea, while the Eastern Channel supplies very few recruits to the North Sea. Similarly, around $20 \%$ of the recruits in VIIe come from VIId, while VIId does not receive significant numbers of juvenile from VIIe. There is also an adult migration between the North Sea and the Channel with $20-30 \%$ of the plaice caught in the winter in VIId were from migratory North Sea fish. The available information also suggests that plaice may migrate from the VIIe into the VIId and the North Sea after spawning.

Comparison with previous assessment and advice
The assessment was considered unreliable due to the conflicting signals of data.

### 1.4.9 Sole in Division IIIa (Skagerrak and Kattegat)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Comment |  |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Likely <br> sustainably <br> exploited | Unknown |  |  |

Based on the most recent estimates of SSB, ICES classifies the stock as having full reproductive capacity. The assessment is uncertain due to substantial discarding and non-reporting in the most recent years. While the SSB estimate is relatively robust against this, the fishing mortality estimate in the most recent year is uncertain, but available information indicates sustainable exploitation.

## Management objectives

There are no management objectives for this stock. However, for any management criteria to meet the proposed precautionary criteria $F$ should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and the SSB should be maintained above the proposed $\mathbf{B}_{\mathrm{pa}}$.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathrm{B}_{\lim }$ is 770 t | $\mathrm{B}_{\mathrm{pa}}$ be set at 1060 t |
|  | $\mathrm{F}_{\mathrm{lim}}$ is 0.47 | $\mathrm{~F}_{\mathrm{pa}}$ be set at 0.30 |
| Target reference points |  | $\mathrm{N} / \mathrm{A}$ |

The assessment has revised the level of SSB considerably for the last 5 years. Because of this, previously defined biomass related reference points need to be re-evaluated.

Technical basis:

| $\mathbf{B}_{\mathrm{lim}}: \mathbf{B}_{\mathrm{pa}}{ }^{*} \exp \left(-1.645^{*} 0.2\right)$ | $\mathbf{B}_{\mathrm{pa}}:$ MBAL |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}:}: \mathbf{F}_{\text {med }} 98$ excluding the abnormal years around 1990 | $\mathbf{F}_{\mathrm{pa}}:$ consistent with $\mathbf{F}_{\text {lim }}$ |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Given the uncertainties in the assessment regarding non-reporting and discarding in recent years, ICES advises a TAC for 2006 not higher than the TAC for 2005 , even though SSB is estimated much higher than $\mathbf{B}_{\mathrm{pa}}$. The estimate of the present (status quo) fishing mortality is uncertain, but status quo fishing mortality is probably at or below $\mathbf{F}_{\mathrm{pa}}$. It is thus not considered precautionary to increase the fishing mortality above status quo irrespective of the actual estimate.

## Short-term implications

Outlook for 2006
On the basis of ICES advice in May 2005 the European Community has set a TAC at 900 t for 2005. This TAC includes both area IIIa and Divisions IIIbcd. Given the uncertainties in catches it is not possible to quantify exactly the historical contributions from Divisions IIIbcd, but official statistics, from 2002 to 2004 indicate that $5-18 \%$ of the TAC was taken outside IIIa.

A short-term forecast using F status quo for 2005 predicts a catch of 805 t in 2005. This catch is for area IIIa only, but seems consistent with a TAC of 900 t for the whole of Subarea III.

Basis: $\mathrm{F}(2005)=\mathbf{F}_{\mathrm{sq}}(2004)$ catch $(2005)=805 \mathrm{t}^{\text {1) }} ; \mathrm{SSB}(2005)=4621 \mathrm{t}$.
2006

|  | 2006 |  |  |  | 2007 |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Biomass | SSB | FMult | FBar | Landings | Biomass |

Shaded scenarios are not considered consistent with the Precautionary Approach.
${ }^{1)}$ Catch includes reported landings plus an overall estimate of non-reporting and discarding of legal-sized sole of $100 \%$ in 2004. The TAC was set mid-2005 by the EU-Commission.

Status quo fishing mortality gives a catch of $823 \mathbf{t}$ for Division IIIa. This value is consistent with a TAC of 900 t for the areas IIIa and IIIbcd combined.

## Management considerations

Due to considerable non-reporting, discarding of fish above minimum landing size caused by restrictive quotas since 2002 and, to a lesser extent misreporting to other species in recent years, the assessment is considered uncertain in relation to the estimate of F in the final year. The forecast presented is based on the best available information from the industry and inspection regarding non-reporting and discards in 2002, 2003, and 2004, but this information is by its nature uncertain. The sensitivity of the assessment and the forecasts to assumptions regarding non-reporting and discarding has been evaluated for a range of likely scenarios. SSB estimates are more stable against such assumptions, but estimates of recent fishing mortalities and thus the projected catches in future years are not.

The estimate of fishing mortality at present is uncertain and the fishing mortality is likely to be at or below $\mathbf{F}_{\mathrm{pa}}$. In order to avoid fishing at a fishing mortality above $\mathbf{F}_{\mathrm{pa}}$ ICES therefore advises that single-stock boundaries for fishing mortality should be below status quo fishing mortality in 2004.

The North Sea RAC has proposed that the entire fishery in Kattegat should be managed by an effort regulation in 2006. The format for an effort regulation in Kattegat is to be discussed during the autumn 2005.

Sole is taken in a directed trawl fishery with bycatch of Nephrops and cod. Also, sole is taken as bycatch in the Nephrops trawl fishery. There is a directed gillnet fishery for sole catches. TAC for sole in 2006 should be set taking into account the status of the Kattegat cod stock, for which ICES advises no fishery in 2006.

## Management plan evaluations

There is no management plan in place.

## The effects of regulations

The Danish fishery is regulated by half-month rations that depend on vessel length and vary over the year. The rations have been reduced since 2002 reflecting the decline in the agreed TAC, and the Danish sole fishery was entirely closed late in the years 2002, 2003, and 2004.

For the period 1991-1993 the precision of the official catch statistics is disputable. It is assumed that there are significant amounts of sole landed without being properly recorded. For Kattegat where most of the sole catches in 1994-2000 were taken under an effort regime, the official statistics are assumed to be fairly accurate. Considerable misreporting by areas in 2000 and 2001 was corrected by ICES for assessment purposes, i.e. North Sea sole reported as caught in Div. IIIa.

Analyses of private logbooks, survey data, and observer data indicate that in 2002-2004 there was considerable economic incentive to land sole without reporting it, as the entire two-week ration in many cases could be taken in just a few hauls. However, it is not known to what extent these catches were discarded or landed as black landings (i.e. without providing both catch and effort data to the official statistics), or distributed to and landed by vessels not having caught their rations. Thus, this information could not be used to quantify discarding and/or non-reporting.

Based on information from the industry non-reporting and discarding is believed to be in the order of magnitude of 50\% in 2002 and $100 \%$ in 2003 and 2004. Although the advice on the stock status is robust to the assumptions, unreported catches in this order of magnitude have a severe impact on the quality of the stock assessment through the estimate of status quo F and need to be quantified properly.

There is a mis-match between the assessment area that is Div. IIIa and the management area that includes Div. IIIa plus the Western Baltic (SD 22-24). Danish vessel rations cover the management area and there are therefore no incentives for misreporting IIIa sole into the Western Baltic.

## Factors affecting the fisheries and the stock

## Changes in fishing technology and fishing pattern

Sole are caught with both gillnet and trawl. The peak season for trawl is from October to January. On average more than $75 \%$ of the annual sole catches with trawl are caught in this 4 -month season. However, September and February are important months for the sole fishery also, but the percentage of sole in the catches is significantly less, indicating that there might be other target species in these periods. The season for sole gillnet fishery is from April to September.

## The environment

The stock is probably influenced by both temperature and salinity because it is located near the physiological limits of the species for both of these factors. Large variations in either factor will therefore influence stock productivity.

The large increase in landings in the early 1990s compared to long-term historical levels ( $1950 \mathrm{~s}-1980 \mathrm{~s}$ ) may represent both changes in environmental conditions and fishery developments (e. g., increased effort), but the relative importance of the two factors is not known.

The Kattegat has also been eutrophicated over the past 50 years, but the specific effects of eutrophication on sole have not been investigated.

## Scientific basis

## Data and methods

The assessment includes CPUE data from seven commercial CPUE series (not previously included in the assessment) and one CPUE series from a Danish scientific trawl survey in quarter 4 . Four of the commercial series were based on data from private logbooks ( 6 trawlers and 3 gillnetters and 2 area combinations) and three of the series based on official logbooks from fisheries outside the main sole fishing seasons when rations were not restrictive (small and large trawlers as well as gillnetters). Assessment results were robust to various combinations of CPUE fleets. As in previous years, the quarter 1 IBTS survey was not used in the assessment, due to their low signal to noise ratio. This is consistent with the practice in the assessment of the North Sea sole, where similarly IBTS indices are not used in the assessment.

The available data from discard sampling is insufficient to be used directly in the assessment. Overall estimates of nonreporting and discarding have been used in the assessment based on information from the industry and from control and enforcement; see the sections on management considerations above and information from the industry below.

The assessment is considered highly uncertain in relation to the estimates of F in the final year, while SSB estimates are more stable to assumed levels of unreported catches.

Due to a closure in the fisheries in the 4th quarter of 2002 to 2004, the commercial data matrix is biased and does not well reflect the strength of the incoming recruitment at the end of the year.

Information from the fishing industry
Collaboration between the Danish Fishermen's Organisation and DIFRES was initiated in 2004 to establish a database with data from private logbooks. Data from 6 trawlers and 3 gillnetters covering the time period 1987 to 2004 were available for the assessment.

The industry provided information on the likely order of magnitude of discarding and non-reporting in 2002-2004.

## Comparison with previous assessment and advice

New data (CPUE series based on private and official logbooks and estimates of non-reporting and discards of legalsized sole in recent years) have been compiled to supplement the data formerly available for the assessment. The assessment includes new CPUE series from private and official logbooks and catch data including an estimate of discard and non-reporting. This assessment revises the perception of the stock in the most recent years and indicates an increasing trend in SSB and decreasing F since the late 1990s. Previous advice was based on a perception of the stock, which was close to $\mathbf{B}_{\mathrm{pa}}$ and fished around $\mathbf{F}_{\mathrm{pa}}$.

### 1.4.10 Sole in Subarea IV (North Sea)

## State of the stock

| Spawning biomass in <br> relation to precautionary <br> limits | Fishing mortality in relation <br> to precautionary limits | Fishing mortality in relation <br> to highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Full reproductive capacity | Harvested sustainably | Overexploited |  |

Based on the most recent estimate of SSB and fishing mortality, ICES classifies the stock as having full reproductive capacity, and as being harvested sustainably. SSB in 2005 was estimated at $41000 \mathbf{t}$ which is above $\mathbf{B}_{\text {pa }}(35000 \mathrm{t}$ ), while F in $2004(0.35)$ is at or near $\mathrm{F}_{\mathrm{pa}}$. The 2001 year class is estimated to be strong, but the 2002 and subsequent year classes are relatively weak.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathrm{B}_{\lim }=25000 \mathrm{t}$ | $\mathrm{B}_{\mathrm{pa}}=35000 \mathrm{t}$ |
|  | $\mathrm{F}_{\mathrm{lim}}$ is undefined | $\mathrm{F}_{\mathrm{pa}}=0.4$. |
| Target reference points |  | $\mathrm{F}_{\mathrm{y}}=$ undefined |

Yield and spawning biomass per Recruit
F-reference points:

|  | Fish Mort <br> Ages 2-6 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| Average last 3 |  |  |  |
| years | 0.479 | 0.171 | 0.336 |
| $\mathbf{F}_{0.1}$ | 0.133 | 0.153 | 1.151 |
| $\mathbf{F}_{\text {med }}$ | 0.380 | 0.172 | 0.427 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\text {max }}$.

Technical basis

| $\mathbf{B}_{\mathrm{lim}}=\mathbf{B}_{\mathrm{loss}}=25000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4 * \mathbf{B}_{\mathrm{lim}}$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ : undefined | $\mathrm{F}_{\mathrm{pa}}=0.4$ implies $\mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}$ and $\mathrm{P}\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<10 \%$. |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality $\left(\mathbf{F}_{s q}\right)$ is estimated at 0.35 , which is above the rate that would lead to high long-term yields. $F_{\text {max }}$ is not well defined and $\mathbf{F}_{0.1}$ is 0.13 . Fishing at $\mathbf{F}_{0.1}$ is expected to lead to landings in 2006 of 5600 t and SSB in 2007 of around 41300 t .

Exploitation boundaries in relation to precautionary limits
The exploitation boundaries in relation to precautionary limits imply landings of less than 11900 t in 2006, which is expected to lead to an SSB equal to $\mathbf{B}_{\mathrm{pa}}(=35000 \mathrm{t})$ in 2007.

## Short-term implications

## Management considerations

Sole are mainly caught in a mixed beam trawl fishery with plaice and other flatfish using $80-\mathrm{mm}$ mesh in the southern North Sea. The minimum mesh size in the mixed beam trawl fishery in the southern North Sea means that large numbers of undersized plaice and cod are discarded. Measures to reduce discarding in the mixed beam trawl fishery would greatly benefit these stocks. An increase in the minimum landing size of sole could provide an incentive to fish with larger mesh sizes and therefore mean a reduction in the discarding of plaice.

The peaks in SSB of North Sea sole are heavily dependent on the occasional occurrence of strong year classes. The SSB and landings in recent years have been dominated by the 1996 and 2001 year classes. The low advice is the result of the weak 2004 year class and the need to maintain SSB above Bpa which requires a reduction in fishing mortality

TACs in recent years have been above the levels associated with $\mathrm{F}_{\mathrm{pa}}$.
Due to a range of factors such as TAC constraints on plaice, effort limitations, and increases in fuel prices, the fishing effort of the major fleets targeting sole has concentrated in the southern part of the North Sea. This is the area where a large part of the juvenile fish of e.g. plaice in the North Sea is found. In addition, juvenile plaice has shown a more offshore distribution in recent years. The combination of a change in fishing pattern and the spatial distribution of juvenile plaice has lead to an apparent increase in discarding of plaice.

The present advice framework implies large inter-annual changes in TAC advice when stocks are just above or just below Bpa. Such variations could be avoided with the development of a long-term management plan.

## Factors affecting the fisheries and the stock

## The effects of regulations

The TACs are assumed to be restricting the fishery. The TAC in 2004 was agreed at 17000 t and for 2005 the TAC was set at 18600 t . Estimated landings are higher than the TAC. This is predominantly due to a discrepancy in the conversion factor between dead weight and live weight. The inspection authorities use a lower conversion factor than the research institutes.

Technical measures applicable to the sole fishery in the North Sea included mesh size regulations, minimum landing size, gear restrictions, and a closed area (the plaice box). Mesh size regulations for towed gears require that vessels fishing north of $55^{\circ} \mathrm{N}$ (or $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$, since January 2000) should have a minimum mesh size of 100 mm , while south of this limit, where the majority of the plaice fishery takes place, an $80-\mathrm{mm}$ mesh is allowed. In the fishery with fixed gears a minimum mesh size of 100 mm is required.

The aggregated beam length of beam trawlers is limited to 24 m . In the 12 -nautical mile zone and in the plaice box the maximum aggregated beam-length is 9 m .

The minimum landing size of North Sea sole is 24 cm . Mesh enlargement would reduce the catch of undersized plaice and cod, but would also result in short-term loss of marketable sole.

The plaice box has been been established in 1989, and the area was closed in all quarters since 1995. The closed area applies to vessels using towed gears, but vessels smaller than 300 HP are exempted from the regulation. The effectiveness of the plaice box has been evaluated by an expert group (Grift et al, 2004. See section 1.4.7 on North Sea plaice) . The proportion of undersized sole inside the plaice box did not change after closure and remained stable at 60 $70 \%$.

## Changes in fishing technology and fishing patterns

The fishing effort of the major fleets exploiting North Sea sole has decreased since the mid-1990s. Recently the combination of days-at-sea regulations, high oil prices, and decreasing TAC for plaice and relatively stable TAC for sole, appear to have induced a more coastal fishing pattern in the southern North Sea. This concentration of fishing effort could result in increased discarding of juvenile plaice that are mainly distributed in those areas.

There are indications that technical efficiency has increased in the sole fishery, which could have counteracted the overall decrease in effort.

The stock assessment is based on an XSA assessment, calibrated with two survey indices and one commercial CPUE index. Survey data for 2005 has been used in recruitment estimation.

Information from the fishing industry
The North Sea Stock Survey was available and has been evaluated (Figure 4.4.5.b.1). Signals from the fisher's survey indicate that sole are becoming more abundant. This is in agreement with the research-vessel survey indices and is likely to be caused by the strong 2001 year class recruiting to the fishery. However, the low uptake of quota until September 2005 indicates that it is unlikely that the TAC will be taken by the end of the year. It is not clear if these two signals are consistent with each other.

Uncertainties in assessment and forecast
There are indications of considerable retrospective underestimation of fishing mortality and some overestimation of abundance. The status quo fishing mortality which was used to forecast the landings in 2005 may therefore be an underestimate.

## Comparison with previous assessment and advice

The assessment is generally consistent with previous assessments, although there is a tendency to underestimate fishing mortality. The low advice is a result of the weak 2004 year class and the need to maintain SSB above $\mathbf{B}_{\mathrm{pa}}$, which requires a reduction in fishing mortality.

### 1.4.11 Sole in Division VIId (Eastern Channel)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | At risk of being <br> harvest <br> unsustainably | Overexploited |  |

Based on the most recent estimate of SSB (12000 t), ICES classifies the stock as having full reproductive capacity. The spawning stock biomass has been fluctuating around a mean of about 10000 t since 1982 , and is presently above $\mathbf{B}_{\text {pa }}$.

Based on the most recent estimates of fishing mortality (0.42), ICES classifies the stock at risk of being harvested unsustainably. The fishing mortality has decreased since 1999 and has been around $\mathbf{F}_{\mathrm{pa}}$ since 2001.

Recent recruitment has been strong, with the 2001 and 2003 year classes being the highest and second-highest, respectively, of the time-series (1982-2004).

## Management objectives

No explicit management objectives are set for this stock.

## Reference points

(unchanged since 1999)

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| There is currently no biological basis for defining $\mathbf{B}_{\mathrm{lim}}$. | $\mathbf{B}_{\mathrm{pa}}$ be set at 8000 t . This is the lowest observed biomass <br> at which there is no indication of impaired recruitment. |
| $\mathbf{F}_{\text {lim }}$ is 0.55. This is a fishing mortality at or above which <br> the stock has shown continued decline. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathbf{F}_{\mathrm{lim}}$. |

Yield and spawning biomass per Recruit
F-reference points:

|  | Fish Mort <br> Ages 3-8 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| Average last 3 |  |  |  |
| years | 0.405 | 0.168 | 0.365 |
| $\mathbf{F}_{\text {max }}$ | 0.308 | 0.169 | 0.501 |
| $\mathbf{F}_{0.1}$ | 0.132 | 0.152 | 1.119 |
| $\mathbf{F}_{\text {med }}$ | 0.396 | 0.168 | 0.375 |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Poor biological basis for definition. | $\mathbf{B}_{\mathrm{pa}}:$ Smoothed $\mathbf{B}_{\text {loss }}$ (no sign of impairment): 8000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is set equal to $\mathbf{F}_{\text {loss }}$, but poorly defined; analogy to <br> North Sea and setting of 1.4 $\mathbf{F}_{\mathrm{pa}}=0.55$. | $\mathbf{F}_{\mathrm{pa}}:$ Between $\mathbf{F}_{\text {med }}$ and 5th percentile of $\mathbf{F}_{\text {loss }} ; \mathrm{SSB}>\mathbf{B}_{\mathrm{pa}}$ |
| and probability $\left(\mathbf{S S B} \mathbf{B}_{\mathrm{mt}}<\mathbf{B}_{\mathrm{pa}}\right), 10 \%: 0.4$. |  |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield. low risk of depletion of production potential and
considering ecosystem effects
Target reference points have not been agreed for this stock. The current fishing mortality ( $\mathbf{F}_{s q}$ ) is estimated at 0.42 , which is above the rate that would lead to high long-term yields ( $F_{0.1}=0.13$ ). $\mathbf{F}_{\text {max }}$ is not well defined. Fishing at $\mathbf{F}_{0.1}$ is expected to lead to landings in 2006 of 2100 t and SSB in 2007 of around 15500 t .

## Exploitation boundaries in relation to precautionary limits

The exploitation within the precautionary limits would imply landings of less than 5720 t in 2006 , which is expected to lead to a $12 \%$ decrease in SSB in 2007.

## Short-term implications

Outlook for 2006:
Basis: $\mathrm{F}(2005)=\mathbf{F}_{\mathrm{sa}}=$ mean $\mathrm{F}(02-04)=0.41 ; \mathrm{SSB}(2005)=11.76 ; \operatorname{SSB}(2006)=13.57$; landings $(2005)=5.99$.

|  | 10.77 | $\mathrm{TAC}\left(\mathbf{F}_{\mathrm{oz}}\right)$ *2.25 | 0.90 | 6.96 | 49\% | 89\% |

(1) It is assumed that the TAC will be implemented and that the landings in 2006 therefore correspond to the TAC.

All weights in thousand tones.
Shaded scenarios are not considered consistent with the Precautionary Approach.

## Management considerations

Due to recent large recruitments, SSB is expected to remain well above $\mathbf{B}_{\mathrm{pa}}$ in the short term, provided the fishing mortality does not exceed $\mathbf{F}_{\mathrm{pa}}$.

Sole is taken in a mixed fishery with plaice, with bycatches of cod and whiting
Due to the minimum mesh size ( 80 mm ) in the mixed beam trawl fishery, a large number of (undersized) plaice are discarded. The $80-\mathrm{mm}$ mesh size is not matched to the minimum landing size of plaice. Measures to reduce discarding in the sole fishery would greatly benefit the plaice stock and future yields. Mesh enlargement would reduce the catch of undersized plaice, but would also result in short-term loss of marketable sole. An increase in the minimum landing size of sole could provide an incentive to fish with larger mesh sizes and therefore mean a reduction in the discarding of plaice.

## Factors affecting the fisheries and the stock

There are 5 main commercial fleets fishing for sole in Division VIId. Belgian and English offshore beam trawlers ( $>300 \mathrm{HP}$ ) fish mainly for sole, but can switch to scallops or move to adjacent areas. French offshore trawlers target roundfish and take sole as bycatch. Numerous inshore (under $10-\mathrm{m}$ vessels) on the English and French coasts using mainly fixed nets target sole in the spring and autumn. The inshore vessels take half the reported landings and sole forms their main source of income. Effort from the beam trawl fleet can change considerably depending on whether the fleet moves to other areas or directs effort at other species such as scallops and cuttlefish.

The minimum landing size for sole is 24 cm . Demersal gears permitted to catch sole are 80 mm for beam trawling and 80 mm for otter trawlers. Fixed nets are required to use $100-\mathrm{mm}$ mesh since 2002, although an exemption to permit 90 mm has been in force since that time.

## The effects of regulations

The EU regulation enforced since 2004 is a limitation of 22 days at sea per month for trawlers with mesh size less than $99 \mathrm{~mm}, 14$ days at sea for beam trawlers, and gillnetters have a derogation of 20 days at sea in the Eastern Channel provided that their mesh size is less than 110 mm . However, these effort limitations from the cod recovery plan are not likely to decrease the effort on sole in Division VIId.

## Changes in fishing technology and fishing patterns

No major changes of fishing technology and fishing pattern have taken place in the assessment period (1982-2004).

## Scientific basis

## Data and methods

The assessment is based on landings data, two commercial CPUE indices and two research-vessel survey indices.

## Uncertainties in assessment and forecast

The past performance of this assessment for estimating this stock has been poor. Discarding of sole is thought to be minor and it is assumed that the lack of discard will not notably affect the assessment results. However, under-reporting from the inshore fleets and misreporting by beam trawlers fishing in adjacent management areas is thought to be significant. The historical landings have been adjusted for misallocated landings between the Eastern and Western Channel over the period 1986-2004. XSA diagnostics and the retrospective analysis indicate a tendency to underestimate fishing mortality and overestimate SSB.

## Comparison with previous assessment

The current assessment has revised the value of SSB in 2003 downwards by $5 \%$. Past recruitment estimates were subject to considerable annual revision.

## State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably | Appropriate |  |

Based on the most recent estimates of SSB and fishing mortality, ICES classifies the stock as having full reproductive capacity and being harvested sustainably. Fishing mortality declined since 1986, and appears to be below $\mathbf{F}_{\mathrm{pa}}$ since 1997. SSB was below $\mathbf{B}_{\mathrm{pa}}$ from 1984 to 1997 (and was below $\mathrm{B}_{\mathrm{lim}}$ from 1990-1993), but increased in the late 1990s and is estimated to have been at or near $\mathbf{B}_{\mathrm{pa}}$ since 1997.

## Management objectives

In 2004 EU and Norway agreed to implement a long-term plan for the saithe stock in the Skagerrak, the North Sea and west of Scotland, which is consistent with a precautionary approach and designed to provide for sustainable fisheries and high yields. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of Spawning biomass (SSB) greater than 106000 tonnes ( $B_{\text {lim }}$ ).
2. Where the $S S B$ is estimated to be above 200000 tonnes the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality rate of no more than 0.30 for appropriate age groups.
3. Where the $S S B$ is estimated to be below 200000 tonnes but above 106000 tonnes the TAC shall not exceed a level which, on the basis of a scientific evaluation by ICES, will result in a fishing mortality rate equal to 0.30 -$0.20^{*}(200000-S S B) / 94000$.
4. Where the SSB is estimated by the ICES to be below the minimum level of SSB of 106000 tonnes the TAC shall be set at a level corresponding to a fishing mortality rate of no more than 0.1.
5. Where the rules in paragraphs 2 and 3 would lead to a TAC which deviates by more than $15 \%$ from the TAC the preceding year the Parties shall fix aTAC that is no more than $15 \%$ greater or $15 \%$ less than the TAC of the preceding year.
6. Notwithstanding paragraph 5 the Parties may where considered appropriate reduce the TAC by more than $15 \%$ compared to the TAC of the preceding year.
7. A review of this arrangement shall take place no later than 31 December 2007.
8. This arrangement enters into force on 1 January 2005.

The saithe management plan has not been evaluated by ICES.

| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.6$, the fishing mortality estimated to lead to stock falling below $\mathbf{B}_{\text {lim }}$ in the long term. | $\begin{aligned} & \mathbf{F}_{\mathrm{pa}}=0.4 \text { implies that } \mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}} \text { and } \\ & \mathrm{P}\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<10 \% . \end{aligned}$ |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

At the present SSB level, F should be below 0.3 to be in accordance with the management plan. This corresponds to catches of less than 108.7 kt in 2006. Unless paragraph 6 is invoked the management plan limits the annual deviation of the TAC to $15 \%$ which would correspond to catches of 136 kt .

## Short-term implications

The short-term prognosis is made using the $\mathbf{F}_{\mathrm{sq}}$ assumption for the intermediate year. An $\mathbf{F}_{\mathrm{sq}}$ landings for 2005 corresponds to 99000 t , which is far below the agreed TACs (145 000 t for the North Sea plus IIIa, and 15000 t for Division VIa).

## Outlook for 2006:

Basis: $\mathrm{F}(2005)=0.27 ; \mathrm{SSB}(2006)=235$; catch $(2005)=99.1$.

Shaded scenarios are not considered consistent with the Precautionary Approach.

## Management considerations

Before 1999, saithe in Subarea VI and saithe in Subarea IV and Division IIIa were assessed as two separate stocks. The ICES advice now applies to the combined areas IIIa, IV, and VI.

The reported landings have been much lower than the TAC the last four years. Information from fishers indicates that very low prices on saithe combined with high fuel prices are causing these reductions in landings. These factors may also have led to increased discarding, although information was not available to quantify this.

The saithe management plan has not been evaluated by ICES. A requirement for consistency with the Precautionary Approachis that the SSB decision parameters are used as lower bounds on SSB, and not as targets and that par 6 will be invoked whenever there is high risk that the SSB may fall below $\mathrm{B}_{\mathrm{lim}}$ in the short term.

## Ecosystem considerations

Because of its life-history, saithe in the North Sea is partly geographically protected from heavy exploitation as juveniles and as large adults.

The geographical distribution of juvenile (< age 3) and adult saithe differs. Typical for all saithe stocks are the inshore nursery grounds. Juvenile saithe in the North Sea are therefore mainly distributed along the west and south coast of Norway, the coast of Shetland, and the coast of Scotland. Around age 3 the individuals gradually migrate from the coastal areas to the northern part of the North Sea ( $57^{\circ} \mathrm{N}-62^{\circ} \mathrm{N}$ ). The age at maturity is between 4 and 6 years, and spawning takes place in January-March at about $200-\mathrm{m}$ depth along the Northern Shelf edge and the western edge of the Norwegian deeps.

Tagging experiments by various countries have shown that exchange takes place between all saithe stock components in the northeast Atlantic.

## Factors affecting the fisheries and the stock

## The effects of regulations

Management of saithe is by TAC and technical measures. In January 2002 the minimum mesh size (in bottom trawls for human consumption) was changed from 100 to 110 mm in EU-waters and from 100 to 120 mm in Norwegian waters (the minimum mesh size for Norwegian vessels was set to 120 mm both in Norwegian and EU waters). This regulation was not strictly enforced in the first half of 2002 to allow a transition period, i.e. the implementation of larger mesh sizes probably happened gradually during 2002. Minimum landing size is 35 cm in the $E U$ zone, 32 cm in the Norwegian zone.

## Changes in fishing technology and fishing patterns

Variations in EU and Norwegian mesh size regulations in the saithe fishery in 2001-2003 might have contributed to changes in the exploitation pattern (spatial and temporal changes in size-specific fishing mortality between years).

## Scientific basis

## Data and methods

There are no discard estimates for the majority of the fishery, and they were thus not included in the assessment.
The stock assessment is based on an XSA model, calibrated by three commercial CPUE series and two survey indices.

## Information from the fishing industry

The reported catch in 2004 was much lower than the TAC and the reported effort was also considerably lower than in 2003. Information from fishers indicates that very low prices on saithe are causing these reductions.

The fishers' survey corresponds with the outcome of the assessment.

## Uncertainties in assessment and forecast

The assessment is considered to be uncertain because of incomplete catch information, residual patterns in catchability, retrospective bias in $F$ and SSB estimates, uncertain recruitment estimates, the age range used to compute mean F uses
ages not fully recruited, and there is no logical explanation for the steady decline in F since the mid-1980s given a rather constant level of landings and an increase in SSB.

The most serious problem with stock forecasts for saithe is the lack of reliable information about year-class strength before age 3 . An annual 0 -group survey has been conducted by the Institute of Marine Research (IMR, Norway) since 1999 in the northern North Sea, but this will not be continued due to lack of relationship between the 0 -group index and later XSA population estimates for the year classes 1999-2001 (the 0 -group index for the 2000 year class is extremely high, while this year class is estimated to be around average for age 4 in this year's assessment). IMR considers starting a new survey along the west coast of Norway to measure the relative abundance of saithe between 1 and 3 years old (when the saithe is distributed along the coast).

Comparison with previous assessment and advice
The estimate of 2004 SSB is about $10 \%$ less than the previous estimate, while the 2003 F was estimated to be similar.

### 1.4.13 Nephrops in Division IIIa (Management Area E)

There are two Functional Units in this Management Area: Skagerrak (FU 3) and Kattegat (FU 4).

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment <br> [used if qualifiers to present state are <br> necessary] |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown. Indices from commercial fishery suggest that the stocks in this Management Area are exploited at sustainable levels. Large amounts of discards in recent years (1999-2000) may indicate strong recruitment.

## Management objectives

No management objectives have been set for this fishery.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Given the apparent stability of the stocks, current levels of exploitation appear to be sustainable.
Due to uncertainty in the available data ICES is not able to reliably forecast catch. Therefore ICES recommends that fishing effort for fleets targeting Nephrops should not be allowed to increase.

## Management considerations

Discards are known to be very high and any improvement of the fishing pattern of the catches would benefit the stock and medium-term yield.

Since most of the trawl fisheries for Nephrops in Division IIIa are mixed fisheries, the effort in these fisheries may affect by-catch levels of other commercial species caught unless the species and size selectivity properties of the Nephrops trawls is improved (e.g. grids and square meshes).

In view of the catch restrictions for cod and other demersal fish species in the North Sea and IIIa it should also be noted that if Nephrops fishing effort is allowed to increase, this may have implications for those stocks in mixed fisheries where Nephrops is targeted, unless species and size selectivity of the gears is improved (see above). Cod and sole are significant bycatch species in these fisheries in IIIa, and even if data on catch including discards of the bycatch gradually become available, they have not yet been used in the management.

## Ecosystem considerations

Individual stocks inhabit distinct areas of suitable muddy sediment. No information is available on the extent to which larval mixing occurs between Nephrops stocks.

Cod have been identified as a predator of Nephrops in some areas, and the generally low level of the cod stock is likely to have resulted in reduced predation.

## Factors affecting the fisheries and the stock

The majority of landings are taken by Denmark and Sweden, with Norway contributing only small landings from the Skagerrak. During the last 10 years, total landings from the Skagerrak have varied between 1900 and 3250 t , while landings from the Kattegat have varied between 900 and 1800 t (with the lowest landings recorded in 1992-1995).

## The effects of regulations

The minimum landing size for Nephrops in Area IIIa is 40 mm carapace length.
Days-at-sea limits restrict Nephrops trawlers to 19 days per month when using $90-\mathrm{mm}$ mesh with no square mesh panel, and 22 days with a square mesh panel. New gear regulations imply that it is mandatory to use a $35-\mathrm{mm}$ species selective grid and 8 metres of $70-\mathrm{mm}$ full square mesh codend and extension piece when trawling for Nephrops in Swedish national waters. As Sweden has bilateral agreements with Denmark and Norway to fish inside the 12 nm limit, the regulations cover only waters exclusively fished by Swedish vessels (inside 3 nm in Kattegat and 4 nm in Skagerrak).

Traditionally, Nephrops have mainly been caught in trawls using $70-89 \mathrm{~mm}$ mesh sizes. In the last five years an increasing proportion of the total landings of Nephrops have been caught by vessels using gears with mesh sizes $>89$ mm (which historically have been used in the fishery for cod, plaice, and other demersal fish species). In Skagerrak and Kattegat mesh sizes between $70-89 \mathrm{~mm}$ have been prohibited since 2005, unless the codend and the extension piece is constructed of square meshed netting with a sorting grid (Council Regulation 27/2005). Those changes in fishing patterns may be seen in the light of the declines in most important demersal fish stocks in the North Sea, Skagerrak, and Kattegat.

## Changes in fishing technology and fishing patterns

Recent reports from industry and gear technologists suggest a more widespread use of "flip-up" gear in twin rig Nephrops trawls (see Graham, WD). This development will allow fleets to expand onto rougher ground, potentially exploiting new Nephrops areas.

## Scientific basis

## Data and methods

LPUE and mean size data are available for both FUs. Length compositions are available from 1991 onwards.

## Uncertainties in assessment and forecast

The assessment of the state of the Nephrops stocks in the Skagerrak and Kattegat area is based on the patterns in fluctuations of total combined LPUE by Denmark and Sweden during the period 1990-2004 and the patterns in fluctuations of discards in the fisheries as estimated from the catch samples for the same period.

However, the quality of LPUE could be affected by changes in catchability (due to sudden changes in the environmental conditions), or changes in selectivity and/or in gear efficiency. Discards are also dependent on selectivity of the gear and on discarding practices.

Comparison with previous assessment and advice:
Due to the ageing problems for Nephrops in general, ICES decided not to conduct age-based assessments of these stocks and no analytical assessments on these FUs were performed in 2005. However, the perception of the state of these stocks based on stock indicators as LPUEs is the same as in 2003.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 6-15 September 2005 (ICES CM 2006/ACFM:09).

### 1.4.14 Shrimp (Pandalus borealis) in Division IIIa and Division IVa East (Skagerrak and Norwegian Deeps)

## State of the stock

| Spawning <br> biomass in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown |  |  | The stock appears to be stable at the same <br> level in 2005 and 2006 as in recent years. |

The current state of the stock appears to be stable and at a rather high level. This assessment is based on 1) evaluation of LPUE from the fishery 1984-2005 and the 2004-2005 survey indices of biomass and 2) production model-based estimates using the 1985-2002 survey and catch data (1984-2005).

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

There are no precautionary reference points.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

Based on the assessment it is recommended that the total landings from IIIa and IVa East in the 2006 are not increased above the recent average (2002-2004) of 13500 t . However, it is likely that the stock may sustain an even higher exploitation.

## Short-term implications

Outlook for 2006
There are no signs indicating that the development in 2005 and 2006 will change dramatically compared to 2004.

## Management considerations

The exploitable biomass comprises only few age groups (1-3) of which age group 2 and older constitute around $70 \%$ in weight of the total catch.

Sorting grids or other means of facilitating the escape of fish should be implemented in this fishery.

## Factors affecting the fisheries and the stock

## Regulations and their effects

The main regulation tool is a TAC which is not fully fished by all countries.

## Changes in fishing technology and fishing patterns

Within the last 5-10 years almost all Danish trawlers had started fishing with twin trawls. This change allowed the individual vessels to increase the swept area (wing end to wing end) by approximately $50 \%$ without increased demands to the vessels' engine capacity or a noticeable increase in fuel consumption.

## The environment

Strong fluctuations in the Pandalus stocks are frequently observed. Predator pressure as well as the few age groups in the stock contributes significantly to such fluctuations. The natural mortality for Pandalus is likely to be substantially higher than the fishing mortality and fluctuates considerably according to the abundance of predators.

## Scientific basis

Data and methods
The perception of the state of the stock in 2004 is based on the result of the stock production model as well as trends in commercial LPUEs combined with a comparison of the 2004 biomass index from a Norwegian survey in May 2004 and 2005. The assessments in previous years (2001-2003) took predation into account and indicated that predators annually remove a much larger fraction of the stock than the fishery. This year's model does not take predation specifically into account.

## Comparison with previous assessment and advice

The production model assessment presented this year confirms last year's LPUE based assessment of the state of stock.

Catch Pandalus IIla \& IVaE

Figure 1.4.14.1 Total landings of Pandalus from the Skagerrak and eastern part of the North Sea.

Figure 1.4.14.2 Landings per unit effort (LPUE) in kg per fishing day and total effort in ' 000 hours trawled.

Figure 1.4.14.3 Survey results: Trends in biomass, 1984-2004. The estimates for 2003 and 2004 are not comparable to the previous estimates. In 2003 a trawl with large mesh size was used in the survey.

### 1.4.15 Pandalus on Fladen Ground (Division IVa)

## State of the stock

The shrimp stock on Fladen Ground has not been assessed since 1992, due to insufficient data. There is a total lack of separate, fishery-independent data. The most recent analytical assessment of this stock was presented in the 1992 ACFM Report (ICES, 1992). Landings have declined gradually from 1999 to 2003, but in 2004 nearly no catches were recorded ( 23 t ). Part of the explanation for this development is the low price for shrimp combined with the rather high fuel costs. No monitoring of this stock has taken place, but it cannot be ruled out that the dramatic drop in 2004 also reflects a serious decline in the stock.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

No reference points have been defined.

## Short-term considerations

ICES recommends that catches are not increased above average recent (2001-2003) landings of about 1300 t .

## Management considerations

The development in the 2004 fishery, as described above, could indicate a low stock level. For the Fladen Ground stock such events have occurred previously, notably in 1987-1988. However, a recovery of the stock after that decline was observed already in 1989-1990 without any management actions.

Catches from Fladen Ground consist mainly of two age groups. During the first two quarters of the year age groups 2 and 3 normally dominate the catches. During the fourth quarter, age group 3 usually disappears from the catches, while age group 1 enter the catches.

## Scientific basis

Some data for use in an analytical assessment for later years have been compiled. However, due to the frequent large seasonal fluctuations in the Fladen Ground fishery, samples for length composition of the catches do not always cover the entire year. There is no survey information available and stock predictions for the Fladen Ground shrimp are not possible.

ICES has, so far, maintained the view that shrimp caught on the Fladen Ground constitute a stock separated from the Pandalus in the Norwegian Deeps and Skagerrak. This assumption is under review; there are indications that the Fladen Ground shrimp and the shrimp in the Norwegian Deep are correlated.

Pandalus Fladen ground - Landings

Figure 1.4.15.1 Total landings of Pandalus on Fladen Ground.

### 1.4.16 Pandalus in Farn Deeps (Division IVb)

## State of Stock

Since 1991, only UK vessels have fished Pandalus in the Farn Deeps. Total landings fell from 500 t in 1988 to none in 1993. In 1995 and 1996 again about 100 ton were reported. Since 1997 the Pandalus fishery in Farn Deeps has been negligible. No assessments of these shrimps are available.

## Source of information

Report of the Pandalus Assessment Working Group, Halifax, 26 October - 4 November 2005 (ICES CM 2006/ACFM:06).

### 1.4.17

State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Reference points <br> not defined | Reference <br> points not <br> defined | unknown | unknown |  |

In the absence of defined reference points, the state of the stock cannot be evaluated with regard to these. An analytical assessment demonstrates that SSB has been slightly increasing over a number of years. The fishing mortality estimates for 2004 are 0.36 for adults and 0.11 for the juveniles ( $0-$ and 1 -ringers). The age structure in the catch over the last three years consistently reflects that the large 1999 year class is now part of the spawning stock. The 2003 year class seems to be above average.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

There are no reference points for this stock.

|  | Fish Mort <br> Ages 3-6 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| Average last 3 | 0.413 | 0.025 | 0.051 |
| years | 0.212 | 0.023 | 0.099 |
| $\mathbf{F}_{0.1}$ | 0.529 | 0.025 | 0.037 |

If target reference points are to be established, $\mathbf{F}_{0.1}$ would be associated with high long-term yields and low risk of reduced reproductive capacity.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Current fishing mortality has led to stable or increased SSB and the fishing mortality should not be allowed to increase. This corresponds to landings of less than 95000 t in 2006.

## Short-term implications

Outlook for 2006
Basis: $F(2005)=\mathbf{F}_{\mathrm{sq}}=0.358 ; \operatorname{SSB}(2005)=194$; catch $(2005)=92$.
Landings are for Division IIIa (spring-spawning herring and western Baltic (Subdivisions 22-24) combined), see further in Section 1.4.18.

| $\mathbf{F}_{0.1}$ | 60 |  | 0.212 | 211 |

Weights in ' 000 t .

## Management considerations

North Sea Autumn-Spawning and the Western Baltic Spring-Spawning herring stocks are exploited and managed simultaneously in Division IIIa. Hence, the management of the herring fisheries in Division IIIa influences both stocks. The advisory emphasis on one or the other stock will vary between periods and depends on their relative status.

In the second half of the 1990 s and the beginning of the 2000s the North Sea Autumn-Spawning stock was depleted and advice on management of herring fisheries in Division IIIa focused on rebuilding the North Sea herring. The herring fishery in Division IIIa was then managed in a manner consistent with the management of the North Sea AutumnSpawning herring. With the rebuilding of the North Sea stock, concerns for the North Sea Autumn-Spawning herring are less and advice on management of the herring fisheries in Division IIIa is now more focused on the Western Baltic stock.

Catch options for the whole stock of Western Baltic Spring-Spawning herring can be partitioned into catches by area. Likewise, the catches of WBSS in Division IIIa also imply catches of North Sea Autumn-Spawning herring which constitute part of the total catch in that area. The basis for the split of the Western Baltic Spring-Spawning herring catch by area and of the catch in Division IIIa by stock was the ratios between the catches in 2004. The current relevant fleet definitions are:

## Division IIIa

Fleet C : Directed herring fisheries with purse seiners and trawlers
Fleet D: Bycatches of herring caught in the small-mesh fisheries

## Subdivision 22-24

The WBSS are exploited by other fleets as well, in Subdivisions 22-24.
The text table below shows the 2004 share of the total catch in tonnes of Western Baltic Spring-Spawning herring by fleet:

| WBSS | Fleet C (IIIa) | Fleet D (IIIa) | SD 22-24 + Fleet A (IV) | Total |
| :--- | :--- | :--- | :--- | :--- |
| 2004 | $16825(22 \%)$ | $11175(15 \%)$ | $48815(64 \%)$ | 76815 |

The text table below shows the proportion of Western Baltic Spring-Spawning herring in the catches by fleet in Division IIIa, as well as for the fleets in SD 2224.

| WBSS | Fleet C | Fleet D | SD22-24 + Fleet A (IV)* |
| :---: | :---: | :---: | :---: |
| 2004 | 0.56 | 0.51 | $\mathbf{1}$ |

* Only WBSS caught in Subarea IV are accounted for in the calculations

The text table below shows the expected catches for each stock and in each area corresponding to a range of total catch options for the Western Baltic Spring-Spawning herring stock:

| Western Baltic Spring-Spawners |  |  | North Sea Autumn-Spawners |  | Both Stocks together |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| All fleets total catches | $\begin{aligned} & \text { Fleet C } \\ & \text { ( } 22 \% \text { of TAC) } \end{aligned}$ | $\begin{aligned} & \text { Fleet D } \\ & \text { ( } 15 \% \text { of TAC) } \end{aligned}$ | $\begin{aligned} & \hline \text { Fleet C } \\ & \text { (WBSS/56\%) } \end{aligned}$ | $\begin{aligned} & \text { Fleet D } \\ & \text { (WBSS/51\%) } \end{aligned}$ | Fleet C | Fleet D |
| 60,000 | 13,100 | 8,700 | 10,500 | 8,400 | 23,600 | 17,100 |
| 65,000 | 14,200 | 9,500 | 11,400 | 9,100 | 25,600 | 18,600 |
| 70,000 | 15,300 | 10,200 | 12,200 | 9,800 | 27,500 | 20,000 |
| 75,000 | 16,400 | 10,900 | 13,100 | 10,500 | 29,500 | 21,400 |
| 80,000 | 17,500 | 11,600 | 14,000 | 11,200 | 31,500 | 22,800 |
| 85,000 | 18,600 | 12,400 | 14,900 | 11,900 | 33,500 | 24,300 |
| 90,000 | 19,700 | 13,100 | 15,700 | 12,600 | 35,400 | 25,700 |
| 95,000 | 20,800 | 13,800 | 16,600 | 13,300 | 37,400 | 27,100 |
| 100,000 | 21,900 | 14,500 | 17,500 | 14,000 | 39,400 | 28,500 |

A TAC of up to 37400 t for the C-fleet is in accordance with the largest advised total catch of 95000 t Western Baltic Spring-Spawning herring, under assumptions of retained catch share among areas and retained proportions among stocks. The corresponding number for the D fleet is 27100 t .

Low recruitment of the three most recent NSAS year classes together with an increase in the WBSS stock is expected to lead to changes in stock composition as well as area distribution and thereby affect near future catch options. Especially consequences for the D-fleet catch options should be closely followed.

## Factors affecting the fisheries and the stock

## Regulations and their effects

ICES considered the effects on the WBSS of the present EU-Norway agreement in 2005 on quota transfer in Division IIIa. The agreement sets 12800 tonnes for Norway of which $50 \%$ can be taken in the North Sea. A bycatch TAC for Division IIIa herring in the small-meshed fishery (fleet-D) is set at 24150 tonnes, none of which is taken by Norway and thus no transfer in this fleet category is possible.

The effect of a transfer of $50 \%$ of Norwegian catches amount to 6400 t and will at the most equal a reduction in outtake of 3600 t in the exploitation of WBSS, since part of the catches will anyway be taken in the transfer area where WBSS are taken. The changes in F and SSB for WBSS will thus be marginal.

## Changes in fishing technology and fishing patterns

Since 2001 the fishery behavior has changed in the German fleet. In former years the dominant part of herring was caught in the passive gears, bottom-set gillnets and trapnets. The proportion of herring, which was caught by trawlers in the area off the Rügen Island coast up to the Arcona Sea (Subdivision 24), increased from $26 \%$ in 2001 to $52 \%$ in 2004. This change was caused by new requirements from a new fish factory on the Rügen Island.

## The environment

Herring in Division IIIa and Subdivisions 22-24 make age- and stage-specific migrations. There are feeding migrations from the Western Baltic into more saline waters of Division IIIa and the eastern parts of Division IVa.

## Scientific basis

## Data and methods

The otolith microstructure method to calculate the proportion of spring and autumn spawners caught in these areas has been used for all catch and IBTS data for the period 1991-2004. Analytical assessment is based on catch data and acoustic and trawl survey results.

In order to continue to improve the assessment, an acoustic survey covering the whole stock is needed. Development of stock identification methods using combinations of genetics and otolith analyses continues. Results from such methods allow exploration of the importance of stock migrations and local stock components in the area.

Uncertainties in assessment and forecast

There is a tendency to overestimate the fishing mortality in the five-year retrospective analysis.
The historical bias in the assessment is small, except in the recruitment. Apparently, the strength of a year class is not firmly estimated before the year class has been followed for $2-3$ years.

Comparison with previous assessment and advice
The current procedure for assessing the stock has given consistent results with respect to fishing mortality and spawning biomass for several years. Compared to last year's assessment, the change in the estimate is $+1 \%$ for the fishing mortality in 2003 and $-2 \%$ for the SSB in 2003.

The assessment carried out in 2004 is in line with the 2003 assessment.

## Information from the fishing industry

The fishing industry suggests that substantial area misreporting occurs from the North Sea to Kattegat.

### 1.4.18 Herring in Subarea IV, Division VIId and Division IIIa (autumn spawners)

State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Full reproductive <br> capacity | Harvested <br> sustainably |  |  |  |

Based on the most recent estimates of SSB and fishing mortality ICES classifies the stock as having full reproduction capacity and as being harvested sustainably. SSB in 2004 was estimated at 1.9 million t , but is expected to decrease to 1.8 million t in 2005, which is above the $\mathbf{B}_{\mathrm{pa}}$ of 1.3 million t . Both the 1998 and the 2000 year classes are strong. However the incoming 2004 year class is estimated to be among the weakest in the time-series, as were the 2002 and 2003 year classes.

Due to the current unusual circumstances of a clearly identified sequence of three poor recruiting year classes of North Sea herring it is particularly important that the imminent decline of this stock is addressed with sufficient determination to ensure the safety of the spawning stock in the next few years.

## Management objectives

## According to the EU-Norway agreement (November 2004):

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the 800,000 tonnes (Blim).
2. Where the SSB is estimated to be above 1.3 million tonnes the Parties agree to set quotas for the directed fishery and for by-catches in other fisheries, reflecting a fishing mortality rate of no more than 0.25 for 2 ringers and older and no more than 0.12 for $0-1$ ringers.
3. Where the SSB is estimated to be below 1.3 million tonnes but above 800,000 tonnes, the Parties agree to set quotas for the direct fishery and for by-catches in other fisheries, reflecting a fishing mortality rate equal to:

$$
\begin{aligned}
& 0.25-\left(0.15^{*}(1,300,000-S S B) / 500,000\right) \text { for } 2 \text { ringers and older, and } \\
& 0.12-\left(0.08^{*}(1,300,000-S S B) / 500,000\right) \text { for } 0-1 \text { ringers. }
\end{aligned}
$$

4. Where the SSB is estimated to be below 800,000 tonnes the Parties agree to set quotas for the directed fishery and for by-catches in other fisheries, reflecting a fishing mortality rate of less than 0.1 for 2 ringers and older and less than 0.04 for $0-1$ ringers.
5. Where the rules in paragraphs 2 and 3 would lead to a TAC which deviates by more than $15 \%$ from the TAC of the preceding year the Parties shall fix a TAC that is no more than $15 \%$ greater or $15 \%$ less than the TAC of the preceding year.
6. Not withstanding paragraph 5 the Parties may, where considered appropriate, reduce the TAC by more than $15 \%$ compared to the TAC of the preceding year.
7. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
8. The allocation of TAC for the directed fishery for herring shall be $29 \%$ to Norway and $71 \%$ to the Community. The by-catch quota for herring shall be allocated to the Community.
9. A review of this arrangement shall take place no later than 31 December 2007.

ICES has examined the performance of this revised harvest control rule and considers the agreement in terms of target F to be consistent with the Precautionary Approach. However, ICES also considers that the strict application of the TAC change limit of $15 \%$ (rule number 5) is not consistent with the Precautionary Approach in a situation like the present when three consecutive weak year-classes have recruited to the population. The harvest control rule is in accordance with the precautionary approach if paragraph 6 is consistently invoked sufficiently early to prevent or minimise the risk of SSB falling below $\mathrm{B}_{\mathrm{pa}}$ even in the case of several consecutive weak year-classes. Assuming that paragraph 6 would be invoked
when TAC constraints would lead to $\operatorname{SSB}$ falling below $B_{\mathrm{pa}}$ it is considered that the revised HCR is in accordance with the Precautionary Approach.

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathbf{B}_{\text {lim }}$ is 800000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 1.3 million t |
|  | $\mathbf{F}_{\text {lim }}$ is not defined | $\mathbf{E}_{\mathrm{pa}}$ be set at: $\mathbf{F}_{\text {ages } 0-1}=0.12$ |
| $\mathbf{F}_{\text {ages } 2-6}=0.25$ |  |  |

Yield and spawning biomass per Recruit
F-reference points:

|  | Mean $\mathbf{F}_{2-6}$ | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |
| :--- | :---: | :---: | :---: |
| Average last 3 years | 0.250 | 0.020 | 0.073 |
| $\mathbf{F}_{\text {max }}$ | 0.412 | 0.013 | 0.041 |
| $\mathbf{F}_{0.1}$ | 0.126 | 0.011 | 0.100 |

Candidates for reference points which are consistent with taking high long-term yields and achieving a low risk of depleting the productive potential of the stock may be identified in the range of $\mathbf{F}_{0.1}-\mathbf{F}_{\mathrm{pa}}$.

Technical basis

| $\mathbf{B}_{\mathrm{lim}}$ : below this value poor recruitment has been <br> experienced | $\mathbf{B}_{\mathrm{pa}}$ : part of a harvest control rule based on simulations |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}$ : Not defined | $\mathbf{F}_{\mathrm{pa}}$ : part of a harvest control rule based on simulations |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to existing management plans
The revised management plan implies TACs and corresponding allocations among fleets as indicated in the catch options tables below.

Management of the autumn-spawning herring must be considered together with the western Baltic Herring.
The management plan is not specific as to when paragraph 6 should be invoked and how much the TAC would be reduced beyond the $15 \%$ limitation. Due to the current unusual circumstances of a clearly identified sequence of three poor recruiting year-classes of North Sea herring it is particularly important that management action should address the imminent decline of the stock with sufficient determination to ensure the safety of the spawning stock in the next few years. ICES has commented that the management plan can only be considered as in accordance with the precautionary approach if paragraph 6 is invoked when TAC constraints would lead to SSB falling below Ba $_{\text {pa }}$, With the three consecutive weak year-classes there is a high risk that SSB in 2008 would fall below $\mathrm{B}_{\mathrm{pa}}$ if the TAC constraint of $15 \%$ is used in both 2006 and 2007, see figure 1.4.18.1. The choice within the management plan is thus either to use the TAC constraint for the TAC for 2006 with a high risk that severe reductions will be necessary for the TAC for 2007 or to invoke paragraph 6 already from the TAC for 2006 and thereby stabilising the stock and reducing the reductions required in 2007.

## Short-term implications

Catch forecasts are presented below for different options of sharing the catch amongst fleets, producing the total fishing mortality given in the table headings. The forecasts are based on an assumption of the fisheries in 2005 taking the TAC. There is firm evidence for significant non-reporting and thus overshoot of the TAC for the A-fleet in 2004. Whether there will be any overshooting in 2005 in not known and is thus not included in the intermediate year (2005) in the forecasts. The forecasts for 2006 thus represent what could be taken in 2006 if there was no non-reporting or other overshoot of the TAC in 2005. If a TAC overshoot in 2005 is included, the forecasted landings in 2006 would be smaller if the F constraint of the harvest control rule is applied (invoking paragraph 6 of the rule). If the maximum TAC change of $15 \%$ was applied the resulting SSB in 2007 would be smaller.

The options presented below conform to the harvest control rule given above and include two main options. The first is with the catches in 2006 to comply with the $F$ constraint in the harvest control rule (assuming that paragraph 6 of the management plan is invoked in view of the decline of the stock). The second shows catch options to comply with a maximum $15 \%$ reduction in TAC. The first table (one line of numerical entries) presents the assumed catch by fleet in 2005 assuming a fishing mortality based on a TAC constraint for the A-fleet.

Since the management plan only stipulates overall fishing mortalities for juveniles and adults, making fleet-wise predictions for 4 fleets, that are more or less independent, provides an extensive range of options for 2006. The following tables include examples of the short-term forecast. In addition, an extensive range of catch options for fleets were investigated and are available from the ICES Secretariat.

The predicted catches in 2006 of North Sea herring corresponding to the advice for herring in 22-24 and IIIa is about 30000 t (approximately 17000 t in fleet C and 13000 t in fleet D).

The TAC constraint for 2005 may be optimistic as the starting point for the 2006 fishery because there have been overshoots of the TAC in recent years, and this would lead to lower stock at the start of 2006.

For 2005 with $\mathrm{F}_{0.1}=0.101$ and $\mathrm{F}_{2.6}=0.302$

## The fleet definition

Fleet A: Directed herring fisheries with purse seiners and trawlers (with $32-\mathrm{mm}$ minimum mesh size) in the North Sea. Bycatches in industrial fisheries by Norway are included.

Fleet B: Herring taken as bycatch in the small-mesh fisheries in the North Sea (with mesh size less than 32 mm ).
Fleet C: Directed herring fisheries in Skagerrak and Kattegat with purse seiners and trawlers (with 32 mm minimum mesh size).

Fleet D: Bycatches of herring caught in the small-mesh fisheries (with mesh size less than 32 mm ) in Skagerrak and Kattegat.

## Management considerations

There are now three recruiting year classes (2002, 2003, and 2004) that are all well below average. This is unusual and managers should take this into account when implementing the HCR as there is an increased risk that the stock may fall below the 1.3 mill. tonnes in the medium-term if the rule of $15 \%$ constraint on TAC variation is applied.

Medium term simulations indicate that using a constraint on the year-to-year variation in TAC for the TAC in 2006 and onwards will lead to a considerable risk that SSB will fall below $\mathrm{B}_{\mathrm{pa}}$ in the period where these year classes will dominate the spawning stock, i.e. around 2008-2010. This risk is exacerbated and a considerable risk of the SSB falling below $\mathrm{B}_{\text {lim }}$ is added if the TAC is overfished and/or the stock is overestimated in the assessment as has been seen in recent years. The risk can be reduced by maintaining the low fishing mortality on juveniles that has been practiced in recent years, and it can be eliminated by removing the constraint on TAC variation, see figure 1.4.18.1. The figure demonstrates that the probability for the stock to be below $\mathrm{B}_{\mathrm{pa}}$ in 2008 is about 0.74 given that the $15 \%$ rule in the agreed management plan is followed. The probability for the stock to be below $\mathrm{B}_{\mathrm{lim}}$ in 2008 is 0.2 . If however paragraph 6 of the management plan is invoked, the probability for the stock to be below $\mathrm{B}_{\mathrm{lim}}$ is reduced to 0 while there is still a 0.12 probability to being below $\mathrm{B}_{\mathrm{pa}}$. This assumes full implementation and enforcement. If the enforcement bias as has been experienced in recent years leading to overshoots of the TAC in the order of $10 \%$ continues the risk of being below $\mathrm{B}_{\mathrm{pa}}$ and $\mathrm{B}_{\text {lim }}$ increases considerably, especially if the TAC constraint is applied.

Misreporting of landings taken in the North Sea, but reported from other areas such as Divisions IIa and IIIa, and VIaN have significantly increased in 2004. The estimates of the total amount of misreported and unallocated catches in 2004 was about 49000 t (roughly $9 \%$ of the total catch in the North Sea). The agreed area flexibility of catches from the Skagerrak that occurred in 2004, may have had a similar effect as this implies flexibility of exploitation among the different herring stocks.

Management of the autumn-spawning herring must be considered together with the western Baltic herring. The options for TACs for the C and D fleets have been selected to be compatible with the exploitation of Western Baltic Spring Spawners (see Section 1.4.17).

The Divisions IVc and VIId Sub-TAC was established for the conservation of the spawning aggregation of Downs herring. The Downs herring has returned to its pre-collapsed state and is now again a major component of the stock, but is currently dominated by one year class. Hence, the management of the fishery on the spawning aggregations of Downs herring should be more cautious than for the North Sea herring as a whole. More knowledge about the dynamics and catches of Downs herring is required.

The advice for a quota on catches in Divisions IVc and VIId for 2003 was that this should not exceed the 2002 quota, and for 2004 and 2005 that the quota should not increase faster than the TAC for the North Sea as a whole. ICES proposes that a share of $11 \%$ on the total North Sea TAC (average share 1989-2002) would be appropriate for distributing the harvesting among Downs Herring and other stock components.

## Management plan evaluations

The HCR has been tested but the present situation with 3 poor year-classes in succession is exceptional. The performance of the present harvest rule is not very good in this situation, since it may easily break down if assessment and/or implementation, enforcement and compliance are sufficiently biased. It is considered by ACFM that the present assessment may possibly be an overestimate, and that the TACs in the consumption fishery have been regularly overshot. For this situation a HCR is required that is robust to errors in the assessment and implementation; the current HCR is not thought to be sufficiently robust to errors in the assessment and implementation. As the stock is set to decrease more rapidly than expected due to the coincidence of three poor year classes, managers should be particularly cautious and ensure that reductions in TACs are sufficient to maintain $F$ at the agreed level of $F=0.25$. In this context it would be
advisable for managers to explicitly include implementation failure, such as area misreporting, into the TAC if they cannot ensure compliance.

Allowance for efficient reduction of the TACs increases the robustness of the regime. In particular, if reduction of the TAC is too heavily constrained when the stock is declining this may lead into a vicious circle, which is clearly demonstrated in some of the examples in the HAWG report. The simulations also show the beneficial effect of reducing the fishing mortality on juveniles. The effect of a lower fishing mortality on adults was not explored in this study, but earlier simulations indicate that the effect is slightly less than for similar reductions in TACs on juveniles.

## Ecosystem considerations

Herring is considered to have a major impact as prey and predator to most other fish stocks and is prey to sea birds and sea mammals in that area. Herring spawning and nursery areas, being near the coasts, are particularly sensitive and vulnerable to anthropogenic influences. The most serious of these is the ever increasing pressure for marine sand and gravel extraction. This has the potential to seriously damage and destroy the spawning habitat and disturb spawning shoals and to destroy spawn if carried out during the spawning season. Similarly, trawling at or close to the bottom in known spawning areas can have the same detrimental effects. It is possible that the disappearance of spawning on the western edge of the Dogger Bank could well be attributable to such anthropogenic influences.

Despite the fact that the stock is considered to have full reproductive capacity, it has recently produced three poor year classes in a row. Larvae surveys, which are considered to be a reliable indicator of the stock size, are carried out annually and show large abundance of larvae in recent years. However, survival of these larvae seems to be very poor. The reasons for this are not known. It is noted that also other stocks, such as sandeel and Norway pout, have shown recruitment failure in recent years, which cannot be related to the state of the stock or the fisheries upon it. It is possible that changes in the environmental conditions in the North Sea are responsible or have contributed to the observed recruitment failures. Volume 1 Section 1.1 (Ecosystem Overview) identify poor feeding conditions (particularly with respect to Calanus) for herring in the North Sea as a cause for concern. Both 2003 and 2004 were unusually warm years, particularly in August and September. The inflowing Atlantic water was also warmer than the long-term mean and the last three years these waters have been the warmest since 1970. The pattern of Atlantic inflow is believed to be important for zooplankton and hence fish populations in the North Sea (ICES CM 2005/ACE:01).

## Factors affecting the fisheries and the stock

## Regulations and their effects

Based on ICES estimates of total catch, TACs for the human consumption fishery in Subarea IV and Division VIId have been exceeded in all recent years. The relative amount of unallocated and misreported catch is estimated around $10 \%$ from 2001 onwards. Prior to 2001, unallocated catches were substantially higher. The largest absolute amounts of unallocated catches occur in Subdivision IVa west (14,000-28,000 tonnes in 2002-2004). The largest relative unallocated catches occur in Divisions IVc and VIId (12-17\% in 2002-2004).

## Scientific basis

## Data and methods

The age-based assessment is based on landings from Subarea IV and Division VIId and on surveys (Acoustic 1-9+wr, IBTS 1-5+wr, MIK 0wr and MLAI larvae SSB indices). Some national catch estimates were corrected for unallocated and misreported catch.

In 2004 the total weight of herring discarded in the North Sea was estimated at about 17000 t , based on the raised figure for two sampled fleets. The estimates in 2002 and 2003 were 17000 t and 4000 t respectively, based on the same two fleets. More complete information on discarding that could be raised by fleet to total catch would be desirable. Information on discards is included in the assessment, when available.

Denmark and Norway provided information on bycatches of herring in the industrial fishery. These are the only countries conducting these fisheries.

## Uncertainties in assessment and forecast

Catch and survey indices show different signals in the residual patterns, which were detected in 2003 and 2004, but show greater magnitude in this year's assessment. Positive residuals in the catch of $2 \mathrm{wr}+$ fish against negative residuals in the acoustic survey and IBTS suggests a slightly higher fishing mortality from the surveys than given by the catch
information. It is considered by ICES that the present assessment may possibly be an overestimate of SSB and an underestimate of F .

## Comparison with previous assessment and advice

The current assessment agrees very closely with the 2004 assessment. In 2005 the SSB for 2003 was estimated at 1.73 mill. tonnes, while in 2004 it was estimated at 1.75 mill. tonnes. Fishing mortality in 2003 was estimated in last year's assessment at 0.25 and is still estimated at 0.25 .

## 1 Preliminary.

4 Catches of Norwegian spring spawners removed (taken under a separate TAC).
5 Landings from the 'lhames estuary area are included in the North Sea catch figure for UK (England).
7 Including any bycatches in the industrial fishery
9 Figures verified and altered if needed in 2003 by SG Rednose (ICES 2003/ACFM:10)
10 Figure altered in 2001
11 Caught in the whole North Sea, partly included in the catch figure for The Netherlands
12 may include misreported catch from VIaN and discards
13 These catches (including some local fjord-type Spring Spawners) are taken by Norway under a separate quota south of $62^{\circ} \mathrm{N}$ and are not included in the Norwegian North Sea catch figure for this area.
14 Figure altered in 2004

Table 1.4.18.2 Herring, catch in tonnes in Division IVa West. These figures do not in all cases correspond to the official statistics and cannot be used for legal purposes.

1 Preliminary.
4 Including IVa East.
5 Negative unallocated catches due to misreporting from other areas.
6 Altered in 2000 on the basis of a Bayesian assessment on misreporting into Vla (North)
7 Including any bycatches in the industrial tishery
8 May include misreported catch from VlaN and discards
9 Figure altered in 2001
10 Including 105 t of local spring spawners
11 Higures veritied and altered if needed in 2003 by SG Kednose (ILES 2OU3/ACHM:IU)

Table1.4.18.3 Herring, catch in tonnes in Division IVa East. These figures do not in all cases correspond to the official statistics and cannot be used for legal purposes.

### 1.4.19 Sprat in Division IIIa

## State of the stock

The state of the stock is unknown. Sprat in this area is short-lived with large annual natural fluctuations in stock biomass. Landings of sprat in Division IIIa averaged about 70000 t in the 1970s, but since 1982 have typically been around 20000 t , except in 1994-1995.

## Management objectives:

There are no explicit management objectives for this stock.

## Reference points

Reference points for this stock have not been defined.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to precautionary limits
As sprat is mainly fished together with juvenile herring the exploitation of sprat will be limited by the restrictions imposed on fisheries for juvenile herring.

## Short-term implications

## Catch forecast for 2006

The available survey results are not reliable indicators of sprat abundance in Division IIIa. Therefore, fishing possibilities in 2005 or 2006 cannot be projected.

## Factors affecting the fisheries and the stock

Sprat cannot be fished without bycatches of herring except in years with high sprat abundance or low herring recruitment. The most recent period when this occurred was 1994-1995. Management of this stock should consider management advice given for herring in Subarea IV, Division VIId, and Division IIIa.

The directed sprat fishery serves a very small market. Most sprat catches are taken in an industrial fishery where catches are limited by herring bycatch restrictions. This combination of factors has prevented full utilisation of the occasional strong year class. Such year classes emerge and disappear very quickly.

## Regulations and their effects

With the current management regime, where there are bycatch ceilings of herring as well as bycatch percentage limits, the sprat fishery is controlled by these factors.

## The environment

Changes in environmental conditions, e.g., long-term changes in the temperature may affect the ecology of this stock. The influence of inflow events is currently unknown.

## Scientific basis

## Data and methods

Insufficient data are available to carry out an assessment.

## Information from the fishing industry

Sprat catches in the beginning of 2005 have been reported by the industry as good.

## Source of information

Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}, 8-17$ March 2005 (ICES CM 2005/ACFM:16).

Table 1.4.19.1 Landings in (' 000 t) 1974-2004. (Data provided by Working Group members). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes. In the period from 1982 to 1992 Sweden only reported total catches from Division IIIa.

State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| unknown | unknown | unknown |  |  |

The available information is inadequate to evaluate the state of the stock and the absolute stock size is unknown. The biomass seems to have increased in recent years. The IBTS (February) 2005 survey results indicated a good 2004 year class recruiting to the 2005 fishery (the age-1 index in 2005 was the highest observed). This suggests that the stock is in good condition.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

No reference points have been defined for this stock.

## Single-stock exploitation boundaries

There are no precautionary limits for this stock. Maintaining the exploitation rate of recent years, the catch in 2005 is predicted to be 244000 t , based on IBTS survey results. The 2005 TAC is set at 257000 t .

## Management considerations

For this stock only in-year catch forecasts are available. Based on the historic relationship between survey and catch, i.e. maintaining the recent exploitation rate, the 2005 survey value indicates an expected catch of 244000 t in 2005 . The present assessment and TAC-setting regime requires a two-year forecast. This means that the estimated TAC for 2006 has to be calculated in 2005 based on commercial catch data collected in 2004. This may not be a realistic approach for a stock consisting of only a few year classes, with a predominance of 1 -year-old fish in the catches. If a TAC regime was necessary and the required data was available, a management approach including a mid-year revision of the TAC and taking into account an estimate of incoming recruitment would have to be considered for sprat. Despite the short comings of the exploratory assessment described below, there are indications that the stock is lightly exploited.

The proportion of herring bycatch in the sprat fishery has been around $8 \%$ for the last four years. In 2005, a low bycatch of 1 -ringer herring is expected to occur during the third and the fourth quarter as the incoming year classes of herring are estimated to be low. However, change in the regulation of bycatches in 2005 (up to $40 \%$ of herring is allowed, compare to $20 \%$ previously) may affect this bycatch level.

## Ecosystem considerations

Multispecies investigations have demonstrated that sprat is one of the important prey species in the North Sea ecosystem. Many of the plankton feeding fish have recruited poorly in recent years. The implications for sprat are at present unknown. There are some indications that there may be interactions between herring and sprat biomass. The current situation is unclear and is further complicated by the increasing presence of sardine and anchovy in the central and southern North Sea (ICES CM 2005/G:06).

The plankton community in the North Sea has changed dramatically in recent years.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Prior to 1993, sprat was caught with a relatively high percentage of herring bycatch. In 1993, 1994, and 1995 the sprat fishery could be conducted with rather low herring bycatch percentages. In some periods in 1997, 2001, and 2002 the sprat fishery was stopped due to high bycatch of herring. Generally, the sprat fishery is not limited by the TAC with the exception of 1998. Bycatch regulation has been changed in 2005.

## Scientific basis

Data and methods
Assessment of a short-lived species like sprat requires reliable survey data. A Catch-Survey Analysis (CSA) was implemented as an exploratory assessment during the Working Group in 2003 (ICES CM 2003/ACFM:17). The method is based on the "modified DeLury" two-stage model (Conser, 1995) and on an implementation tested on simulated data presented to the Methods Working Group in 2003 (Mesnil, 2003). The model assumes that the population consists of two stages: the recruits (preferably a single year class which corresponds to the group of 1 -year-olds) and the fully recruited ages (the $2+$ group). ICES regards this assessment as exploratory.

## Source of information

### 1.4.21 North Sea horse mackerel (Trachurus trachurus) (Division IIIa (Eastern part), Divisions IVb,c VIId)

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown | No assessment available, due to limited data. |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown. Catches increased rapidly in the late 1990s and have remained high since then.

## Management objectives

No explicit management objectives have been established for this stock.

## Reference points

Not available.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary considerations

ICES reiterates the recommendation made in 2004 to limit the catches to below the 1982-1997 average of 18000 t , in order to constrain the fishery until there is more information about the structure of horse mackerel stocks, and sufficient information to show that higher exploitation rates are sustainable.

## Short-term implications

No forecast can be made for this stock.

## Management considerations

ICES advised in 1999 to constrain an expansion of the fishery until there was a scientific basis for advice, because high catch rates can be maintained in pelagic fisheries even when the stock is in decline.

North Sea horse mackerel migrate to areas where they mix with the western horse mackerel stock. The present agreed TAC is for the North Sea and Division IIa, and these areas do not correspond to the distribution area of the stock. The TAC should apply only to those areas where the North Sea horse mackerel are fished, i.e. Divisions IIIa, IVb,c, and VIId.

The allocation of catches to the different horse mackerel stocks is based on the temporal and spatial distribution of the fishery. It is therefore important that catches be reported by ICES rectangle and by quarter.

The points listed below should be taken into account when considering management options for the North Sea horse mackerel:

1) The stock units are incompatible with the management units.
2) Catches have increased during the last decade. The major part of the increased catches is taken in Division VIId in quarters 1 and 4 , which is adjacent to the boundary of the western stock. It is also adjacent to an area where juveniles of the western horse mackerel stock are found.
3) Recent catches are above the advised TACs of 18000 t . The average annual catch in the period 1995-2004 was 31000 t .
4) There is a bycatch of mackerel in the horse mackerel fishery.

## Factors affecting the fisheries and the stock

## Changes in fishing technology and fishing patterns

In earlier years, the majority of the catch was taken as bycatch in the small-mesh industrial fishery. In recent years, most of the catch has come from a directed fishery for human consumption, mainly in Division VIId. This has led to a change in the age composition of the landings with a higher proportion of younger age groups.

## Scientific basis

## Data and methods

The stock cannot be assessed because sampling is insufficient and fishery-independent indices of abundance are lacking.

Eggs surveys for horse mackerel were carried out during the period 1988-1991. New information indicates that horse mackerel is probably an indeterminate spawner. Therefore, it is not possible currently to provide a realistic estimate of the spawning biomass. The mackerel egg surveys in the North Sea do not cover the spawning area of horse mackerel.

Comparison with previous assessment and advice
There is no assessment on which to base the status of this stock. The current advice reiterates last year's advice based on average catches observed between 1982 and 1997.

### 1.4.22 Norway pout in ICES Subarea IV (North Sea) and Division IIIa (Skagerrak Kattegat)

## State of the stock

| Spawning biomass in <br> relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Reduced reproductive <br> capacity | Reference points <br> not defined | Reference <br> points not <br> defined | Biomass-based limit reference points have been <br> formulated on the basis of the lowest biomass ever <br> observed from which the stock has been shown to <br> recover, as well as a biomass point which will lead to <br> below-average recruitment. |

Based on the most recent estimates of SSB, ICES classifies the stock as suffering from reduced reproductive capacity (Stock biomass is below $\mathbf{B}_{\text {lim }}$ in 2005). Estimated fishing mortality has decreased in recent years and was in 2004 at the lowest level in the time-series, and because of the fishery closure in 2005, fishing mortality is likely to be close to zero in 2005. Recruitment has been below average in the period 2000-2004, with a record low in 2003-2004. Estimates of the 2005 year class from a single survey indicates a recruitment slightly below average.

## Management objectives

There are no explicit and specific management objectives for this stock.
Reference points (unchanged since 1997)

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Limit reference points | $\mathbf{B}_{\lim }$ is 90000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 150000 t |
|  |  |  |
| Target reference points |  | $\mathbf{F}_{\mathrm{y}}$ not defined |

Technical basis

| $\mathbf{B}_{\text {lim }}:$ lowest observed biomass | $\mathbf{B}_{\mathrm{p}}:$ Below-average recruitment when SSB is less than <br> 150000 t |
| :--- | :--- |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

The fishery should remain closed until information is available which assures that the stock can be rebuilt to Bpa by 2007. The information on which this could be based includes the IBTS surveys in January-February and AugustSeptember 2006.

## Short-term implications

Outlook for 2006
In the case of a zero catch in 2005 and an estimated recruitment of age 0 fish of 112 billions in second quarter of 2005, based on the SGF in 3 quarter 2005, the SSB is forecasted to be 78000 t in 2006 compared to 57000 in 2005. With no catch in 2006 the 2005 year class alone will result in a SSB estimate at 150000 t in 2007, such that the total SSB including an unknown 2006 year class is above the Bpa. Because the estimate of recruitment in 2006 is only based on one survey, the estimate is likely to be uncertain, and the estimate has to be confirmed by surveys in 2006.

## Management considerations

The stock was in the first part of 2005 considered by ICES to be below $\mathbf{B}_{\text {lim }}$. The stock is expected to still be below $\mathbf{B}_{\text {lim }}$ in 2006. EU and Norway agreed to close the fishery in 2005 based on the advice from ICES.

In managing this fishery, bycatches of haddock, whiting, herring, and blue whiting should be taken into account and existing measures to protect these bycatch species should be maintained.

The 3rd and 1st quarter IBTS survey and the 4th quarter commercial fishery (when it exists) indices provide relatively good indicators of the year-class strengths and the size of the stock. This information could be used as real-time monitoring of this stock.

## Ecosystem considerations

The population dynamics of Norway pout in the North Sea and Skagerrak are very dependent on changes caused by recruitment variation and variation in predation mortality (or other natural mortality causes). Recruitment is highly variable and influences SSB and TSB rapidly, due to the short life span of the species. With present fishing mortality levels the status of the stock is more determined by natural processes and less by the fishery. However, there is a need to ensure that the stock remains high enough to provide food for a variety of predator species (e.g. saithe, haddock, and mackerel).

## Factors affecting the fisheries and the stock

Historically, the fishery includes bycatches especially of blue whiting, haddock, whiting, and herring.
Norway pout are currently taken as bycatch in the blue whiting fishery.

## Scientific basis

## Data and methods

The assessment (SXSA) is considered appropriate to indicate trends in the stock. It provides stock status of all year classes up to the second quarter of the assessment year 2005. Also, it gives an indication of the likely recruitment by January 1 of the following year.
Comparative runs with the SXSA, SMS, and SURBA assessment models gave consistent estimates of stock status and dynamics. Consequently, the accepted assessment using small artificial landings in the first and second quarter of the year 2005 does not change the perception of the stock status.

## Uncertainties in assessment and forecast

Studies indicate that natural mortality used in the assessment may be inappropriate.

## Comparison with previous assessment and advice

The estimates of the SSB, recruitment, and the average fishing mortality of ages 1 and 2 , are consistent with the estimates of previous years assessment.

## Source of information

Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 6-15 September 2005 (ICES CM 2006/ACFM:09).

### 1.4.23 Sandeel in Division IIIa (Skagerrak - Kattegat)

## State of the stock

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown.

## Management objectives

There are no explicit management objectives for this stock.

## Management considerations

The fishery is an extension of the North Sea fishery into Division IIIa, but with smaller vessels working closer inshore, mostly along the coast of Jutland.

The available information suggests that Subarea IV and Division IIIa can be combined to one stock unit. No assessments of sandeel in Division IIIa have been carried out so far. Biological data for this area are sparse and would have to be evaluated before a decision is made about treating sandeels in Subarea IV and Division IIIa as one stock.

### 1.4.24 Sandeel in Subarea IV

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Reduced <br> reproductive <br> capacity | F reference <br> points are not <br> defined | Unknown |  |

Based on the most recent estimates of SSB, ICES classifies the stock as having reduced reproductive capacity. SSB in 2004 and 2005 were below $\mathbf{B}_{\mathrm{lim}}$. In the absence of a defined F reference point, the state of the stock cannot be evaluated with regard to sustainable harvest. The fishing mortality in 2004 ( 0.61 ) was equivalent to the time-series mean and below that of the last 4 years.

## Management objectives

There are no explicit management objectives for this stock.

## Reference points

Reference points have been unchanged since 1999.

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathrm{B}_{\lim }$ is 430000 t | $\mathrm{B}_{\mathrm{pa}}$ be set at 600000 t |
|  | $\mathrm{F}_{\mathrm{lim}}$ is undefined | $\mathrm{F}_{\mathrm{pa}}$ is undefined |
| Target reference points |  | $\mathrm{F}_{\mathrm{y}}$ is undefined |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ The lowest observed biomass that gave recruitment <br> about the average level | $\mathbf{B}_{\mathrm{pa}}:$ set to $1.4 * \mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}:$ None proposed | $\mathbf{F}_{\mathrm{pa}}:$ None proposed |
|  | $\mathbf{F}_{\mathbf{y}}:$ None proposed |

## Single-stock exploitation boundaries

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Management of fisheries should try to prevent local depletion of sandeel aggregations, particularly in areas where predators congregate.

## Exploitation boundaries in relation to precautionary limits

The fishery should remain closed until information is available which assures that the stock can be rebuilt to $\mathbf{B}_{\mathrm{pa}}$ by 2007. The information on which this could be based includes a survey in December 2005 and exploratory fishing in April 2006.

## Short-term implications

The high natural mortality of sandeel and the few year classes in the fishery make the stock size and catch opportunities largely dependent on the size of the incoming year classes. In 2005 there was a very low fishery in the second half year, because of the stop of the fishery from July 2005 and onwards. This makes it impossible to get any indications of the 2005 year class from the fishery. Furthermore, age-0 CPUE is only giving indications of year class sizes and its predictive power is poor, which means that deterministic forecasts are not generally considered appropriate. However,
the critical state of the sandeel stock indicated by the current assessment requires a provisional forecast which illustrates the likely consequences in case recruitment continues to be low. The forecast is thus not a prediction of the most likely outcome but an illustration of the development in the case that recruitment is not improved.

The prediction was made using half-year time steps. In the absence of information about the recruitment a low recruitment was assumed for 2005 and 2006. This was chosen because recruitments in the last 3 years have been low. Recruitment in 2005 and 2006 was assumed to be $32710^{9}$, which is the 25 th percentile of the long-term average recruitment. Stock and catch weights for the second half year of 2005 and for 2006 were taken as averages of half-year values in 2003-2004. Stock numbers at 1st of January 2005 were taken from the final SXSA assessment. Fs-at-age for the forecasts were taken as the average exploitation pattern for 2003-2004, scaled to $\mathbf{F}_{1-2}$ in 2004. 2004 first half year $\mathrm{F}_{\mathrm{sq}}=0.454$ and 2004 second half year $\mathrm{F}_{\mathrm{sq}}=0.148$.

Low recruitment (25th percentile of time-series recruitment) was used for 2005 and 2006.
Basis: $F(2006)=F(2004)$ scaled over 2003 and 2004; $\operatorname{SSB}(2006)=446000$ t; landings $(2005)=167000 \mathrm{t}$.

Weights in ' 000 t.
Shaded scenarios are not considered consistent with the Precautionary Approach.

## Management considerations

Stock abundance in the prediction year is highly dependent on the incoming year class for which no reliable estimate exists. If the survey to be carried out in late 2005 indicates that the 2005 year class is at least about average, then realtime monitoring of a fishery in 2006 could be implemented. The monitoring would provide a more accurate estimate of the size of the 2005 year class and enable more effective management of the fishery. It is, however, paramount that the harvest control rules are enforced expediently. In 2005 the fishery was closed when the main sandeel season was over, despite the recommendation from STECF to close the fishery in the middle of May.

The Council of the EU agreed during the December 2004 meeting that the Commission should implement a fishing effort regulation for vessels fishing for sandeel in the North Sea and the Skagerrak. Effort for the 2005 fishery was not allowed to exceed $40 \%$ of the 2004 level. This maximum effort level was to be revised as early as possible based on the strength of the 2004 year class.

The regulation was implemented through a real-time monitoring of the sandeel fishery on the basis of a methodology developed by an STECF ad hoc working group in 2004. The method was improved in 2005 by STECF in order to improve the identification of small year classes. The method for estimating the 2004 year class used data from the Danish fishery in April of 2005, where approximately $10 \%$ of the annual catches are taken. DIFRES was responsible for all data gathering and model runs. Quality assurance was achieved by data and model output exchange between DIFRES, CEFAS, and FRS on a weekly basis. The STECF working group produced a short summary of the final model output to STECF by the 9 May, and STECF advised shortly thereafter, that the fishery should be closed. The fishery in the EU zone was closed 2nd of July, when the $40 \%$ effort level was reached. The final regulation from the Commission was submitted in July and the closure of the fishery was enforced by 19th of July when the sandeel season was nearly over.
$\mathbf{B}_{\text {lim }}$ was derived as the lowest observed SSB that gave recruitment about the average level. Until 2003 the sandeel stock has been considered to be within safe biological limits, and the stock has been able to sustain the fishing mortality. However, the 2005 final assessment estimates SSB in 2004 to be historic low and under $\mathbf{B}_{\mathrm{lim}}$, and to be below $\mathbf{B}_{\mathrm{pa}}$ from 2000 and for the rest of the time-series.

The low stock size increases the risk of local depletion. There is therefore a need to monitor the stock situation and hence the fishery on a finer spatial scale. Access to VMS data is a prerequisite for this.

There has been a $50 \%$ decline in the number of vessels fishing sandeels from 2004 to 2005.
The Danish fishing industry has proposed effort limitations and closed seasons for the 2006 sandeel fishery.

## Management plan evaluations

There are no management objectives set for this stock. There is a need to develop management objectives that ensure that the stock remains high enough to provide food for a variety of predator species.

## Ecosystem considerations

Mortality appears to be determined mostly by natural causes rather than by fishing. The recruitment of sandeels seems more linked to environmental factors than to the size of the spawning stock biomass.

In the light of studies linking low sandeel availability to poor breeding success of kittiwake, all commercial fishing in the Firth of Forth area has been prohibited since 2000, except for a maximum of 10 boat days in each of May and June for stock monitoring purposes. The closure was maintained for three years and has been extended until 2006, with an increase in the effort of the monitoring fishery to 20 days, after which the effect of the closure will be evaluated.

The ecosystem effects of industrial fisheries are discussed in the Report of the ICES Advisory Committee on Ecosystems, June 2003, Section 11 (ICES CRR 262). The direct effects of industrial fishing that have been identified on other species fished for human consumption, e.g. haddock and whiting, are relatively small in comparison to the effects of directed fisheries for human consumption species. Sandeel is an important prey species for many marine predators. However, there is still relatively scant information on the effects of fisheries targeting these stocks (sandeel, Norway pout, sprat), and further analysis of the ecological impacts of these fisheries is required. The effects of variation in the sizes of most industrial stocks on their predators are also poorly known.

## Factors affecting the fisheries and the stock

## The effects of regulations

The Council of the EU agreed in December 2004 that the Commission should implement a fishing effort regulation in 2005 for vessels fishing for sandeel in the North Sea and the Skagerrak. The Council of the EU adopted a harvest control rule based on the size of the 2004 year class. The Commission based this regulation on advice from STECF.

From the estimate of the 2004 year class, STECF recommended in May that the agreed HCR for sandeel given in Annex V of Council Regulation (EC) 27/2005 should be implemented with immediate effect, which meant a closure of the fishery for North Sea sandeel for the remainder of 2005. Furthermore, STECF stressed the importance of rapid action to close the fishery as the HCR depends on swift action to function correctly. However, the sandeel fishery in the EU zone was first closed 2nd July and the closure enforced by 19th July, when the main sandeel fishing season was over.

## The environment

The decline in the density of sandeel in the entire North Sea is not limited to the fished areas. If this change in the stock situation is caused by changes in the environment this may suggest that the reference points used for sandeels need to be revised. However, presently there is not data to quantify a link between changes in the environment and sandeel population dynamics.

## Other factors

Sandeel is taken by trawlers using small mesh gear. The fishery is seasonal, taking place mostly in the spring and summer. There is a targeted 0-group fishery carried out in autumn (3rd quarter). Most of the catch consists of Ammodytes marinus, but other sandeel species are caught as well. There is a low percentage bycatch of other species, including species for which a TAC has been set.

Sandeels are largely stationary after settlement and the North Sea sandeel must be considered as a complex of local populations. Recruitment to local areas may not only be related to the local stock, as interchange between areas seems to take place during the early phases of life before settlement. The Shetland sandeel stock is assessed as a separate unit.

## Scientific basis

## Data and methods

The assessment of sandeel is carried out without fisheries-independent indices of abundance. Different sampling approaches have been tried during scientific surveys, but at present no scientific survey time-series exist that can be used for the assessment.

The assessment method used is Seasonal XSA (SXSA), which allows the use of data by half-year. Catches from $1^{\text {st }}$ half of 2005 are included and because the fishery was closed in July this represent almost all the catches for 2005. As in previous assessments, effort data from the commercial fishery in the northern and southern North Sea are treated as two independent tuning fleets, separated into half-years. In order to improve the model fit, the CPUE series were split into two time periods, i.e. before and after 1999.

At the 2005 WG meeting, the SMS model was used for exploratory analyses and compared to the SXSA. SXSA and SMS explorative runs gave similar results for the time trend of SSB, but the absolute levels differ between model configurations.

## Uncertainties in assessment and forecast

The major source of uncertainty in this assessment is a result of the lack of a fishery-independent survey. This required use of standardized commercial CPUE at age. This may result in auto-correlation problems between the tuning series and the catch-at-age data which may mask uncertainty in the analysis.

As no recruitment estimates from surveys are available, recruitment estimates are based exclusively on commercial catch-at-age data. The tuning diagnostics indicate that the 0 -group CPUE is a rather poor predictor of recruitment.

Comparison with previous assessment and advice
The changes made in the present assessment (changes in the configuration of the tuning fleets) gives a more pessimistic view on the stock situation than the 2004 assessment, by downscaling both SSB and recruitment and increasing F for the most recent years.

Sandeel in Subarea IV Results of the most recent assessment in comparison with results of previous assessments.

### 1.4.25 Sandeel in the Shetland area

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary limits | Fishing mortality <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Comment |
| :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk, so the state of the stock is unknown.

It is believed that fishing mortality is well below natural mortality. This means that natural processes largely drive stock variations. Landings in 2004 were 186 t , substantially lower than in landings in preceding years, and below the TAC of 7000 t .

An assessment made in 2001 based on survey data alone suggests that the SSB in 2000 is close to its lowest observed value and that recent recruitment has been weak.

## Management objectives

There is a national management plan in force taking both fisheries and wildlife conservation in consideration.

## Reference points

No reference points have been defined for this stock.

## Single-stock exploitation boundaries

ICES considers that no advice can be given for the stock.

## Short-term implications

There is no short-term forecast given for this stock.

## Management considerations

The Shetland sandeel fishery re-opened in 1995 subject to a multi-annual management regime. This was revised for the 1998 fishing season onwards. The new regime consists of an annual TAC of 7000 t and a closure during the months of June and July. The seasonal closure is to avoid any possibility of direct competition between the fishery and seabirds during the chick-rearing season. There is also a limit on vessel size to boats of 20 m or less. These arrangements were renewed in 2001 for another three years.

The landings in 2004 are only a small fraction of the agreed TAC.

## Management plan evaluations

ICES suggested in October 2001 that the management plan be evaluated before the agreed end date. The evaluation has been carried out and all interest groups have agreed to the continuation of the current measures. An update of the assessment for this stock is required for 2005.

## Ecosystem considerations

Fishing grounds are close inshore and often adjacent to large colonies of seabirds for which the sandeel population is an important food supply, especially during the breeding season. For some seabird species the availability of 0 -group sandeel as prey is very important.

In some years, most of the recruitment comes from spawning areas away from Shetland. The availability of 0-group sandeel is, therefore, not closely linked to the local spawning population. The sandeel population is also an important food source for other predator species in the Shetland area.

## Factors affecting the fisheries and the stock

## Other factors

The sandeel population at Shetland is not a separate stock, but forms part of a larger complex of sub-populations. Estimates of the consumption of sandeel by seabirds and other predators greatly exceed the quantities taken by the fishery in recent years.

### 1.4.26

Nephrops in Divisions IVa, rectangles 44-48 E6-E7+44 E8 (Management Area F)

There are two Functional Units in this Management Area: a) Moray Firth (FU 9) and b) Noup (FU 10).

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

The available fishery information is inadequate to use analytical methods to evaluate spawning stock or fishing mortality relative to risk. Results from TV surveys suggest that all stocks in this Management Area are exploited at sustainable levels.
a) Moray Firth: The TV survey estimate of abundance for Nephrops in the Moray Firth suggests that the population increased in 2002-2003, and has remained relatively stable at this higher level since then. Abundance is estimated to be over $40 \%$ higher in recent years (2002-2004) compared to the previous period (1999-2001). Indications from the fishery support this and suggest an increase in recruitment in 1995 and 2002.
b) Noup: The TV survey estimate of abundance for Nephrops in the Noup suggests that the population declined between the two surveys in 1994 and 1999, but unfortunately no newer data are available. Landings have fluctuated between 200 and 400 tonnes since 1995, with no long-term trend, although effort has declined and LPUE has increased over the same timescale. There is no evidence to suggest any concerns for this stock at the present levels of exploitation.
c) Small quantities of landings are made outside the main Fladen Ground Functional Unit but within the Management Area.

## Management objectives

No management objectives have been set for this fishery.

## Reference points

No reference points have been determined for Nephrops.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Due to uncertainty in the available fishery data, ICES is not able to reliably forecast catch. The effort in this fishery should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data on both target and by-catch species.

## Short-term implications

Outlook for 2006
The harvest ratio is a proxy for relative effort. Historically for this stock the harvest ratio has been around $15 \%$. As an indication of relation between landings (tonnes) and effort the table below shows calculated landings for a range of harvest ratios applied to TV survey biomass results

| HR\% | Landings | $95 \%$ |
| :---: | :---: | :---: |
| 7.5 | 1054 |  |
| 10 | 1405 | $+/-453$ |
| 15 | 2108 | $+/-679$ |
| 20 | 2811 | $+/-906$ |
| 25 | 3513 | $+/ 1132$ |
| 30 | 4216 | $+/-1359$ |

Shaded options are not in accordance with the advice as this implies increased effort

## Management considerations

In the North Sea TAC (which comprises eight Nephrops stocks), the present aggregated management approach runs the risk of unbalanced effort distribution. Adoption of management initiatives to ensure that effort can be appropriately controlled in smaller areas within the overall TAC area is recommended.

## Ecosystem considerations

Throughout its distribution, Nephrops is limited to a muddy habitat, and requires sediment with a silt and clay content of between $30-100 \%$ to excavate its burrows, and this means that the distribution of suitable sediment defines the species distribution. Adult Nephrops only undertake very small scale movements (a few 100 m ), but larval transfer may occur between separate mud patches in some areas. In the Moray Firth area the Nephrops stock inhabits a single continuous area of muddy sediment extending from north of Fraserburgh to Inverness.

Cod has been identified as a predator of Nephrops in some areas, and the generally low level of the cod stock is likely to have resulted in reduced predation.

## Factors affecting the fisheries and the stock

Landings from this fishery are predominantly reported from Scotland, with very small contributions from England in the mid-1990s, but not recently.

About three quarters of the landings are made by single-rig trawlers, a high proportion of which use a $70-\mathrm{mm}$ mesh. In 1999, twin-rig vessels predominantly used a $100-\mathrm{mm}$ mesh, with $90 \%$ of the twin-rig landings made using this mesh size. Legislative changes in 2000 permitted the use of an $80-\mathrm{mm}$ mesh.

Discarding rates averaged over the period 2002 to 2004 for this stock were $30 \%$ by number, or $14 \%$ by weight. This represents a small increase in discarding rate compared to the 2002 to 2004 period.

## The effects of regulations

The minimum landing size for Nephrops in the Moray Firth is 25 mm CL.

## Changes in fishing technology and fishing patterns

Recent reports from industry and gear technologists suggest a more widespread use of "flip-up" gear in twin rig Nephrops trawls (see Graham, WD). This development will allow fleets to expand onto rougher ground, potentially exploiting new Nephrops areas.

## Scientific basis

## Data and methods

There is considerable uncertainty about landings, discard and effort data for these stocks. Underwater TV survey estimates are available for 1993-1994 and from 1996 onwards for the Moray Firth, and only in 1994 and 1999 for the Noup stock.

LPUEs are available from 1965 for the Moray Firth stock and from 1980 for the Noup stock.
Length compositions are available from 1980 for the Moray Firth stock and from 1996 for the Noup stock.

## Information from the fishing industry

The NSCFP stock survey shows a continuous increase in Nephrops in the Northeast of Scotland (including Fladen Grounds) since 2001.

Uncertainties in assessment and forecast
There are concerns over the accuracy of landings and effort data and because of this the final assessment adopted is independent of official statistics.

LPUE may also be affected by changes in catchability (due to sudden changes in the environmental conditions), or changes in selectivity and/or in gear efficiency.

Discards are also dependent on selectivity of the gear and on discarding practices. Thus trends in mean size of the catch are difficult to interpret.

Comparison with previous assessment and advice:
TV surveys suggest the abundance of the stock has increased compared to the recent past. Previously advice for the Moray Firth has been based largely on analytical catch-at-age assessments using XSA, and average historical landings, while advice for the Noup has been based mainly on LPUE. There is considerable doubt about the quality of fisheries data and assessments cannot be based on these data, i.e. catch and CPUE. The advice is therefore for no increase in effort as it is not possible to provide a catch prediction based on fisheries data. As reliable fisheries data are not available the TV underwater survey biomass estimates are used to indicate landings associated with various effort levels.

### 1.4.27 Nephrops in Division IVa, West of $2^{\circ} \mathrm{E}$, excluding Management Area F (Management Area G)

There is one Functional Unit in this Management Area: Fladen (FU 7).
State of the stock

| Spawning biomass in relation to precautionary limits | Fishing mortality in relation to precautionary limits | Fishing mortality in relation to highest yield | Fishing mortality in relation to agreed target | Comment [used if qualifiers to present state are necessary] |
| :---: | :---: | :---: | :---: | :---: |
| Unknown | Unknown | Unknown |  |  |

The available fishery information is inadequate to use analytical methods to evaluate spawning stock or fishing mortality relative to risk. Results from TV surveys, however, suggest that the stock in this Management Area appear to be exploited at a sustainable level.

The TV survey estimate of abundance for Nephrops in the Fladen Ground suggests that the population increased between 1992 and 1994 and then declined to a stable level between 1997 and 2000 (no survey was conducted in 1996). Following this the population increased again to 2002, and has since declined to the pre-2002 stable level in the most recent years.

Small quantities of landings are made outside the main Fladen Ground Functional Unit but within the Management Area.

## Management objectives

There are no management objectives set for this fishery.

## Reference points

No reference points have been determined for Nephrops.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to existing management plans
There is no agreed management plan for this stock.

## Exploitation boundaries in relation to precautionary limits

Information on these stocks is considered inadequate to provide an advice based on precautionary limits. The effort in this fishery should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data on both target and by-catch species.

## Short-term implications

## Outlook for 2006

The harvest ratio is a proxy for relative effort. Historically for this stock the harvest ratio has been around $7.5 \%$.. As an indication of relation between landings (tonnes) and effort the table below shows calculated landings for a range of harvest ratios applied to TV survey biomass results. The range is more restricted than for other N Sea stocks owing to the more limited information on stock dynamics:

| Harvest Ratio \% | Landings (t) | $95 \%$ confidence limits |
| :--- | :---: | :---: |
| 5 | 8627 | $+/-1402$ |
| 7.5 | $\mathbf{1 2 9 4 0}$ | $+/-2103$ |
| 10 | $\mathbf{1 7 2 5 4}$ | $+/-2804$ |
| 15 | 25880 | $+/-4206$ |
| 20 | 34507 | $+/-5608$ |

Shaded options are not in accordance with the advice as this implies increased effort

## Management considerations

In the North Sea TAC (which comprises eight Nephrops stocks), the present aggregated management approach runs the risk of unbalanced effort distribution. Adoption of management initiatives to ensure that effort can be appropriately controlled in smaller areas within the overall TAC area is recommended.

## Ecosystem considerations

Throughout its distribution, Nephrops is limited to a muddy habitat, and requires sediment with a silt and clay content of between $30-100 \%$ to excavate its burrows, and this means that the distribution of suitable sediment defines the species distribution. Adult Nephrops only undertake very small scale movements (a few 100 m ), but larval transfer may occur between separate mud patches in some areas. In the Fladen area the Nephrops stock inhabits a generally continuous area of muddy sediment extending from $57^{\circ} 30^{\prime} \mathrm{N}$ to $60^{\circ} \mathrm{N}$, and from $1^{\circ} \mathrm{W}$ to $1^{\circ} 30^{\prime} \mathrm{E}$, with other smaller patches to the north. The Fladen Ground is the largest known Nephrops ground, with around $28200 \mathrm{~km}^{2}$ of suitable mud substrate, and is the only major offshore ground in Scottish waters.

Cod have been identified as a predator of Nephrops in some areas, and the generally low level of the cod stock is likely to have resulted in reduced predation.

## Factors affecting the fisheries and the stock

Although the Fladen Ground is extensive, fishing effort is primarily directed to the region that can be reached within 12 hours steaming from ports along the NE coast of Scotland. The fleet fishing the Fladen Ground for Nephrops comprises approximately 215 trawlers, which are predominantly Scottish ( $>97 \%$ ), based along the Scottish NE coast, with very few landings made in the UK by foreign vessels.

About $67 \%$ of the landings are reported as made by single-rig vessels, two thirds of which are taken with $100-\mathrm{mm}$ meshes and about one third with 70 - to $80-\mathrm{mm}$ meshes. Twin-rig vessels account for the remaining $33 \%$ of the landings. As with the single-rig vessels, approximately two thirds of these are taken using $100-\mathrm{mm}$ meshes, and the remainder with $70-$ to $80-\mathrm{mm}$ meshes. There are concerns over the accuracy of reporting to gear type, however, and the vast majority of landings are thought to be made by twin-rig vessels.

Nearly $40 \%$ of the Nephrops landings are reported as bycatch, where fish are the main target species. This may, however, be an artefact of the method of reporting to the Fishery Offices, since the mesh sizes used on the Fladen Ground tend to be larger (i.e. 100 mm ) than in other areas. The consequence is that vessels using a $100-\mathrm{mm}$ mesh are sometimes regarded as whitefish-directed, even if they actually have been targeting Nephrops.

## The effects of regulations

The minimum landing size for Nephrops in the Fladen Ground is 25 mm CL. Discarding takes place at sea, but because of the larger mesh sizes used proportionally fewer undersized animals need to be discarded than in other areas. Discarding rates averaged over the period 2002 to 2004 for this stock were $13 \%$ by number, or $7 \%$ by weight. This represents a small decrease in discarding rate compared to the 2000 to 2002 period.

## Changes in fishing technology and fishing patterns

Recent reports from industry and gear technologists suggest a more widespread use of "flip-up" gear in twin-rig Nephrops trawls (see Graham, WD). This development will allow fleets to expand onto rougher ground, potentially exploiting new Nephrops areas.

## Scientific basis

## Data and methods

There is considerable uncertainty about landings, discard and effort data for these stocks. The underwater TV survey is presented as the best available information on the Fladen Nephrops stock. This survey provides a fishery-independent estimate of Nephrops abundance. At present it is not possible to extract any length or age structure information from the survey, and it therefore only provides information on absolute abundance over the area of the survey.

## Information from the fishing industry

The NSCFP stock survey shows an increase in Nephrops between 2001 and 2002, a slight decrease to 2003, and a marked increase since this date. This supports the suggestion of an increase in abundance for this area, but does not indicate any change in the levels of discards or recruits.

Uncertainties in assessment and forecast
The trends in abundance observed in the TV survey data have not been reflected in LPUE data or mean size data. This may be owing to the short time-series of discard data, or to spatial changes in the fishery.

Comparison with previous assessment and advice
The results of the most recent TV surveys are consistent with those of 2003. There is considerable doubt about the quality of fisheries data and assessments cannot be based on these data, i.e. catch and LCPUE. The advice is therefore for no increase in effort as it is not possible to provide a catch prediction based on fisheries data. As reliable fisheries data are not available the TV underwater survey biomass estimates are used to indicate landings associated with various effort levels. Previously advice for the Fladen Ground has been based on a $7.5 \%$ harvest ration of fishery-independent underwater TV survey estimates of abundance.

### 1.4.28 Nephrops in Division IVa, East of $2^{\circ} \mathrm{E}+$ rectangles 43 F5-F7 (Management Area S)

There is only one Functional Unit in this Management Area: Norwegian Deep (FU 32).
State of the stock

| Spawning biomass <br> in relation to pre- <br> cautionary limits | Fishing mortal- <br> ity in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing mor- <br> tality in rela- <br> tion to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk.
This stock has mainly been exploited by Danish vessels. LPUEs from the Danish fishery have been rather stable over the last 10 years even though landings increased $50 \%$ in this period. A slight decrease in mean size in the catches and landings in 2004 could indicate a high exploitation pressure in recent years, and that this Nephrops stock is fully exploited. However, the trends in Danish LPUE figures do not indicate any decline in stock abundance.

## Management objectives

There are no management objectives set for this fishery.

## Reference points

No reference points have been determined for Nephrops.

## Single-stock exploitation boundaries

Exploitation boundaries in relation to existing management plans
There is no agreed management plan for this stock.

## Exploitation boundaries in relation to precautionary limits

Information on this stock is considered inadequate to provide advice based on precautionary limits.

## Management considerations

The Danish LPUE figures for this FU increased dramatically from 1992 to 1994, and then levelled off. Since then they have fluctuated around $200 \mathrm{~kg} /$ day. In the last 2 years an increasing trend is seen. It could be that only part of the stock is exploited at present. Sediment maps for this Management Area indicate that there are possibilities to let the fishery expand into new grounds, which have scarcely been fished to date.

## Factors affecting the fisheries and the stock

The majority of the landings from this FU are made by Denmark and Norway, where Denmark accounts for around $80 \%$. During the last five years, landings have fluctuated between 750 t and 1216 t , with the highest (provisional) figures recorded in 2002. The LPUEs of Danish vessels have increased from $50-75 \mathrm{~kg} /$ day in the early 1990 s to more than $200 \mathrm{~kg} /$ day in late 2004 . Mean sizes in both research vessel catches and commercial landings are high compared to neighbouring areas (Skagerrak and Kattegat).

## The effects of regulations

Due to changes in the management regime (mesh size regulations in the Norwegian zone of the northern North Sea in 2002) there was a switch to increasing Danish effort targeting Nephrops in the Norwegian Deep.

Traditionally the Norwegian effort for Nephrops has been low, and the majority of the Norwegian Nephrops landings from FU 32 has largely been as bycatch from the Pandalus fishery. Because of the landings restrictions for Pandalus,
shrimp trawlers have started fishing more specifically for Nephrops in the most recent years. Also, there are an increasing number of boats that target Nephrops year-round, making one-week trips and landing their catches in Denmark.

## Scientific basis

Data and methods
The perception of the stock is based on Danish LPUE data.

## Information from the fishing industry

The NSCFP stock survey shows an increase in Nephrops between 2001 and 2002, a slight decrease to 2003, and a marked increase since this date. This supports the suggestion of an increase in abundance for this area, but does not indicate any change in the levels of discards or recruits.

Uncertainties in assessment and forecast
Due to "technological creeping" there are concerns over effort data, because of changes in selectivity or in gear efficiency. Furthermore, LPUE may be affected by changes in catchability (due to sudden changes in the environmental conditions).

Discards could reflect the strength of the recruitment, but are also dependent on selectivity of the gear and on discarding practices. Thus trends in mean size of the catch are difficult to interpret without any information on changes in the fishing pattern and practices.

Comparison with previous assessment and advice
No assessment is presented for this stock.

### 1.4.29

There are two Functional Units in this Management Area: a) Farn Deeps (FU 6) and b) Firth of Forth (FU 8).
State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

The available information is inadequate to use analytical methods to evaluate spawning stock or fishing mortality relative to risk. Results from TV surveys, however, suggest that the stock in this Management Area appear to be exploited at a sustainable level.

Effort currently appears to be at its lowest level since 1984 and LPUE appears to be at its highest in the series. The TV surveys appear to confirm this recent increase in abundance. CPUE trends suggest that recruitment has not been strong over the last few years, but the increase in the mesh size could have masked any recruitment signals. All signs suggest that the stock is healthy although the males in this stock do suffer greater fishing pressure.

All stocks in this Management Area appear to be exploited at sustainable levels.
a) Farn Deeps: LPUEs fluctuated around a generally upward trend up to 1993, were stable for some years, and then after a dip in 2000 increased to an all time high in 2004 despite apparent declining effort. The increase in the estimate of autumn abundance from the TV surveys in the last few years corresponds to this increase in LPUE, but still remains within the range over the series. Mean size of the smaller length groups for males and females has increased in recent years, but the LPUE for these length groups has remained fairly static. CPUE trends and trends in mean size do not give any clear signals about recruitment; they suggest recruitment has been variable but fairly consistent over recent years.
b) Firth of Forth: The TV survey estimate of abundance for Nephrops in the Firth of Forth suggests that the population declined between 1993 and 1998 (although no surveys were conducted in 1995 or 1997), increased to a stable level between 1999 and 2001, and then increased to 2003 , declining slightly in the most recent year. The recent average abundance (2002-2004) is $23 \%$ higher than the previous period (1999-2001). The increases in abundance in the late 1990s and most recent years have been reflected in CPUE and mean size data, in that they suggest an increase in recruitment in 1998 and 2003.
c) Some landings are made outside the Functional Units but inside the Management Area.

## Management objectives

There are no management objectives for this fishery.

## Reference points

No reference points have been proposed for Nephrops.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Information on these stocks is considered inadequate to provide advice based on precautionary limits. The effort in this fishery should not be allowed to increase and the fishery must be accompanied by mandatory programmes to collect catch and effort data on both target and by-catch species.

## Short-term implications

Outlook for 2006
The harvest ratio is a proxy for relative effort. Historically for these stocks the harvest ratio has been around $15 \%$.

As an indication of relation between landings (tonnes) and effort the table below shows calculated landings for the Farn Deeps Functional Unit for a range of harvest ratios applied to TV survey biomass results

| Harvest ratio (\%) | Landings (t) | 95\% confidence limits |
| :--- | ---: | ---: |
| 10 | 1983 | $+/-248$ |
| 15 | 2975 | $+/-372$ |
| 20 | 3966 | $+/-496$ |
| 25 | 4958 | $+/-620$ |
| 30 | 5950 | $+/-744$ |

Shaded options are not in accordance with the advice as this implies increased effort
As an indication of relation between landings (tonnes) and effort the table below shows calculated landings for the Firth of Forth Functional Unit for a range of harvest ratios applied to TV survey biomass results

| Harvest ratio (\%) | Landings (t) | $95 \%$ confidence limits |
| :--- | ---: | ---: |
| 10 | 868 | $+/-187$ |
| 15 | 1302 | $+/-281$ |
| 20 | 1736 | $+/ 375$ |
| 25 | 2170 | $+/-468$ |
| 30 | 2604 | $+/-562$ |

Shaded options are not in accordance with the advice as this implies increased effort

## Management considerations

Discards are known to be very high and any improvement of the fishing pattern of the catches would benefit the stock and the medium-term yield.

In the North Sea TAC (which comprises eight Nephrops stocks), the present aggregated management approach runs the risk of unbalanced effort distribution. Adoption of management initiatives to ensure that effort can be appropriately controlled in smaller areas within the overall TAC area is recommended.

Between 1993 and 2002, landings from this Management Area have exceeded the TAC recommended by ICES. Up to the early 1990s, effort has increased much faster in the Farn Deeps than in the Firth of Forth. While effort has recently decreased in both FUs, there is still the potential for an imbalance in the exploitation rates. With the current large North Sea TAC area (which comprises eight Nephrops FUs), there is no mechanism for controlling effort locally. Management should therefore be carried out at the FU level recommended by ICES.

Effort currently appears to be at its lowest level since 1984 while LPUE appears to be at its highest in the series.

## Ecosystem considerations

Throughout its distribution, Nephrops is limited to a muddy habitat, and requires sediment with a silt and clay content of between $30-100 \%$ to excavate its burrows, and this means that the distribution of suitable sediment defines the species distribution. Adult Nephrops only undertake very small-scale movements (a few 100 m ), but larval transfer may occur between separate mud patches in some areas. In the Farn Deeps area the Nephrops stock inhabits a large continuous area of muddy sediment extending North from $54^{\circ} 45^{\prime}-54^{\circ} 35^{\prime} \mathrm{N}$ and $0^{\circ} 40^{\prime}-1^{\circ} 30^{\prime} \mathrm{N}$, with smaller patches to the east and west.

## Factors affecting the fisheries and the stock

Since the beginning of the time-series, the UK fleet has accounted for virtually all landings from the Farn Deeps. Landings from the Firth of Forth fishery are predominantly reported from Scotland, with very small contributions from England.

Effort currently appears to be at its lowest level since 1984 while LPUE appears to be at its highest in the series.
Estimated discarding during this period has fluctuated around $40 \%$ by weight of the catch, similar to levels recorded since the beginning of the data series in 1985.

## The effects of regulations

Restrictions on other fisheries, e.g. cod recovery measures - catch composition regulations and days at sea - and technical conservation measures have already impacted the effort on these stocks.

## Changes in fishing technology and fishing patterns

Changes in fleet capacity, average size of vessels, and power and fuel prices will affect the spatial dispersal of effort. Smaller vessels will not fish so far out and will be limited far more by weather.

The differences between LPUE figures for individual vessels suggest that earlier years could have included less truly directed effort. Restrictions on finfish fishing over the last five years will have restricted total effort in FU 6, thereby reducing the more casual effort on Nephrops.

## The environment

This species is essentially sedentary and stocks are limited geographically to muddy sediment. Weather and sea temperature will effect the dispersal and settlement of larvae which to be successful depends on retention gyres and the speed in development of the zoea. Catch rates and length compositions are dependent on burrow density and are affected by weather, tides, and light intensity.

Reduction in the size and number of predators, primarily cod, may have been beneficial to these stocks.

## Other factors

Catch rates are affected by emergence behaviour which in turn is affected by tides, light intensity, moult cycles, and sexual development.

## Scientific basis

## Data and methods

There is considerable uncertainty about landings, discard and effort data for these stocks. Underwater TV surveys of the Farn Deeps have been conducted at least once a year from 1996 onwards, and for the Firth of Forth since 1993 (missing surveys in 1995 and 1997).

## Information from the fishing industry

For FU 6 the NSCFP fishermen's survey shows an increase between 2001 and 2002, a relatively stable period to 2004, and an increase in 2005. Although the sample size in the NSCFP fishermen's survey is relatively small for area 4 $(\mathrm{n}=15)$ the abundance trend appears to agree with the recent increase in abundance from the TV estimates for FU6.

For FU 8 the NSCFP survey shows a continuous increase in Nephrops since 2001. This supports the suggestion of an increase in abundance since 2001, with generally moderate or high numbers of recruits.

## Uncertainties in assessment and forecast

There are concerns regarding the accuracy of landings and effort data and because of this the final assessment adopted is independent of official statistics.

LPUE may also be affected by changes in catchability (due to sudden changes in the environmental conditions), or by changes in selectivity and/or in gear efficiency.

Discards could reflect the strength of the recruitment but are also dependant on selectivity of the gear and on discarding practices. Thus trends in mean size of the catch are difficult to interpret without any information on any change in the fishing pattern and practices.

Farn Deeps: the distinct seasonality in this fishery leads to much higher exploitation in males than females. Bearing this in mind, a harvest ratio considered appropriate for stocks with more balanced exploitation may be too high for this stock.

## Comparison with previous assessment and advice

Previously advice has been based largely on analytical catch-at-age assessments using XSA, and average historical landings. There is considerable doubt about the quality of fisheries data and assessments cannot be based on these data, i.e. catch and LCPUE. The present advice is therefore for no increase in effort as it is not possible to provide a catch prediction based on fisheries data. As reliable fisheries data are not available the TV underwater survey biomass estimates are used to indicate landings associated with various effort levels.

### 1.4.30

Nephrops in Divisions IVb,c, East of $1^{\circ}$ E, excluding rectangles 43 F5-F7 (Management Area H)

There are two Functional Units in this Management Area: a) Botney Gut (FU 5) and b) Off Horn Reef (FU 33).

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest <br> yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment <br> [used if qualifiers to present state are <br> necessary] |
| :--- | :--- | :--- | :--- | :--- |
| Unknown | Unknown | Unknown |  |  |

The available information is inadequate to evaluate spawning stock or fishing mortality relative to risk.
a) Botney Gut: In its 2003 assessment of the Nephrops stock in the Botney Gut-Silver Pit area (FU 5), WGNEPH concluded that the stock was fully exploited and recommended that the TAC for FU 5 be maintained at the previously recommended level of 1100 t (ICES, 2003). The evidence of a (temporary) shift in the length composition of the landings stresses the need to closely monitor this stock, but is not of such a nature that further restrictions of the fishery need to be envisaged. Current levels of exploitation appear to be sustainable.
b) Off Horn Reef: Trends in LPUE data suggest that stock levels are remaining relatively stable. The current exploitation level seems to be sustainable.

## Management objectives

There are no management objectives for this fishery.

## Reference points

No reference points have been determined for Nephrops.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to precautionary limits

Information on these stocks is considered inadequate to provide advice based on precautionary limits. Therefore ICES recommends that the level of exploitation, i.e. effort on these stocks should not be increased.

## Management considerations

In the North Sea TAC (which comprises eight Nephrops stocks), the present aggregated management approach runs the risk of unbalanced effort distribution. Adoption of management initiatives to ensure that effort can be appropriately controlled in smaller areas within the overall TAC area is recommended.

For FU 5 (Botney Gut) mean sizes of males in the landings show evidence of an overall downward trend, while mean sizes of females seem to have stabilised, albeit at a level that is considerably lower than in the early 1990s. For FU 33 (Horns Reef) there is no evidence of shifts in the size composition in the catches over the years 2001-2004.

Although the observed shift apparently was of a temporary nature, it stresses the need to closely monitor this stock. As a matter of fact, shifts of this type may be indicative of increased fishing pressure on the oldest age classes in the population and/or of a change in discarding practices, towards retaining more of the smaller Nephrops.

## Factors affecting the fisheries and the stock

2003 and 2004 saw a further decline in the Belgian Nephrops fishery in the Botney Gut-Silver Pit area. Up to 1995, the Belgian fleet used to take over $75 \%$ of the international landings from this stock, but since then, its share has dropped to less than $25 \%$. The Netherlands is now the most important player in FU 5, with over $60 \%$ of the total international landings being taken by Dutch trawlers, for first sale in the Netherlands or in Belgium.

Long-term effort of the Belgian Nephrops fleet has shown an almost continuous decrease since the all-time high in the early 1990 s.

Denmark accounts for most of the Nephrops landings from FU 33. Landings from this area have been steadily increasing since 2000.

## Scientific basis

## Data and methods

The perception of the stock is based on LPUE only.

## Information from the fishing industry

The NSCFP stock survey trends show an increase between 2001 and 2002, a stable period to 2004, and an increase in 2005. There were no strong indications of changes in recruitment or discarding levels.

Uncertainties in assessment and forecast
For the Botney Gut The LPUE values for 2003 and 2004 (Belgian trawlers) should be treated with caution since (a) they are based on a very small number of vessels only, (b) the Nephrops specialist trawlers remaining are the ones operating twin-rigs (which do have higher catch rates than the single rigs that were in use in the 1980s and 1990s), and (c) there is a tendency - also amongst the specialist trawlers - to concentrate fishing effort in the season with the highest catch rates.

The lack of discards information for all the components of the Botney Gut fishery prevent any firm conclusion on the state of the stock based on a trend in the mean size of the catch.

## Comparison with previous assessment and advice

Previous assessments have considered this stock to be fully exploited. LPUE trends have been relatively stable up to the most recent years. Interpretation of recent changes are complicated by changes in the fleet providing the data. Changes in size distribution data may suggest increases in recruitment in 2001 and 2002.

This year's advice is for a non-increase in effort.

### 1.4.31 Demersal elasmobranchs in the North Sea, Skagerrak, and eastern English Channel

## State of the stocks

Landings of skates and rays in the North Sea, Skagerrak, and eastern English Channel have generally declined, and this is associated with changes in species composition and relative abundance.

Thornback ray (Raja clavata) - distribution area and abundance have strongly decreased over the past century. The area occupied has significantly decreased since 1990. Although local abundance remains high, the North Sea stock is considered depleted.

Spotted ray (Raja montagui) - area occupied and abundance has fluctuated without trend. Stock status is uncertain.
Starry ray (Amblyraja radiata) - catch rates increased from the early 1970s to the early 1990s and decreased slightly in abundance.

Cuckoo ray (Leucoraja naevus) - since 1990 the area occupied has fluctuated without trend, while abundance has decreased since the early 1990s. Stock status is uncertain.

Common skate (Dipturus batis) - is depleted. It was formerly widely distributed in the North Sea but is now only rarely found and only in the northern North Sea.

Blonde ray (Raja brachyura) - has a patchy occurrence in the North Sea. It is at the edge of its distributional range in this area and consequently ICES does not provide advice for this species.

Lesser spotted dogfish (Scyliorhinus canicula) - abundance and area occupied are increasing.
Smooth hound and starry smooth hound (Mustelus mustelus and M. asterias) - abundance appears to have been increasing in recent years, but the stock status is very uncertain. Identification by species is considered unreliable in the surveys.

Angel shark (Squatina squatine) is now extinct in the North Sea.

## Management objectives

None have been suggested or adopted. An elasmobranch action plan has been under development since 2001.

## Reference points

Not defined.

## Single-stock exploitation boundaries

The stocks of common skate and thornback rays are depleted. Target fisheries should not be permitted, and bycatch in mixed fisheries should be reduced to the lowest possible level.

If the fisheries for rays continue to be managed with a common TAC for all ray species, this TAC should be set at zero for 2006.

## Management considerations

North Sea demersal elasmobranchs are being landed as a bycatch in the demersal fisheries for teleosts. Only a few inshore vessels target skates and rays. They are usually landed and reported in mixed categories such as "skates and rays" and "sharks". For assessment purposes species-specific landings data are essential.

Given the relatively low value of rays, they are largely taken as bycatch. TACs only regulate the landings, and a low TAC on a low-value bycatch species could induce more discards. Because the elasmobranch species are caught as a bycatch in demersal fisheries, they would benefit from a reduction in the overall demersal fishing effort.

At least 12 species of rays have been reported from North Sea surveys, but only 4 of them are fairly common. Also 8 demersal sharks have been reported, of which only lesser spotted dogfish (Scyliorhinus canicula) is common.

Elasmobranchs are typically slow growing, have a high age-at-maturity and a low reproductive capacity. Measures to afford protection to the largest individuals are required.

The most vital part of the thornback ray spawning stock occurs in the southwestern North Sea. Measures to protect thornback ray in this area should be evaluated.

Landings of demersal sharks are not effectively restricted in the North Sea. Given their increased abundance and their general high discards survival, there is no immediate need to initiate regulation for these species.

## Ecosystem considerations

Skates, rays, and demersal sharks are widely spread over the North Sea. They are caught as a bycatch targeting demersal teleosts. Due to their life history characteristics (slow growth, high age at maturity and low reproduction rates) they are usually very susceptible for fisheries. The larger elasmobranchs such as angel shark Squatina squatina, common skate Dipturus batis, and thornback ray Raja clavata tend to be the most vulnerable. The angel shark has completely disappeared from the North Sea area, Dipturus batis is nowadays only rarely caught in the northern North Sea, and the stock of R. clavata in the North Sea may be depleted, being confined mainly to the southwestern bight. Only the smaller species seem to be stable/increasing: Amblyraja radiata, the lesser spotted dogfish Scyliorhinus canicula, and possibly Mustelus spp.

## Factors affecting the fisheries and the stock

## The effects of regulations

In 1999 the EC introduced a TAC for skates and rays. The current TAC does not restrict the landings. Furthermore, the discarding of rays is thought to be high.

## Scientific basis

## Data and methods

Survey data are the basis for the assessments of skates, rays, and demersal sharks in the North Sea.

## Uncertainties in assessment and forecast

In most countries skates and rays are landed together, most often sorted in particular size categories, rather than by species. They are usually gutted, and sometimes only wings are being landed. For assessment purposes, species-specific catch data are essential. Only some countries report (part of) the landings by species, e.g. Sweden and France. As a result of market sampling programmes the species composition of the landings can now be estimated for part of the countries landing skates and rays.

Comparison with previous assessment and advice
ICES has never produced advice for these species. However, in 1997 and 2004, ACFM gave an overview of the rela tive status of the main ray species in the North Sea.
