### 4.1 Ecosystem overview

This Section has not been updated in 2012. The most recent ecosystem overview is available in ICES Advisory Report 2008, Section 4.1. This overview can also be found on the ICES website: http://www.ices.dk/committe/acom/comwork/report/2008/2008/4.1-4.2\ Faroe\% $\% 20$ plateau $\% 20$ ecosvstem $\% 20$ overview.pdf

### 4.2 Human impacts on the ecosystem

### 4.2.1 Fishery effects on benthos and fish communities

This Section has not been updated in 2012. The most recent description on Fishery effects on benthos and fish communities is available in ICES Advisory Report 2008, Section 4.2. This description can also be found on the ICES website http://www.ices.dk/committe/acom/comwork/report/2008/2008/4.1-4.2\ Faroe\% $\% 20$ plateau $\% 20$ ecosvstem $\% 20$ overview.pdf:

### 4.3 Assessments and Advice

### 4.3.1 Assessment and advice regarding protection of biota and habitats

In 2012, ICES has not provided advice regarding protection of biota and habitats for this area.

### 4.3.2 Assessments and Advice regarding fisheries

## Mixed fisheries and fisheries interactions

This Section has not been updated in 2012. The most recent description on mixed fisheries and fisheries interactions is available in ICES Advisory Report 2008, Section 4.3. ## Sources of Information

ICES. 2008. Report of the ICES Advisory Committee, 2008. ICES Advice, 2008. Book 4.
n The state and advice of the individual stocks are presented in the stock sections. The state of stocks and advice (according to the Section 1.2) are summarized in the table below.
Table 4.3.2.1 State of the stock and advice in the Faroe Plateau ecoregion.

| Stock | State of the stock |  |  |  | Outlook options |  |  | ICES advice (in tonnes or effort) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Fishing mortality in relation to $\mathrm{F}_{\mathrm{MSY}}$ | Fishing mortality in relation to precautionary approach ( $\mathrm{F}_{\mathrm{PA}} / \mathrm{F}_{\text {lim }}$ ) | Spawning <br> biomass <br> relation <br> MSY <br> Mriger | Spawning biomass <br> relation  <br> precautionary <br> approach $\left(\mathrm{B}_{\mathrm{PA}} / \mathrm{B}_{\mathrm{lim}}\right)$  <br>   | MSY approach (within the precautionary approach) | Precautionary approach / considerations | Management plan |  |
| Faroe Plateau Cod | Above target | Increased risk | Below trigger | Increased risk | Effort should be reduced such that fishing mortality in 2013 will be no more than $\mathrm{F}=0.20$, corresponding to a $63 \%$ reduction in the present fishing mortality | F below Fpa of 0.35 translate into reduction in fishing mortality by $30 \%$ as compared to the average of the last 3 years | - | MSY approach: $F<0.20$ |
| Faroe Bank Cod | $\qquad$ | $\qquad$ | $\qquad$ | $\qquad$ | - | Closure of the fishery | - | Same advice as last year: Zero catch |
| Faroe Haddock | Above target | Increased risk | Below trigger | Reduced reproductive capacity | F in 2013 should be no more than FMSY * B2013 / MSY Btrigger $=$ 0.15 | No direct fishing; minimize bycatch; implement recovery plan | - | Precautionary considerations: Zero catch |
| Faroe Saithe | Above target | Harvested unsustainably | Above trigger | Full reproductive <br> capacity  <br>   | Effort should be reduced such that fishing mortality in 2013 will be no more than $\mathrm{F}=0.28$, corresponding to an $44 \%$ reduction in the present fishing mortality | Fishing mortality to be no more than $\mathrm{Fpa}=0.28$, resulting in a reduction of $44 \%$ in present fishing mortality | - | MSY approach: <br> $\mathrm{F}<0.28$  |

The advice for Ling appears in ICES Advice 2012. Section 9.4.10.3 on Widely Distributed Stocks. This is a biennial advice.
Table 4.3.2.2 Summary of the stock categories in the Faroe Plateau ecoregion (see section 1.2 for category definitions).

| Total Number of stock in the ecoregion | 4 |
| :--- | :--- |
| Data rich stocks | 3 |
| Data-limited stocks | 1 |

Status of data rich stocks ( $\mathrm{n}=3$ ) for the Faroe Plateau ecoregion relative to MSY and PA reference points for Fishing Mortality (F) and Spawning Stock Biomass (SSB). Table shows percentage of stocks per stock status. Values in brackets denote the number of data rich stocks per stock status.

## ECOREGION Faroe Plateau ecosystem <br> STOCK Cod in Subdivision $\mathbf{V b}_{1}$ (Faroe Plateau)

## Advice for 2013

ICES advises on the basis of the MSY approach that effort should be reduced such that fishing mortality in 2013 will be no more than $\mathrm{F}=0.20$, corresponding to a $63 \%$ reduction in the present fishing mortality.

## Stock status

Figure 4.4.1.1 Cod in Subdivision $\mathrm{Vb}_{1}$ (Faroe Plateau). Summary of stock assessment (weights in thousand tonnes). Top right: SSB/F for the time-series used in the assessment.

SSB has remained around $B_{l i m}$ since 2005. Fishing mortality has decreased since 2002 and is now between $F_{\text {lim }}$ and $F_{p a}$. but still above $\mathrm{F}_{\mathrm{MSY}}$. The 2009 year class is estimated to be below average.

## Management plans

A group representing the Ministry of Fisheries, the Faroese industry, the University of the Faroe Islands, and the Faroe Marine Research Institute has developed a management plan based on general maximum sustainable yield (MSY) principles developed by ICES. The plan has not yet been discussed by the political system.

## Biology

Recent work suggests that cannibalism is a controlling factor of recruitment. In periods with low ecosystem productivity, the individual growth of cod is slow, and some of them move into the nearshore nursery areas of 1-group cod, which reduce the recruitment of 2-year-old cod the following year.

## Environmental influence on the stock

The productivity of the Faroe Shelf ecosystem is important to the cod stock. Cod recruitment depends both on stock size and primary production of the Faroe Shelf ecosystem. The indices of primary production have been low since 2002, excepting 2004 and 2008-2010 when they were estimated to be above average. Cod individual growth is highly correlated with the ratio of total phytoplankton production to total fish biomass (cod+haddock+saithe), i.e. "food per fish", in the outer areas (water depth $130-500 \mathrm{~m}$ ) of the Faroe Plateau. Phytoplankton production in those areas has remained above average since 2000 .

## The fisheries

Cod are mainly taken in a directed cod and haddock fishery with longlines, in a directed jigging fishery, and as bycatch in the trawl fishery for saithe.

Catch distribution Total landings (2011) are 10 kt , where $62 \%$ was taken by the longlines, $7 \%$ by jigging, $31 \%$ by trawlers, and $0.1 \%$ by other gear types. There was no industrial bycatch or unaccounted removals.

## Quality considerations

The landing data are considered accurate. There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. Estimates of F in the terminal year have varied considerably.

Figure 4.4.1.2 Cod in Subdivision $\mathrm{Vb}_{1}$ (Faroe Plateau). Historical assessment results (final year recruitment estimates included).

## Management plan

A management system based on number of fishing days, closed areas, and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced precautionary approach (PA) and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the haddock exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\mathrm{MSY}}$ of 0.35 and 0.32 respectively. ICES considers this to be inconsistent with the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be consistent with the ICES advice. This new management plan should include a stepwise reduction of the fishing mortality to $\mathrm{F}_{\mathrm{MSY}}$ in 2015 and a recovery plan if the SSB declines below the $\mathrm{B}_{\text {trigger }}$. The MSY $\mathrm{B}_{\text {trigger }}$ has been defined at 40 kt (the former $\mathrm{B}_{\mathrm{pa}}$ ) and $\mathrm{F}_{\mathrm{MSY}}$ at 0.32 . If the SSB declines below the MSY $\mathrm{B}_{\text {trigger }}$, the fishing mortality will be reduced by the relationship $\mathrm{F}_{\mathrm{MSY}} * \mathrm{~B}_{\text {act }} / \mathrm{B}_{\text {trigger }}$ until the SSB has increased again above the MSY $B_{\text {trigger }}$ and is thereafter kept at $\mathrm{F}_{\text {MSY }}$.

## MSY approach

ICES advises on the basis of the MSY approach to reduce fishing mortality by $63 \%$ in 2013 to 0.20 . This is $38 \%$ below $\mathrm{F}_{\text {MSY }}$, because SSB in 2013 is $38 \%$ below MSY $\mathrm{B}_{\text {trigger }}$.

## Precautionary approach

The fishing mortality should be kept below an $\mathrm{F}_{\mathrm{pa}}$ of 0.35 . This translates into a reduction in fishing mortality by $30 \%$ as compared to the average of the last 3 years ( 0.51 ).

## Additional considerations

## Management considerations

The present estimate of $\mathrm{F}_{\text {MSY }}$ should be regarded as provisional. Simulation studies that take the productivity of the ecosystem into account have been tried, but this model is still under development.

One of the expected benefits of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are at low levels. However, low prices on saithe and haddock and high prices for cod have kept the fishing mortality high on cod; the economic factors seem to be more important than the relative abundance of the stocks in determining which species is targeted. When considering future management, protection mechanisms should be included to ensure that appropriate action is taken when one or more stocks or fisheries develop in an unfavourable way.

It is not easy to control fishing mortality by effort management if catchability varies. For baited hook gear, catchability may be related to the amount of food available in the ecosystem (Steingrund et al., 2009). Therefore, during the current low-productive period, fishing mortality may increase even though the number of fishing days is decreased.

## Regulations and their effects

An effort management system was implemented 1 June 1996. Fishing days are allocated to all fleets fishing in waters $<380 \mathrm{~m}$ depth for the period 1 September-31 August. In addition the majority of the waters <ca. 200 m depth are closed to trawlers, and are mainly utilized by longliners. The main spawning areas for cod are closed for nearly all fishing gears during spawning time. In 2011, additional areas were closed in order to protect incoming year classes of cod.

## Changes in fishing technology and fishing patterns

The effort management system can lead to improvement of fishing technology and efficiency. Presently, ICES is not able to quantify these changes.

Comparison with last year's assessment and advice
The perception of the status of the stock with respect to reference points and trends in this year's assessment is similar to that of last year's assessment.. Comparing the 2010 estimates in last year's assessment (2011) with this year's assessment (2012) shows that recruitment has been revised downwards by $21 \%$, the spawning-stock biomass revised downwards by $23 \%$, and the fishing mortality revised upwards by $42 \%$.

The basis of the advice is the same as last year.

## ECOREGION Faroe Plateau ecosystem STOCK Cod in Subdivision $\mathbf{V b}_{\mathbf{2}}$ (Faroe Bank)

## Advice for 2013

New data on landings and indices from the two annual Faroese surveys ( 2011 summer, 2012 spring) do not change the perception of the stock since 2008 and do not give reason to change the advice from 2011. The advice for the fishery in 2013 is therefore the same as the advice given since 2008: "Because of the very low stock size ICES advises that the fishery should be closed. Reopening the fishery should not be considered until both survey indices indicate a biomass at or above the average of the period 1996-2002".

## Management considerations

The Faroe Bank has been closed to fishing since 1 January 2009. However, in 2010 and 2011, respectively, a total of 61 and 100 fishing days were allowed to small jiggers in the shallow waters of the Bank. The closure advice should apply to all fisheries.

## ECOREGION <br> Faroe Plateau ecosystem <br> STOCK

## Advice for 2013

ICES advises that there should be no directed fishery on haddock in 2013. Measures should be put in place to minimize by-catches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

## Stock status

Figure 4.4.3.1 Haddock in Division Vb. Summary of stock assessment (weights in thousand tonnes). Top right: SSB/F for the time-series used in the assessment.

SSB has decreased since 2003 and in 2012 it is estimated to be below $\mathrm{B}_{\text {lim. }}$. The fishing mortality has decreased from above $\mathrm{F}_{\text {lim }}$ in 2003 to just above $\mathrm{F}_{\text {MSY }}$ for the last 3 years. Year classes from 2003 onwards have all been well below the long-term average.

## Management plans

A group representing the Ministry of Fisheries, the Faroese industry, the University of the Faroe Islands, and the Faroe Marine Research Institute has developed a management plan based on general maximum sustainable yield (MSY) principles developed by ICES. The plan has not yet been discussed by the political system.

## Biology

Since the mid-1970s, recruitment has fluctuated with 1-3 strong year classes followed by several weak to moderate ones. Mean weights-at-age have also fluctuated in this period.

## Environmental influence on the stock

A positive relationship has been documented between primary production and the individual fish growth and recruitment $1-2$ years later.

## The fisheries

Haddock are mainly caught in a directed longline fishery for cod and haddock and as by-catches in trawl fisheries for saithe. Normally, longline gears account for $80-90 \%$ of the catches. In 2011 longlines accounted for $82 \%$ of the catches.

Catch distribution Total landings (2011) are 3.5 kt , where longliners accounted for $82 \%$ and trawlers for $18 \%$. No discards and no unaccounted removals.

## Quality considerations

The landings data are considered accurate. There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. No major problems have been observed with the tuning indices (the two surveys).

Figure 4.4.3.2 Haddock in Division Vb. Historical assessment results (final-year recruitment estimates included).

## Scientific basis

| Assessment type | XSA using age-disaggregated indices. |
| :--- | :--- |
| Input data | Two survey indices (spring and summer survey). |
| Discards and bycatch | No discards included. Discarding is not considered to be a major problem in this fishery. |
| Indicators | Primary productivity index. |
| Other information | Biomass indices from two commercial fleets. |
| Working group report | NWWG |

## Management plan

A management system based on number of fishing days, closed areas, and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced precautionary approach (PA) and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the haddock exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\text {MSY }}$ of 0.25 . ICES considers this to be inconsistent with the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be consistent with the ICES advice. This management plan includes a stepwise reduction of the fishing mortality to $\mathrm{F}_{\text {MSY }}$ in 2015 and a recovery plan if the SSB declines below the MSY $\mathrm{B}_{\text {trigger. }}$. The MSY $\mathrm{B}_{\text {trigger }}$ has been defined at 35 kt (the former $\mathrm{B}_{\mathrm{pa}}$ ) and $\mathrm{F}_{\text {MSY }}$ at 0.25 . If the SSB declines below the MSY $\mathrm{B}_{\text {trigger }}$, the fishing mortality will be reduced by the relationship $\mathrm{F}_{\text {MSY }} * \mathrm{~B}_{\text {act }} /$ MSY $\mathrm{B}_{\text {trigger }}$ until the SSB has increased again above the MSY $\mathrm{B}_{\text {trigger }}$ and is thereafter kept at $\mathrm{F}_{\mathrm{MSY}}$.

## MSY approach

Based on stochastic simulations MSY preliminary analyses suggested an $\mathrm{F}_{\text {MSY }}=0.25$. Work is still needed to confirm these analyses. Using this $\mathrm{F}_{\text {MSY }}$ value and given that SSB in 2013 is estimated below MSY $\mathrm{B}_{\text {trigger }}$, fishing mortality should be reduced further. F in 2013 should be no more than $\mathrm{F}_{\mathrm{MSY}} * \mathrm{~B}_{2013} / \mathrm{MSY} \mathrm{B}_{\text {trigger }}=0.15$.

## Precautionary approach

Given the recent poor recruitment and slow growth and the low SSB, the forecast indicates that even a zero fishing mortality in 2013 will not result in getting the stock above $\mathrm{B}_{\mathrm{lim}}$ in 2014. There should therefore be no directed fishery on haddock. Measures should be put in place to minimize bycatches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

## Additional considerations

## Management considerations

An expected benefit of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are in bad shape. This assumption is, however, not always correct; e.g. low prices for saithe and haddock and high prices for cod kept the fishing mortality higher than expected for cod. Management should include measures that avoid a disproportionate targeting of depleted stocks.

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability may be related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease haddock production and increase the catchability of longline gear.

An explicit management plan based on the MSY approach needs to be implemented, clearly stating what to do when the stock is very low.

In recent years only a fraction of the allocated number of fishing days has actually been utilized.

## Impacts of the environment on the fish stocks

The productivity of the Faroe Shelf ecosystem is important to the haddock stock. The recruitment depends both on the spawning-stock biomass and on the productive state of the Faroe Shelf ecosystem. A positive relationship has been demonstrated between primary production and the cod and haddock individual fish growth and recruitment 1-2 years later. The primary production indices were above average in 2008-2010; however, this has resulted in only marginally improved recruitment of haddock.

## Regulations and their effects

An effort management system was implemented 1 June 1996. Fishing days are allocated to all fleets fishing in waters $<380 \mathrm{~m}$ depth for the period 1 September-31 August. In addition, the majority of the waters $<\mathrm{ca} .200 \mathrm{~m}$ depth are closed to trawlers and are mainly utilized by longliners.

## Changes in fishing technology and fishing patterns

The effort management system can lead to improvement of fishing technology efficiency. Presently, ICES is not able to quantify these changes.

## Uncertainties in assessment and forecast

Recent years have revealed a consistent retrospective pattern of overestimating SSB and underestimating F. This bias seems to be small in the most recent years, however.

## Comparison with previous assessment and advice

This year's assessment shows that the 2011 assessment overestimated the 2010 recruitment by around $30 \%$, underestimated the fishing mortality in 2010 by $8 \%$, and overestimated the 2010 total and spawning-stock biomasses by $15 \%$ and $12 \%$, respectively.

The advice last year was for no directed fishery on haddock in 2012, based on the precautionary approach and to minimize bycatches in other fisheries. This year's advice is based on the MSY approach.

## ECOREGION Faroe Plateau ecosystem <br> STOCK Saithe in Division Vb

## Advice for 2013

ICES advises on the basis of the MSY approach that effort should be reduced such that fishing mortality in 2013 will be no more than $\mathrm{F}=0.28$, corresponding to an $44 \%$ reduction in the present fishing mortality.

Figure 4.4.4.1 Saithe in Division Vb. Summary of stock assessment (weights in thousand tonnes). Top right: SSB/F for the time-series used in the assessment.

SSB has decreased substantially since 2006 but remains above MSY $B_{\text {trigger }}$. Recruitment in 2011 was above average. Fishing mortality has decreased since 2009 and is above $\mathrm{F}_{\mathrm{MSY}}$.

## Management plans

A group representing the Ministry of Fisheries, the Faroe industry, the University of the Faroe Islands, and the Faroe Marine Research Institute has developed a management plan based on general maximum sustainable yield (MSY) principles developed by ICES. The plan has not yet been discussed by the political system.

## Biology

Saithe in Division Vb is regarded as one management unit although tagging experiments have demonstrated migrations between the Faroes, Iceland. Norway, west of Scotland, and the North Sea. Nursery areas for saithe are found very close to land (in the littoral zone). These areas are not covered by the existing surveys and therefore recruitment estimates are not available until saithe enter the fishery at age 3 ; this hampers the prediction of biomass and catch.

## Environmental influence on the stock

Preliminary studies suggest a positive relationship between ocean productivity (gyre index) and the biomass of saithe.

## The fisheries

Saithe are mainly caught in a directed trawl fishery (pair and single trawlers), with bycatches of cod and haddock.
Catch distribution Total landings (2011) are 29 kt , of which $91 \%$ was taken by pair trawlers. $4.5 \%$ by single trawlers, and $3.6 \%$ by jiggers.

## Quality considerations

There are no incentives to discard fish under the effort management system. The sampling of the landings has increased since 2009 and is considered to be adequate. Recruitment indices are only available from age 3 and this is a source of uncertainty in recent recruitment estimates and forecast.

## Management plan

A management system based on number of fishing days, closed areas, and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced precautionary approach (PA) and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the haddock exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\text {MSY }}$ of 0.25 . ICES considers this to be inconsistent with the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be consistent with the ICES advice. This management plan includes a stepwise reduction of the fishing mortality to $\mathrm{F}_{\text {MSY }}$ in 2015 and a recovery plan if the SSB declines below the MSY $\mathrm{B}_{\text {trigger. }}$. The MSY $\mathrm{B}_{\text {trigger }}$ has been defined at 55 kt (the former $\mathrm{B}_{\mathrm{pa}}$ ) and $\mathrm{F}_{\text {MSY }}$ at 0.28 . If the SSB declines below the MSY $\mathrm{B}_{\text {trigger, }}$, the fishing mortality will be reduced by the relationship $\mathrm{F}_{\mathrm{MSY}} * \mathrm{~B}_{\text {act }} / \mathrm{B}_{\text {trigger }}$ until the SSB has increased again above the MSY $\mathrm{B}_{\text {trigger }}$ and is thereafter kept at $\mathrm{F}_{\text {MSY }}$.

## MSY approach

Following the ICES MSY framework implies that fishing mortality in 2013 should be no more than $\mathrm{F}_{\mathrm{MSY}}=0.28$, resulting in a reduction of $44 \%$ in the present fishing mortality.

## Precautionary approach

Following the precautionary approach implies that fishing mortality in 2013 should be no more than $\mathrm{F}_{\mathrm{pa}}=0.28$, resulting in a reduction of $44 \%$ in present fishing mortality.

## Additional considerations

## Management considerations

The number of fishing days for pair trawlers was reduced by $10 \%$ for the fishing year (2010/2011), but a further reduction of effort is required to bring F at or below $\mathrm{F}_{\text {MSY }}$. The present spawning closures should be maintained for pair trawlers and applied for other fleets also.

## Regulations and their effects

The principal fleets fishing for saithe are pair trawlers, single trawlers, and jiggers. The average annual landings from these fleets since the introduction of the present management system are about $78 \%, 17 \%$, and $4 \%$, respectively. The pair trawlers, jiggers, and single trawlers are regulated by total number of allocated fishing days and by area closures.

Limited sampling in the blue whiting fishery in Faroese waters indicates that bycatches of saithe have been minor since the mandatory use of sorting grids was introduced from 15 April 2007 in the areas west and northwest of the Faroe Islands.

## Changes in fishing technology and fishing patterns

The effort management system can lead to improvement of fishing technology and efficiency. Presently, ICES is not able to quantify these changes.

## Uncertainties in the assessment and forecast

The potential for bias in commercial cpue (for example hyper-stability) is a serious concern for shoaling species such as saithe. For this assessment, in addition to the pairtrawler cpue, which is a measure of saithe density in its core area of distribution, the range of the spatial distribution of saithe was considered, using survey information, when constructing an abundance index for saithe. This approach is considered to reduce the bias. The assessment is very uncertain, with large revisions from year to year. Recruitment indices are only available from age 3 and this is a source of uncertainty in recent recruitment estimates and forecast.

Comparison with last year's assessment and advice
SSB in 2010 and 2011 has been revised downwards by $35 \%$ and $40 \%$, respectively, compared to last year's estimates. F in 2009 and 2010 has been revised upwards by $14 \%$ and $40 \%$, respectively. The basis for the advice is the same as last year.
