### 1.1 Introduction

This report has been produced by ICES in response to requests from the North Atlantic Salmon Commission (NASCO). The report has been prepared by the Advisory Committee on Fisheries Management on the basis of analysis undertaken by the Working Group on North Atlantic Salmon. This report represents summaries of background and conclusions regarding issues on which information has been requested. Details of the underlying analysis and detailed data are available in the report of the Working Group (ICES CM 2005/ACFM:17). The analysis undertaken and the advice given have been subject to independent peer review.

### 1.2 Requests from NASCO to ICES

NASCO has requested ICES to provide advice on the following issues (CNL(04)13). The section in which this request is addressed is indicated:

| a) With respect to Atlantic salmon in the North Atlantic area: | Section 2 |
| :---: | :---: |
| i. provide an overview of salmon catches and landings, including unreported catches by country and catch and release, and worldwide production of farmed and ranched salmon in 2004; | 2.1 and 2.2 |
| ii. report on significant developments which might assist NASCO with the management of salmon stocks; | 2.3 |
| iii. provide a compilation of tag releases by country in 2004; | 2.4 |
| iv. identify relevant data deficiencies, monitoring needs and research requirements. | 6 |
| b) With respect to Atlantic salmon in the North-East Atlantic Commission area: | Section 3 |
| i. describe the key events of the 2004 fisheries and the status of the stocks; | 3.9 |
| ii. provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved; | 3.10 |
| iii. iii. further develop the age-specific stock conservation limits where possible based upon individual river stocks; | 3.3 |
| iv. iv. provide catch options or alternative management advice, if possible based on forecasts of PFA, for northern and southern stocks, with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding; | 3.4, 3.6 |
| V v. provide an estimate of bycatch of salmon in pelagic fisheries. | 3.11 |
| c) With respect to Atlantic salmon in the North American Commission area: | Section 4 |
| i. describe the key events of the 2004 fisheries and the status of the stocks; | 4.9 |
| ii. provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved; | 4.10 |
| iii. update age-specific stock conservation limits based on new information as available; | 4.3 |
| iv. provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding; | 4.4, 4.6 |
| v. provide an analysis of any new biological and/or tag return data, to identify the origin and biological characteristics of Atlantic salmon caught at St. Pierre and Miquelon. | 4.11 |
| d) With respect to Atlantic salmon in the West Greenland Commission area: | Section 5 |
| i. describe the events of the 2004 fisheries and the status of the stocks; | 5.9 |
| ii. provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved; | 5.11 |
| iii. provide information on the origin of Atlantic salmon caught at West Greenland at a finer resolution than continent of origin (river stocks, country or stock complexes); | 5.9.3 |
| iv. provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding. | 5.4, 5.6 |

#### Abstract

Notes: NASCO's International Atlantic Salmon research Board's inventory of on-going research relating to salmon mortality in the sea will be provided to ICES to assist it in this task. In the responses to questions b.i, c.i and d.i ICES is asked to provide details of catch, gear. effort, composition and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the following categories: in-river; estuarine; and coastal. Any new information on non-catch fishing mortality of the salmon gear used and on the bycatch of other species in salmon gear, and of salmon in any existing and new fisheries for other species is also requested. In response to questions b.iv, c.iv and div provide a detailed explanation and critical examination of any changes to the models used to provide catch advice.

In response to question d.i, ICES is requested to provide a brief summary of the status of North American and North-East Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to questions b.i and c.i.

### 1.3 Management framework for salmon in the North Atlantic

The advice generated by ICES is in response to terms of reference posed by the North Atlantic Salmon Conservation Organisation (NASCO), pursuant to its role in international management of salmon. NASCO was set up in 1984 by international convention (the Convention for the Conservation of Salmon in the North Atlantic Ocean), with a responsibility for the conservation, restoration, enhancement, and rational management of wild salmon in the North Atlantic. While sovereign states retain their role in the regulation of salmon fisheries for salmon originating from their own rivers, distant water salmon fisheries, such as those at Greenland and Faroes, which take salmon originating from rivers of another Party are regulated by NASCO under the terms of the Convention. NASCO now has seven Parties that are signatories to the Convention, including the EU which represents its Member States.

NASCO discharges these responsibilities via the three Commission areas shown below:

### 1.4 Management objectives

NASCO (NASCO CNL31.210) has identified the primary management objective of that organisation as:
"To contribute through consultation and co-operation to the conservation, restoration, enhancement and rational management of salmon stocks taking into account the best scientific advice available".

NASCO further stated that "the Agreement on the Adoption of a Precautionary Approach states that an objective for the management of salmon fisheries is to provide the diversity and abundance of salmon stocks" and NASCOs Standing Committee on the Precautionary Approach interpreted this as being "to maintain both the productive capacity and diversity of salmon stocks".

NASCO's Action Plan for Application of the Precautionary Approach (NASCO, 1999) provides interpretation of how this is to be achieved, as follows:
"Management measures should be aimed at maintaining all stocks above their conservation limits.....by the use of management targets"

Socio-economic factors could be taken into account in applying the Precautionary Approach to fisheries management issues":
"The precautionary approach is an integrated approach that requires, inter alia, that stock rebuilding programmes (including as appropriate, habitat improvements, stock enhancement, and fishery management actions) be developed for stocks that are below conservation limits".

### 1.5 Reference points and application of precaution

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted this definition of CLs (NASCO, 1998). Therefore, the CL is a limit reference point ( $\mathrm{S}_{\mathrm{lim}}$ ) which should be avoided with high probability. Management advice for Atlantic salmon is referenced to the $S_{\text {lim }}$ conservation limit, therefore stocks assessed here are reported as being outside precautionary limits when the confidence limits of the most recent stock estimate includes $S_{\text {lim }}$.

Management targets have not yet been defined for North Atlantic salmon stocks. When these have been defined they will play an important role in ICES advice.

For the assessment of the status of stocks and advice on management of national components and geographical groupings of the stock complexes in the NEAC area, where there are no specific management objectives:

ICES requires that the lower bound of the $95 \%$ confidence interval of the current estimate of spawners is above the CL for the stock to be considered at full reproductive capacity.

When the lower bound of the confidence limit is below the CL, but the mid-point is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.

Finally, when the mid-point is below the CL, ICES considers the stock to suffer reduced reproductive capacity.
It should be noted that this is equivalent to the ICES precautionary target reference points ( $\mathrm{S}_{\mathrm{pa}}$ ). Therefore, stocks are regarded by ICES as being at full reproductive capacity only if they are above the precautionary reference point ( $\mathrm{S}_{\mathrm{pa}}$ ). This approach parallels the use of precautionary reference points used for the provision of catch advice for other fish stocks in the ICES area.

For catch advice on fish exploited at West Greenland (non-maturing 1SW fish from North America and non-maturing 1SW fish from Southern NEAC), ICES has adopted a risk level of $75 \%$ (ICES, 2003) as part of an agreed management plan. ICES applies the same level of risk aversion for catch advice for homewater fisheries on the North American stock complex.

## 2

### 2.1 Catches of North Atlantic Salmon

### 2.1.1 Nominal catches of salmon

Nominal catches of salmon reported for each salmon-producing country in the North Atlantic are given in Table 2.1.1.1 for the years 1960 to 2004. These catches (in tonnes) are illustrated in Figure 2.1.1.1 for four North Atlantic regions. Catch statistics in the North Atlantic also include fish farm escapees and, in some North-East Atlantic countries, also ranched fish. Reported catches for the three NASCO Commission Areas for 1996-2004 are provided below:

| Area | $\mathbf{1 9 9 6}$ | $\mathbf{1 9 9 7}$ | $\mathbf{1 9 9 8}$ | $\mathbf{1 9 9 9}$ | $\mathbf{2 0 0 0}$ | $\mathbf{2 0 0 1}$ | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| NEAC | 2750 | 2074 | 2225 | 2073 | 2736 | 2876 | 2495 | 2303 | 1922 |
| NAC | 294 | 231 | 159 | 154 | $\mathbf{1 5 5}$ | 150 | 150 | 144 | $\mathbf{1} 62$ |
| WGC | 92 | 59 | $\mathbf{1 1}$ | 19 | 21 | 43 | 9 | 9 | $\mathbf{1 5}$ |
| Total | 3135 | 2364 | 2396 | 2246 | 2913 | 3069 | 2654 | 2456 | 2099 |

The catch data for 2004 are provisional, but the total nominal catch of 2099 t is the lowest on record. Catches for most countries were below the recent 5 - and 10 -year averages, and in three countries were the lowest in the time-series.

The nominal catch (in tonnes) of wild fish in 2004 was partitioned according to whether the catch was taken in coastal, estuarine, or riverine fisheries. These are shown below for the NEAC and NAC Commission Areas. It was not possible to apportion the small Danish catches in 2004 and these have been excluded from the calculation. The percentages accounted for by each fishery varied considerably between countries. In total, however, coastal fisheries accounted for $50 \%$ of catches in North East Atlantic countries compared to $17 \%$ in North America, whereas in-river fisheries took $42 \%$ of catches in North East Atlantic countries compared to $66 \%$ in North America.

| Area | Coast |  | Estuary |  |  | River | Total <br> Weight |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Weight | $\%$ | Weight | $\%$ | Weight | $\%$ | 1919 |
| NEAC | 967 | 50 | 137 | 7 | 815 | 42 | 66 |
| NAC | 27 | 17 | 28 | 18 | 106 | 66 | $\mathbf{1 6 2}$ |

### 2.1.2 Catch and release

Catch and release data have been provided since the early 1990s by 6 countries. In 2004, the percentage of the total rod catch that was released ranged from $16 \%$ in Iceland to $76 \%$ in Russia. Catch and release rates have generally increased over the last decade. Overall, almost 144000 salmon were reported to have been released in 2004, the highest in the time-series.

### 2.1.3 Unreported catches

The estimated unreported catch within the NASCO Commission Areas in 2004 was 686 t (Table 2.1.1.1), or $25 \%$ of the total catch (reported and unreported). Levels of unreported catch have declined over the past six years as a result of various measures. For example, the introduction of carcass tagging programmes in Ireland and UK (N. Ireland) has lead to reductions in unreported catches in these countries. After 1994 there are no available data on the extent of possible salmon catches in international waters. Limited surveillance flights, which were the basis of past estimates of catches in international waters, have not reported any such salmon fishing in recent years. Estimates (in tonnes) of unreported catches for the three Commission Areas for the period 1996-2004 are given below:

| Area | $\mathbf{1 9 9 6}$ | $\mathbf{1 9 9 7}$ | $\mathbf{1 9 9 8}$ | $\mathbf{1 9 9 9}$ | $\mathbf{2 0 0 0}$ | $\mathbf{2 0 0 1}$ | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| NEAC | 947 | 732 | 1108 | 887 | 1135 | 1089 | 946 | 719 | 575 |
| NAC | 156 | 90 | 91 | 133 | $\mathbf{1 2 4}$ | 81 | 83 | 118 | $\mathbf{1 0 1}$ |
| WGC | 20 | 5 | 11 | 13 | 10 | 10 | 10 | 10 | 10 |
| Int'l. waters |  |  |  | Not available |  |  |  |  |  |

Expressed as a percentage of the total North Atlantic catch, unreported catch estimates range from $0 \%$ to $12 \%$ for individual countries. However, it should be noted that methods of estimating unreported catch vary both within and among countries. The non-reporting rates range from $1 \%$ to $57 \%$ of the total national catch in individual countries. An allowance for unreported catch is included in the assessments and catch advice for each Commission area.

### 2.2 Production of farmed and ranched salmon

The provisional estimate of farmed Atlantic salmon production in the North Atlantic area was 796839 t in 2004, broadly similar to that in 2003 and $13 \%$ above the average of the previous five years. Most of the production in the North Atlantic took place in Norway (64\%) and UK (Scotland) (22\%).

World-wide production of farmed Atlantic salmon has been in excess of one million tonnes since 2002. Total production in 2004 is provisionally estimated at over 1.1 million tonnes (Figure 2.2.1), similar to that in 2003. Production outside the North Atlantic is currently estimated to account for about $30 \%$ of the total farmed production, with Chile ( 261000 t ) contributing the largest proportion of the production in this area. World-wide production of farmed Atlantic salmon in 2004 was almost 550 times the reported nominal catch of Atlantic salmon in the North Atlantic. As a result, farmed salmon dominate world markets.

Catches of ranched salmon have declined substantially from a high of over 500 t in 1993 to around 12 t in 2004 (Figure 2.2.2). This is due to the cessation of salmon ranching in Iceland from 1999.

### 2.3 NASCO has asked ICES to report on significant developments which might assist NASCO with the management of salmon stocks.

### 2.3.1 Update on the estimation of natural mortality at sea of Atlantic salmon

ICES examined further datasets for evidence of changes in M for NAC and NEAC Atlantic salmon stocks, particularly in the second year at sea. The reviews of natural mortality undertaken by ICES in 2002 to 2004 were motivated by concerns about whether the value for natural mortality (M) assumed in the run reconstruction models was appropriate (ICES, 2002, 2003, 2004a). In 2005, ICES reviewed further data from NAC and NEAC stocks to examine for trends in M over time and among stocks.

There was no evidence in the analyses presented that marine mortality had declined and in some stocks from both NAC and NEAC areas, there was an indication that mortality had increased (Figure 2.3.1). In the northern and southern NEAC areas, both wild and hatchery smolts show a constant decline in marine survival over the last two decades, with the sharpest decline in the wild smolts of the southern NEAC area. Similar declines in return rates of hatchery and wild salmon to the NAC area were also reported and return rates of recent years were low compared to historic levels. Return rates of maiden salmon to repeat spawning in some monitored stocks has increased over the last decade suggesting that the mortality factors affecting smolts and non-maturing salmon in the second year may be different from those interacting with the larger repeat spawning fish.

These analyses confirmed the previous conclusion that monthly mortality in the second year at sea was greater than $1 \%$ and distributed around $3 \%$ for the wild fish.

### 2.3.2 Progress in developing precautionary catch advice for Irish salmon fisheries

In 2004 and 2005, the precautionary catch advice for Irish fisheries was modified to take account of the risk of not achieving fisheries management objectives (conservation limits in all rivers within a district), uncertainty in biological reference points (i.e. sex ratio and required egg deposition), and the formulation of pre-agreed management actions in the form of procedures to be applied over a range of stock conditions (harvest guidelines). The harvest level corresponding to a desired probability of meeting the CL can be interpolated from risk plots.

The following harvest guidelines (illustrated using fishery districts) apply to the catch advice:
Generally, the harvest option providing a $75 \%$ chance of meeting the CL in a given district is chosen as the precautionary catch advice (Figure 2.3.2.1).

In following a precautionary approach, increases over the average catch for the period 2000 to 2004 should not be permitted even if the harvest option at the $75 \%$ probability of meeting the CL is higher. This is because each district fishery catches salmon destined for other districts and there is clearly a need to protect vulnerable stocks in these other districts. This advice will be reviewed annually to assess any improvement in the status of these vulnerable stocks (Figure 2.3.2.2).

Where there is no harvest option which will provide a $75 \%$ chance of meeting the district CL, then the precautionary catch advice is that there is no surplus of fish to support a harvest (commercial or rod). This is illustrated in Figure 2.3.2.3.

This advice is predicated on wild fish only (i.e. estimated returns from hatchery-released smolts have been removed). It also relates to the total removal of fish by all means, and is not restricted to commercial fisheries. There are eight districts, mainly located on the east and south coasts, where the CL will probably not be met even in the absence of harvests of salmon. A further six districts reductions in the average catch in 2005 would be required if there is to be a $75 \%$ chance of meeting the CL. The remaining districts are meeting or exceeding their CLs. In this instance, the average catch is advised for 2005 , even where the harvest option providing a $75 \%$ chance of meeting the CL is higher. This recognizes the fact that these fisheries intercept salmon destined for districts that are below their CL. The status of these districts will be assessed on an ongoing basis, and the advice will change in line with any significant and consistent improvement in stock size. The maximum harvest by all methods being recommended is 122541 one-sea winter salmon for the 2005 season.

### 2.3.3 Catch and release

The practice of catch and release in salmon rod fisheries has become a common management/conservation measure. In some areas of Canada and USA, anglers have been required to practice catch and release since 1984. More recently it has also been widely used in many NEAC countries both as a regulation and a voluntary practice. In 2004, anglers reported releasing almost 144000 salmon around the North Atlantic, the highest number in the time-series.

A probabilistic method to predict the risk of mortality for caught and released salmon from the Penobscot River USA was reviewed. Simulations drawing from a random binomial function for temperature dependent mortality (i.e. 0.05 to 0.30 for temperatures greater than $20^{\circ} \mathrm{C}$ ) were done to calculate the number of hooked and released fish that died. The resulting distribution described the mortality losses from reported numbers of caught and released salmon. The simulations suggest that mortality following capture can be low. A recent radio tracking study in northwest England found that upwards of $85 \%$ of released spring salmon can be expected to survive to spawning (UK Environment Agency, 2003).

The survivors of catch and release angling are vulnerable to being hooked again. Additional information from rod fisheries on four Icelandic rivers documented that $24.4 \%$ (range: 22.1-27.8\%) of salmon were captured for a second time. Salmon captured a third time were rare (1.8\%). Exploitation rates in these rivers range from $45 \%$ to $60 \%$. These results provide a means for adjusting the catch and release statistics to account for multiple recapture in these rivers and potentially for Iceland as a whole.

### 2.3.4 Regional growth patterns

Systematic collection of salmon scales from anglers' catches has been carried out in seven rivers in Norway. Back calculated growth of the first year at sea of 1SW fish was systematically lower than that of MSW fish of the same smolt year class in all rivers. For six of the seven river stocks, the first year growth of 1 SW and MSW fish of the same smolt year class was significantly correlated.

Growth of salmon the first year at sea varied among years and stocks, with a systematic trend for slower growth in salmon originating from Northern latitudes. There were significant correlations in growth between salmon originating from nearby rivers, whereas growth in more distant stocks were less correlated.

The marine growth of the four most northerly salmon stocks was significantly correlated with the mean sea temperature at $50-\mathrm{m}$ depth in the Norwegian Sea ( $66^{\circ} \mathrm{N} ; 2^{\circ} \mathrm{E}$ ) and mean temperature in the $0-50 \mathrm{~m}$ layer in the Barents Sea $\left(70^{\circ} 30^{\prime} \mathrm{N}-72^{\circ} 30^{\circ} \mathrm{N}\right.$; $33^{\circ} 30^{\prime} \mathrm{E}$ ) during July-December. However, the most northerly populations were more strongly correlated with temperatures in the north than with temperatures in the southern area. Growth of salmon from rivers in mid-Norway showed the highest correlation with temperatures in the Norwegian Sea. Salmon growth from the three most southern rivers was not correlated with temperatures at any of the two areas.

Further support to the regional grouping of rivers is provided by analyses from three subarctic rivers running to the Barents Sea within a small geographic area in northeastern Europe. Salmon from the rivers Teno/Tana (Finland and Norway), Näätämöjoki/Neidenelva (Finland and Norway), and Kola (Russia) showed significant temporal synchrony in marine growth and variation in abundance, and these variables were also significantly correlated with the sea water temperature in the Barents Sea.

These findings support the contention that PFA should be developed at a regional scale. In the case of Norwegian stocks, at least two regions should be established, divided by the Lofoten Islands at a latitude of $68^{\circ} \mathrm{N}$.

### 2.3.5 Long-term projections for stock rebuilding

In 2004, ICES advised that further stock rebuilding projections should reflect declining stock trajectories and population viability given that the probability of rebuilding in the short term is low in most areas and that the main result of recent management measures may have been to reduce this rate of decline rather than lead to any significant stock rebuilding.

### 2.3.5.1 Long-term projections of PFA for North America

Seven different types of regression models have been used to relate lagged spawners (LS) and Pre-Fishery Abundance for North America ( $\mathrm{PFA}_{\mathrm{NA}}$, Section 5.10). Some of these allow for a "regime shift" in the relationship identified by ICES (ICES, 2003), whereby early years in the time-series demonstrate higher PFA per lagged spawner while the more recent years demonstrate lower PFA per lagged spawner. The LS value for the current year is used to predict a distribution of the expected $\mathrm{PFA}_{\mathrm{NA}}$ in the current year which is used to provide catch advice for the upcoming fishing season in West Greenland. However, medium-term (up to 5 years) and long-term (up to 20 years) projections have not been developed to date. Therefore ICES has adapted and extended the analysis in Section 5.10 to complete the cycle over a longer time period to examine potential long-term trajectories in stock size. The only new assumption made is that the allocation by region of surviving fish after the West Greenland fishery in year $t$ is proportional to the distribution of the lagged spawners by region that produced the predicted $\mathrm{PFA}_{N \mathrm{~A}}$ for that year. This additional assumption allows medium- and long-term predictions for $\mathrm{PFA}_{\mathrm{NA}}$ to be made, demonstrating directly the implications of the different relationships between LS and $\mathrm{PFA}_{N A}$ and also providing a basis for comparison with the simple Population Viability Analysis (PVA) results presented to ICES in 2004 (ICES, 2004a).

PFA projections were made assuming either no fishing, or that a fishery occurs in West Greenland at 20, 50, or 100 t annually for the next 20 years, and that all home river fisheries are stopped (Figure 2.3.5.1). The harvest in tonnes was converted to numbers of fish and split between North America and Europe following the standard approach. In all three West Greenland harvests considered, PFAs from the high phase projections were essentially the same with large increases up to an ad hoc cap of five million fish. In contrast, PFA from the low phase projections showed a strong response to West Greenland harvest, with a continued harvest of 100 tonnes causing the median PFA to decline to zero by 2013 (Figure 2.3.5.1). The overlap of medians for the first five years of projections is due to the fact that the lagged spawners that produced these PFA values come from spawners that are already back in the river for most SFAs. Thus, there is no feedback from the cycling nor from forecast catches in West Greenland in this period.

These results demonstrate that medium- to long-term forecasts of PFA depend most on the phase used for projections. The PFA is much more resilient to fishing when in the high phase than when in the low phase. The ability to detect a switch from the current low phase to the high phase depends on future PFA estimates from observed returns that are much higher than expected from the low phase model. A single observation is not sufficient to claim that a change in phase has occurred, multiple years in the high phase will be required. There is a time lag between observing large PFA and the feedback through the cycle to generate higher returns, spawners, and PFA that needs to be considered when making management decisions.

### 2.3.5.2 Potential for rebuilding two multi-sea-winter salmon stocks of the Maritime Provinces

Catch advice for the management of the West Greenland fishery and the management of NAC homewater fisheries (ICES, 2003) has been provided on the basis of achieving conservation objectives of the four northern regions (Labrador, Newfoundland, Quebec, and Gulf) and an alternate objective for the southern regions of achieving at least a $10 \%$ increase or a $25 \%$ increase relative to the average returns to the regions during a specified time period (Chaput et al., 2005). In this regard it is presumed that stocks in these areas have the potential to rebuild if adequate spawning occurs. The stock status and potential for rebuilding of two multi-sea-winter salmon stocks (Mirimichi and Saint John rivers) of the Maritime Provinces of eastern Canada were examined in this context.

For a population to replace itself, one egg in the recruitment is required for every egg spawned. For the Miramichi River, the wild salmon stock produced maiden fish recruitment surplus to spawners for most year classes between 1971 and 1989, but was consistently below replacement for the 1990 to 1997 year classes. The eggs in the maiden returns of the 1998 year class (the last year where an assessment was possible) are estimated to have been equivalent to the eggs which were spawned. For the Saint John River, wild salmon production had varied around the replacement line for the 1972 to 1988 year classes but decreased sharply and remained well below replacement for the 1989 to 1999 year classes.

There has been a decline in the proportion of the eggs produced in the lifetime of the year class by maiden MSW salmon of the Miramichi River. For the 1981 and subsequent year classes, the lifetime egg production from MSW maiden salmon amounts to about $50 \%$ of the lifetime production of the year class. This is a decline from the previous time period and parallels a decline in 2 SW maiden salmon abundance and an increase in the repeat spawner abundance.

This contrasts with the Saint John River stock in which the MSW maiden salmon continue to contribute over $80 \%$ of the eggs in the lifetime of the year class, with a slight decline for the recent three year classes.

Calculations of replacement ratio indicate that the Miramichi River population had the potential historically to produce a surplus of maiden egg production. In the recent decade, maiden egg production (i.e. recruit egg production) has been well below replacement for a time period when spawner egg depositions exceeded the conservation requirements by $50 \%$ to $100 \%$. With a decline in egg depositions, returns of maiden fish have resulted in at least the replacement of the parental stock and the potential for increased returns appear feasible. An examination of the spawners to recruits indicated that there was a greater chance that the recruitment will be less than the spawners when egg depositions exceed 150 million eggs (equivalent to 2.7 eggs $^{-2}$ ) than when egg depositions were less than 150 million.

The prognosis for the Miramichi remains positive. Marine return rates of 1SW and 2SW maiden salmon appear sufficient to replace the eggs that produced them. Size-at-age has increased, such that every female now has the potential to produce more eggs, there is a high survival to second and third spawning, and the interstage survival of the juvenile stages have not changed over time.

In contrast, the Saint John River population has failed to achieve replacement ratio throughout the time-series. For the last ten year classes, the eggs from the returns of maiden salmon have been substantially below replacement. There are no positive changes in life history characteristics of this stock (e.g. increased size at age or proportion female, or increased survival of previous spawners) and it is likely that the stock will continue to decline.

The continued decline in the Saint John stock contrasted with the apparent rebuilding of the Miramichi stock suggests that the factors which contributed to the decline differ. The restriction in fisheries exploitation, both marine and freshwater, has not been sufficient to arrest the decline in salmon abundance in the Saint John River, whereas reductions in fisheries resulted in the Miramichi in increased spawning escapement and the production of juvenile salmon to record levels. Clearly, declines in stocks and sustained failures to achieve conservation limits may result from a number of factors which may be related or unrelated to insufficient stock abundance and exploitation patterns.

### 2.3.5.3 Catch advice and projected attainment of conservation limits for an Irish salmon fishing district

The theoretical recovery trajectories developed by ICES (2004a) were extended with a case study using data from an Irish district salmon fishery to examine the implications of current catch advice and other catch levels to the objective of meeting district conservation limits in subsequent years. Catch advice has been provided for this district based on $75 \%$ probability of achievement of the total conservation requirement for all 14 rivers in the district. Consequences of this catch level for individual rivers, along with the district as a whole were examined.

Obtaining recruits for seven years (the longest period required to obtain complete recruitment) initialized projections at the selected starting stock size before accumulating recruits for any trajectory. In the simulations, since the district is currently estimated to be at $63 \%$ of $\mathrm{S}_{\text {opt }}$ (before exploitation in commercial and recreational fisheries) each river had its starting spawning stock sizes set to $63 \%$ of their $S_{\text {opt }}$. Although the 14 rivers had quite similar stock recruitment relationships on an eggs $\mathrm{m}^{-2}$ basis, they varied in size considerably. The CL for the individual rivers ranged from 67 to 13646 fish, with three rivers accounting for $91 \%$ of the total of 39164 . Projections were run using either no catch or linear increases of catches from zero to 10000,20000 , or 50000 fish. Forward simulations of 20 years were run 10 000 times in an @Risk ${ }^{\odot}$ framework in Excel $\odot$. The current mean catch from the district (2000-2004) is just over 15 000 fish.

Forward simulations were applied, while maintaining the catch at 0 , immediately resulting in a high probability ( $>75 \%$ ) of achieving the total district CL, which was maintained throughout the projected time-series (Figure 2.3.5.3.1). Linearly increasing catch from zero to 10000 fish over 20 years produced a decrease in the probability of meeting the CL in the first few years, but this increased subsequently. Doubling this rate of increase initially caused a decrease in the probability of meeting the CL, followed by an increase, suggesting that this rate of increase could be sustained for a short period while rebuilding occurred. Within 10 years however, the probability of meeting the CL decreased significantly as the catch became too large relative to the available population. A catch option building to 50000 over 20 years caused an immediate and consistent decline in the probability of meeting the CL.

The probability for the alternative management objective of achieving CL simultaneously for all 14 rivers increased significantly in the projection at zero catch, however, it was never higher than $65 \%$ (Figure 2.3.5.3.2). None of the other catch options provided a high probability of meeting the CLs. The apparent difficulty in meeting the CL in each river is due to:

- Uncertainties in input data, including $s / r$ parameters.
- Surpluses in some rivers, which allow the district CL to be met, despite some individual rivers being below CL.

While the probability of achieving the CL in every river is a much more difficult management objective to achieve than the total CL objective, it is clearly desirable from a precautionary perspective.

This analysis provides some information about the implications of being below CL. In this example the district was $63 \%$ of its CL. In these simulations, where stocks have been below CL and when catches have been kept at zero for an initial seven-year period, it is possible to increase the advised catch as the stocks improve. However, these simulations show that rates of increase must be carefully managed. Clearly, the attainment of CL in all rivers simultaneously may be difficult to achieve but is still a desirable objective. Following rebuilding, if exploitation is close to the optimum exploitation rate ( $h_{\text {opt }}$ ) annual assessments and catch advice are warranted. However, when stock status is fully satisfactory, and when fishing below optimum exploitation rates, continual assessments and annual catch advice may not be required.

### 2.3.5.4 DST- tagging of salmon in the Norwegian Sea

In an inter-Nordic study in which Data Storage Tags (DST) were applied to 406 pre-adult and adult salmon in the Norwegian Sea, 4 fish have to date been recovered in mid-Norway, and 1 fish was recovered in SW Sweden. DSTs were set to log depth and temperature at intervals varying from 1-120 minutes and yielded 439 days of observations. After an initial period of inactivity of 14-20 days, the five fish exhibited varying periods of intense diving (up to 150 m ) during migration, until they presumably arrived in shallower coastal waters and entered the home river (e.g. salmon recovered in Sweden, Fig. 2.3.5.4.1). Further tags might still be returned from the 2005 fishing season.

These tags provide new insights to the behaviour of salmon at sea. These data can be used for assessing mean swimming depths and specifically time spent at depths where the fish may risk interception by pelagic fishing gear.

### 2.4 Compilation of Tag Releases and Finclip Data by ICES Member Countries in 2004

Data on releases of tagged, fin-clipped, and otherwise marked salmon in 2004 were provided by ICES and are compiled as a separate report. In summary (see Table 2.4.1), about 4.95 million salmon were marked in 2004, an increase from the 3.94 million fish marked in 2003. The adipose clip was the most used primary mark ( 3.49 million), with microtags ( 0.9 million) the next most common primary mark. Most marks were applied to hatchery-origin juveniles ( 4.83 million), while 110461 wild juveniles and 17899 adults were marked. ICES also reports information on various types of tags including DST, radio and/or sonic transmitting tags (pingers).

ICES noted that a number of commercial fish farms are applying tags to fish placed in sea cages. Two jurisdictions, USA-Maine and Iceland, require that some or all of the sea-cage farmed fish reared in their area are marked. In Maine some producers have opted for genetic 'marking' procedure. In Iceland, coded wire tags are being applied to about 10\% of sea-cage farm produced fish, and are included in the tag compilation.

[^0]Figure 2.1.1.1 Nominal catches of salmon in four North Atlantic regions, 1960-2004

Figure 2.2.1. World-wide farmed Atlantic salmon production, 1980-2004.

Figure 2.3.1 Estimates of marine mortality in the second year at sea from two stocks in the NAC area (upper panel) and two stocks in the NEAC area (lower panel) based on the inverse-weight method assuming linear growth at sea and the maturity schedule method for one stock. The de la Trinite River and Corrib River are wild stocks. The River Bush is for wild and hatchery stocks whereas the Lahave River is a hatchery stock.

Figure 2.3.2.1
Risk plot showing the probability of meeting or exceeding the district CL and the harvest options by all methods (commercial and rods) of 1 SW salmon. The average catch for the Lismore district (2000 to 2004, all methods, excluding sea trout and hatchery fish, but including an unreported catch) was 153801 SW salmon. At this level of harvest there is less than $25 \%$ chance that the CL will be met. The harvest option which provides a $75 \%$ chance of meeting the CL is approximately

7200 1SW salmon and this has been recommended as the precautionary catch advice for 2005.
Figure 2.3.2.2 Risk plot showing the probability of meeting or exceeding the district CL (CL) and the harvest options by all methods (commercial and rods) of 1 SW salmon. The average catch for the Ballinakill district ( 2000 to 2004, all methods, excluding sea trout and hatchery fish, but including an unreported catch) was 7308 1SW salmon. At this level of harvest there is an $85 \%$ chance that the CL will be met. The harvest option which provides a $75 \%$ chance of meeting the CL is approximately 90001 SW salmon. As the average catch is lower than the harvest option at $75 \%$, the lower catch is selected as the precautionary catch advised for 2005. This is because the Ballinakill district fishery catches salmon destined for other districts and there is clearly a need to protect vulnerable stocks in these other districts.

Figure 2.3.2.3. Risk plot showing the probability of meeting or exceeding the district CL (CL) and the harvest options by all methods (commercial and rods) of 1SW salmon. The average catch for the Galway district ( 2000 to 2004, all methods, excluding sea trout and hatchery fish, but including an unreported catch) was 4580 1SW salmon. At this level of harvest there is no chance that the CL will be met. Similarly, there is no harvest option which provides $75 \%$ chance of meeting the CL. In this instance there is no surplus of fish over spawning requirements to support a harvest.

Figure 2.3.5.1 Comparison of medians of PFA from projections assuming different levels of catch in the West Greenland fishery each year for all models except those that have a flat relationship between LS and PFA (models 1 and 3).

Figure 2.3.5.3.1 Probability that the total CL is achieved in the district each year under four levels of catch.

Figure 2.3.5.3.2 Probability that all 14 rivers achieve their CL for each year under four levels of catch.

## Measurement time 24 april, 17:00 h - 30 August, 18:00 h

Figure 2.3.5.4.1 Data records of a salmon recovered in R. Ätran, Sweden. Depth above and temperature track below. To the left of A) post-release period, and probable periods of B) feeding and migration activity, C) Coastal migration (rising temperature), D) Estuarine dwelling and migration followed by in-river dwelling when the diving activity ceases.

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted this definition of CLs (NASCO, 1998). In this regard, the CL is a limit reference point ( $\mathrm{S}_{\mathrm{lim}}$ ) which should be avoided with high probability. Management advice for Atlantic salmon is referenced to the $S_{\text {lim }}$ conservation limit, therefore stocks assessed here are reported as being outside precautionary limits when the confidence limits of the most recent stock estimate includes $\mathrm{S}_{\text {lim }}$.

For the assessment of the status of stocks and advice on management of national components and geographical groupings of the stock complexes in the NEAC area, where there are no specific management objectives:

ICES requires that the lower bound of the $95 \%$ confidence interval of the current estimate of spawners is above the CL for the stock to be considered at full reproductive capacity.

When the lower bound of the confidence limit is below the CL, but the mid-point is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.

Finally, when the mid-point is below the CL, ICES considers the stock to be suffering reduced reproductive capacity.
It should be noted that this approach is consistent with ICES precautionary target reference points $\left(S_{p a}\right)$ used in the provision of catch advice for other fish stocks in the ICES area, i.e. stocks are regarded by ICES as being at full reproductive capacity only if they are above the precautionary reference point $\left(S_{p a}\right)$.

For stock assessment purposes, ICES groups NEAC stocks into two stock groupings; northern and southern NEAC stocks. The composition of these groups is shown below:

## Southern European Countries:

## Northern European Countries:

| Ireland | Finland |
| :--- | :--- |
| France | Norway |
| UK(England \& Wales) | Russia |
| UK(Northern Ireland) | Sweden |
| UK(Scotland) | Iceland (north/east regions) |
| Iceland (south/west regions) (from 2005) | Iceland (south/west regions) (until 2004) |

### 3.1 Status of stocks/exploitation

The status of stocks is shown in Figure 3.1.1.
ICES classifies the stock complexes with respect to conservation requirements as follows:
All 4 stock complexes (Northern European 1SW, Northern European MSW, Southern European 1SW and Southern European MSW) were estimated to be outside precautionary limits.

In the evaluation of the status of stocks in Figure 3.1.1, Estimated recruitment (PFA) values should be assessed against the Spawning Escapement Reserve while the Estimated spawning escapement values should be compared with the conservation limit.

Northern European 1SW stocks: Recruitment of maturing 1SW salmon (potential grilse) showed a steady decline from the mid-1980s to the mid-1990s (Figure 3.1.1). Following an upturn in the late 1990s, there has been a steep downturn in recent years. The number of 1 SW spawners has been outside the precautionary limits for most of the timeseries. Although it was within these limits for 5 of the last 6 years, the 2004 spawner value is again outside precautionary limits. This is consistent with a decline in PFA over the recent period.

Northern European MSW stocks: Numbers of non-maturing 1SW recruits (potential MSW returns) (Figure 3.1.1) are also estimated to have fallen throughout the period from the early 1980s to the late 1990s. The number of MSW spawners was outside the precautionary limits for most of the time-series. Although it has been within these limits since 2000, the 2004 spawner value has again fallen outside precautionary limits. These trends in recruitment for the Northern European stocks are broadly consistent with the data available on the marine survival of monitored stocks in the Northern area.

Southern European 1SW stocks: The estimated numbers of maturing 1SW recruits have fallen substantially since the 1970s (Figure 3.1.1). With the exception of the early 1970 s and two years in the late 1980s, the number of 1SW spawners has been outside the precautionary limits for most of the time-series and remained so in 2004. This pattern is consistent with the data obtained from a number of monitored stocks which showed that survival of wild smolts to return as 1SW fish fell to very low levels in the Southern European area.

Southern European MSW stocks: The PFA estimates suggest that the number of non-maturing 1SW recruits has followed a fairly steady and substantial decline over the past 30 years (Figure 3.1.1). The number of MSW spawners was generally within the precautionary limits for most of the time-series until 1995. Thereafter, spawners have been outside precautionary limits. This is broadly consistent with the general pattern of decline in marine survival of 2SW returns in most monitored stocks in the area.

In assessing stock status for the major geographic stock complexes in the NEAC area, it was considered appropriate to aggregate the National CLs. On a national level, they can be used to provide a general indicator of overall stock status based on the same criteria adopted for the stock complexes (i.e. relative location of the mean and lower $95 \%$ confidence limit). However, they may not be appropriate for the provisional catch advice at this level. Stock status, expressed as outside or within precautionary limits, and the method by which conservation limit was determined is summarised by country below.

| Country | 1SW Spawners | MSW Spawners | Determination of Conservation <br> Limit |  |
| :--- | :--- | :--- | :--- | :---: |
| Northern NEAC | outside | outside | National CL model |  |
| Finland | outside | outside | National CL mode |  |
| Iceland | outside | outside | National CL model |  |
| Norway | outside | outside | National CL model |  |
| Russia | within | within | National CL model |  |
| Sweden |  |  |  |  |
| Southern NEAC |  |  |  |  |
| France | outside | outside | River Specific |  |
| Ireland | outside | outside | River Specific |  |
| UK(England \& Wales) | outside | outside | River Specific |  |
| UK (Northern Ireland) | within | within | National CL model |  |
| UK (Scotland) | outside | outside | National CL model |  |

For individual rivers the status with respect to conservation requirements may vary considerably from this picture.
An overview of the estimates of marine survival for wild and hatchery-reared smolts returning to homewaters (i.e. before homewater exploitation) for the 2003 and 2002 smolt year classes (returning 1SW and 2SW salmon, respectively) is presented in Figure 3.1.2. The survival values presented are standardized ( Z -score) indices relative to the averages of the time-series. An overall trend in both the Northern and Southern NEAC areas, both wild and hatchery smolts, show a constant decline in marine survival over the past $10-20$ years. The steepest decline appears for the wild smolts in the Southern NEAC area. Results from these analyses are consistent with the information on estimated returns and spawners (Section 3.1), and suggest that returns are strongly influenced by factors in the marine environment.

### 3.2 Management objectives

This commission area is subject to the general NASCO management objectives as outlined in Section 1.3.

### 3.3 Reference points

Section 1.4 describes the derivation of reference points for these stocks and stock complexes.

### 3.3.1 Progress with setting river-specific conservation limits

Specific progress in individual countries is summarised below:
A new compliance assessment scheme designed to assess the performance of salmon stocks in UK (England Wales), and provide an early warning that a river has fallen below its CL, was introduced in 2004. The approach retains the
same underlying statistical assumptions and operating characteristics as before, and provides a way of summarising the performance of a river's salmon stock over the last 10 years, including the current year, in relation to its CL. The new scheme also allows extrapolation beyond the current year in order to predict the likely future performance of the stock relative to its CL, and so assess the likely effect of recent management intervention and the need for additional measures.

Changes to management using river-specific CLs were applied for Irish salmon rivers in 2005. These changes increased the probability of meeting the required female:male ratio and the probability that the CL will be achieved simultaneously in every river in each of the 17 salmon fishing districts. This resulted in an increase in the CL for each river individually and a resultant increase in the National CL from 212910 to 251378 . It is planned to use automatic fish counters in approximately 15 rivers to assess the status of individual stocks relative to the attainment of riverspecific CLs and as an independent index of district compliance with CLs in future assessments.

### 3.3.2 National Conservation Limits

The national model has been run for all countries for which no river-specific conservation limits have been developed, i.e. all countries except France, Ireland, and UK (England \& Wales). For Iceland, Russia, Norway, UK (Northern Ireland), and UK (Scotland) the input data for the PFA analysis (1971-2004) have been provided separately for more than one region; the lagged spawner analysis has therefore been conducted for each region separately and the estimated conservation limits combined for the country. ICES has previously noted that outputs from the national model are only designed to provide a provisional guide to the status of stocks in the NEAC area.

For catch advice to NASCO, conservation limits are required for stock complexes. These have been derived either by summing of individual river CLs to national level, or by taking overall national CLs, as provided by the national CL model. For the NEAC area, the conservation limits have been calculated by ICES as 269194 1SW spawners and 144 263 MSW spawners for the northern NEAC grouping, and 610520 1SW spawners and 277985 MSW spawners for the southern NEAC grouping.

### 3.4 Advice on management

ICES has been asked to provide catch options or alternative management advice, if possible based on a forecast of PFA, with an assessment of risks relative to the objective of exceeding stock conservation limits in the NEAC area.

ICES emphasised that the national stock conservation limits discussed above are not appropriate for the management of homewater fisheries, particularly where these exploit separate river stocks. This is because of the relative imprecision of the national conservation limits and because they will not take account of differences in the status of different river stocks or sub-river populations. Nevertheless, ICES agreed that the combined conservation limits for the main stock groups (national stocks) exploited by the distant water fisheries could be used to provide general management advice to the distant water fisheries.

Given the status of the stocks ICES provides the following advice on management:
Northern European 1SW stocks: ICES recommends that the overall exploitation of the stock complex should decrease so that the conservation limit can be consistently met. In addition it should be noted that the inclusion of farmed fish in the Norwegian data results in the stock status being overestimated. Since very few of these salmon have been caught outside homewater fisheries in Europe, even when fisheries were operating in the Norwegian Sea, management of maturing 1SW salmon should be based upon local assessments of the status of river or sub-river stocks. Thus, the only fisheries on maturing 1 SW salmon should be on river stocks shown to be within precautionary limits.

Northern European MSW stocks: ICES considers that the overall exploitation, particularly in mixed stock fisheries, should immediately decrease, so that the conservation limit can be consistently met. In addition it should be noted that the inclusion of farmed fish in the Norwegian data results in the stock status being overestimated. Thus, the only fisheries on non-maturing 1SW salmon should be on river stocks shown to be within precautionary limits.

Southern European 1SW stocks: ICES considers that, as this stock complex remains outside precautionary limits, reductions in exploitation are required for as many stocks as possible, to increase the probability of the complex meeting conservation limits. Furthermore, due to the different status of individual stocks within the stock complex, mixed stock fisheries present particular threats to stocks below reproductive capacity. Thus, the only fisheries on maturing 1SW salmon should be on river stocks that are shown to be within precautionary limits.

Southern European MSW stocks: This stock complex is currently outside precautionary limits and the quantitative forecast of PFA for 2005 (486000) indicates that stock levels will remain close to current levels at least in the next
year. ICES considers that reductions in exploitation are required for as many stocks as possible, to increase the probability of the stock complex meeting conservation limits. Furthermore, due to the different status of individual stocks within the stock complex, mixed stock fisheries present particular threats to stocks below reproductive capacity. Thus, the only fisheries on non-maturing 1SW salmon should be on river stocks that are shown to be within precautionary limits. (quantitative catch advice for this stock complex at West Greenland is provided in the context of a risk framework in Section 5).

### 3.5 Relevant factors to be considered in management

For all fisheries, ICES considers that management should be based upon assessments of the status of individual stocks. Fisheries on mixed stocks, either in coastal waters or on the high seas, pose particular difficulties for management, as they cannot target only those stocks that are within precautionary limits. Conservation would be best achieved if fisheries can be targeted at stocks that have been shown to be within precautionary limits. Fisheries in estuaries and rivers are more likely to fulfil this requirement.

National outputs of the NEAC PFA model are combined into northern and southern groups to provide NASCO with catch advice or alternative management advice for the distant water fisheries at West Greenland and Faroes.

The groups were considered appropriate as they fulfilled an agreed set of criteria for defining stock groups for the provision of management advice, criteria that were considered in detail by ICES (2002). In 2005, ICES re-evaluated tag recapture information previously provided by Iceland (ICES, 2002) and decided that the south/west region of Iceland would be included in the southern grouping while the north/east regions would remain in the northern grouping.

Consideration of the level of exploitation of national stocks at both the distant water fisheries resulted in the proposal that advice for the Faroes fishery (both 1SW and MSW) should be based upon all NEAC area stocks, but that advice for the West Greenland fishery should be based upon Southern European MSW salmon stocks only (comprising UK, Ireland, France, and Iceland (south/west regions)).

### 3.6 Catch forecast for 2005

In order to develop quantitative catch options for NEAC stock complexes, forecasts of PFA are required for each stock complex and for each sea age component. These are currently only available for the MSW component of the southern European stock complex. The forecast of PFA for 2005 has been used in the catch advice for West Greenland for 2005 (Section 5). ICES has adopted a model to forecast the pre-fishery abundance (PFA) of non-maturing (potential MSW) salmon from the Southern European stock group (ICES, 2002, 2003). Model options were re-evaluated in 2004 when ICES explored the relative contribution of several variables to predictions of PFA (ICES, 2004a). In 2004, ICES decided to apply a model that used only the Year and Spawners terms to predict the PFA of non-maturing salmon. This model was again used in 2005 where it was fitted to data from 1978-2003 and used to update the PFA in 2004 and to forecast the PFA in 2005 (Figure 3.6.1).

Forecasts and $95 \%$ confidence limits of PFA non-maturing 1SW salmon (all values in thousands) for Southern NEAC are given below:

| Year | Forecast | Lower limit | Upper limit |
| :---: | :---: | :---: | :---: |
| 2004 | 524 | 338 | 813 |
| 2005 | 486 | 313 | 755 |

### 3.7 Medium- to long-term projections

The quantitative forecast for the southern NEAC MSW stock component gives a projected PFA (at $1^{\text {st }}$ January 2005) of 486000 fish for catch advice in 2005 . No projections are available beyond that, or for other stock components or complexes in the NEAC area.

### 3.8 Comparison with previous assessment

## PFA forecast model

The revised forecast of the southern NEAC non-maturing 1SW PFA for 2004 provides a PFA mid-point of 524000 . This is close to the value forecast last year at this time of 489000 . However, in comparing these two forecasts it must be noted that the estimate derived this year now includes Iceland (south/west) in the Southern European stock complex. The Iceland (south/west) non-maturing 1SW component represents about 10700 fish added to the PFA of this stock complex.

## Developments to the National PFA model and national or other conservation limit models

Five countries made changes to the input data to these models.
Unreported catch rates for France in 2002 and 2003 were increased to take account of (a) recent information on illegal net catches in the coastal zone and (b) the absence of estimated catches for the drift net fishery of the Adour estuary.

- The proportion of 1 SW salmon in the UK (Northern Ireland) catch has been decreased from $95 \%$ to $93 \%$ throughout the time-series following analysis of scale sample data. Rod catch data for 2002 onwards have also become available, following introduction of a carcass tagging scheme, and are included in the analysis.
- Size and sea age composition of the returns in 2003 for Russia (Pechora River) region was based on limited sample data and has been revised using data from other years.
- In Ireland, the CL was increased from 212910 to 251378 for 1 and 2SW salmon combined (see Section 2.3.2 for details of the methods and justification) and catches have been corrected to account for some of the hatchery-reared returns which are not considered to contribute significantly to spawning or to returns in subsequent generations. New exploitation rate indices for wild stocks ( 1 and 2SW) are being developed which may replace exploitation rates used in the current model in the future.
- Corrections to the estimations of river-specific conservation limits have led to revised figures for UK (England \& Wales), which have resulted in a $58 \%$ increase in the national total.

ICES also noted that some countries are developing PFA models for national management. For example, in Norway, the development of national PFA estimates has been initiated, and some provisional modification to the NEAC model is proposed. The NEAC model uses total exploitation rate. In Norway it is more appropriate to use freshwater exploitation rate, as there are more data available and they are easier to estimate. In contrast to the NEAC model the Norwegian catch in the River Tana is included. The output from the Norwegian model was similar to the results for Norway from the NEAC model.

ICES encourages further development of assessment models reflecting stock characteristics in areas or countries to replace the National Conservation Limits approach.

### 3.9 NASCO has requested ICES to describe the key events of the 2004 fisheries and the status of the stocks

### 3.9.1 Fishing in the Faroese area 2003/2004 commercial fishery

No fishery for salmon was carried out in 2003/2004 or, to date, in 2004/2005. Consequently, no sample data are available from the Faroese area for this season. No buyout arrangement has been made since 1999.

## Homewater fisheries in the NEAC area:

### 3.9.2 Significant events in NEAC homewater fisheries in 2004

In several countries, national measures aimed at reducing exploitation were implemented or strengthened in 2004. These include: a reduction of net fisheries in UK (England \& Wales) with the aim of reducing mixed stock fisheries and the use of a TAC to limit catches and the continuation of a carcass tagging scheme to monitor catches in Ireland.

### 3.9.3 Gear and effort

No significant changes in the types of gear used for salmon fishing were reported in the NEAC area and the number of licensed gear units has, in most cases, continued to fall. There are no such consistent trends for the rod fishing effort in NEAC countries over this period.

### 3.9.4 Catches

In the NEAC area there has been a general reduction in catches since the 1980s (Table 2.1.1.1). This reflects the decline in fishing effort as a consequence of management measures as well as a reduction in the size of stocks. The provisional declared catch in the NEAC area in 2004 was 1922 tonnes, $17 \%$ down on 2003 ( 2302 t ) and also below the previous 5year mean. The catch in the Southern area declined from about 4500 t in 1972-1975 to less than 1000 t in the last two years. The catch trend features two sharp declines, one in 1976 and the other in 1989-1991. The catch in the Northern area also shows an overall decline over the time-series, but this is less steep than for the Southern area. The catch in the Northern area varied between 1850 t and 2700 t from 1971 to 1986 , falling to a low of 962 t in 1997, before increasing
to over 1500 t in 2001. The catch has declined again since this time to 1058 t . Thus, the catch in the Southern area, which comprised around two-thirds of the NEAC total in the early 1970s, is now lower than that in the Northern area.

### 3.9.5 Catch per unit effort (CPUE).

An overview of the CPUE data for the NEAC area was undertaken. In the Southern NEAC area, CPUE shows a general decrease in UK (Scotland) net and coble fisheries, whereas no trend was observed in UK (Scotland) fixed-engine fisheries, UK (England \& Wales) net fisheries, and in France rod fisheries. In UK (Northern Ireland), the river Bush rod fishery CPUE showed a general increase until the late 1990s, followed by a decrease, but has slightly increased after 2002, which was the lowest level in recent years. In most of the Northern NEAC area, there has been a generally increasing trend in the CPUE figures for various fisheries in recent years, but the figures since 2002 have generally been lower than before.

CPUE can be influenced by various factors, and it is assumed that the CPUE of net fisheries is a more stable indicator of the general status of salmon stocks than rod CPUE since the latter may be more affected by varying local factors.

### 3.9.6 Age composition of catches

One Sea Winter salmon comprised $58 \%$ of the total catch in the Northern area in 2004 which was below the 5-and 10year means ( $63 \%$ and $64 \%$ resp.). In general, there has been greater variability in the proportion of 1SW fish between countries in recent years (since 1994) than prior to this time. For the Southern European countries, the overall percentage of 1 SW fish in the catch ( $59 \%$ ) was close to the 5 - and 10 -year mean ( $60 \%$ ).

### 3.9.7 Farmed and ranched salmon in catches

The contribution of farmed and ranched salmon to national catches in the NEAC area in 2004 was again generally low ( $<2 \%$ in most countries) and is similar to the values that have been reported in previous reports (e.g. ICES, 2004a). Thus, the occurrence of such fish is usually ignored in assessments of the status of national stocks. However, in Norway farmed salmon continue to form a large proportion of the catch in coastal, fjord, and rod fisheries. An assessment of the likely effect of these fish on the output data from the PFA model was included in ICES (2001).

### 3.9.8 National origin of catches

Only one specific analysis outlining the national origin of catches in fisheries in the NEAC area was made available.
ICES reviewed information resulting from analysis of coded wire tagging (CWT) programmes in UK (England \& Wales) and tag recovery programmes in Ireland to estimate the effects of Irish fisheries on salmon stocks returning to UK (England \& Wales). The favoured approach for estimating exploitation rates in distant water fisheries is working backwards from estimates of the numbers of each sea-age class of salmon returning to spawn (Potter and Dunkley, 1993; Rago et al., 1993; Potter et al., 2004). River-specific models based on this run reconstruction approach were presented for a number of English and Welsh stocks and ICES notes the inclusion of confidence limits on the estimates of exploitation, which were a further advance on earlier models.

The tagging studies demonstrated that salmon from all parts of England and Wales are exploited in the Irish coastal fishery. However, levels of exploitation have varied between stocks from different regions and from year to year, and have also declined following the introduction of management measures in the Irish fishery in 1997. Based on aggregated data for all available years, the extant exploitation rates for the modelled stocks (1SW fish only) were estimated for the periods before and after the management changes in the Irish fishery.

Prior to the introduction of the management measures, exploitation rates in the Irish fishery were estimated at about $1 \%$ for stocks from the north east of England, higher (15 to 22\%) for the two rivers in Wales, but highest ( $28 \%$ ) for the River Test in southern England. Since the introduction of the regulatory changes, exploitation rates have fallen to $0.5 \%$ for the Tyne (data for one year only), $2-10 \%$ for Welsh rivers, and $12 \%$ for the River Test. While it was not possible to use the modelling approach to estimate exploitation rates for other stocks, the overall pattern of tag recapture rates was consistent with this regional pattern of exploitation.

Noting that exploitation rates in the Irish fishery were higher on hatchery stocks than on wild stocks (e.g. Burrishoole and Bush) ICES advised applying a correction factor where tags from hatchery-reared and wild salmon had been combined to provide adequate tag returns for the analyses.

It therefore appears that exploitation on salmon from northeast England in the Irish fishery is negligible, that exploitation on stocks from northwest England and north Wales is currently low, but that levels increase for rivers further south in Wales and for rivers in southern and possibly southwest England. ICES also recognised that
exploitation rates varied considerably from year to year and that exploitation rates on particular stocks may still be relatively high in some years and negligible in others. For stocks below their conservation limit, ICES noted that even low levels of exploitation may represent an impediment to stock recovery.

In 2004, a number of tags originating from fish released from other countries ( 34 from UK (Northern Ireland), 8 from UK (England \& Wales), 2 from UK (Scotland), 2 from Spain, and 2 from Denmark) were recovered in Irish fisheries.

### 3.10 NASCO has requested ICES to provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved

The effect of specific management measures on stocks and fisheries has been evaluated in a number of NEAC countries. In summary:

## NEAC northern area

Russia - commercial catches have continued to decline as a result of various management changes, including the prohibition of some important in-river fisheries, aimed at reducing the fishing effort and enhancing the development of recreational and catch-and-release fisheries. The mean commercial catch in the last five years (2000-2004) is $26 \%$ below that of the previous five years (1995-1999).

## NEAC southern area

Ireland - legislation has been introduced recently with the objectives of reducing exploitation and increasing escapement. This has resulted in a general decline in exploitation rate on wild salmon from $65 \%$ (pre-1997) to $48 \%$ (post-1997) for wild salmon, and a reduction from $82 \%$ to $67 \%$ for hatchery returns for the same periods. Exploitation on salmon from UK (England \& Wales) in the Irish fishery has also been reduced by about half following the introduction of the management measures in the fishery in 1997 (Section 3.9.8). In the context of increasing escapement, information from index rivers suggests a marginal increase in freshwater survival from $5.1 \%$, on average, (pre-1997) to $5.6 \%$ (post-1997). An increase in returns to freshwater for hatchery stocks is also noted ( $0.8 \%$ to $1.4 \%$ ) for the same periods.

With the recent provision of catch advice for Irish salmon fisheries on a district basis, the emphasis is beginning to shift towards the objective of meeting or exceeding conservation limits in all districts. Although the process is only recent (2002 starting year), and TACs have been set which result in significant reductions in commercial catches, this objective is not as yet being met.

UK (Northern Ireland) - Significant management measures came into effect in 2002, aimed at reducing exploitation on salmon stocks in the Fisheries Conservancy Board (FCB) area. A voluntary buyout agreement with commercial licensed net operators has resulted in a reduction in nets licensed from 27 in 2000 to 6 for the 2004 season. Accompanying measures to regulate angling, first introduced on a voluntary basis in 2001, operated again in 2004. While the impact of these measures on stock status will require some years to fully evaluate, it is noted that the voluntary net buyout scheme probably contributed to the reduction in net catch in the FCB area from 23.4 t in 2001 to 5.8 t in 2004.

UK (England \& Wales) - a review in 2004 demonstrated that, whilst many conservation measures had been implemented, the majority of stocks remained below the CL and a significant number were in decline. An action plan has been drawn up to take forward the recommendations from the review. A range of local and national measures have been implemented over recent years to address concerns about stock status. In particular, measures have been implemented to safeguard MSW 'spring' fish and phase out coastal mixed stock fisheries.

Reductions in spring salmon exploitation were estimated, in 2004, to have increased escapement from net fisheries by around 1200 salmon and by around 2200 from rod fisheries. It is estimated that spawning escapement of spring salmon may have increased by up to one-third on some rivers as a result of these measures.

In 2003, compensation arrangements helped accelerate the phasing out of the mixed stock fishery on the northeast coast. Nine other small coastal mixed stock fisheries have also been subject to reductions in recent years, eight of which are no longer operating. The overall effect of these measures has been to reduce the catches in these coastal fisheries from an average of about 41000 fish for the period 1988-92 to a little under 32000 for the period 1998-2002 and around 11 000 fish in 2003 and 2004.

UK (Scotland) - concerns about the status of early-running MSW salmon led to a voluntary agreement to delay fishing until the beginning of April. Members of the Salmon Net Fishing Association, to which the majority of active net operators are affiliated, have observed this agreement since 2000 . This has resulted in about an $80 \%$ reduction in the
catch of MSW salmon by nets and fixed engines in the months of February and March compared with the previous five years.

France - various measures have been introduced with the objective of reducing exploitation, on MSW fish in particular, and increasing spawning escapement and compliance with river-specific CLs:

Sport and commercial fisheries in the Loire-Allier basin have been closed since 1994 to aid recovery of the population. However, this did not seem to enhance salmon numbers. Physical obstructions and other environmental factors are now considered the more likely impediments to recovery of this population.

In Brittany and Lower Normandy, TACs introduced in 1996 have been successful in reducing catches, although the only monitored river, the Scorff, has failed to meet its CL consistently since 1994. Early season restrictions failed to protect spring salmon. MSW TACs have led to temporary closures on some rivers and have reduced MSW catches in Brittany since 2000 and Lower Normandy since 2003.

In the Adour-Gaves basin, management measures introduced between 1999 and 2003 resulted in some reduction in rod catch, although not in the proportion of MSW caught. Rod catches increased in 2004 once the measures lapsed and there has also been a steady increase in fishing effort and catches in the estuary drift net fishery over the last 5 years. The current regulations have therefore been unable to reduce overall exploitation on MSW salmon.

In conclusion, most management measures introduced in recent years in relation to national and local objectives have aimed to reduce levels of exploitation on NEAC stocks. However, despite these, it is noted that all four NEAC stock complexes are currently outside precautionary limits (Section 3.1).

### 3.11 NASCO has requested ICES to provide an estimate of bycatch of salmon in pelagic fisheries

### 3.11.1 Estimate of bycatch of salmon in pelagic fisheries

Reports over a number of years have indicated the possibility of post-smolts and salmon being intercepted in various pelagic fisheries and in trawl fisheries in particular. However, preliminary estimates derived from observed ratios of salmon and mackerel taken in research and commercial fisheries scaled with the total mackerel catch in the Norwegian Sea have been highly variable (ICES, 2002, 2003, 2004a).

In 2005, ICES reviewed new data made available on disaggregated catches and fishing operations in pelagic fisheries and provided the following guidelines applicable to developing estimates of bycatch of salmon:
only disaggregated pelagic trawl catch data provided on a weekly basis for 2000-2003 would be used, as data prior to then were incomplete.
as some individual years of the Institute of Marine Research (Norway) pelagic surveys had produced very few salmon recaptures resulting in insufficient temporal or spatial coverage, the salmon recapture data series would be pooled (1990-2003).

The weekly distribution of post-smolts and the overlap with pelagic catches was compared for each of the weeks for which post-smolt distributions were available (weeks 21 to 31). Some overlap was noted throughout the period, more significant overlap was identified in weeks $26-28$. The entire period and the more restricted period were both used when estimating the potential post-smolt bycatch.

The detailed description of the various pelagic fisheries was given in ICES (2004b). Based on the area covered and fishing depth, the fishery with the greatest potential to intercept post-smolts was identified to be the near-surface mackerel trawl fishery in the Norwegian Sea.

A number of differences were noted between survey trawls and commercial trawls and it was concluded that only the Russian pelagic survey trawl had design properties similar to the commercial gears in use in the fishery.

Since the end of the 1990s scientific observers have been working onboard Russian vessels fishing herring, mackerel, and blue whiting in the Norwegian Sea. The vessels are subject to inspection by Russian, Norwegian, Faroese, and NEAFC authorities. In addition, all the Russian commercial catches of mackerel, herring, and blue whiting are essentially handled more or less individually and the probability of detecting salmon (either post-smolts or adults) should therefore be very high.

For the purposes of estimating bycatch, it was therefore decided that only the catch data from the Russian research survey and the commercial trawl catch scanning should be used for extrapolation purposes (ICES, 2004). The catch rate
data from Norwegian research surveys targeted at salmon were not used in developing bycatch estimates, as these employ gear which differs substantially in design and use from that used in the commercial fisheries.

## Estimates of the bycatch of post-smolt salmon

Two estimates of post-smolt catch rate (i.e. post-smolts/tonne mackerel) were available based on :
a) Russian research trawl catches;
b) Russian observer-based screening of commercial mackerel catches.

Bycatch estimates were developed by applying these catch rates to disaggregated trawl catches of mackerel:

- Estimates were calculated for the whole area IIA, IVa, and Vb, using disaggregated catches of mackerel in 2001 and 2002;
- Two standard time periods were selected i.e., the total period from which post-smolt records exist (weeks 2131), and the peak period (weeks 26-28);
- Only mackerel catches in rectangles with simultaneous salmon catches were included.

The results indicate a wide variation in potential post-smolt bycatch depending mainly on the catch rates used (Table 3.11.1.1).

ICES notes that the resultant estimates based on the research trawl (40,188-154,482 post-smolts, depending on the range of weeks considered), may overestimate the ratio of post-smolts taken compared to mackerel, as the research trawl operates at lower speed and may thus be less effective in catching mackerel.

In contrast, the estimates based on ratios derived from the observer-based screening and individual handling on board factory ships (14-52 post-smolts, depending on the range of weeks considered), may be underestimates, due to difficulties in observing smolts amongst a large catch of mackerel on board a commercial vessel.

ICES notes that despite using the best available information, including appropriate disaggregation of catches, there is a very wide variation in the results. Therefore, although the estimates are thought to encompass the likely range of bycatch, these values cannot be regarded as formal estimates of bycatch for any particular year or fishery. Further developments and data would be required before bycatch estimates could be used as part of the overall assessment of salmon stocks in the NEAC area or for specific management advice.

Due to the absence of documented ratios of post-smolts or salmon to catches of other species of pelagic fish it is not possible to make any estimates of bycatches from fisheries other than mackerel fisheries at present. ICES recommends that future estimates should be refined, if possible with annual estimates, based on observer-based screening of catches. As yet, no other relevant pelagic fisheries have provided salmon catch rate data, but in the light of information presented to ICES, the possible interception of salmon by e.g. herring or blue whiting fisheries should be further investigated.

Despite this, ICES notes that the upper estimate of potential salmon post-smolt bycatch in the mackerel fishery (154 482 ) represents approximately $5 \%$ of the estimated combined PFA for the NEAC stock complexes (10-year average 3.4 million). As PFA is estimated at $1^{\text {st }}$ January of the first sea winter and the post-smolt surveys are carried out in June/July of the first year at sea, further mortality will take place between the survey and the estimate of PFA; therefore, the percentage of PFA accounted for as bycatch will be lower.

## Estimates of the bycatch of adult salmon

As adult salmon were reported also from the Russian scientific surveys and the observer-based screenings, ICES expanded the analysis carried out on post-smolt bycatch to provide an estimate of adult salmon bycatch.

An example was developed using mackerel catches in weeks 21-32 in 2001, using the whole area approach similar to the post-smolt estimates. The observed ratios of adult salmon to total catch of mackerel from the Russian scientific and commercial fishery have been scaled with the tonnage of mackerel taken in the overlapping rectangle for a specific period, in this case $\pm 2$ weeks from the time when the post-smolt capture was registered. Only catches from those rectangles where salmon have been recorded were used for scaling up. Extrapolation from the research catch shows that the number of adult salmon potentially taken was zero in 2002 and 4460 in 2003. The observer-based estimates were 15 salmon in 2002 and 32 salmon in 2003. The reasons for the differences between adult bycatch estimates are expected to parallel those discussed for the post-smolt estimates.

These estimates only apply to adult salmon in the mackerel fisheries. Similar information was not available for other pelagic fisheries, therefore ICES was not in a position to make estimates for pelagic fisheries other than mackerel.

While it is recognised that direct onboard observation is the most reliable method of bycatch estimation, ICES draws attention to the possibility of using indirect estimation methods (surveys, polls) of commercial fishers to estimate the occurrence and frequency of salmon bycatch in different areas, fisheries, and time of year. These methods may also provide an approximation of the potential number of salmon taken. ICES underlines the importance of having recognised and proven survey professionals operating in such fields as social science research and socio-economic evaluation.

### 3.11.2 Sampling of post-smolts and pre-adults in Norway and the Norwegian Sea

There was only one Norwegian research cruise targeting salmon at sea in 2004. Relevant data was also collected during two surveys aimed at investigating sea lice infections in selected southwestern Norwegian fjords. The targeted cruise for salmon took place in the last part of April between $66-68^{\circ} \mathrm{N}$ and was designed to tag and release adult salmon with DST tags (Section 2.3). There were no cruises dedicated to post-smolt investigations at sea, but the salmon trawl was used during a mackerel egg survey in the area north of Ireland up to the Shetland- Faroes Channel. During this cruise 124 post-smolts were caught at 8 of 14 stations sampled. The last time this area was surveyed was in 1995-97, so these captures extend the database on the temporal and spatial distribution of post-smolts. Relative to other years, the CPUE for post-smolts in the southern area was considered high at 16.2. CPUE for adult salmon captures was calculated for the first time.

Table 3.11.1.1 Estimates of bycatch of salmon post-smolts potentially taken in the Norwegian Sea for two periods in 2001 and 2002

| 2001 | Smolt catch rate/ t mackerel | Period <br> weeks | Catch (t) | Bycatch (n) |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| Russian research survey | 5.93 | $21-31$ | 26051 | 154482 |
| Russian observer programme | 0.002 | $21-31$ | 26051 | 52 |
|  |  |  |  |  |
| Russian research survey | 5.93 | $26-28$ | 6777 | 40188 |
| Russian observer programme | 0.002 | $26-28$ | 6777 | 14 |

| $\mathbf{2 0 0 2}$ | Smolt catch rate/t mackerel | Period <br> weeks | Catch (t) | Bycatch (n) |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| Russian research survey | 5.93 | $21-31$ | 21265 | 126101 |
| Russian observer programme | 0.002 | $21-31$ | 21265 | 43 |
|  |  |  |  |  |
| Russian research survey | 5.93 | $26-28$ | 7594 | 45032 |
| Russian observer programme | 0.002 | $26-28$ | 7594 | 15 |

Figure 3.1.1 Estimated recruitment (PFA), with $95 \%$ confidence limits, and Spawning Escapement Reserve for maturing and non-maturing salmon in Northern \& Southern Europe.

Estimated spawning escapement with $95 \%$ confidence limits,
and conservation limits for 1SW and MSW salmon in Northern \& Southern Europe.

Northern Europe

## Southern Europe

Figure 3.1.2 An overview of the estimated survival indices of wild and hatchery smolts to adult returns to homewaters (prior to coastal fisheries) in Northern and Southern NEAC area. Index values represent averages of standardized ( Z -score) survival estimates for monitored rivers and experimental facilities, and are relative to the average of the time-series ( 0 ). The number of rivers included are indicated in each panel legend.

Figure 3.6.1
PFA trends and predictions (+/- 95\% confidence intervals) for non-maturing 1SW European stock
Note: open square is 2004 update and blocked square is 2005 forecast

Figure 3.11.1.1 ICES fishing Areas.

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted this definition of CLs. Therefore, the CL is a limit reference point ( $\mathrm{S}_{\mathrm{lim}}$ ) which should be avoided with high probability. Management advice for Atlantic salmon is referenced to the $\mathrm{S}_{\text {lim }}$ conservation limit, therefore stocks assessed here are reported as being outside precautionary limits when the confidence limits of the most recent stock estimate includes $\mathrm{S}_{\text {lim }}$.

Management targets have not yet been defined for North Atlantic salmon stocks. When these have been defined they will play an important role in ICES advice.

For catch advice on fish exploited at West Greenland (non-maturing 1SW fish from North America and non-maturing 1SW fish from Southern NEAC), ICES has adopted a risk level of $75 \%$ (ICES, 2003) as part of an agreed management plan. ICES applies the same level of risk aversion for catch advice for homewater fisheries on the North American stock complex.

### 4.1 Status of stocks/exploitation

In 2004, the overall conservation limit $\left(\mathrm{S}_{\mathrm{lim}}\right)$ for 2SW salmon was only met in the Newfoundland area, therefore the stock complexes in the other regions are considered to be outside precautionary limits.

Estimates of pre-fishery abundance suggest a continuing decline of North American adult salmon over the last 10 years. The total population of 1 SW and 2 SW Atlantic salmon in the northwest Atlantic has oscillated around a generally declining trend since the 1970s (Figure 4.9.5.2). During 1993 to 2004, the total population of 1SW and 2SW Atlantic salmon was about 600000 fish, about half of the average abundance during 1972 to 1990 . A $21 \%$ increase however has occurred between 2001 and 2003, the most recent year for which it is possible to estimate the total population. The decline from earlier higher levels of abundance has been more severe for the 2 SW salmon component than for the small salmon (maturing as 1SW salmon) age group.

The returns in 2004 of 2SW fish increased slightly from 2003 in Labrador, Newfoundland, the Gulf of St. Lawrence, and the USA (Figure 4.1.1). In Quebec and Scotia-Fundy, 2SW returns decreased from the previous year. In Newfoundland, the 2SW salmon are a minor age group component of the stocks in this area and even here, decreases of about $30 \%$ have occurred from peak levels of a few years ago. Returns of 1 SW salmon increased from 2003 in all areas (Figure 4.1.2).

When compared to conservation limits, 2SW spawners in 2004 only exceeded the limit in one area (Newfoundland $113 \%$ ); the other areas were less than (Gulf $85 \%$, Quebec 70\%), or substantially less than (Labrador 32\%, Scotia-Fundy $9 \%$, USA 4\%) the limits.

In 2004, estimated return rates for 1SW fish improved somewhat in 2 of 3 hatchery stocks, and 10 out of 11 wild stocks compared to 2003. By contrast, 2SW fish estimated return rates in 2004 decreased in 4 of 6 wild stocks and improved in 2 of 3 hatchery stocks compared to 2003. Measures of marine survival rates over time indicate that survival of North America stocks to home waters has not increased as expected as a result of fisheries changes. There have been no significant increasing trends in survival indices of any of the stock components following the commercial closures in 1992.

Based on the generally improved 1SW returns in 2004, an increase is expected for large salmon in 2005 although return rates of $2 S W$ salmon in monitored stocks remain low. An additional concern is the low abundance level of many salmon stocks in rivers in eastern Canada, particularly in the Bay of Fundy and the Atlantic coast of Nova Scotia. USA salmon stocks exhibit these same downward trends. Most salmon rivers in the USA are hatchery-dependent and remain at low levels compared to conservation requirements. Despite major changes in fisheries management, returns have continued to decline in these southern areas and many populations are "listed" and/or currently threatened with extirpation.

The rank of the estimated returns in the 1971-2004 time-series and the proportion of the 2SW conservation limit achieved in 2004 for six regions in North America is shown below:

Egg depositions by all sea-ages combined in 2004 exceeded or equaled the river specific conservation limits in 43 of the 87 assessed rivers ( $49 \%$ ) and were less than $50 \%$ of conservation limits in 27 other rivers ( $31 \%$ ) (Figure 4.1.3).

### 4.2 Management objectives

This commission area is subject to the general NASCO management objectives as outlined in Section 1.3.

### 4.3 Reference points

In Atlantic Canada, CLs have been set on the basis of stock and recruitment studies which provided for MSY on a limited number of river stocks where data was available, and these derived egg deposition rates were used on the remainder of rivers where only habitat area and spawner demographics were available, as documented in $\mathrm{O}^{\prime}$ Connell et al. (1997). The added production from lacustrine areas in SFA 14B of Labrador and throughout Newfoundland was also accommodated. In USA, conservation limits were set following a similar approach. Recently, for stocks in Quebec, stock-recruitment analysis for six local rivers was used to define the CL, defined as the $\mathrm{S}_{\text {MSY }}$ level at $75 \%$ probability level, calculated by Bayesian analysis. For the purposes of management, egg deposition requirements are converted into 2SW fish equivalents.

There are no changes recommended in the 2SW salmon conservation limits ( $\mathrm{S}_{\mathrm{lim}}$ ) from those identified previously. Conservation limits for 2SW salmon for Canada now total 123349 and for the USA, 29 199, for a combined total of 152548.

### 4.4 Advice on management

As the biological objective is to have all rivers reaching their conservation requirements, river-by-river management is necessary. On individual rivers where spawning requirements are being achieved, there may be surplus available for harvest. Advice regarding management of this stock complex in the fishery at West Greenland is provided in Section 5.4.

### 4.5 Relevant factors to be considered in management

For all fisheries, ICES considers that management should be based upon assessments of the status of individual stocks. Fisheries on mixed stocks, either in coastal waters or on the high seas, pose particular difficulties for management as they cannot target only those stocks that are within precautionary limits. Conservation would be best achieved if fisheries can be targeted at stocks that have been shown to be within precautionary limits. Fisheries in estuaries and rivers are more likely to fulfil this requirement.

## $4.6 \quad$ Catch forecast for 2005

Catch options are only provided for the non-maturing 1SW and maturing 2SW components as the maturing 1SW component is not fished outside of home waters, and in the absence of significant marine interceptory fisheries, is managed in homewaters by the producing nations.

It is possible to provide catch advice for the North American Commission area for two years. The revised forecast for 2005 for 2 SW maturing fish is based on an updated forecast of the 2004 pre-fishery abundance and accounting for fish which were already removed from the cohort by fisheries in Greenland and Labrador in 2004 as 1SW non-maturing fish. The second is an estimate for 2006 (see Section 4.7) based on the pre-fishery abundance forecast for 2005 from Section 5.6.

The updated forecast of the pre-fishery abundance for 2004 provides a PFA mid-point of 118600 .
In order to compare the PFA to conservation limits, the pre-fishery abundance of 118600 can be expressed as 2SW equivalents by considering natural mortality of $3 \%$ per month for 11 months (a factor of 0.72 ), resulting in 85392 2SW salmon equivalents. There have already been harvests of this cohort as 1 SW non-maturing salmon in 2004 for both the Labrador (459) and Greenland (2775) fisheries for a total of 32342 SW salmon equivalents. Adjusted for natural mortality, this equates to 82158 2SW salmon potentially returning to North America in 2005.

As the predicted number of 2 SW salmon returning to North America ( 82 158) in 2005 is substantially lower than the 2SW conservation limit ( $\mathrm{S}_{\text {lim }}$ ) of 152548 , there are no harvest possibilities at forecasted levels (at probability levels of $75 \%$ ). Harvest possibilities refer to the composite North American fisheries. As the biological objective is to have all rivers reaching their conservation requirements, river-by-river management is necessary. On individual rivers where spawning requirements are being achieved, there may be surplus available for harvest.

### 4.7 Medium- to long-term projections

Catch advice for 2006 fisheries on 2SW maturing salmon
Most catches (85\%) in North America now take place in rivers or in estuaries. The commercial fisheries are now closed and the remaining coastal food fisheries in Labrador by aboriginal peoples are mainly located close to river mouths and likely harvest few salmon from other than local rivers. Fisheries are principally managed on a river-by-river basis and, in areas where retention of large salmon is allowed, it is closely controlled.

Catch options which could be derived from the pre-fishery abundance forecast for 2005 (median 120460 ) would apply principally to North American fisheries in 2006, and hence the level of fisheries in 2005 needs to be accounted for before providing them.

Accounting for mortality and the conservation limit and considering an allocation of $60 \%$ of the surplus to North America, the only risk averse catch option for 2SW salmon in 2006 is "zero" catch. This "zero" catch option refers to the composite North American fisheries.

### 4.8 Comparison with previous assessment and advice

The revised forecast of the pre-fishery abundance for 2004 provides a PFA mid-point of 118600 . This is about $18 \%$ higher than the 100400 value forecast last year. This is mainly due to slight changes in the input values to the model used to forecast PFA for these stocks, as detailed in Section 5.10.

### 4.9 NASCO has asked ICES to describe the key events of the 2004 fisheries and the status of the stocks

### 4.9.1 Gear and effort

Canada

There were no commercial fisheries in Canada in 2004.
Salmon fisheries in the Maritime provinces of Canada are managed by the Department of Fisheries and Oceans in 23 Salmon Fishing Areas (SFAs); and in Québec by the Société de la Faune et des Parcs du Québec, in fishing areas Q1 through Q11 (Figure 4.9.1.1). Three user groups exploited salmon in Canada in 2004: Aboriginal peoples, residents fishing for food in Labrador, and recreational fishers. For the first time in 2004, the Labrador Metis Nation was included in arrangements for a food fishery. The Metis fishery was controlled by a negotiated quota of 10 t . On an individual fisher basis, the catch was limited by the issuance of 6 tags, which had to be applied to the fish. No fish could be landed without a tag.

There were no other changes in gear and effort in Canada.

## USA

There was no fishery for sea-run Atlantic salmon in the USA in 2004 as a result of angling closures in 1999. Therefore, effort measured by license sales, was zero.

## France (Islands of St. Pierre and Miquelon)

In 2004, there were 13 professional and 42 recreational gillnet licenses issued for the fishery that operates between May 1 and July 31. Due to a sharp decline in other fish resources exploited by the professional fishermen (lumpfish, snow crab, and cod), more of them have expressed interest in having salmon licenses. An increase in the number of professional licences could be compensated by a reduction in the number of recreational licences.

| Year | Number of <br> Professional <br> Licenses | Number of <br> Recreational <br> Licenses |
| :---: | :---: | :---: |
| $\mathbf{1 9 9 5}$ | 12 | 42 |
| $\mathbf{1 9 9 6}$ | 12 | 42 |
| $\mathbf{1 9 9 7}$ | 6 | 36 |
| $\mathbf{1 9 9 8}$ | 9 | 42 |
| $\mathbf{1 9 9 9}$ | 7 | 40 |
| $\mathbf{2 0 0 0}$ | 8 | 35 |
| $\mathbf{2 0 0 1}$ | 10 | 42 |
| $\mathbf{2 0 0 2}$ | 12 | 42 |
| $\mathbf{2 0 0 3}$ | 12 | 42 |
| $\mathbf{2 0 0 4}$ | 13 | 42 |

### 4.9.2 Catches in 2004

Catch histories of salmon, expressed as 2SW salmon equivalents, which could have been available to the Greenland fishery, 1972-2004, are provided in Tables 4.9.2.1 and 4.9.2.2. The Newfoundland-Labrador commercial fisheries were historically, mixed stock fisheries and harvested both maturing and non-maturing 1SW salmon as well as 2SW maturing salmon. Mortalities within North America peaked at about 365000 in 1976 and are now about 13200 2SW salmon equivalents. In the most recent five years estimated (that is those since the closure of the Labrador commercial fishery), those taken as non-maturing fish in Labrador comprise 3\%, or less, of the total in North America.

Of the North American fisheries on the cohort destined to be 2 SW salmon, $74 \%$ of the catch comes from terminal fisheries in the most recent year. This value has ranged from as low as $20 \%$ in 1973, 1976 and 1987 to values of 74$91 \%$ in 1996-2004 fisheries (Table 4.9.2.1). The percentage increased significantly since 1992 with the reduction and closures of the Newfoundland and Labrador commercial mixed stock fisheries however this value decreased in 2004 to $74 \%$ from $83 \%$ in 2003. The number of 2SW salmon equivalents taken in the food fisheries in Labrador (3412) in 2004 was the highest since the commercial fishery closed in 1997.

The percentage of the total 2SW equivalents that have been harvested in North American waters has ranged from 48$100 \%$, with the most recent year estimated at $87 \%$ (Table 4.9.2.2.)"

## Canada

The provisional harvest of salmon in 2004 by all users was 159 t , about $13 \%$ higher than the 2003 harvest (Figure 4.9.2.1). The 2004 harvest was 52726 small salmon and 12941 large salmon, $13 \%$ more small salmon and $15 \%$ more large salmon, compared to 2003.

Aboriginal food fishers accounted for harvests in 2004 of $60.4 \mathbf{t}$, about 18400 fish ( $56 \%$ small by number) and were up $35 \%$ from both the 2003 and the previous 5 -year average harvest, while for residents fishing for food in Labrador the estimated catch in 2004 was 2.2 t , about 880 fish ( $75 \%$ small salmon by number).

Harvest in recreational fisheries in 2004 totalled 46377 small and large salmon, $2 \%$ below the previous 5 -year average, $8 \%$ above the 2003 harvest level, and the second lowest total harvest reported (Figure 4.9.2.2). The small salmon harvest of 41802 fish was $3 \%$ below the previous 5 -year mean. The large salmon harvest of 4575 fish was about $2 \%$ greater than the previous five-year mean. Small and large salmon harvests were up $9 \%$ and down $3 \%$ from 2003, respectively. In 2004, about 57000 salmon were caught and released, representing about $55 \%$ of the total number caught. This was a $6 \%$ increase from the number released in 2003.

Unreported catches in Canada were estimated at about 118 t .

All fisheries (commercial and recreational) for sea-run Atlantic salmon within the USA remained closed, including rivers previously open to catch-and-release fishing. Thus, there was no legal harvest of sea-run Atlantic salmon in the USA in 2004.

Unreported catches in the USA were estimated to be 0 t .

## France (Islands of St. Pierre and Miquelon)

The total harvest in 2004 was reported to be 2.8 t from professional and recreational fishers, about the same as in 2003 and among the largest recorded since 1983. There was no estimate of unreported catch.

### 4.9.3 Origin and composition of catches

The Aboriginal peoples' and resident food fisheries that exist in Labrador may intercept some salmon from other areas of North America although there are no reports of tagged fish being captured there. The fisheries of Saint-Pierre and Miquelon catch salmon of North American origin. Sampling was carried out on this fishery in 2003 and 2004 (Section 4.11).

The returns in 2004 to the majority of the rivers in Newfoundland and to most rivers of the Gulf of St. Lawrence and Québec were comprised exclusively of wild salmon. Hatchery-origin salmon made up varying proportions of the total returns and were most abundant in the rivers of the Bay of Fundy, the Atlantic coast of Nova Scotia, and the USA.

Aquaculture escapees were noted in the returns to the Magaguadavic and St. Croix rivers of the Bay of Fundy. In the Magaguadavic River, which is located in close proximity to the centre of both the Canadian and USA east coast salmon farming areas, the proportion of the adult run composed of fish farm escapees has been high (greater than $50 \%$ ) since 1994 and $89 \%$ in 2004. However, while fish farm escapees have dominated the run in terms of percentages, in absolute terms, their numbers have been trending downwards. Fish farm escapees were also monitored in the international St. Croix River (Canada/USA border), and Maine's Dennys, Narraguagus, and Union rivers. Percentages of returns that were fish farm escapees in the returns to the St. Croix in 2004 were $29 \%$, whereas no escapees were noted in the USA rivers.

### 4.9.4 Exploitation rates

## Canada

There is no exploitation by commercial fisheries and exploitation rates for the remaining fisheries have not been reported.

## USA

There was no exploitation of USA salmon in home waters.

### 4.9.5 Pre-Fishery Abundance

ICES used the North American run-reconstruction model to estimate pre-fishery abundance, which serves as the basis of abundance forecasts used in the provision of catch advice. The catch statistics used to derive returns and spawner estimates are routinely updated from those used in the previous year (ICES 2004/ACFM:20). In addition, in 2005, ICES revised the basis for updating estimates of returns and spawners for Labrador, as follows:

The basis for estimates of 2SW and 1SW salmon returns and spawners for Labrador (SFAs 1, 2 \& 14B) prior to 1998 are catch data from angling and commercial fisheries. In 1998, the commercial fishery in Labrador was closed and so the model developed to determine returns and spawners from commercial catch data could not be used. In 2002-2004, salmon counting facilities were installed on four out of about 100 Labrador rivers with salmon (one in SFA 1B, northern Labrador and three in SFA 2).

Based on three years of data, small and large salmon returns per accessible drainage area in these four rivers were extrapolated to accessible drainage areas of unmonitored rivers in Labrador. The accessible drainage areas in Labrador were $9267 \mathrm{~km}^{2}$ for Lake Melville (SFA 1A), $25485 \mathrm{~km}^{2}$ for northern Labrador (SFA 1B), $28160 \mathrm{~km}^{2}$ for southern Labrador (SFA 2), and $2651 \mathrm{~km}^{2}$ for the Straits Area (SFA 14B). Accessible drainage area in the monitored rivers was $1878 \mathrm{~km}^{2}$, resulting in an expansion factor of 35 to one.

Not all rivers in Lake Melville were included due to a lack of information on the presence of salmon. ICES recognized that this was a crude method for deriving returns and spawners for Labrador and encouraged the installation of additional counting facilities and collection of additional information on drainage areas and salmon occurrence, particularly for Lake Melville.

Comparison of PFA values including the new data for deriving returns and spawners for Labrador, 2002-2004, indicated only minor differences in results between old and new PFA values. Thus, ICES adopted these PFA values for predictive purposes and the provision of catch advice.

As the pre-fishery abundance estimates for potential 2SW salmon requires estimates of returns to rivers, the most recent year for which an estimate of PFA is available is 2003. This is because pre-fishery abundance estimates for 2004 require 2SW returns to rivers in North America in the year 2005. The 2003 abundance estimates ranged between 78572 and 146249 salmon. The mid-point of this range ( 112410 ) is almost identical to the 2002 value ( 112282 ) and is the $5^{\text {th }}$ lowest in the 32 -year time-series (Figure 4.9.5.1). Even though the 2003 value has increased by $33 \%$ from the 84561 value in 2001, which was the lowest in the time-series, the general trend towards lower values in recent years is still evident and current year values are still much lower than the 917282 in 1975.

For the 1 SW cohort, the mid-point values of the pre-fishery abundance are shown in Figure 4.9.5.1. The mid-point of the range of pre-fishery abundance estimates for 2004 (456 002) is $15 \%$ higher than in 2003 ( 395831 ) and $48 \%$ higher than the low 1994 value of 309034 , which was the lowest estimated in the time-series 1971-2004. The reduced values observed in 1978 and 1983-84 and 1994 were followed by large increases in pre-fishery abundance.

Although the declining trend appears common to both maturing and non-maturing (Figure 4.9.5.2) portions of the cohort, non-maturing 1 SW salmon have declined further.

### 4.10 NASCO has requested ICES to evaluate the extent to which the objectives of any significant management measures introduced in recent years have been achieved

New management measures introduced in Labrador in 2004 resulted in changes within allocations among Aboriginal peoples' food fisheries. It is not possible yet to evaluate the effects of these management measures.

### 4.11 NASCO has asked ICES to provide an analysis of any new biological and/or tag return data to identify the origin and biological characteristics of Atlantic salmon caught at St. Pierre and Miquelon

Sampling of the fishery took place in both 2003 and 2004 and was reported to ICES in 2005. The sampling programme was designed to provide a representative sample of the fishery. Approximately $30 \%$ of the reported catch was sampled in each year:

|  | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ |
| :--- | :---: | :---: |
| No. periods | 12 | 11 |
| Sampling Time Period | June 4- July 6 | June 5 - June 29 |
| Gutted weight sampled (kg) | 872 | 837 |
| Number of fish sampled | 340 | 355 |
| Fish sampled for scales | 0 | 166 |
| Fish sampled for genetics | 0 | 25 |

The size distribution of fish sampled was similar in both years. Two distinct size modes were noted, with the smaller fish averaging approximately 56 cm and the larger fish averaging approximately 76 cm . The smaller sized fish represented about $80 \%$ of those sampled.

Scale analysis provided information on the age of salmon captured in the fishery in 2004 . There were three sea-ages noted in the 143 usable scale samples: 1SW (81.1\%), 2SW ( $18.2 \%$ ), and a repeat spawner ( $0.7 \%$ ). River-age distributions (based on 141 fish) were: river-age $1(0.7 \%) ; 2(29.8 \%) ; 3(49.7 \%) ; 4(17.7 \%)$, and $5(2.1 \%)$.

Results were not yet available on the genetic origin of the 25 sampled fish. The river-age distribution is generally characteristic of eastern Canadian wild stocks, except for the single river-age 1 fish, which likely originated from a hatchery in Canada or from a hatchery or river in the USA. No tag returns were obtained from this fishery in 2004.

### 4.12 Data deficiencies and research needs

Data deficiencies and research needs are presented in Section 6.

| Year i | CANADA |  |  |  |  |  |  |  |  |  | USA | Total | Terminal Fisheries as a \% of Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | MIXED STOCK |  |  |  | TERMINAL FISHERIES IN YEAR i |  |  |  |  |  |  |  |  |
|  | NF-LAB Comm 1SW (Year i-1) (b) | Year i $\%$ 1SW of total 2SW equivalents | Year i NF-LAB Comm 2SW (b) | $\begin{gathered} \text { Year i } \\ \text { NF-Lab } \\ \text { comm total } \end{gathered}$ | Labrador rivers (a) | Nfld rivers <br> (a) | Quebec Region | $\begin{array}{r} \text { Gulf } \\ \text { Region } \\ \hline \end{array}$ | Scotia Fundy Region | $\begin{gathered} \text { Canadian } \\ \text { total } \\ \hline \end{gathered}$ |  |  |  |
| 1972 | 20,857 | 9 | 153,775 | 174,632 | 314 | 633 | 27,417 | 22,389 | 6,801 | 232,186 | 346 | 232,532 | 25 |
| 1973 | 17,971 | 6 | 219,175 | 237,146 | 719 | 895 | 32,751 | 17,914 | 6,680 | 296,105 | 327 | 296,433 | 20 |

### 5.1 Status of stocks/exploitation

## ICES considers the stock complex at West Greenland to be outside precautionary limits.

The salmon caught in the West Greenland fishery are mostly ( $>90 \%$ ) non-maturing 1 SW salmon, most of which would be destined to return to homewaters in Europe or North America as MSW fish if they survived. There are also 2SW salmon and repeat spawners. The most abundant European stocks in West Greenland are thought to originate from the UK and Ireland, although low numbers may originate from northern European rivers. Most MSW stocks in North America are thought to contribute to the fishery at West Greenland.

## North American stocks

ICES notes that the North American stock complex of non-maturing salmon has declined to record low levels and is in tenuous condition. The forecast PFA for this stock complex for 2005 is 120400 . Despite the closure of Newfoundland (1992), Labrador (1998), and Québec (2000) commercial fisheries, sea survival of adults returning to rivers has not improved and in some areas has declined further. The abundance of maturing 1SW salmon has also declined in many areas of eastern North America. Smolt production in 2003 and 2004 in monitored rivers of eastern Canada was similar to the average of the last five years. Unless sea survival improves, the abundance of non-maturing 1 SW salmon in the Northwest Atlantic is not expected to increase above the levels of the last five years and is more likely to decline.

A summary of the stock status by region is provided below:

| Newfoundland: | 2SW spawners are within precautionary limits. |
| :--- | :--- |
| Labrador: | 2SW spawners are outside precautionary limits $\left(32 \%\right.$ of $\left.2 \mathrm{SW} \mathrm{S}_{\text {lim }}\right)$. |
| Québec: | 2SW spawners are outside precautionary limits $\left(70 \%\right.$ of $\left.2 \mathrm{SW} \mathrm{S}_{\text {lim }}\right)$. |
| Gulf of St. Lawrence: | 2SW spawners are outside precautionary limits $\left(85 \%\right.$ of $\left.2 \mathrm{SW} \mathrm{S}_{\text {lim }}\right)$. |
| Scotia-Fundy: | 2SW spawners are outside precautionary limits $(9 \%$ of 2 SW S |
| Unim $).$ |  |
|  | 2SW spawners are outside precautionary limits $\left(4 \%\right.$ of 2 SW Ster $\left.\mathrm{S}_{\text {lim }}\right)$. Stocks in 8 rivers are <br> listed as Endangered under the Endangered Species Act |

ICES noted that tentative exploitation rates for non-maturing 1SW fish at West Greenland can be calculated by dividing the recorded harvest of 1 SW salmon of North American origin at West Greenland by the PFA estimate for the corresponding year. This indicates that exploitation rates in the last five years have averaged around $5 \%$ compared to values prior to 1993 averaging $26 \%$, and suggests that recent management measures in this fishery have reduced exploitation in this stock complex.

## European stocks

ICES also noted that the non-maturing 1SW salmon from southern Europe have been declining steadily since the 1970s (Figure 3.6.1), and the preliminary quantitative prediction of pre-fishery abundance for this stock complex is low for 2005 (486 000 fish).

The main contributor to the abundance of the European component of the West Greenland stock complex is nonmaturing 1SW salmon from southern Europe. The percentage of European fish in catches at West Greenland was around $30 \%$ in the early 1990 s and the 2000s, but was below $20 \%$ from 1996 to 1999 . The contributions of countries within NEAC, based on historic tagging data are: France, 2.7\%; Ireland, 14.7\%; UK (England \&Wales), 14.9\%; UK (Northern Ireland), $<0.01 \%$; UK (Scotland), $64.5 \%$; and northern NEAC countries, $3.2 \%$. Southern European MSW salmon stocks in the NEAC area consistently declined over the past $10-15$ years, and the stock complex has been outside precautionary limits in recent years.

A summary of the status of multi-sea winter (MSW) stocks known to contribute to the West Greenland fishery and which originate from the southern NEAC countries is presented below:

| France: | MSW spawners are outside precautionary limits |
| :--- | :--- |
| Ireland: | MSW spawners are outside precautionary limits |
| UK (England \& Wales): | MSW spawners are outside precautionary limits |
| UK (Northern Ireland): | MSW spawners are within precautionary limits |
| UK (Scotland): | MSW spawners are outside precautionary limits |

The status of stocks in the NEAC and NAC areas are presented in the relevant commission sections of this report.

ICES notes that the relative proportions of the historical and forecast PFA values for the NAC and southern NEAC stock complexes are not consistent with the relative proportions of the NAC and Southern NEAC salmon in the fishery at West Greenland, as determined from the sampling programme (Section 5.9). The reasons for this apparent discrepancy are not immediately obvious but warrant further investigation.

### 5.2 Management objectives

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted this definition of CLs (NASCO, 1998). Therefore, the CL is a limit reference point ( $\mathrm{S}_{\mathrm{lim}}$ ) which should be avoided with high probability. Management advice for Atlantic salmon is referenced to the $S_{\text {lim }}$ conservation limit.

For management advice for the West Greenland fishery, NASCO has adopted a precautionary management plan:
NASCO considers quotas at West Greenland with the management objectives of meeting the conservation limits $\left(\mathrm{S}_{\mathrm{lim}}\right)$ simultaneously in the four northern regions of North America: Labrador, Newfoundland, Quebec, and Gulf.

Further, for the two southern regions, Scotia-Fundy and USA, where there is a zero chance of meeting conservation limits, the alternate objective has been to achieve increases in returns relative to previous years with the hope that this may lead to the rebuilding of stocks.

In 2004, ICES established 1992 to 1996 as the range of years to define the baseline for the Scotia-Fundy and USA regions to assess $\mathrm{PFA}_{\mathrm{NA}}$ abundance and fishery options. Improvements of greater than $10 \%$ and greater than $25 \%$ relative to returns during this base period are evaluated.

The management plan in place for this stock complex at West Greenland does not require that this total conservation requirement is achieved, this provides NASCO with consistent criteria to assess performance of the fisheries management being considered. Although not a formal management objective, ICES also calculates the probability of returns to North America being equal or less than the previous five-year average when considering the current low marine survival and the recent status of the stock complex.

### 5.3 Reference points

Sampling of the fishery at West Greenland since 1985 has shown that European and North American stocks harvested are primarily (greater than $90 \%$ ) 1SW non-maturing salmon destined to mature as either 2 or 3 SW salmon. Usually less than $3 \%$ of the harvest is composed of salmon that have previously spawned and a few percent are 2SW salmon that would mature as 3SW or older salmon. Therefore, conservation limits defined for North American stocks have been limited to the 2SW salmon. These numbers have been documented previously by ICES and are in Section 4.3. The 2SW spawner limits of salmon stocks from North America total 152548 fish.

Conservation limits for the NEAC area have been split into 1SW and MSW components on the basis of the average age composition of catches in the past ten years. The stocks have also been partitioned into northern and southern stock complexes, as tagging information and biological sampling indicates that the majority of the European salmon caught at West Greenland originate from the southern stock complex. The current conservation limit estimate for southern European MSW stocks is approximately 278000 fish (Section 3.3). There is still considerable uncertainty in the conservation limits for European stocks and estimates may change from year to year as the input of new data affects the estimate of CL from the pseudo-stock-recruitment relationship.

### 5.4 Advice on management

ICES provides management advice for the West Greenland fishery, based on the NAC stocks, and for the combined NAC and NEAC stock complexes.

ICES advises that there should be no catch on these stock complexes in 2005 at West Greenland.
Analyses carried out in Section 4 illustrate that attainment of CLs for the NAC stock complex is highly sensitive to the magnitude of catch at West Greenland. Therefore, where catches are allowed, it is imperative that fishing is closely monitored and full details are provided to ICES (Section 5.9.1).

For all fisheries, ICES considers that management should be based upon assessments of the status of individual stocks. Fisheries on mixed stocks, either in coastal waters or on the high seas, pose particular difficulties for management as they cannot target only those stocks that are within precautionary limits. Conservation would be best achieved if fisheries can be targeted at stocks that have been shown to be within precautionary limits. Fisheries in estuaries and rivers are more likely to fulfil this requirement.

### 5.6 Catch forecast for 2005

## Catch forecast for the NAC area

For 2005, the $\mathrm{PFA}_{\mathrm{NA}}$ forecast remains among the lowest of the time-series with a median value of 120400 fish and a $75 \%$ probability that the abundance will be less than 153200 fish (i.e. highly unlikely to meet the 2SW spawner reserve of 212189 salmon to North America) (Figure 5.6.1). In the absence of any marine-induced fishing mortality, there is a very low probability ( $9 \%$ probability) that the returns of 2 SW salmon to North America in 2006 will be sufficient to meet the conservation requirements of the four northern regions (Labrador, Newfoundland, Quebec, and Gulf) (Table 5.6.1). There is essentially no chance ( $<1 \%$ ) that the returns in the southern regions (Scotia-Fundy and USA) will be greater than the returns observed in the 1992 to 1996 base period.

## None of the stated management objectives would allow a fishery to take place.

Furthermore, ICES notes that even in the absence of a fishery there is a $64 \%$ probability that returns of 2 SW fish in these regions in 2006 will be less than the average of the period 1999 to 2003.

## Catch forecast for the NAC/NEAC combined

ICES followed the process developed last year for providing catch advice for West Greenland, using the PFA and CLs of the NAC and NEAC areas. The PFA for NAC and NEAC are applied in parallel to the Greenland fishery and then combined at the end of the process into a single catch advice table. In the absence of any fishery at West Greenland, there is a less than $75 \%$ probability that the MSW conservation limit for southern Europe will be met (Table 5.6.1).

## None of the stated management objectives in NAC or NEAC would allow a fishery to take place.

### 5.7 Medium- to long-term projections

Projections of PFA are not made beyond one year for either the NAC or the NEAC. Based on available lagged spawners the provision of catch advice for the West Greenland fishery would be possible up to 2007. However, to extend the forecast, a number of assumptions in addition to those within the current models would need to be made. In order to progress with this objective, ICES carried out further exploratory analyses (Section 2.3.5) to extend PFA predictions over medium- and long-term ( 5 and 20 years) time scales.

### 5.8 Comparison with previous assessment and advice

The current modelling approach was applied to the PFA ${ }_{\text {NA }}$ series that now includes the 2003 PFA to update the 2004 forecast. The median value of the updated analysis has increased to 114600 fish from 100000 based on the previous year's model and data. The upper bound on the distribution remained unchanged.

### 5.9 NASCO has requested ICES to describe the events of the 2004 fishery and status of the stocks

At its annual meeting in June 2004 NASCO agreed to restrict the fishery at West Greenland to that amount used for internal subsistence consumption in Greenland, which in the past has been estimated at $20 t$. Consequently, the Greenlandic authorities set the commercial quota to nil, i.e. landings to fish plants, sale of salmon to shops, and commercial export of salmon from Greenland was forbidden. Licensed fishermen were allowed to sell salmon at the open markets, to hotels, restaurants, and institutions. A private fishery for personal consumption without a license was allowed. All catches, licensed and private, were to be reported to the License Office on a daily basis. In agreement with the Organisation for Fishermen and Hunters in Greenland the licensed fishery for salmon was allowed from the $9^{\text {th }}$ of August to the end of the year. The consequences in terms of overall catches of extending the allowed fishing period are unknown.

By the end of the season a total of 14.7 t of landed salmon were reported. In total, 169 reports were received. The geographical distribution of the reported catches differed from all recent years with catches in NAFO Div. 1A and 1B comprising approximately $27 \%$ of landings reported. The catch from NAFO Division $1 F$ was less than $15 \%$ of the reported landings (Table 5.9.1.1). In the last few years approximately $50 \%$ of the catch was in NAFO Div 1F. The catch was distributed relatively evenly across the weeks, perhaps even increasing in weeks 44 and 45 . In the last few years, reported catches decreased during the season.

The number of active participants in the salmon fishery has decreased sharply since 1987 , when a catch of more than 900 tons was allowed and more than 500 licenses were active in the fishery. In 2004 there were 151 licenses issued, similar to the 152 in 2003. In 2004, of the 66 fishers who reported catch, only 24 were licensed. However, the total number of fishers reporting is an increase from approximately 40 active fishers in 2002 and 2003. ICES notes that sampling provided more fish than were reported in Nuuk, confirming that the nominal catch is an underestimate. In addition, ICES has been unable to estimate average CPUE values for several years.

There is presently no quantitative approach to estimating the magnitude of personal consumption or subsistence fishing in this fishery. Since 2000, an arbitrary figure for unreported catch of 10 t has been proposed; however, there is no method to verify the accuracy.

### 5.9.2 Biological characteristics of the catches

The international programme to sample landings at West Greenland has continued. The sampling program in 2004 included sampling teams from Greenland, Ireland, United Kingdom, and United States. Teams were in place at the start of the fishery and continued through October. In total, 1890 specimens, representing $40 \%$ by weight of the reported landings, were sampled for presence of tags or fork length, weight, scales, and tissue samples for DNA analysis. The broad geographic distribution of the subsistence fishery caused practical problems for the sampling teams. However, the sampling program adequately sampled the Greenland catch temporally. The sampling teams at Nuuk sampled larger amounts of salmon than reported for sale in the official statistics. Therefore, the total reported landings were corrected for the total weight of fish sampled for assessment purposes.

Tissue and biological samples were collected from three landing sites: Qaqortoq (NAFO Div. 1F), Nuuk (NAFO Div. 1D), and Maniitsoq (NAFO Div. 1C) (Figure 5.9.1.1). Biological characteristics (length, weight, or age) were recorded from approximately 1800 fish in catches from NAFO Div. 1C, 1D and 1F in 2004 (Table 5.9.1.1). The smallest fish sampled was 54 cm fork length and weighed 1.46 kg gutted weight, while the largest was 95 cm and weighed 10.30 kg . The average weight of a fish from the 2004 catch was 3.18 kg , with North American 1 SW fish averaging 64.7 cm and European 1SW fish averaging 64.2 cm in length (Table 5.9.1.1). The mean lengths and mean weights for the 2004 samples were among the highest in the last decade.

The river ages of European salmon ranged from 1 to 5 (Table 5.9.1.1). Over half ( $58 \%$ ) of the European fish in the catch were river-age 2 and $20 \%$ were river-age 3 . Although the proportion of the European origin river-age 1 salmon in the catch has been variable in the last 15 years, it has been between $9 \%$ and $18 \%$ since 2001 . North American salmon up to river-age 6 were caught at West Greenland in 2004, with over half being river-age 3 ( $52 \%$ ).

In $2004,97 \%$ of the European samples were 1 SW salmon, with previous spawners $0.2 \%$ of the samples and 2 SW salmon $2.8 \%$. One sea winter salmon dominated (97\%) the North American component, with repeat spawners comprising $2.5 \%$ of the samples (Table 5.9.1.1).

The sampling team stationed in Nuuk obtained 120 whole fish for disease testing. Tissue samples were tested for the presence of ISAv by RT-PCR assay only and all test results were negative. The sex of 115 salmon collected in Nuuk was determined; of these $35(30 \%)$ were males and $80(70 \%)$ females. ICES recommends that sex be determined on as many whole fish as practicable, and methods be considered for determining sex on gutted fish.

A total of 1639 samples were genotyped at four microsatellites. In total, 1192 (72.7\%) of the salmon sampled from the 2004 fishery were of North American origin and 447 (27.3\%) fish were determined to be of European origin (Table 5.9.1.1). Applying the continental percentages to the nominal total catch (14.7 t) resulted in estimates of 9.9 t of North American origin and 4.8 t of European origin fish ( 3900 and 1500 rounded to the nearest 100 fish, respectively) landed in West Greenland in 2004 (Fig. 5.9.2.1). Greenland at a finer resolution than continent of origin (river stocks, country or stock complexes).

In 2005 an updated probabilistic genetic assignment (PGA) model was applied to the 2000-2002 West Greenland fisheries data, assigning both continent and country of origin based on genotyping at 11 loci traditionally used for continent of origin assignment (King et al., 2001). The suite of 11 loci allowed for suitable classification accuracy within North America to the country of origin level.

The PGA model 90\% confidence intervals for the North American and European contributions to the West Greenland fishery encompass the deterministic point estimates previously reported by ICES. Canadian origin fish dominated the North American component of the harvest, ranging from $96 \%$ to $99 \%$ for the period 2000-2002.

ICES has previously noted that reference baseline datasets for the European and Canadian stock complexes lacked adequate spatial and temporal coverage for finer scale assignments with acceptable accuracy. Some progress has been made to bolster reference datasets; however, deficiencies remain, particularly for NEAC stocks. An international collaboration is currently establishing a reference genetic dataset to improve the ability of assigning origin of Atlantic salmon caught during any mixed stock fishery or sampling endeavour at a finer resolution than continent of origin (river stocks, country, or stock complexes).

### 5.10 NASCO has requested ICES to provide a detailed explanation and critical examination of any changes to the models used to provide catch advice

The forecast model used to estimate pre-fishery abundance of 2 SW salmon in 2005 was the same as that used in 2004 (ICES, 2003). The approach accounts for uncertainty in the data and in model selection. The overall approach of modelling the natural log transformed $\mathrm{PFA}_{\mathrm{NA}}$ and $\mathrm{LS}_{\mathrm{NA}}$ using linear regression and the Monte Carlo method used to derive the probability density for the $\mathrm{PFA}_{\mathrm{NA}}$ forecast was also retained from 2004.

The lagged spawner variable used in the forecast model is an index of the 2SW parental stock of the PFA. It provides a means of examining the value in managing for spawning escapement and predicting recruitment in existing fisheries. The lagged spawner index was the sum of the lagged spawner estimates for six regions of North America. ICES developed a method for deriving Labrador spawners for the recent years and therefore Labrador is again included in the index (Section 4.9.5). With the inclusion of Labrador, the lagged spawner series begins in the 1978 year of PFA.

### 5.10.1 North American Forecast Model

The advice for any given year has been dependent on obtaining a reliable predictor of the abundance of non-maturing 1SW North American stocks prior to the start of the fishery in Greenland. A two-phase regression between North American pre-fishery abundance ( $\mathrm{PFA}_{\mathrm{NA}}$ ) and lagged spawners $\left(\mathrm{LS}_{\mathrm{NA}}\right)$, assuming a break between the phases occurred during 1989 or 1990, was described in 2003 and elaborated upon in 2004. This pattern was reinforced with the addition of the $2003 \mathrm{PFA}_{\mathrm{NA}}$ estimate (Figure 5.10.1.1). The relative recruits $\left(\mathrm{PFA}_{N A}\right)$ per spawner index $\left(\mathrm{LS}_{\mathrm{NA}}\right)$ has declined from an average of 5.7 during 1978-1989 to an average of 1.9 during the period 1990 to 2003 (Figure 5.10.1.1).

As in 2004, 42 models were fitted to each dataset derived using Monte Carlo simulation. These models included two models without phase shifts, plus five models with phase shifts and with eight possible break year points (1986 to 1993) for each model (Table 5.10.1.1). In each simulation the most parsimonious model was selected using Akaike's Information Criterion and this selected model was used to generate a value for the probability density for the 2005 $P F A_{N A}$.

Seven models and eight break years (1986 to 1993) were run for ten thousand datasets of $\mathrm{PFA}_{\mathrm{NA}}$ and $\mathrm{LS}_{\mathrm{NA}}$ created based on the estimated ranges for each year and PFA. One $\mathrm{PFA}_{N A}$ prediction was carried forward for the parsimonious model for each randomly selected dataset. For phase shift models, the probability of being in either phase was based on changes in PFA $_{N A}$ from year $t$ to year $t-2$ (Figure 5.10.1.2). The approach taken in 2005 was identical to the method used in 2003 and 2004. The two-year lag is used because current year PFA (i.e 2004) is not available due to its dependence upon $2 S W$ returns in the next year.

Although it was possible that up to 42 models might be represented in estimating the distribution of $\mathrm{PFA}_{\mathrm{NA}}$, those selected most often were model III and VII and break years 1989 through 1992 (see below). The lagged spawner index variable was informative for $\mathrm{PFA}_{\mathrm{NA}}$ in $63 \%$ of the simulated data sets. In such cases, the break years describing the phase shift were mostly 1991 and to lesser extents, 1992, 1989, and 1988. Model VII (intercept through the origin) was favoured more often ( $57 \%$ of all models). In $37 \%$ of the data sets, the lagged spawner variable (Model III) was uninformative and therefore this model with two means describing phases in PFA was selected. The corresponding break years were 1991 and 1992. For the 2005 forecast of $\mathrm{PFA}_{N A}$, the probability (runs/10 000) of being in the high phase was negligible ( $0.6 \%$ ) and the probability of being in the lower productivity phase was over $99 \%$.

| Model | Phase | $\mathbf{1 9 9 8}$ | $\mathbf{1 9 8 9}$ | $\mathbf{1 9 9 0}$ | $\mathbf{1 9 9 1}$ | $\mathbf{1 9 9 2}$ | $\mathbf{1 9 9 3}$ | Models |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| III | High | $\mathbf{0}$ | 0 | 0 | $\mathbf{0}$ | $\mathbf{1}$ | 0 | $\mathbf{0}$ |
|  | Low | 0 | 0 | 0 | 2260 | $\mathbf{1 3 9 5}$ | 0 | 3656 |
| VII | High | $\mathbf{1}$ | 4 | 1 | 29 | 12 | 0 |  |
|  | Low | 273 | $\mathbf{1 3 7 5}$ | $\mathbf{1} 62$ | 2616 | 1206 | $\mathbf{1}$ | 5680 |
| IV to VI | High | 10 | 6 | 0 | 0 | 0 | 0 |  |
|  | Low | 300 | 285 | 4 | 48 | 11 | 0 | 664 |

|  | Low | 573 | $\mathbf{1 6 6 0}$ | $\mathbf{1 6 6}$ | 4924 | 2612 | $\mathbf{1}$ | 9936 |

### 5.10.2 Critical evaluation of model updates

Critical evaluations of updates to the model input data were documented during the process of developing catch advice. These include:

- Application of the updated model to estimate the 2004 PFA produced a higher estimate (median 118600 ) than the estimate provided last year (median 100000 ).
- The lagged spawner variable used in the model declined in 2005 to its lowest value and was used to predict PFA using spawner abundances that are outside the range of previously observed values. The uncertainty of associations increases as the predictor variable gets farther from the mean, which has been the case for the 2004 and 2005 projections.

### 5.11 Provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved

Based on the previous five-year average biological characteristics of 1SW non-maturing salmon in the fishery at West Greenland, each tonne of salmon catch equates to $316-366$ fish ( $5^{\text {th }}$ to $95^{\text {th }}$ percentiles). After discounting for eleven months of natural mortality, each tonne not harvested equates to 159 to 187 ( $5^{\text {th }}$ to $95^{\text {th }}$ percentiles) fish returning to home waters in North America and 64 to 80 ( $5^{\text {th }}$ to $95^{\text {th }}$ percentiles) salmon returning to European home waters. Because these spawners are distributed among a large number of rivers on both continents, it has been difficult to show direct benefits to individual stocks. No further information is available on the effect of recent management measures.

### 5.12 Data deficiencies and research needs

Data deficiencies and research needs for West Greenland are presented in Section 6.

Table 5.6.1 Probability of meeting the 2SW conservation limits simultaneously in the four northern areas of North America (Labrador, Newfoundland, Quebec, Gulf), of achieving increases in returns from the 1992 to 1996 base year average in the two southern areas (Scotia-Fundy and USA) of the NAC area, and of meeting the MSW conservation limit of the southern European stock complex relative to quota options for West Greenland. A sharing arrangement of $40: 60\left(\mathrm{~F}_{\mathrm{NA}}\right)$ of the salmon from North America and southern European MSW stocks was assumed.

| West Greenland <br> Harvest <br> (t) | Simultaneous |  | Improvement (SF, USA) |  | Conservation |
| :---: | :---: | :---: | :---: | :---: | :---: |

### 6.1 Data deficiencies and research needs

## Recommendations from Section 2 - Atlantic salmon in the North Atlantic Area:

1) ICES recommends that in regions where fishery closures have not resulted in stock rebuilding, urgent research work should be continued to forecast population viability, to determine the cause or causes of declines, and activities should be implemented to reverse declining population trends.
2) Coordinated tagging/tracking studies should be carried out to give information on migration, distribution, survival, and growth of escaped farmed salmon.
3) Further basic research is needed on the spatial and temporal distribution of salmon and their predators at sea to assist in explaining variability in survival rates:

- As depth and temperature recording tags (DSTs) have proven to be a good method in assessing the marine life history of salmon, further DST-tagging experiments on smolts, adult salmon, and kelts should be conducted in different areas of the North Atlantic area.
- Experimental trawling surveys should be conducted to evaluate the vertical distribution of post-smolts and older salmon in the sea, if possible in combination with tagging of post-smolts and salmon with DST tags.

## Recommendations from Section 3-Fisheries and Stocks from the North East Atlantic Commission Area:

1) Further progress should be made in establishing a PFA predictive model using the PFA of maturing 1SW salmon, in addition to the spawner term, as a predictor variable for the PFA of non-maturing 1SW in the northern NEAC area.
2) Efforts should be made in developing PFA estimation models for smaller units than national levels as marine survival may vary between rivers and regions and temporal variation in marine growth and abundance are more correlated between rivers in small geographical areas than between rivers more distant to each other.

## Recommendations from Section 4 - Fisheries and Stocks from the North American Commission Area:

1) There is a need to develop habitat-based spawner requirements in Labrador, and to monitor salmon returns in the Ungava region of Québec.
2) There is a need to investigate changes in the biological characteristics (mean weight, sex ratio, sea-age and river-age composition) of returns to rivers, of smolt output, of spawning stocks of Canadian and US rivers, and the harvest in food fisheries in Labrador. These data and new information on measures of habitat and stock recruitment are necessary to re-evaluate existing estimates of spawner requirements in Canada and USA and for use in the run reconstruction model.
3) ICES recommends that the smolt age distribution for the six North American areas be re-evaluated on a five-year schedule.

## Recommendations from Section 5 - Atlantic Salmon in the West Greenland Commission Area:

1) Continued efforts should be made to improve the estimates of the annual catches of salmon taken for private sales and local consumption in Greenland.
2) Efforts should be made by the Home Rule Government of Greenland to provide information on the extent of fishing activity by all license holders.
3) The mean weights, sea and freshwater ages and continent of origin are essential parameters to provide catch advice for the West Greenland fishery. In addition, sampling to determine sex on as many whole fish as practicable and methods to test for ISAv and other diseases in Atlantic salmon caught in West Greenland should be included in the program. Methods for determining sex on gutted individuals should be considered. ICES recommends that the sampling program be continued and closely coordinated with a fishery harvest plan to be executed annually in West Greenland.

ICES considers that the identification of data deficiencies and research requirements, although mainly driven by specific tasks under the terms of reference, was assisted by reference to the NASCO inventory of on-going research into salmon mortality in the sea.
