# ICES COOPERATIVE RESEARCH REPORT 

## RAPPORT DES RECHERCHES COLLECTIVES

NO. 246

# Report of the ICES Advisory Committee on Fishery Management, 2001 

Copenhagen, 22 May - 31 May 2001
Copenhagen, 9 October - 17 October 2001

## PART 1 OF 3

[^0]
## TABLE OF CONTENTS

PART 1 OF 3
Section PagePreface
Participants at Meetings, Spring and Autumn 2001
1 ICES ADVICE ..... i
1.1 The Form of ICES Advice ..... i
2 INTRODUCTORY ITEMS ..... iv
2.1 Introduction ..... iv
2.2 Quality of Fishery Statistics ..... v
2.3 Catch projections for the current and following year ..... v
3 REVIEW OF STOCKS .....  1
3.1 Stocks in the North-East Arctic (Sub-areas I and II) .....  1
3.1.1 Overview .....  .1
3.1.2 Cod in Sub-areas I and II ..... 3
3.1.2.a North-East Arctic cod ..... 3
3.1.2.b Norwegian coastal cod ..... 11
3.1.3 North-East Arctic Haddock (Sub-areas I and II) ..... 17
3.1.4 North-East Arctic saithe (Sub-areas I and II) ..... 25
3.1.5 Redfish in Sub-areas I and II ..... 31
3.1.5.a Sebastes mentella in Sub-areas I and II ..... 31
3.1.5.b Sebastes marinus in Sub-areas I and II ..... 38
3.1.6 Greenland halibut in Sub-areas I and II ..... 44
3.1.7.a Norwegian spring-spawning herring. ..... 52
3.1.7.b Answer to special request on Norwegian spring-spawning herring ..... 60
3.1.8 Barents Sea capelin (Sub-areas I and II, excluding Division IIa west of $5^{\circ} \mathrm{W}$ ) ..... 65
3.1.9 Shrimp (Pandalus borealis) ..... 71
3.2 Stocks in North-Western Areas (Division Va and Sub-areas XII and XIV) ..... 75
3.2.1 Overview ..... 75
3.2.2 Cod ..... 77
3.2.2.a Greenland cod (ICES Sub-area XIV and NAFO Sub-area 1) ..... 77
3.2.2.b Icelandic cod (Division Va) ..... 82
3.2.3 Icelandic haddock (Division Va) ..... 89
3.2.4 Saithe in Icelandic waters (Division Va) ..... 94
3.2.5 Greenland halibut in Sub-areas V and XIV ..... 100
3.2.6 Redfish in Sub-areas V, VI, XII and XIV ..... 109
3.2.6.a Overview ..... 109
3.2.6.b Sebastes marinus in Sub-areas V, VI, XII and XIV ..... 124
3.2.6.c Deep-sea Sebastes mentella on the continental shelf in Sub-areas V, VI and XIV ..... 129
3.2.6.d Pelagic fishery for Sebastes mentella in the Irminger Sea ..... 135
3.2.7 Icelandic summer-spawning herring (Division Va) ..... 140
3.2.8 Capelin in the Iceland-East Greenland-Jan Mayen area (Sub-areas V and XIV and Division Ila west of $5^{\circ} \mathrm{W}$ ) ..... 146
3.2.9 Answer to Special Request on Redfish ..... 150
3.3 Demersal stocks at the Faroe Islands (Division Vb) ..... 153
3.3.1 Overview ..... 153
3.3.2 Cod ..... 157
3.3.2.a Faroe Plateau cod (Sub-division $\mathrm{Vb}_{1}$ ) ..... 157
3.3.2.b Faroe Bank cod (Sub-division $\mathrm{Vb}_{2}$ ) ..... 164
3.3.3 Faroe haddock (Division Vb ) ..... 168
3.3.4 Faroe saithe (Division Vb) ..... 174
3.3.5 Answer to Special Request on Probability Profiles of Fishing Mortalities ..... 180
3.4 Stocks in the Skagerrak and Kattegat (Division IIA) ..... 181
3.4.1 Overview ..... 181
3.4.2 Cod in the Kattegat ..... 184
3.4.3 Whiting in Division IIIa (Skagerrak - Kattegat) ..... 190
3.4.4 Plaice in Division IIIa (Skagerrak - Kattegat) ..... 192
3.4.5 Sole in Division IIIa ..... 198
3.4.6 Pandalus borealis in Division IIIa and Division IVa East (Skagerrak and Norwegian Deeps) ..... 204
3.4.7 Herring in Sub-divisions 22-24 and Division IIIa (spring spawners) ..... 209
3.4.8 Sprat in Division HIa ..... 215
3.4.9 Sandeel in Division IIIa (Skagerrak - Kattegat) ..... 218
3.4.10 Anglerfish in Division IIIa (Skagerrak - Kattegat) ..... 219
3.5 Stocks in the North Sea (Sub-area IV) ..... 221
3.5.1 Overview ..... 221
3.5.2 Cod in Sub-area IV (North Sea), Division VIId (Eastern Channel) and Division IIIa (Skagerrak) ..... 230
3.5.3 Haddock in Sub-area IV (North Sea) and Division IIla (Skagerrak - Kattegat) ..... 241
3.5.4 Whiting in Sub-area IV (North Sea) and Division VIIId (Eastern Channel) ..... 250
3.5.5 Saithe in Sub-area IV (North Sea), Division IIIa (Skagerrak) and Sub-area VI (West of Scotland and Rockall) ..... 258
3.5.6 Plaice in Sub-area IV (North Sea) ..... 266
3.5.7 Sole in Sub-area IV (North Sea) ..... 273
3.5.8 Herring in Sub-area IV, Division VIId and Division IIIa (autumn spawners) ..... 280
3.5.9 Sprat in the North Sea (Sub-area IV) ..... 296
3.5.10 Mackerel (North Sea component) ..... 300
3.5.11 North Sea horse mackerel (Trachurus trachurus) (Division IIIa (eastern part), Divisions IVb,c, VIId) ..... 300
3.5.12 Norway pout in Sub-area IV (North Sea) and Division IIIa (Skagerrak - Kattegat) ..... 305

## TABLE OF CONTENTS

## PART 2 OF 3

Section Page
3.5.13 Sandeel ..... 311
3.5.13.a Sandeel in Sub-area IV ..... 311
3.5.13.b Sandeel in the Shetland area ..... 319
3.5.14 Pandalus borealis ..... 321
3.5.14.a Pandalus borealis in Division IVa (Fladen Ground) ..... 321
3.5.14.b Pandalus borealis in Division IVb (Farn Deeps) ..... 324
3.5.15 Anglerfish in Sub-area IV ..... 326
3.6 Stocks in the Eastern Channel (Division VIId) ..... 327
3.6.1 Overview ..... 327
3.6.2 Sole in Division VIId (Eastern Channel) ..... 328
3.6.3 Plaice in Division VIId (Eastern Channel) ..... 334
3.7 Stocks in Sub-area VI ..... 340
3.7.1 Overview ..... 340
3.7.2 Cod ..... 342
3.7.2.a Cod in Division VIa (West of Scotland) ..... 342
3.7.2.b Cod in Division VIb (Rockall) ..... 348
3.7.3 Haddock ..... 350
3.7.3.a Haddock in Division VIa (West of Scotland) ..... 350
3.7.3.b Haddock in Division VIb (Rockall) ..... 356
3.7.3.c Meeting to address Request from NEAFC to ICES on Rockall haddock ..... 361
3.7.4 Whiting ..... 399
3.7.4.a Whiting in Division VIa (West of Scotland) ..... 399
3.7.4.b Whiting in Division VIb (Rockall) ..... 404
3.7.5 Saithe in Sub-area VI (West of Scotland and Rockall) ..... 406
3.7.6 Megrim in Sub-area VI (West of Scotland and Rockall) ..... 406
3.7.7 Anglerfish in Sub-area IV (North Sea) and Sub-area VI (West of Scotland and Rockall) ..... 410
3.7.8 Herring West of Scotland ..... 416
3.7.8.a Herring in Division VIa (North) ..... 416
3.7.8.b Clyde herring (Division VIa) ..... 420
3.7.9 Norway pout in Division VIa (West of Scotland) ..... 422
3.7.10 Sandeel in Division VIa ..... 424
3.8 Stocks in the Irish Sea (Division VIIa) ..... 427
3.8.1 Overview ..... 427
3.8.2 Cod in Division VIIa (Irish Sea) ..... 429
3.8.3 Haddock in Division VIIa (Irish Sea) ..... 435
3.8.4 Whiting in Division VIIa (Irish Sea) ..... 440
3.8.5 Plaice in Division VIIa (Irish Sea) ..... 446
3.8.6 Sole in Division VIIa (Irish Sea) ..... 452
3.8.7 Irish Sea herring (Division VIIa) ..... 458
3.9 Stocks in the Celtic Sea (Divisions VIIf-k), Western Channel (Division VIIe) and northern parts of the Bay of Biscay (Divisions VIIIa,b-d, and e) ..... 463
3.9.1 Overview ..... 463
3.9.2 Cod in Divisions VIIe-k ..... 465
3.9.3 Whiting in Divisions VIIe-k ..... 473
3.9.4 Celtic Sea plaice (Divisions VIIf and g) ..... 478
3.9.5 Sole in Divisions VIIf and $g$ (Celtic Sea) ..... 484
3.9.6 Plaice in Division VIle (Western Channel) ..... 489
3.9.7 Sole in Division VIle (Western Channel) ..... 495
3.9.8 Sole in Divisions VIIIa,b (Bay of Biscay) ..... 501
3.9.9 Celtic Sea and Division VIIj herring ..... 508
3.9.10 Sprat in Divisions VIId, ..... 511
3.9.11 Megrim (L. whiffiagonis) in Sub-area VII and Divisions VIIIa,b,d ..... 513
3.9.12 Anglerfish in Divisions VIIb-k and VIIIa,b (L. piscatorius and L. budegassa) ..... 518
3.10 Stocks in Divisions VIIb,c,h-k (West of Ireland) ..... 528
3.10.1 Overview ..... 528
3.10.2 Demersal Stocks ..... 529
3.10.2a Haddock in Divisions VIIb-k ..... 529
3.10.3 Herring in Divisions VIa (South) and VIIb,c ..... 531
3.11 Stocks in the Iberian Region (Division VIItc and Sub-areas IX and X) ..... 537
3.11.1 Overview ..... 537
3.11.2 Hake - Southern stock (Divisions VIIIc and IXa) ..... 539
3.11.3 Megrim (L. boscii and $L$. whiffiagonis) in Divisions VIHc and IXa ..... 545
3.11.4 Anglerfish in Divisions VIIIc and IXa (L. piscatorius and L. budegassa) ..... 553
3.11.5 Mackerel in Divisions VIIIc and IXa (Southern component) ..... 558
3.11.6 Southern horse mackerel (Trachurus trachurus) (Divisions VIIIc and IXa) ..... 558
3.11.7 Sardine ..... 564
3.11.7.a Sardine in Divisions VIIIc and IXa ..... 564
3.11.8 Anchovy ..... 570
3.11.8.a Anchovy in Sub-area VIII (Bay of Biscay) ..... 570
3.11.8.b Anchovy in Division IXa ..... 576
3.12 Widely Distributed and Migratory Stocks ..... 579
3.12.1 Overview ..... 579
3.12.2 Hake - Northern stock (Division IIIa, Sub-areas IV, VI and VII and Divisions VIIIa,b,d) ..... 580
3.12.3 Mackerel ..... 590
3.12.3.a Mackerel (combined Southern, Western and North Sea spawning components) ..... 590
3.12.4 Western horse mackerel (Trachurus trachurus) (Divisions IIa, IVa, Vb, VIa, VIIa-c, e-k, VIIIa,b,d,e) ..... 608
3.12.5 Blue whiting combined stock (Sub-areas I-IX, XII and XIV ..... 618

## TABLE OF CONTENTS

## PART 3 OF 3

Section Page
3.12.6 Deep-water Fisheries Resources south of $63^{\circ} \mathrm{N}$ ..... 625
3.12.6.a Answer to Special Request on the Management of Deep-water Species ..... 625
3.13 Stocks in the Baltic ..... 642
3.13.1 Overview ..... 642
3.13.2 Nominal catches in the Baltic Area ..... 645
3.13.3 Herring in Sub-divisions 22-24 and Division IIla (spring spawners) ..... 651
3.13.4 Herring in Sub-divisions 25-29 (including Gulf of Riga) and 32 ..... 652
3.13.4.a Herring in the Gulf of Riga ..... 663
3.13.5 Herring in Sub-division 30, Bothnian Sea ..... 669
3.13.6 Herring in Sub-division 31, Bothnian Sea ..... 677
3.13.7 Sprat in Sub-divisions 22-32 ..... 682
3.13.8 Cod in Sub-divisions 22-24 (including Sub-division 23) ..... 692
3.13.9 Cod in Sub-divisions 25-32 ..... 699
3.13.10 Flounder ..... 705
3.13.11 Plaice ..... 711
3.13.12 Dab ..... 714
3.13.13 Turbot ..... 716
3.13.14 Brill ..... 719
3.13.15 Salmon and Sea Trout ..... 721
3.13.15.a Overview ..... 721
3.13.15.b Salmon in the Main Basin and Gulf of Bothnia (Sub-divisions 22-31) ..... 724
3.13.15.c Salmon in the Gulf of Finland (Sub-division 32) ..... 738
3.13.15.d Sea Trout ..... 743
3.13.16 In-year revision of Baltic cod TAC ..... 745
3.13.17 Cod catches in pelagic fisheries ..... 745
3.13.18 Reference points for herring and sprat - Maturity ogive ..... 748
3.13.19 Answer to special request from IBSFC on the selection properties of trawls with double netting ..... 753
3.13.20 Discards of cod in the Baltic ..... 754
3.14 Nephrops Stocks ..... 756
3.14.1 Overview of Nephrops Stocks ..... 756
3.14.2.a Nephrops in Division IIIa (Management Area E) ..... 762
3.14.2.b Nephrops in Division IVa, rectangles 44-48 E6-E7+44 E8 (Management Area F) ..... 766
3.14.2.c Nephrops in Division IVa, West of $2^{\circ}$ E, excluding Management Area F (Management Area G) ..... 769
3.14.2.d Nephrops in Division IVa, East of $2^{\circ} \mathrm{E}+$ rectangles 43 F5-F7 (Management Area S) ..... 773
3.14.2.e Nephrops in Divisions IVb,c, West of $1^{\circ} \mathrm{E}$ (Management Area I) ..... 776
3.14.2.f Nephrops in Divisions IVb,c, East of $1^{\circ}$ E, excluding rectangles 43 F5-F7 (Management Area H) ..... 780
3.14.2.g Nephrops in Division VIId,e (Management Area K) ..... 784
3.14.2.h Nephrops in Division VIa (Management Area C) ..... 785
3.14.2.i Nephrops in Division Vb (EU zone) and VIb (Management Area D) ..... 790
3.14.2.j Nephrops in Division VIIa north of $53^{\circ} \mathrm{N}$ (Management Area J) ..... 791
3.14.2.k Nephrops in Divisions VIlb,c,j,k (Management Area L) ..... 795
3.14.2.1 Nephrops in Divisions VIIf,g,h, excluding rectangles 31 E1 and 32 E1-E2 + VIIa, south of $53^{\circ} \mathrm{N}$ (Management Area M) ..... 799
3.14.2.m Nephrops in Division VIIIa,b (Management Area N) ..... 803
3.14.2.n Nephrops in Division VIIIc (Management Area O) ..... 807
3.14.2.0 Nephrops in Divisions VIIId, (Management Area P) ..... 811
3.14.2.p Nephrops in Division IXa (Management Area Q) ..... 812
3.14.2.q Nephrops in Division IXb and Sub-area X (Management Area R) ..... 817
3.15 Preliminary Answer to EC on Request for Information on Sea Bass ..... 818
3.16 European eel ..... 819
4 ATLANTIC SALMON IN THE NORTH ATLANTIC AREA ..... 829
4.1 Catches of North Atlantic Salmon ..... 829
4.1.1 Nominal catches of salmon ..... 829
4.1.2 Catch and release ..... 829
4.1.3 Unreported catches of salmon ..... 829
4.1.4 Production of farmed and ranched salmon ..... 829
4.2 Use of Case Studies to Illustrate Options for Taking Account of Risk in the Provision of Catch Advice ..... 830
4.2.1 Case studies for calculating risk for the provision of catch advice ..... 831
4.2.2 Case studies for use of management targets as a means of minimizing risk ..... 833
4.3 Differences in the occurrence of escaped farmed salmon in fisheries and stocks in different areas. ..... 835
4.4 Recent Research Developments ..... 835
4.4.1 Infectious salmon anaemia: implications for wild salmon management ..... 835
4.4.2 Causes of fish farm escapes ..... 836
4.4.3 Causes of post-smolt mortality in the marine phase ..... 836
4.4.4 Marine growth checks as evidence for sub-catchment population structuring. ..... 837
4.4.5 Estimates of $M$ at sea for Atlantic salmon ..... 837
4.4.6 Potential impact of climate change on juvenile salmon ..... 838
4.4.7 Compilation of Tag Releases and Finclip Data by ICES Member Countries in 2000 ..... 838
5 ATLANTIC SALMON IN THE NORTH-EAST ATLANTIC COMMISSION AREA ..... 838
5.1 Events of the 2000 Fisheries and Status of Stocks ..... 838
5.1.1 Fishing in the Faroese area 1999/2000 commercial fishery ..... 838
5.1.2 Homewater fisheries in the NEAC area ..... 839
5.1.3 Status of stocks in the NEAC area ..... 839
5.2 Evaluation of the Effects on Stocks and Homewater Fisheries of Significant Management Measures Introduced Since 1991 ..... 840
5.2.1 Evaluation of the effects of management measures introduced in Faroes since 1991 ..... 840
5.3 Expected Abundance of Salmon in the North East Atlantic ..... 841
5.4 Development of Age-Specific Conservation limits ..... 842
5.5 Catch Options or Alternative Management Advice ..... 842
5.6 Data deficiencies and research needs in the NEAC Area ..... 843
6 ATLANTIC SALMON IN THE NORTH AMERICAN COMMISSION AREA ..... 844
6.1 Events of the 2000 fisheries and status of stocks ..... 844
6.1.1 Fisheries in the NAC area. ..... 844
6.1.2 Status of stocks in the NAC area. ..... 844
6.2 Effects on US and Canadian stocks and fisheries of the quota management and closure after 1991 in Canadian commercial salmon fisheries, with special emphasis on the Newfoundland stocks ..... 846
6.3 Age-specific stock conservation requirements ..... 847
6.4 Catch options or alternative management advice with an assessment of risks ..... 847
6.4.1 Catch option for 2001 fisheries on 2 SW maturing salmon. ..... 847
6.4.2 Catch option for 2002 fisheries on 2 SW maturing salmon. ..... 848
6.4.3 Data deficiencies, monitoting needs and research requirements ..... 848
7 ATLANTIC SALMON IN THE WEST GREENLAND COMMISSION AREA. ..... 849
7.1 Events in the 2000 fisheries and status of stocks ..... 849
7.1.1 Fishery in the WGC area ..... 849
7.1.2 Status of stocks in the WGC area ..... 849
7.1.3 Changes in the continent of origin of salmon captured at West Greenland including changes in migration patterns ..... 850
7.2 Effects on European and North American stocks of the West Greenland management measures since 1993851
7.3 Age-specific stock conservation limits for all stocks occurring in the WGC area. ..... 851
7.4 Catch options or alternative management advice with an assessment of risks ..... 851
7.4.1 Overview of provision of catch advice ..... 851
7.4.2 Forecast model for pre-fishery abundance of North American 2 SW salmon. ..... 852
7.4.3 Development of catch options for 2001 ..... 853
7.4.4 Risk assessment of catch options. ..... 853
7.5 Changes to the model used to provide catch advice ..... 854
7.6 Catch advice ..... 854
7.7 Deterministic calculation of quota for a low abundance period. ..... 869
7.8 Deterministic calculation of quota for a moderate abundance period ..... 869
APPENDIX 1 ..... 855
APPENDIX 2 ..... 857

## Preface

The ICES Advisory Committee for Fishery Management met twice in 2001, 22-31 May and 9-17 October. The first meeting was held at Højstrupgård in Helsingér, Denmark while the other was held at the ICES Headquarters, Palægade $2-4$, Copenhagen. Attendance is listed on the following pages.

ACFM in its advice includes a proposal for how the Precautionary Approach can be interpreted. This proposal is described in the Introduction and the advice given in Chapters 3-6 of the report is based on that proposal.

The reports are in response to requests from Management Commissions (EC, IBSFC, NEAFC, and NASCO) and from member countries. The management advice is presented stock by stock in Sections 3 to 6 where also the answers to special requests are given.

The requests from Management Commissions are divided into two parts: recurrent advice that is specified by Memorandum of Understanding between the Management Commissions and ICES and Special Requests. Recurrent advice includes assessment of stock status and management advice for the more important stocks in the Northeast Atlantic. This advice is provided in the same form as used by ICES Advisory Committee for Fishery Management in recent years.

## ACFM REPORT 2001 PART 1 OF 3

## 1.1

The Form of the ICES Advice

ICES recognises that "changes in fisheries systems are only slowly reversible, difficult to control, not well understood, and subject to change in the environment and human values" (FAO 1996). Therefore ICES agrees that a precautionary approach should be applied to fishery management. Reference points, stated in terms of fishing mortality rates or biomass and management plans are key concepts in implementing a precautionary approach. They should be regarded as signposts giving information of the status of the stock in relation to predefined limits that should be avoided to ensure that stocks and their exploitation remain within safe biological limits.

The concept of safe biological limits was introduced in ICES advice in 1981 and further developed in 1986 (Serchuk and Grainger, 1992). The concept of "safe biological limits" is explicitly referred to in the UN Agreement on Straddling Fish Stocks and Highly Migratory Fish Stocks. ICES uses it in an expanded way, consistent with the precautionary approach.
"Safe biological limits" has a specific meaning in ICES advice. A stock outside safe biological limits suffers increased risk of low recruitment, i.e. average recruitment will be lower than if the stock were at its full reproductive capacity. This causes a reduction of the potential catch fisheries can take from the stock. A stock that suffers severely reduced productivity is considered to be "collapsed". A stock "outside safe biological limitst is not, however asually at risk of extinction. A fish stock can be "outside safe biological limits" even if the number of spawners is several orders of magnitude larger than levels considered when evaluating whether stocks are at risk of extinction.

In order for stocks and fisheries exploiting them to be within safe biological limits, there should be a high probability that 1 ) the spawning stock biomass is above the threshold where recruiment is impaired, and 2) the fishing mortality is below that which will drive the spawning stock to the biomass threshold, which must be avoided. The biomass threshold is defined as $\mathbf{B}_{\text {im }}$ (iim stands for limit) and the fishing mortality threshold as $\mathrm{F}_{\text {lim }}$. In order to have a high probability to avoid the thresholds, management action must be taken before the thresholds are approached. The precision with which the thresholds and current status of the stocks are known, and the risk which is tolerable, are important factors in determining the distance away from the threshold that management action is required. The greater the precision of the assessment, the smaller the distance between limit and precautionary reference points. If the assessment is less reliable, the distance will be greater. ICES has defined $\mathbf{B}_{\mathrm{pa}}$ ( pa stands for precautionary approach) as the biomass below which action should be taken and $F_{F a}$ as the fishing mortality above which
management action should be taken. The distance between the limit and the precautionary approach reference points is also related to the degree of risk that fishery management agencies are willing to accept. Therefore, although ICES sees its responsibility to identify limit reference points, it will suggest precautionary reference points for management use.

Formal definitions are provided below:
$\mathrm{F}_{\text {lim }}$ is the limit fishing mortality which should be avoided with high probability because it is associated with unknown population dynamics or stock collapse. There are very few stocks for which $\mathbf{F}_{\text {lin }}$ is accurately known. Some stocks in the ICES area have collapsed in the past when fishing mortality exceeded $\mathbf{F}_{\text {lim }}$, but generally speaking, the fishing mortality rate at which the probability of stock collapse becomes unacceptably high remains unknown. In order to have a high probability that fishing mortality will be below $F_{\text {lim }}$, a precautionary reference point, $\mathbf{F}_{\mathrm{pa}}$ lower than $\mathbf{F}_{\mathrm{lim}}$, is defined. Used as a constraint on fishing, $\mathbf{F}_{\mathrm{pa}}$ is designed to ensure that there is a high probability that $F_{\text {lim }}$ will be avoided and that the spawning stock biomass will remain above the threshold below which the probability of good to average recruitment is decreased. In other words, $F_{p a}$ is a device to ensure that recruitment overfishing does not take place. It is the upper bound on fishing mortality rate to be used by ICES in providing advice. $F_{p a}$, given uncertainties, must have a high probability of being below $\mathbf{F}_{\text {lim }}$, and it must have a high probability of being sustainable based on the history of the fishery; i.e., it should be set in the range, and imply a biomass, within those previously perceived to be acceptable. Fishing mortality rates in excess of $\mathbf{F}_{\mathrm{pa}}$ will be regarded as "overfishing".
$\mathbf{B}_{\text {lim }}$ is the limit spawning stock biomass, below which recruitment is impaired or the dynamics of the stock are unknown. Stocks may become depleted due to reduced recruitment even if fishing mortality is successfully maintained at or below $\mathbf{F}_{\mathrm{pa}}$. Furthermore, efforts to restrain fishing below $F_{p a}$ may not be successful and biomass may decline as a result. Clearly, therefore, in addition to a constraint on fishing mortality, it is desirable to have a biomass-based constraint to prevent stock decline to values where expected recruitment is low or unknown.

Whereas $\mathbf{F}_{\mathrm{pa}}$ defines an "overfishing threshold", a definition of when the stock is regarded as being in a "depleted state" is also necessary. A threshold in this respect, $\mathbf{B}_{\mathrm{pa}}$, needs to be set to ensure a high probability of avoiding reducing the stock to a point, $\mathbf{B}_{\text {lim }}$, below which recruitment is impaired or the dynamics of the stock are unknown. $\mathbf{B}_{\mathrm{lim}}$ is in general equal to previously defined MBAL values for those stocks where MBAL
has been based on considerations of stock-recruitment relationships. $\mathrm{B}_{\mathrm{pa}}$ is the biomass below which the stock would be regarded as potentially depleted or overfished.

## Framework for advice

Advice from ICES will be constrained by $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{p}^{a}}$. If fishery management decisions lead to $\mathbf{F}_{\mathrm{pa}}$ being exceeded, then this would be regarded as overfishing and management would not be regarded as consistent with a precautionary approach. The development of a management plan to reduce fishing mortality to no greater than $\mathbf{F}_{\mathrm{pa}}$ would be advised. If no such plan were developed, ICES would generally advise that management was not consistent with a precautionary approach. Because $\mathbf{F}_{\mathrm{pa}}$ would be set such that $\mathbf{B}_{\mathrm{pa}}$ were unlikely to be reached, and because $\mathbf{B}_{\mathrm{pa}}$ is chosen to provide a high probability of avoiding recruitment failure, if $S S B$ were to fall below $B_{p a}$, advice to reduce fishing mortality would be likely. This would depend, however, on whether or not $\mathbf{F}_{\text {pa }}$ were also being exceeded and on the prognosis for SSB trends and the probability of recovering to above $\mathbf{B}_{\mathrm{pa}}$ in the short term. If $\operatorname{SSB}$ were predicted to remain below $B_{p a}$ in the short to medium term, the development of a recovery plan would be advised. But in general, $\boldsymbol{B}_{\mathrm{pa}}$ is the biomass threshold triggering advice for a reduction in F to a value below $\mathbf{F}_{\text {pa }}$.
$\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{pa}}$ are thus the main devices in the ICES framework for providing advice. They are thresholds which constrain advice or which likely trigger advice for the implementation of management/recovery plans. If the development of plans were proposed, fishery management agencies, scientists and perhaps other parties would need to work together on their development. Such plans might involve explicit harvest control rules or sets of decision rules. If the development of plans were recommended, but not taken up, ICES would have to advise that management was not consistent with a precautionary approach. If plans were developed and not effectively implemented, again the advice would be that management was not consistent with a precautionary approach.

Note that if a stock is regarded as being in a depleted state, or even if overfishing is taking place, the development and effective implementation of a rebuilding plan which is regarded as sufficient to reduce fishing mortality to no higher than $\mathrm{F}_{\mathrm{pa}}$ and to rebuild SSB to above $\mathbf{B}_{\text {pa }}$, within a "reasonable" period, would satisfy the condition that management were consistent with a precautionary approach.

ICES proposed a number of "lim" and "pa" reference points in 1998 as a provisional step to the implementation of a precautionary approach. ICES continues to keep the reference points under review and has revised some of the original proposals based on updated information on stock productivity. It was recognised that the estimates of thresholds could change as the concept evolved or with additional knowledge of stock and fishery dynamics. Further discussion of the implementation of the precautionary approach both within ICES (e.g. the $11^{\text {th }}$ Dialogue Meeting in January 1999 and the Follow-up Meeting in February 2000) and elsewhere (NAFO, FAO, etc.), can be expected to result in further development and clarification of concepts and changes in terminology.

### 2.1 Introduction

The assessments presented in this report are carried out using the best catch data available to ICES. These data are not necessarily identical with the official statistics but, where appropriate, include estimates of unreported landings as well as corrections for misallocation of catches by area and species. Despite considerable effort exerted on this problem, there is no guarantee that all instances of misreporting were discovered. Often the catch data used by ICES are collated on a stock rather than an area basis, and so straightforward comparisons between these figures and the official statistics, which are provided on an area basis, are not appropriate.

In the assessments, ICES tries to estimate the total catch taken, including slipped catches, discards, landings which are not officially reported, and the composition of the industrial by-catches. These amounts of different species, which have to be included in the estimates of what has been taken from a given stock in order for the assessments to be correct, thus appear in the tables and figures in this report. These discards, slipped fish, unreported landings, and industrial by-catches vary considerably between different stocks and fisheries, being negligible in some cases and constituting important parts of the total removal from other stocks.

The catch data used in the assessments are given in the "table" section of this report. In cases where there might be doubt, it has been indicated if discards, by-catches, and estimates of unreported landings are included in the assessments. Estimates of catches landed as by-catches, especially from the industrial fisheries, are included in the assessments wherever data allow it and are included in the catch options.

It should be noted that, in general, catches in the industrial fisheries of protected species above the minimum landing size which are sorted and landed for human consumption, are included in the estimates of human consumption landings, both in the catch input data and in the projected catch options. Estimates of industrial by-catches cover, in most cases, that part of the by-catch which is used for reduction purposes.

In the past there have been problems associated with discrepancies between the official landing figures reported to ICES by member countries and corresponding catch data used by ICES. ICES recognises the need for a clear identification of the categories of the catch data used for assessments and whenever possible specifies the composition of the catch data used to estimate fishing mortalities. ICES also attempts to identify factors contributing to the total fishing mortality in the various stocks, e.g.:

- recorded landings,
- discards at sea,
- slipping of unwanted catches,
- losses due to burst nets etc.,
- unreported landings,
- catch reported as other species,
- catch reported as taken in other areas,
- catch taken as by-catch in other fisheries.

It is recognised that it may not always be possible to reveal the sources of the data. It is, however, indicated whether the data originate from sampling programmes, field observations, interviews, etc., in order to allow ICES and other interested parties to evaluate the quality of the data, and hence the basis for the assessment.

The overall responsibility for obtaining reliable, adequate and timely fisheries statistics for publication in ICES Fisheries Statistics does not rest with ICES. It is the opinion of ICES that national offices for fisheries statistics are responsible for providing the catch data needed for assessments. These offices should ensure that catch statistics are collected on a gear basis and that the species composition of landings is determined in the case where landings are made unsorted by species.

### 2.2 Quality of Fishery Statistics

ICES expressed the greatest concern in past ACFM advice over the quality of catch and effort data from most of the important fisheries in the ICES area. ICES stressed that the immediate consequences of this are that ICES will be unable to provide reliable estimates of current stock sizes and forecasts that have been used to set TACs. Trends in stock size and the overall status of the stock can sometimes be evaluated from research vessel surveys, but such information alone cannot be used to give the shortterm TAC advice usually required.

### 2.3 Catch projections for the current and following year

The Catch Option table is a basis part of the ICES advice and these catch options are based on assumptions about the total catch in the current or intermediate year. This value has been debated, especially when it is larger than the total TAC for the given year.

The catch assumption is a projection of trends in the fisheries and the projection is based on case specific conditions. In many cases, ICES considers two alternatives: 1) to assume that the catch will be equal to the TAC (a TAC constraint) or 2) to assume that the fishing mortality, F , will continue equal to that of previous year (a $\mathrm{F}_{\text {status quo }}$ constraint). In some cases the
stock unit used by ICES does not match the TAC area used by the management agencies. In those cases it can be difficult to establish how the TAC will restrict the catch from the stock and often the F status quo is used.

Calculation of the best estimate of the status quo fishing mortality by age varies between stocks. The form of the estimate depends of temporal trends in the fishing mortalities and in the exploitation pattern. Also the variance of the estimate in individual years needs to be considered. In several cases a mean over the last three years are used sometimes scaled to the level of fishing mortality in the most recent year.

## Structure of the Report

Information and advice are provided on an area basis. Thus, all stocks belonging to a given area are placed in a separate section, together with an overview of the state of the stocks and fisheries in that area. Special requests from Commissions or member countries of ICES are placed in the section dealing with the respective area and stock.

Exceptions to this structure are that the report to the North Atlantic Salmon Conservation Organization and reports on Nephrops (section 3.14) and on European eel (Section 3.16) are provided as separate sections. Section 3.15 provides some preliminary information on the status of European Sea bass stocks.

### 3.1 Stocks in the North-East Arctic (Sub-areas I and II)

### 3.1.1 Overview

## Major Stocks and Landings

The total landings of fish and invertebrates in this area in 2000 were in the order of 2.8 million $t$. These catches were taken from a variety of demersal and pelagic stocks.

The major demersal stocks in the North-East Arctic include cod, haddock, saithe and northern shrimp. In addition, redfish, Greenland halibut and flatfishes (e.g., long rough dab, plaice) are common on the shelf and at the continental slope, with ling and tusk found also at the slope and in deeper waters. In 2000 , landings of 0.7 million $t$ were taken from the stocks of cod, haddock, saithe, redfish and Greenland halibut. An additional catch of about 100000 t was taken from demersal stocks, including crustaceans, not assessed at present.

The major pelagic stocks are capelin, herring and polar cod. The highly migratory species blue whiting and mackerel extend their feeding migrations into this region. The international fishery for herring in 2000 was 1.21 million $t$. The capelin fishery in the Barents Sea in 2000 was 406000 t . In addition, there were landings from Sub-areas I and II of 92000 t mackerel (including Division Vb) and 276000 t blue whiting (including Division Va).

Invertebrate species of krill, copepods and amphipods are considered to be important food resources for the fish stocks in this area. Marine mammals play an important role as predators on fish. Several other species of fish and invertebrates are found in the area. Species with relatively small landings include salmon, halibut, hake, pollack, whiting, Norway pout, anglerfish, wolffish, lumpsucker ${ }_{+}$argentines, grenadiers, flatfishes, horse mackerel, dogfishes, skates, crustaceans and molluscs.

## Fleets and Fisheries

The fleets operating in this area are:

1. Factory and freezer trawlers operating in the whole area all year round targeting mainly cod, haddock and saithe and taking other species as bycatch. The number of these vessels has been stable in recent years, at a lower level than previously.
2. Fresh fish trawlers operating in Sub-area I and Division Ma all year round targeting mainly cod
and baddock, taking other species as by-catch. The number of these vessels has been reduced in recent years.
3. Freezer trawlers operating in Sub-area 1 and Division IIb fishing shrimp. The number of these vessels has been stable.
4. Large purse seiners and pelagic trawlers targeting herring, mackerel, blue whiting, capelin and polar cod in seasonal fisheries in this region. These vessels fish some of the same species in other areas as well.
5. Small fresh fish trawlers targeting shrimp and capelin in near coast areas in Sub-area I. The size of this fleet has decreased in recent years.
6. A fleet of vessels using conventional gears (gillnet, longline, handline and Danish seine) mainly in near-shore fisheries targeting various demersal species all around the year. This fleet, together with fleets 7 and 8 , accounts for approximately $30 \%$ of landings of demersal stocks. This share is maintained by quota allocation. When vessels in this fleet are modernised or replaced, there is a trend towards medium-sized (app. 15-20 m) multi-gear vessels with crews of 3-5.
7. Small purse seiners targeting saithe in coastal waters in a seasonal fishery, to a large extent vessels belonging to the group using conventional gears.
8. Longliners operating offshore targeting non TACrestricted species, mainly ling, blue ling and tusk. These vessels are generally larger than those in the coastal fisheries and use technologically advanced auto-line systems.

## Management Measures

The fisheries in Sub-areas I and II are managed by TAC constraints for the main stocks and by allocation of TAC shares amongst states with established fishing interests. These sub-areas consist mainly of waters within EEZs but also contain some waters outside EEZs.

For the main species the fisheries in the EEZs are regulated by quotas at a variety of scales (vessels, fleets,
species, season). Management measures also regulate minimum landing size, mesh size, and use of sorting grids. Since January 1997 use of sorting grids in the trawl fisheries has been mandatory for most of the Barents Sea and Svalbard area. Minimum landing size is also a minimum catching size implying that vessels have to avoid fishing grounds with small-sized fish. Discarding is prohibited in some EEZs. Time and area closures may be implemented to protect small fish.

Compilation of effort data relevant to the different species is difficult when the fisheries are regulated by vessel quotas. In some cases the effort targeted at the main species, e.g., cod, may be calculated but it is almost impossible to calculate effort for non-target species.

## Current status in the North-East Arctic

The recent developments in the stocks of cod, haddock, saithe, Greentand halibut, redishes, herring and capelin are summarised in the following.

The stocks of cod and Sebastes mentella are outside safe biological limits, haddock is harvested outside safe biological limits while saithe is within safe biological limits.

The status of the Greenland halibut stock is not precisely known, but it is considered to be outside safe biological limits. SSB in 2001 is the lowest in the time series and recruitment in recent years is estimated to be among the lowest in the time series.

The available information on Sebastes marinus is insufficient to assess the stock properly, but there are signs in the surveys of reduced recruitment and the coastal survey also indicate a decrease for larger fish.

The capelin stock is within safe biological limits although the recent stock increase has culminated and the stock may dectease over the next few years.

The spawning stock of Norwegian spring-spawning herring is declining, but the stock is still considered to be within safe biological limits. High recruitment is infrequent and the adult stock is now dominated by two strong year classes.

Considerable effort has been devoted to investigate multispecies interactions. Some of these investigations have reached the stage where quantitative results are available for use in assessments. Growth of cod depends on availability of prey such as capelin, and variability in cod growth has had major impacts on the cod fishery. Cod are able to compensate only partially for low capelin abundance, by switching to other prey species. Low capelin abundance has caused high cannibalism on juvenile cod, and increased predation in impacts on other prey species, e.g. juvenile herring and haddock. Herring predation on capelin larvae is believed to be partially responsible for the recruitment failure of capelin when young herring are abundant in the Barents Sea.

The annual consumption of herring and capelin by marine mammals (particularly harp seals and minke whales) has been estimated to be in the order of 1.5-2.0 million t . The composition and distribution of species in the Barents Sea depend considerably on the position of the polar front which separates warm and salty Atlantic waters from colder and fresher waters of arctic origin. Variation in the recruitment of some species including cod and herring has been associated with changes in the influx of Atlantic waters into the Barents Sea.

### 3.1.2.a North-East Arctic cod

State of stock/fishery: The stock is outside safe biological limits. Fishing mortality in the last four years has been among the highest observed and well above $F_{p a}$, even above $\mathbf{F}_{\text {limu }}$, and is not sustainable. SSB has been below $\mathbf{B}_{\text {Fa }}$ since 1998. Surveys indicate below average 1998 and 2000 year classes and a very poor 1999 year class.

Management objectives: In recent years, the advice has been to reduce fishing mortality below $\mathrm{F}_{\mathrm{pa}}(=0.42)$ and to keep the spawning stock above 500000 t , which was considered to be the minimum value required to have a low probability of bad recruitment. This approach was incorporated into a management objective in the years 1997-1999. The latest agreement in the Russian-Norwegian Fisheries Commission sets a TAC of 435000 t (including 40000 t Norwegian coastal cod) for 2001, 2002, and 2003. The intention is that this TAC could be revised either if the stock situation is more serious than known at the time of the agreement, or if the stock is assessed to be within safe biological limits. ICES considers that TACs under this agreement are well above those that would correspond to the application of the precautionary approach.

Precautionary Approach reference points: The biological information on historic stock and recruitment sizes has been revised. These revisions have altered some of the historic values substantially, with two consequences. Spawning biomasses associated with some historic recruitment are now estimated to have been lower, suggesting that current reference points may be slightly too high. However, the new data appears better to separate the strong environmental impact on recruitment from the biological productivity of the stock. The pattern suggests that the biological productivity of the stock at low SSB may be lower than previously thought, and this may affect the selection of the reference points. This will allow a more robust analysis of the biological dependency of recruitment on SSB, the results of which would be the basis for yet further revisions to reference points. Rather than revising the reference points this year and again next year when the analysis will further separate environmental and biological contributions to stock productivity, ICES continues to advise using the previous reference points. The advice in the short term would be very similar using either the present or the candidate revised reference points, and the mediumterm consequences can be re-evaluated when the further analyses are complete.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is $112000 t$, the SSB below which no above-average <br> year classes have been observed | $\mathbf{B}_{\mathrm{pa}}$ is set at 500000 t , the value below which the <br> probability of below-average year classes increases |
| $\mathbf{F}_{\text {lign }}$ is 0.70 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.42. This value is considered to have a <br> $95 \%$ probability of avoiding the $\mathrm{F}_{\text {lim }}$ |

## Technical Basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=$ examination of stock-recruit plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Median value of $\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}^{\mathrm{a}}}=5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}=\mathbf{F}_{\text {liom }} \times 0.6$ |

Advice on management: ICES recommends a considerable reduction in fishing mortality to well below $\mathrm{F}_{\mathrm{pa}}$ (0.42). A rebuilding plan for this stock is required. Rebuilding the spawning stock to above the $B_{p a}(500000$ t) by 2003 requires a $F$ in 2002 of less than 0.25 . This corresponds to catches in 2002 of less than 181000 t . The rebuilding plan should also include measures ensuring that all catches are reported fully and that the exploitation pattern be improved.

Relevant factors to be considered in management: The TAC for 2001 was set considerably higher than recommended by ICES. The agreed TAC for 2002
(435000 t, including 40000 t of Norwegian coastal cod) is expected to be taken with a fishing mortality well above $\mathbf{F}_{\mathrm{pa}}$. As a result of this, SSB is expected to remain below $\mathbf{B}_{\mathrm{pa}}$ in 2003.

Evidence of recent under-reporting of catches during the 1990 s is accumulating. Both discards and unreported landings will reduce the effect of management measures and it is important that management agencies ensure that all catches are counted against the TAC regulations.

Since fishing mortality is still far above $\mathbf{F}_{\text {max }}$ ( 0.24 ) the stock is growth-overfished.

The majority of the spawning stock comprises first time spawners. Evidence has shown that the eggs and larvae of first-time spawners are less viable than those of other mature fish, but also that the overall spawning period is reduced when the spawning stock consists of fewer age groups. Both these factors can reduce the reproductive potential of the stock for the same biomass.

Comparison with previous assessment and advice: In previous assessments, fishing mortality $\mathrm{F}(5-10)$ in the most recent years was often underestimated and stock numbers overestimated in the annual assessments of the stock. The current assessment does not present such retrospective patterns, although it is too early to infer whether this over/underestimation has ceased to be a problem for this assessment.

In the past, ICES has presented a TAC-constrained forecast for the intermediate year in prediction, rather than assuming status quo fishing mortality. This year ICES presents a status quo forecast for the following reasons:

- It is believed that under-reporting of catches continues to be a problem for this stock, in which case a TAC constraint is inappropriate;
- For NEA cod, a TAC constraint requires a reduction in fishing mortality compared to status quo, whilst for NEA haddock, (mostly caught in association with cod), an increase in fishing mortality would be required for a TAC constraint. This inconsistency suggests that the TAC constraint is being used as an ad hoc "fix" for assessments that provide uncertain catch forecasts from year to year, rather than reflecting an actual constraint on fishing mortality;
- The practice is consistent with most other stocks in the ICES area. Experience with TACs suggest that precise and unbiased assessments, as well as compelling reasons to assume that TACs act as a constraint on catches, are needed before applying a TAC constraint on forecasts.

## Catch forecast for 2002:

Basis: $F_{s q}=F(2001)=F(2000)=0.91 ;$ Landings $(2001)=530 ; \operatorname{SSB}(2002)=272$.

**assuming 20000 t of the total quota taken as Norwegian Coastal cod.
***assuming 0 t of the total quota taken as Norwegian Coastal cod.
Weights in '000 t.
Shaded scenarios considered inconsistent with the precautionary approach.

Elaboration and special comment: Changes in growth, maturity and cannibalism are linked to abundance of the capelin stock, which has increased since 1997 and is expected to stay at a high level in
2001. So far, a reduction in cannibalism has been observed. Models relating cannibalism and capelin abundance have been used to predict natural mortality for 2001 onwards.

The fishery for North-East Arctic cod is conducted both by an international trawler fleet operating in offshore waters, and by vessels using gillnets, longlines, handlines, and Danish seine operating both offshore and in the coastal areas. Quotas were introduced in the trawl fishery in 1978 and for the fisheries with conventional gears in 1989. In addition to quotas the fisheries are regulated by mesh size limitations (including sorting grids), a minimum catching size, a maximum by-catch of undersized fish, maximum bycatch of non-target species, closure of areas with high densities of juveniles, and by seasonal and area restrictions. Since January 1997 sorting grids have been mandatory for the trawl fisheries in most of the Barents Sea and Svalbard area. The fisheries are controlled by inspections of the trawler fleet at sea, by a requirement. of reporting to catch control points when entering and leaving the EEZs, and by inspections for all fishing vessels when landing the fish. Keeping a detailed fishing $\log$-book on board is mandatory for most vessels, and large parts of the fleet report to the authorities on a daily basis. There is some evidence that the present catch control and reporting systems are not sufficient to prevent under-reporting of catches.

The assessment is based on analysis of catch-at-age data, using two commercial cpue series and three survey series. Estimates of cannibalism are included in the natural mortality. Alternative assessment methods (Fleksibest) are in development.

While the area coverage of the surveys was incomplete in 1997, 1998, and the summer of 2000 , the coverage was normal in 1999 and during the winter surveys in 2000 and 2001.

### 3.1.2.b Norwegian Coastal cod

State of stock/exploitation: There are no reference points proposed for this stock. The SSB in 2001 is the lowest observed in the time series extending back to 1984. The stock has declined continuously since 1994, and fishing mortality has increased since 1991. Recruitment in recent years has been below average. The landings increased steadily from 1991 and up to 1997; since then they have decreased. The assessment reflects the general trends in the development of the stock, although it is not regarded as accurate.

Management objectives: There are no explicit management objectives for this stock. Management objectives should be defined, taking the status of the stock into consideration.

Advice on management: ICES advises that catches in 2002 should be reduced by the same proportion as for North-East Arctic cod.

Rebuilding plan: Although no precautionary reference points have been established for this stock a rebuilding plan is required. The rebuilding plan for this stock should complement the provisions taken in a similar plan developed for North-East Arctic cod as a result of ICES' advice for that stock.

Relevant factors to be considered in management: The $\mathrm{S} S \mathrm{~B}$ is at an historical low, and the year classes recruiting to the SSB over the next 4 years seem to be well below average. Unless fishing mortality is reduced considerably a further decrease in the total stock biomass and SSB is expected. Management measures should be implemented to ensure that catches in particular are reduced in areas where, and in seasons when the proportion of Norwegian Coastal cod is large compared to North-East Arctic cod.

Norwegian Coastal cod is managed as part of the Norwegian North-East Arctic cod fishery. An expected yield of 40000 t from the Coastal cod has been added annually since the mid-1970s to the quota for NorthEast Arctic cod. If this practice is followed in 2002 and the quota is taken, both the stocks (Norwegian Coastal cod and North-East Arctic cod) will continue to be overexploited. If Norwegian Coastal cod could be managed independently of North-East Arctic cod, ACFM would advise a reduction of at least $65 \%$ of the fishing mortality in 2000 in order to halt the decline in the spawning stock.

Comparison with previous assessment and advice: In this year's assessment the fishing mortalities ( $\mathbf{F}_{4-7}$ ) for 1997-1999 are higher and the stock biomasses and the spawning stock biomasses are lower compared with last year's assessment.

Catch forecast for 2002:
Basis: TAC; $\mathrm{F}(2001)=0.96 * \mathrm{~F}(2000)=0.48$; Landings $(2001)=34 ; \operatorname{SSB}(2002)=49$.

| $\mathrm{F}(2002$ <br> onwards $)$ | Basis | Catch <br> $(2002)$ | Landings <br> $(2002)$ | SSB <br> $(2003)$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.01 | $0.02 * \mathbf{F}_{s \mathrm{c}}$ |  | 1.0 | 72 | SSB 2003=SSB 1999 |
| 0.10 | $0.20 * \mathbf{F}_{s q}$ |  | 7.4 | 66 | SSB 2003=SSB 2000 |
| 0.17 | $0.34 * \mathbf{F}_{s q}$ |  | 12.0 | 61 | SSB 2003 = SSB 2001 |
| 0.20 | $0.40 * \mathbf{F}_{s q}$ |  | 14.0 | 59 |  |
| 0.30 | $0.60 * \mathbf{F}_{s q}$ |  | 19.9 | 53 |  |
| 0.35 | $0.70 * \mathbf{F}_{s q}$ |  | 23.0 | 50 | SSB 2003 = SSB 2002 |
| 0.40 | $0.80 * \mathbf{F}_{s q}$ |  | 25.1 | 48 |  |
| 0.50 | $\mathbf{F}_{s q}$ |  | 29.8 | 43 |  |

Weights in '000 t.

Although a TAC-constrained prediction is presented, this is very close to the status quo forecast that would have been preferred by ACFM. Because the difference is so minor, the prediction has not been re-run.

Elaboration and special comment: The fishery for Norwegian Coastal cod is part of a directed fishery on cod in Norway using a variety of traditional gears, including trawl, and has been conducted for several decades. The catches include both North-East Arctic cod and

Norwegian Coastal cod in some areas and in some periods of the year. In Finnmark 43 likely spawning areas for Norwegian Coastal cod have been identified. Among these 24 are closed for Danish seine fishery in the first five months of the year. Trawl fisheries for roundfish are not allowed at any time of the year within 4 nautical miles of the coast.

A method of catch separation by otolith pattern has been used in recent years to estimate landings from the Norwegian Coastal cod stock. The landings data are not considered to be estimated precisely.

The stock was assessed by XSA using commercial catch-at-age data and an acoustic survey series. The catch data used in analysis go back to 1984 and the survey series to 1995.

### 3.1.3 North-East Arctic haddock (Sub-areas I and II)

State of stock/exploitation: The stock is harvested outside safe biological limits. Fishing mortality in 2000 is estimated to be well above the proposed $\mathbf{F}_{\mathrm{pa}}$ and has been close to, or above $\mathrm{F}_{\mathrm{lim}}$ since 1997. The SSB in 2001 (79000 t) is estimated at $\mathbf{B}_{\mathrm{pa}}(80000 \mathrm{t})$. The 1998 and 1999 year classes are indicated to be above average.

Management objectives: There are no explicit management objectives for this stock. For management objectives to meet precautionary criteria, their aim should be to reduce or maintain F below $\mathrm{F}_{\mathrm{pa}}$ and to increase or maintain spawning stock biomass above $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 2000):

| ICES considers that: | ICES proposes that: |
| :---: | :---: |
| $\mathbf{B}_{\text {lim }}$ is 50000 t , the SSB below which only poor year classes have been observed. | $\mathbf{B}_{\mathrm{pa}}$ be set at 80000 t , which is considered to be the minimum SSB required to provide a $95 \%$ probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty in the assessments and stock dynamics. |
| $\mathbf{F}_{\text {lim }}$ is 0.49 , the fishing mortality associated with potential stock collapse. | $\mathbf{F}_{\mathrm{p}}$ is set at 0.35. This value is considered to have a high probability of keeping $F$ below $\mathbf{F}_{\text {lim }}$. |

## Technical Basis:

$\mathbf{B}_{\mathrm{im}}$ : only poor recruitment has been observed from $4 \mid \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{ina}} * 1,67$. years of SSB $<50000 \mathrm{t}$, and all moderate or large year classes have been produced at higher SSB.
$\mathbf{F}_{\text {lim }}=$ median value of $\mathbf{F}_{\text {less }} . \quad \mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }}$. The stock has sustained higher fishing mortality for most of the period after 1950 without collapsing; however, low SSB has often resulted in poor year classes.

Advice on management: In order to harvest the stock within safe biological limits, ICES recommends that fishing mortality be reduced to below $F_{p a}=0.35$, corresponding to catches of less than 67000 t in 2002.

Relevant factors to be considered in management: A substantial portion of the Northeast Arctic haddock catch is taken as by-catch in the NEA cod fishery. A reduction in North-East Arctic cod catches as advised for 2002 may help to achieve the advised reduction in fishing mortality for haddock as well.

Fishing mortality has been above $\mathbf{F}_{\text {lim }}$ a number of times during the 50 -year time series. The stock has been able to withstand these periods of overfishing due to the occasional recruitment of exceptionally strong year classes. A lower fishing mortality would lead to better harvesting of the occasional strong year classes and would lead to more stable catches.

Comparison with previous assessment and advice: In recent years there appears to be a tendency to underestimate fishing mortality and to overestimate SSB.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}_{s q}=\mathrm{F}(97-99$ scaled to 00$)=0.46$; Landings $(2001)=61 ; \operatorname{SSB}(2002)=76$.

| F (2002) | Basis | Catch (2002) | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: | :---: |

| \%SV楽 |  |  | Wive | 41 |
| 4.46 | Kis. |  |  |  |

## Weights in ' 000 t .

Shaded scenarios considered inconsistent with the precautionary approach.
Medium-term projections not reliable.

In the past, ICES has presented a TAC-constrained forecast for the intermediate year in prediction rather than assuming status quo fishing mortality. This year it has presented a status quo forecast for the following reasons:

- For NEA cod, a TAC constraint requires a reduction in fishing mortality compared to status quo, whilst for NEA haddock, a species caught mostly in association with cod, an increase in fishing mortality would be required for a TAC constraint. This inconsistency suggests that the TAC constraint is being used as an ad hoc "fix" for assessments that provide uncertain catch forecasts from year to year, rather than reflecting an actual constraint on fishing mortality;
- The practice is consistent with most other stocks in the ICES area. Experience with TACs suggests that precise and unbiased assessments, as well as compelling reasons to assume that TACs act as a constraint on catches, are needed before applying a TAC constraint on forecasts.

Elaboration and special comment: In addition to exploitation at fishing mortality above the precautionary limits, SSB has decreased as the influence of the 1990 year class has reduced together with a decrease in individual growth and maturity. In addition, high levels of predation by cod have reduced recruitment to the $S S B$.

The results of the forecast are also sensitive to the estimates of variable maturity and natural mortality rates. The latter will very much depend on the development of the capelin and cod stocks in the near future.

The fishery is mainly a trawl fishery, in some periods only as by-catch in the fishery for cod. The fishery is regulated by TAC, minimum landing size, a minimum mesh size in trawls and Danish seine, a maximum bycatch of undersized fish, closure of areas with high density of juveniles, and other area and seasonal restrictions.

The analytical assessment is based on catch-at-age data, 3 surveys, and CPUE for one commercial fleet, and it includes predation by NEA cod.

### 3.1.4 North-East Arctic saithe (Sub-areas I and II)

State of stock/exploitation: The stock is within safe biological limits. Fishing mortality in 2000 is at $\mathbf{F}_{\mathrm{pa}}$ and SSB in 2001 is well above $\mathbf{B}_{\text {pa }}$. After a long period of low stock size, the stock recovered during the 1990 s with the recruitment of several above-average year classes. The exploitation pattern is better than in the past.

Management objectives: There are no explicit management objectives for this stock. For management objectives to meet precautionary criteria, their aim should be to reduce or maintain fishing mortality below $\mathbf{F}_{\mathrm{pa}}$ and to increase or maintain spawning stock biomass above $\boldsymbol{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lind }}$ is 89000 t , the lowest observed SSB in the $35-\mathrm{year}$ <br> time series | $\mathbf{B}_{\mathrm{pa}}$ is set at 150000 t, the SSB below which the <br> probability of poor year classes increases |
| $\mathbf{F}_{\text {lim }}$ is 0.45, the fishing mortality associated with <br> potential stock collapse | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.26. This value is considered to have a <br> $95 \%$ probability of avoiding the $\mathrm{F}_{\text {lim }}$ |

Technical Basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=$ examination of stock-recruit plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lian }}=$ Median value of $\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {lim }} * 0.6$ |

Advice on management: ICES advises that fishing mortality should be below $\mathrm{F}_{\mathrm{pa}}$, corresponding to a catch in 2002 of less than 152000 t .

Comparison with previous assessment and advice: There has been a tendency to overestimate fishing mortality in recent years. Fishing mortality is now
estimated to correspond to $\mathbf{F}_{\text {par }}$ indicating a change from harvesting outside safe biological limits. The estimated SSB continues to remain above $\boldsymbol{B}_{\mathrm{pa}}$. The estimate of the SSB in most recent years is about $30 \%$ higher than in last year's assessment.

## Catch forecast for 2002:

Basis: $F(2001)=F_{s q}=F(98-00$ scaled $)=0.26 ;$ Landings $(2001)=135 ; \operatorname{SSB}(2002)=304$.

| $\mathrm{F}(2002$ onwards $)$ | Basis | Catch <br> $(2002)$ | Landings <br> $(2002)$ | SSB (2003) |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.
Medium-term projections not reliable

Elaboration and special comment: Since the early 1960s, the fishery has been dominated by purse seine and trawl fisheries, with a traditional gill net fishery for spawning saithe as the third major component. The purse seine fishery is conducted in coastal areas and fjords. Historically, purse seiners and trawlers have taken roughly equal shares of the catches. Recent regulation changes led to less relative amounts taken by purse seine in 2000.

Based on the TAC set and estimates of catches for other gears, quotas are set for purse seine and trawl fisheries. In the Norwegian fishery, quotas may be transferred between purse seiners and trawlers based on negotiations if it becomes clear that the quota allocated to one of the fleets will not be taken.

In addition to quotas, the fisheries are managed by minimum mesh size limitations, minimum landing size, by-catch regulations, and area closures. In 1999
the minimum landing size was increased to 45 cm ， except for $40-42 \mathrm{~cm}$ for different areas for purse seine．

The analytical assessment is based on catch－at－age data， an acoustic survey data，and revised CPUE data from two commercial fleets．

### 3.1.5.a $\quad$ Sebastes mentella in Sub-areas I and II

State of stock/exploitation: The stock is considered to be outside safe biological limits. Although the current assessments are only indicative of the relative trends in stock size, they show that the spawning stock is close to its historical low. The 1991-2000 year classes are indicated to be well below those of the 1980s.

Management objectives: No explicit management objectives have been established for this stock. Consistent with the precautionary approach a management plan, including monitoring of the development of the stock and of the fishery, with corresponding regulations, should be developed and implemented.

Reference points: No precautionary reference points have been proposed for this stock.

Advice on management: ICES recommends that there be no directed fishery on this stock until a significant increase in spawning stock biomass has been detected in surveys with a following increase in the number of juveniles. In addition, the by-catch of redfish in other fisheries should be reduced to the lowest possible level.

Relevant factors to be considered in management: Recruitment failure has been observed in surveys since 1991, and this indicates that the stock will decrease unless immediate action is taken. In this connection it is of vital importance that the juvenile age classes be given the strongest protection from being caught as bycatch in any fishery, i.e., the shrimp fisheries in the Barents Sea and Svalbard area. This will ensure that the recruiting year classes can contribute as much as possible to the stock rebuilding.

The 1987-1990 year classes (approx. $27-34 \mathrm{~cm}$ ) are currently about to recruit to the spawning stock. These year classes will be followed by at least 10 poor ones and consequently offer the last opportunity of increasing the spawning stock for a number of years to come. This opportunity will be lost unless the year classes are exploited with significantly reduced fishing mortality.

Based on estimates of current SSB and the size of year classes in the 1990 s , this stock will not be able to support a directed fishery for at least several more years. Rather, it will be necessary to prevent the stock from declining further, to maintain measures to protect this stock from bycatch in other fisheries in the medium term to SSBs much below any previously observed.

Elaboration and special comment: The only directed fishery for $S$. mentella is a trawl fishery. In addition, by-catches are taken in cod and shrimp-trawl fisheries. After the introduction of sorting grids in 1993, discarding in the shrimp fishery was reduced. Small redfish less than $18-20 \mathrm{~cm}$ are, however, not sorted out by the grid, and criteria for the maximum number of redfish per kilogram shrimp are enforced ( 10 juvenile redfish per 10 kg shrimp). Additional protection for adult $S$. mentella comprise area closures.

Traditionally, the directed fishery was conducted by Russia and other East-European countries on grounds from south of Bear Island towards Spitsbergen. From the mid-1970s to the mid-1980s large catches were taken annually. From the mid-1980s Norwegian trawlers started fishing along the continental slope
(around 500 m depth) further south, on grounds never harvested before, and inhabited primarily by mature fish. After a sharp decrease in the landings from the traditional area until 1987, this fishery on new grounds resulted in a temporary increase in the landings until 1991, after which the landings declined. Since 1991 the fishery has been dominated by Norway and Russia.

Because of the slow growth of this species, the surveys should detect improvements to incoming year classes for several years before they contribute to the fisheries or the spawning population.

### 3.1.5.b Sebastes marinus in Sub-areas I and II

State of stock/exploitation: It has not been possible to assess the status of this stock with respect to safe biological limits. Available data from the Barents Sea/Svalbard surveys and commercial CPUE on larger fish do not indicate any large recent changes in the adult stock, but the data are too noisy to detect moderate changes. However, results from the coastal and fjord survey series indicate a decrease also for larger fish since 1995. Indices from surveys in young fish areas in the Barents Sea and Svalbard waters indicate a declining trend in recruitment.

Reference points: No precautionary reference points have been proposed for this stock.

Management objectives: No explicit management objectives have been established for this stock.

Advice on management: Consistent with a precautionary approach, ICES recommends that a management plan, including monitoring of the development of the stock and of the fishery, with
corresponding regulations, should be developed and implemented as a prerequisite to continued fishing.

Relevant factors to be considered in management: The low abundance of pre-recruit fish in the recent surveys suggests that a decline in the stock can be expected over the next few years.

Elaboration and special comment: The fishery is mainly conducted by Norway accounting for $80-90 \%$ of the total catch. Germany also has a long tradition of a trawl fishery for this species. The fish are caught mainly by trawl and gillnet, and to a lesser extent by longline, Danish seine, and handline, in that order. Some of the catches are taken in mixed fisheries together with saithe and cod. Important fishing grounds are the Møre area (Svinøy), Halten Bank, outside Lofoten and Vesteralen, and at Sleppen outside Finnmark.

Source of information: Report of the Arctic Fisheries Working Group, May 2001 (ICES CM 2001/ACFM:19).

### 3.1.6 Greenland halibut in Sub-areas I and II

State of stock/exploitation: The status of the stock is not precisely known, but it is considered to be outside safe biological limits. SSB in 2001 is the lowest in the time series. Fishing mortality is estimated to be above the long-term average, and recruitment in recent years is estimated to be amongst the lowest in the time series.

Management objectives: No explicit management objectives have been established for this stock.

Reference points: No limit or precautionary reference points for the fishing mortality or the biomass are proposed.

Advice on management: ICES recommends to reduce catches to below 11000 t for 2062 in order to rebuild the stock. Furthermore, additional measures to control catch should be implemented.

Rebuilding plan: Although no precautionary reference points have been established for this stock a rebuilding plan is required. Precautionary reference points should also be defined.

Comparison with previous assessment and advice: In this year's assessment the fishing mortalities ( $\mathrm{F}_{6-10}$ ) for 1997-1999 are higher and the stock biomasses and the spawning stock biomasses are lower compared with last year's assessment. Reported landings from the fishery so far in 2001 indicate that the expected catch of Greenland halibut in 2001 will be much higher than the corresponding ICES advice.

Relevant factors to be considered in management: The exploitation history of this stock indicates that it is unable to withstand the current level of fishing mortality. Current management measures have not been effective in reducing fishing mortality. Additional management measures to control catches, e.g. TACs, area closures and reduced by-catch limits, need to be introduced and enforced effectively.

Based on the results of the Russian survey and experimental fishery for Greenland halibut Russian
scientists consider that this stock has shown a positive trend in recent years.

In general during the 1990s, SSB increased when catches were circa 10000 t or less, but decreased when catches were greater than 10000 t .

Elaboration and special comment: The assessment is considered uncertain due to age-reading problems and evidence of unreported landings that could not be taken account of. Nevertheless, it is considered that the assessment reflects the status of the stock reasonably well.

The assessment indicates that, on average, recruitment has been lower after 1980 compared to previous years.

Since 1992, the fishery has been regulated by allowing a directed fishery only by small coastal longline and gill net vessels. By-catches of Greenland halibut in the trawl fisheries have been limited by permissible bycatch per haul and an allowable by-catch retention limit on board the vessel.

Analytical assessment was based on commercial catch-at-age data, two survey series, and one experimental commercial CPUE series.

Source of information: Report of the Arctic Fisheries Working Group, May 2001 (ICES CM 2001/ACFM:19).

Yield and spawning biomass per Recruit F-reference points:

### 3.1.7.a Norwegian spring-spawning herring

State of stock/exploitation: The stock is harvested slightly above $\mathbf{F}_{\mathrm{pa}}=0.15$. The stock biomass is within safe biological limits. The recruitment of the very strong 1992 year class led to an increase in SSB in 1997 to 9 million $t$, but this has since declined to approximately 6.0 million $t$ in 2001 . Continued fishing under the present management agreement, and given the recruitment prospects, gives a low probability of the spawning stock falling below $\mathbf{B}_{\mathrm{pa}}(5.0$ million t$)$ in the medium term.

Management objectives: EU, Faroe Islands, Iceland, Norway and Russia agreed in 1999 to implement a longterm management plan. This plan consists of the following elements:

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the critical level ( $\mathbf{B}_{\text {lim }}$ ) of 2500000 t .
2. For the year 2001 and subsequent years, the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing
mortality rate of less than 0.125 for appropriate age groups as defined by ICES, unless future scientific advice requires modification of this fishing mortality rate.
3. Should the $\$ \$ B$ fall below a reference point of $5000000 \mathrm{t}\left(\mathbf{B}_{\mathrm{pa}}\right)$, the fishing mortality rate, referred under paragraph 2 , shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adoptions shall ensure a safe and rapid recovery of the SSB to a level in excess of 5000000 t .
4. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES.

ICES considers that the objectives of this agreement are consistent with the precautionary approach.

Precautionary Approach reference points (establised in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 2.5 million $t$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 5.0 million t. |
| $\mathbf{F}_{\text {lim }}$ not considered relevant for this stock | $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathrm{F}=0.15$ |

Technical basis:

| $\mathbf{B}_{\text {lim: }}:$ MBAL | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * \exp (0.4 * 1.645)$ (ICES Study Group 1998) |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}:}$ | $\mathbf{F}_{\mathrm{pa}}:$ ICES Study Group 1998 |

Advice on management: ICES advises that this fishery should be managed according to the agreed management plan corresponding to a catch of 853000 t in 2002.

Comparison with previous assessment and advice: The present assessment is in accordance with the stock size that was estimated in 2000 . The catch forecasted for 2002 is higher than was forecasted in 2000 for 2001. This is due to higher estimates of recruitment than was used earlier.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=0.135$; Landings (2001) $=\mathrm{TAC}=850000 \mathrm{t} ; \mathrm{SSB}(2002)=5.7$ million t .

| $\mathrm{F}(2002$ <br> onwards) | Basis | Catch <br> $(2002)$ | Landings <br> $(2002)$ | SSB <br> $(2003)$ | Medium term effect of fishing at given level |
| :--- | :---: | :---: | :---: | :---: | :--- |
| 0 | 0 | 0 | 0 | 7,814 | Increasing spawning stock |
| 0.05 | $0.28^{*} \mathbf{F}_{\text {W2000 }}$ | 351 | 351 | 7,491 | Increasing spawning stock |
| 0.08 | $0.45^{*} \mathbf{F}_{\text {W2000 }}$ | 548 | 548 | 7,312 | Increasing spawning stock |

| 0.125 | $0.70 * \mathbf{F}_{\text {W2000 }}$ | 853 | 853 | 7,035 | Increasing spawning stock |
| 0.15 | $0.84^{*} \mathbf{F}_{\mathrm{W} 2000}$ | 1,002 | 1,002 | 6,901 | Increasing spawning stock |
| 0.2 | $1.17 * \mathbf{F}_{\mathrm{W} 2000}$ | 1,315 | 1,315 | 6,621 | Increasing spawning stock |
|  | Stable catch of <br> 850 | 850 | 850 | 7,038 | Increasing spawning stock |

Weights in 000 t .
For 2001 landings of 850000 t were assumed to correspond to the agreed TAC. In recent years the actual catch was close to the TAC.

Medium- and long-term projections: The medium term view of the stock, based on simulations of stock development, is more optimistic than forecasted last year. The reason for this is an upgrade of the estimate of the 1999 year class, which will recruit to the spawning stock in 2004. Last year, the only data available for this year class was an abundance index from the 0 -group survey in the Barents Sea in autumn 1999. This survey indicated a moderate to poor year class. However, the results from a Russian acoustic survey for young herring in the Barents Sea in May 2000 indicate that this is a strong year class. Thus the estimate of this year class in the medium term simulations has been adjusted accordingly, resulting in a more optimistic medium term view.

Elaboration and special comment: The main catches from the fishery in 2000 were taken by Norway ( 714000 t ), Iceland ( 186000 t ), Russia ( 163000 t ) and Faeroe Islands ( 69000 t). Smaller catches were taken by a number of EU fleets. The fisheries in general follow closely the migration of the stock as it moves from the wintering and spawning grounds along the Norwegian coast to the summer feeding grounds in the Jan Mayen and international areas. The Norwegian fishery exploits the stock as it migrates to and remains on the wintering areas and during the spawning period. The Icelandic fishery takes place mainly in May and June and most catches are taken in the Jan Mayen EEZ. The main Russian catches are taken along the shelf region of the Norwegian EEZ in spring as the stock moves from the spawning grounds and also in August and September in the eastern part of the international area and in the Norwegian zone. The Faroese catches, taken mainly in spring and early summer, are from the Norwegian zone and from the Jan Mayen area. Most of the EU catches are taken in the international area and the Norwegian Sea.

A large increase in fishing effort, new technology and environmental changes contributed to the collapse of this stock around 1970. Recruitment failed when the SSB was reduced below 2.5 million t . In the years following the collapse the aim was to rebuild the spawning stock above
this minimum limit. In order to reach this goal, fishing mortality was kept low. However, recruitment remained poor and SB increased only slowly until a very strong year class occurred in 1983. As this year class recruited, management between 1985 and 1993 aimed at restricting the fishing mortality to 0.05 , although the actual $F$ was much higher in some year. Year classes after 1983 were on average more than four times stronger than those produced between 1970 and 1982, and SSB continued to increase. Starting in 1989 a succession of above average to very strong year classes were produced, promoting full recovery of the SSB and allowing expansion of fisheries. Up to 1994, the fishery was almost entirely confined to Norwegian coastal waters. Since 1992 the coastal fishery has increased sharply. During the summer of 1994 there were also catches in the offshore areas of the Norwegian Sea for the first time in 26 years. The geographical extent of this fishery increased in 1995, with nine nations participating and a total catch exceeding 900000 t . The fishery expanded further in 1996 and the anmual level of the fishery was in the order 1.2-1.5 million $t$ in the period 1996-2000. An international management agreement includes a TAC consistent with a maximum fishing mortality of $\mathrm{F}=0.125$ from 2002.

There are indications from surveys that the 1998 and 1999 year class may be strong. This has yet to be confirmed as strong recruiment to the fishery.

Multispecies dimension: Juveniles and adults of this stock form an important part of the ecos;stem in the Barents Sea and the Norwegian Sea. The herring has an important role as transformer of the plankton production to higher trophic levels (cod, seabirds and marine mammals). It is therefore important to facilitate a high production of the herring stock by allowing the stock to be kept above $\mathbf{B}_{\text {lim }}$ In the late 1950s the spawning stock was in the order of $5-10$ million $t$.

A report based on the distribution of herring over the summer feeding areas in 2001 by an international ICES co-ordinated survey will be available in September 2001.

Data and assessment: Analytical assessment based on catch and survey data (acoustic estimates of adults and recruits, tagging estimates, larval index).

Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, April 2001 (ICES CM 2001/ACFM:17).

$\mathrm{A}=$ catches of adult herring in winter.
$B=$ mixed herring fishery in remaining part of the year.
$\mathrm{C}=$ by-catches of 0 - and 1 -group herring in the sprat fishery.
$D=$ USSR-Norway by-catch in the capelin fishery (2-group).
Includes also by-catches of adult herring in other fisheries.
In 1972, there was also a directed herring 0-group fishery.
${ }^{3}$ Includes 26,000 t of immature herring (1983 year class) fished by USSR in the Barents Sea.
${ }_{5}^{4}$ Preliminary, as provided by Working Group members.
5 Details of catches by fishery and ICES area given in ICES 1999.
6 Details of catches by fishery and ICES area given in ICES 2000.
7 Details of catches by fishery and ICES area given in Tables 3.2.3-3.2.5.
Total catch of Norwegian spring spawning herring (tonnes) since 1972. Data provided by Working Group members.

### 3.1.7.b Answer to special request on Norwegian spring-spawning herring

## Norway requested ICES to:

1. provide catch options for 2001 based on fishing mortalities in the range $\mathrm{F}=0.08$ to 0.15 including $\mathrm{F}=0.125$.
2. evaluate the probability that the $\operatorname{SSB}$ will fall below $\mathbf{B}_{\mathrm{pa}}$ of $5,000,000 \mathrm{t}$ and $\mathbf{B}_{\text {lim }}$ of $2,500,000$ tonnes in a 5 and 10 -year period at various levels of constant fishing mortalities while the SSB is above $\mathbf{B}_{\mathrm{pa}}$ including values in the range of $\mathrm{F}=0.05$, $0.08,0.10,0.125,0.15,0.2$. From each of these combinations, ICES should evaluate the expected average percentage change in catches from year to year and the expected average catches over the same ten-year period.
3. continue to evaluate adaptive recovery strategies, including an option with linear reduction in $F$, in the event $\$ S B$ falls below $\mathbf{B}_{\mathrm{p}^{a}}$ of 5000000 tonnes.

The strategies should aim at preventing the SSB falls below $\mathbf{B}_{\mathrm{pa}}$ of 5000000 t . The strategies should aim at preventing the SSB from falling below $\mathbf{B}_{\text {lim }}$ with a high probability and ensure the safe recovery of the stock to above $\mathbf{B}_{\mathrm{pa}}$ at various time horizons.

## ICES responses are given below:

1. The requested options are given in the Catch Option table.
2. Table 3.1.7.b.1. Average yield, probability of SSB falling below $\mathbf{B}_{\mathrm{pa}} / \mathbf{B}_{\mathrm{lim}}$ and average annual percentage change in catch for Norwegian spring spawning herring, 5 and 10 year periods.

|  |  | 5 year |  |  |  | 10 year |  |  |  |

3. Evaluation of adaptive recovering strategies in the event $S S B$ falls below $\mathbf{B}_{\text {pa }}$.

Item 3) in the agreement on the long-term management of Norwegian spring-spawning herring considers management action in case the SSB falls below the agreed $\mathbf{B}_{\mathrm{pa}}$ of 5000000 t . It is stated that if the SSB falls below a reference point of $5000000 \mathrm{t}\left(\mathbf{B}_{\mathrm{pa}}\right)$, the fishing mortality rate of 0.125 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptations shall ensure a safe and rapid recovery of the $\operatorname{SSB}$ to a level in excess of 5000000 t .

ICES previously has on several occasions evaluated consequences of adapting $F$ in case of $\operatorname{SSB}$ falling below $\mathbf{B}_{\mathrm{pa}}$. Two types of adaptive recovery strategies have been investigated:
a) Restoring SSB to above $\mathbf{B}_{\mathrm{pa}}$ within a time constraint

A harvest control rule aiming at restoring SSB to above $\mathbf{B}_{\mathrm{pa}}$ within a time constraint (strategies that would ensure a probability of 50 to $80 \%$ of restoring the SSB
to above $\mathbf{B}_{\mathrm{pa}}$ within 2 to 5 years) was evaluated in 2000 . ICES made the following comment: "The request was regarded as relevant but it was pointed out that this type of general rebuilding approach may not be useful as a rule for stocks that show a highly variable recruiment, including the stock of Norwegian spring-spawning herring. There may be situations when the SSB is fairly low, but strong year classes are expected to recruit to the spawning stock in the near future. On the other hand there may be situations when SSB is expected to decline in the short and medium term to levels below $\mathbf{B}_{\mathrm{pa}}$ since no strong year class has been observed among the recruiting year classes. In the latter case it may not be possible to restore the SSB to above $\mathbf{B}_{\mathrm{pa}}$ within 2 to 5 years even if the fishery is stopped" (ICES 2001).

## b) Linear reduction in $F$

This type of harvest control rule has been evaluated several times. Different reduction rates in F have been considered and the general conclusions can be summed up as follows: "Medium term simulations indicate that the probability of SSB falling below $\mathrm{B}_{\mathrm{lim}}$ is almost halved when a reduction in F at SSB levels below $\mathrm{B}_{\mathrm{pa}}=$
5.0 million $t$ is applied. An example of such a reduction would be to reduce $F$ linearly to 0.05 as the $S S B$ falls from 5.0 million $t$ to 2.5 million ." (ICES 1999)

There are other advantages in applying a linear reduction in F in a harvest control rule in case SSB falls below $\mathbf{B}_{\mathrm{pa}}$ : "The fishery continues at a reduced level after the threshold is crossed, resulting in a continuity of yield; rather than open or close fisheries depending on the stock's position relative to $\mathbf{B}_{\mathrm{lim}}$. At the same time, more stringent conservation measures are applied as the stock worsens; errors in the estimation of SSB become less critical; additional time and flexibility is obtained to evaluate whether the stock is in a transition phase from one stationary state to another; short term changes in biomass levels imply only small changes in $F$ rather than permanent or large-scale changes in fishing operations; and small changes in F may be less contentious and more easily accepted than large ones". Further, NAFO has in many cases illustrated the role of a linear reduction in fishing mortality in its precautionary framework

The stock of Norwegian spring spawning herring has a highly dynamic recruitment, the development depending on the occurrence of strong year classes, whose
probabilities are affected by both SSB and environmental conditions. The consequences of actions taken if $\operatorname{SSB}$ approaches $\mathbf{B}_{\mathrm{pa}}$ will depend on the prospects of the recruitment of such year classes. Correspondingly, a suitable harvest control rule should allow for the possibility of a change in productivity, even if productivity regimes cannot be modelled accurately. Even in such a dynamic context, a linear reduction adapts the exploitation rate to the abundance of the spawning stock, and is regarded by ICES as an appropriate strategy which significantly lowers the risk for the spawning stock to come below $\mathbf{B}_{\text {lim }}$. This type of harvest control rule will in addition have some practical elements such as the continuation of fisheries even if the $B_{\mathrm{pa}}$ is crossed.
4. Medium-term projections with adaptation of F when $S S B$ is below $\mathbf{B}_{\mathrm{pa}}$
Medium term simulations were run with a linear reduction in $F$ when $S S B$ is below $B_{p a}$, from $F=0.125$ (or other relevant levels) at $\mathbf{B}_{\mathrm{pa}}$ to $\mathrm{F}=0.05$ at $\mathbf{B}_{\text {lim }}$ and lower. In accordance with the evaluation given in the section above this type of adaptation will reduce the probability of falling below $\mathbf{B}_{1 \mathrm{~m}}$ in the medium term to almost half the probability when not adapting the $F$ when SSB is below $\mathrm{B}_{\mathrm{pa}}$.

The projections that have been carried out are described in the table below:

| Parameter | Request from coastal states | Technical performance values |
| :---: | :---: | :---: |
| Fishing mortality for SSB above $\mathbf{B}_{\mathrm{pa}}$ | $0.05,0.08,0.10,0.125,0.15,0.2$ | As requested; in addition a projection with no fishing ( $\mathrm{F}=0$ ) was run for illustrative purposes |
| Catch ceiling | None | 1.5 million t. One run with catch ceiling of 850000 t , the level of the TAC for 2001. |
| Value of $\mathrm{B}_{\mathrm{pa}}$ | 5.0 million t | As requested |
| Value of $\mathrm{B}_{\text {lim }}$ | 2.5 million t | As requested |
| Time range | 5 and 10 years | As requested |
| Fishing mortality for F below $\mathrm{B}_{\mathrm{pa}}$ | Evaluate adaptive recovery strategies, including an option with linear reduction in $F$, in the event SSB falls below $\mathbf{B}_{\mathrm{pa}}$. The strategies should aim at preventing the $S S B$ from falling below $\mathbf{B}_{\text {lim }}$ with a high probability and ensure recovery to above $\mathbf{B}_{\mathrm{pa}}$ at various time horizons. | Linear decrease in F from 0.125 at $\mathbf{B}_{\mathrm{pa}}$ to 0.05 at $\mathbf{B}_{\mathrm{lim}}$ (Section 3.9) (similar decreases were also made with other requested $\mathrm{F}^{\prime} \mathrm{s}$ ( 0.05 , $0.08,0.10,0.15,0.2)$ ). |
| Measure of stability of catches | Average percentage change in catches from year to year | As requested |
| Yield | Average catches over the same ten year period | Average annual yield (tonnes) of the time range for the simulation run (5 or 10 years). |
| Risk | Probability that SSB will fall below $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{B}_{\text {lm }}$ in a 5 and 10 year period | As requested, risk to fall below $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{lim}}$ within the time range for the simulation run (5 or 10 years). |

It should be noted that, this year, the uncertainty in the initial stock is smaller than compared with last year. A constraint of 1000 billion 0 -group fish was enforced, as was done last year. The Beverton-Holt recruitment model was used also this year with the modification that the largest year classes were treated separately. Figure 1 shows the spawning-stock recruitment points used
together with the Beverton-Holt function fitted on these points with the largest year classes excluded. Russian data show (that good recruiment is associated with good egg production. Including egg production into the recruitment function gives some promise for explaining more of the observed variation.

Figure 3.1.7.b. 1 Spawning stock - recruitment points (million tonnes - billion) for Norwegian spring spawning herring based on Run 1 and the SeaStar VPA ( $F$ at oldest true age is calculated as a population weighted average of $F$ for ages $8-13$ ). The line shows a fitted Beverton-Holt relation based on the $90 \%$ smallest recruitment values (shown in black).

The projections started at January 12001 and the allocated catch for 2001 of 850000 t was enforced for all simulations. The F-value by age applied during the simulation was obtained from the F -value in the harvest control rule and the exploitation pattern used last year.

500 simulations were performed for each harvest control rule. For various harvest control rule parameters, the average yields and probabilities for the SSB to fall below $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{B}_{\text {lim }}$ for the 5-year period 2001-2005 and 10-year period 2002-2011 are given in Table 3.7.1.b.1 (see above). The average percentage change in annual catch over the 10 -year period is also given. The medium term simulations give a more positive picture of the stock development compared to last year's results. The main reason for this is the high estimate (more than 100 billion individuals) of the 1999 year class obtained in the acoustic surveys in the Barents Sea in May 2000. However, as the estimates of this year class from different surveys is conflicting, the uncertainty associated with its abundance may be greater than expressed by the formal statistical estimate. Therefore the results should be interpreted with caution.

1. Continued fishing at $\mathrm{F}=0.125$ (international agreed maximum fishing mortality) and a reduction in $F$ when $\operatorname{SSB}$ is below $\mathbf{B}_{\mathrm{pa}}$ and a catch ceiling of 1.5 million $t$, gives a low probability ( $7 \%$ ) of the stock falling below $\mathbf{B}_{\mathrm{pa}}$ in the medium-term ( 10 years). This harvesting strategy results in a $9 \%$ average annual change in the TAC.
2. The medium term simulations give no reasons to reject the conclusions that the present agreed long time strategy for this stock is in accordance with the precautionary approach in fisheries.

Figures 3.7.1.b. 2 and 3.7.1.b. 3 show the development of SSB and yield for $\mathrm{F}=0.125$ above $\mathrm{B}_{\mathrm{Fa}}=5.0$ million t with a linear reduction to $\mathrm{F}=0.05$ at $\mathbf{B}_{\mathrm{lim}}=2.5$ million t and a catch ceiling of 1.5 million $\mathrm{t} .5,25,50,75$ and 95 percentiles are given to illustrate the uncertainty in the prognosis. The spawning stock rises to above 10 million t when the 1998 and 1999 year classes mature. The impression is that the harvest control rule corresponds to rational harvesting and stabilization of the stock above $\mathbf{B}_{\mathrm{pa}}$.

According to the table the following conclusions can be drawn:

Figure 3.1.7.b. $2 \quad 10$-year stochastic projections of spawning stock biomass (million tonnes) of Norwegian spring spawning herring for $\mathrm{F}=0.125$ above $\mathbf{B}_{\mathrm{pa}}=5.0$ million t with a linear reduction to $\mathrm{F}=0.05$ at $\mathrm{B}_{\mathrm{im}}=$ 2.5 million $t$ and a catch ceiling of 1.5 million $t .5,25,50,75$ and 95 percentiles are given to illustrate the uncertainty in the prognosis.

Figure.3.1.7.b.3 10-year stochastic projections of catch (million tonnes) of Norwegian spring spawning herring for $\mathrm{F}=0.125$ above $\mathbf{B}_{\mathrm{pa}}=5.0$ million t with a linear reduction to $\mathrm{F}=0.05$ at $\mathbf{B}_{\mathrm{lim}}=2.5$ million t and a catch ceiling of 1.5 million $t$. $5,25,50,75$ and 95 percentiles are given to illustrate the uncertainty in the prognosis.

## 3. Management considerations

The juveniles and adults of this stock form a central component of the ecosystem in the Barents Sea and Norwegian Seas, respectively. The herring has an important role as a transformer of the production of zooplankton biomass and energy to a form that is available to organisms at a higher level of the food chain.

The Coastal states (the European Union, Faeroe Islands, Iceland, Norway and Russia) have agreed on a longterm management plan and on precautionary reference point ( $\boldsymbol{B}_{\mathrm{pa}}=5.0$ million t ) and limit reference point $\left(\boldsymbol{B}_{\text {liu }}\right.$
$=2.5$ million t) for this stock. The limit reference point ( 2.5 million t ) is seen as a spawning stock threshold that, if crossed, can result in a high probability of impaired recruitment, and the $\mathbf{B}_{\mathrm{pa}}$ as a safeguard measure.

A study on the population fecundity of the Norwegian spring-spawning stock that compared corresponding year classes and environmental factors concluded:

1. When the spawning stock level is at or above 6.9 million $t$ the probability of resulting weak year classes is low.
2. When the spawning stock is above 3.4 million t , its reproductive success seems to be strongly influenced by environmental variability. In other words, strong year classes will likely be produced under favourable survival conditions,
3. medium year classes under average conditions and only poor year classes when survival conditions are unfavourable. In the 7 -year period (1990-1996), when the SSB has been above the level of 3.4 million $t, 2$ strong, 3 medium and only 2 low abundance year classes of herring at age 3 appeared.
4. As the spawning stock drops below 3.4 million $t$, the probability of producing poor year classes increases. For a 27-year period (1963-1989), when the SSB was below 3.4 million t, 23 poor, 2 medium and only 1 abundant year class appeared.
5. If the SSB drops to or below 0.3 million $t$ the probability of the appearance of a strong year class is extremely low.

The current stock assessment indicates a spawning stock in 2001of approximately 6 million t , stock abundance having declined from 9 million $t$ since 1997. The future prospects indicate an increasing spawning stock if the stock is exploited at the agreed fishing mortality ( $\mathrm{F}=0.125$ ). However, this positive view is based on expectation of a strong 1999 year class from the Barents Sea. The survey series from this area gives different indications of the size of this year class and the estimate is uncertain.

### 3.1.8 Barents Sea capelin (Sub-areas I and II, excluding Division Ha west of $5^{\circ}$ W)

State of stock/exploitation: The stock is within safe biological limits. The maturing component in autumn 2001 was estimated to be 2.0 million $t$, and is predicted to be 1.2 million $t$ at the time of spawning in 2002 without fishing. This is above $\mathbf{B}_{\text {tIII }}$ with a very high probability.

Management ohjectives: The fishery is managed according to a target escapement strategy, with a harvest control rule allowing (with $95 \%$ probability) the SSB to be above $\mathbf{B}_{\text {tinl }}$, taking account of predation by cod.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {im }}$ is set equal to 200000 t , which is above the $\mathrm{SSB}_{1989}$, <br> the lowest SSB that has produced a good year class. | $\mathbf{B}_{\mathrm{pa}}$ not defined (not relevant). |
| $\mathbf{F}_{\text {lim }}$ not defined (not relevant). | $\mathbf{F}_{\mathrm{pa}}$ not defined (not relevant). |

#### Abstract

Advice on management: In order for the SSB to stay above $B_{\text {lim }}$ with more than $95 \%$ probability, the catch in 2002 should be less than 650000 t . ICES further recommends that the fishery should be directed on the spawning stock in the period January-April.

Relevant factors to be considered in management: The estimated annual consumption of capelin by cod has varied between 0.2 and 3.0 million $t$ over the period 1984-2000. Young herring consume capelin larvae, and this predation pressure is thought to be one of the causes for the poor year classes of capelin in the periods 1984-1987 and in 1992-1994. The quantity of young herring in the Barents Sea during 1999-2001 has again increased towards the same level as in those two periods of poor capelin recruitment. The 1999 year class of herring has been estimated to be above average, while the 2000 and 2001 year classes of herring seem to be poor. The abundance of herring in the Barents Sea is believed to decrease again from an intermediate level in 2001 to a low level in 2002.

For this stock, a $\mathbf{B}_{\text {lim }}$ equal to the 1989 spawning stock biomass, which is the lowest SSB having produced an outstanding year class, is considered a good basis for such a reference point in a non-herring situation. Such a situation is expected in 2002. The median value of the 1989 spawning stock biomass is 69000 t . However, the assessment model may not yet account for all sources of uncertainty, and there are inconsistencies in the data series. Thus, it may be appropriate to use a somewhat higher $\mathbf{B}_{\text {lim }}$. In recent years ICES has used a $\mathbf{B}_{\text {lim }}$ of 200000 t .

The $\mathbf{B}_{\text {lim }}$ rule is intended to be a safeguard against recruitment failure. However, it is possible that the recruitment would be larger at a larger spawning stock, especially for moderately good recruitment conditions. In such a situation a target-based control rule in addition to the $\mathbf{B}_{\mathrm{lm}}$-based rule could be appropriate. The negative influence of herring on capelin
recruitment should be included in the $\mathbf{B}_{\text {linin }}$-based nule if such a relationship can be described quantitatively. Adjustments of the harvest control rule should be investigated further to take the uncertainty in the predicted amount of spawners and the role of capelin as a prey item into account.

Catch forecast for 2002: The spawning stock in 2002 is predicted from the acoustic survey in September 2001, by a model, which estimates maturity, growth and mortality (including predation by cod). The model takes account of uncertainties both in the survey estimate and in other input data. For catches in 2002 below 650000 t , the probability of having an SSB below 200000 t is less than $5 \%$ and the expected amount left for spawning is 620000 t . Only catches of mature fish have been considered. The proportion of large fish (suitable for human consumption) in the spawning stock is similar to the three previous years, but high compared to most years in the time series.

Elaboration and special comments: The spawning stock in 2002 will consist almost exclusively of fish from the 1998 and 1999 year classes. The survey estimate at age 1 of the 2000 year class is the lowest since the 1996 year class, and is below the long-term average. Observations during the international 0 -group survey in August 2001 indicated that the 2001 year class is weaker than the 1997-2000 year classes. The stock size is thus expected to decrease in the next two years.

Since 1979 the fishery has been regulated by a bilateral agreement between Norway and Russia (formerly USSR). The catches have been very close to the advice in all years since 1987.

The assessment and stock history is based on joint Russian-Norwegian acoustic surveys during September each year. From 1998 onwards, a model incorporating predation from cod has been used for predicting SSB and for estimating the historical time series of SSB.

[^12]

Figure 3.1.8.1 Maturing biomass and recruitment.

### 3.1.9 Shrimp (Pandalus borealis)

State of stock/exploitation: This stock is probably within safe biological limits. Surveys indicate that the biomass is close to the 1985-2000 average (Figure 3.1.9.1). No estimates of fishing mortality are available. Fishing effort for both Russia and Norway generally declined during the 1990 s, but has increased in the most recent years and is also associated with an increase in efficiency through the use of multi-trawl fishing gears.

Management objectives: There are no explicit management objectives for this stock.

Reference points: No precautionary reference points have been proposed for this stock.

Advice on management: ICES advises that current catch rates are sustainable.

Relevant factors to be considered in management: Shrimp is an important prey for several fish species, especially cod. Consumption by cod significantly influences shrimp population dynamics and should be taken into account in management. Cod consumption estimates are on average much higher than shrimp landings (Figures 3.1.9.3 and 3.1.9.4). The biomass of shrimp consumed by cod increased in 2000 and is expected to contribute to a reduction of the shrimp stock biomass in 2001. However, survey indices since 1985 indicate that the shrimp biomass has varied cyclically without trend over that period.

Elaboration and special comment: Reported landings for all countries show a substantial increase in catches between $1996(33000 \mathrm{t})$ and $2000(79000 \mathrm{t})$ (Table 3.1.9.1 and Figure 3.1.9.4). Catch increases from 1994 1999 encouraged the fishery to invest in larger vessels and new technology. The adoption of multiple trawl gears, predominantly by Norway, is not accounted for in the Norwegian CPUE series (Figure 3.1.9.2).

In the Svalbard area the shrimp fisheries are regulated by number of effective fishing days and number of vessels by country. In the Barents Sea and Svalbard area, Norwegian rules stipulate that the fisheries are to be regulated by smallest allowable shrimp size (a maximum $10 \%$ of the catch weight may consist of shrimp less than 15 mm carapace length, CL) and by provisions of the fishing licenses. The Russian Economic Zone TAC is established each year by Russian authorities. In the Barents Sea and the Svalbard area fishing grounds are closed if by-catch limits for cod, haddock, redfish or Greenland halibut are exceeded.

No analytical assessment is available, Commercial CPUE series and survey series are considered to be of reasonable quality, although in the future account will have to taken of efficiency increases due to the use of multi-rig trawls.

### 3.2.1 Overview

## The fisheries

Stocks in the north-western areas have been exploited mainly by Icelandic vessels since the mid-seventies. However, vessels of other nationalities have also been operating in Sub-areas XII and XIV during this period. In the most recent years freezer and factory trawlers of various nationalities have been increasing in number in the pelagic deep-water fishery on redfish in Sub-areas XII and XIV. Norwegian vessels have also taken part in the capelin fishery, mainly in the Jan Mayen area.

The fisheries for the main pelagic species, Icelandic summer-spawning herring and capelin in the IcelandEast Greentand-Jan Mayen area, are almost exclusively carried out by purse seiners, although in recent years catches of herring by pelagic trawls have increased. The demersal species are mainly exploited by stern trawlers but considerable fisheries for cod are also carried out by gill nets, longline and handline. In general, effort is considered to be increasing or to have stabilised at high levels in recent years. Exceptions to this include the, herring and capelin, where harvest control rules have been implemented. Fisheries in these areas use the most up-to-date equipment both for navigation and in fishdetection. More effective fishing gears have been introduced in the fisheries, not least pelagic trawls but there have also been substantial improvements of other gears such as bottom trawl, longline and handline. New fishing technology permits fishing deeper with pelagic trawis.

## Management measures

The demersal fisheries have been managed by TACs since 1984 and the pelagic fisheries since the seventies (except of pelagic redfish, which have been regulated since 1989). Fisheries in these areas are managed on a transferable quota system basis considered to lead to economic benefits in the long term. Each vessel (or factory) is allocated a proportion of the TAC of a fish stock and this proportion can be traded on a free-market. All fisheries are subject to a range of other management measures such as fishing gear regulations, closed areas and closed seasons. Efforts have been made to prohibit discards through the introduction of a minimum catching size instead of a minimum landing size. These measures, however, are partly counterbalanced by other constraints on the fisheries such as quotas.

## The state of stocks

The fish stocks considered in this report include the largest stocks in these areas capelin, cod and redfish. These and other species spawn in the warmer regions of Atlantic water but they differ substantially in their distribution patterns during other periods of their life
cycle. Greenland halibut and deep-sea Sebastes mentella are the only demersal deep-water species among the stocks considered. Saithe is migratory and migrations between Norway and Iceland have been observed. Pelagic redfish (both pelagic deep-sea and oceanic Sebastes mentella) constitute a vast resource although increasing effort is directed towards it. A number of other demersal commercial stocks inhabit both the continental shelf, e.g. flatfish species, and deeper waters, e.g. ling, blue ling and tusk Most of these stocks are not regulated by TACs.

Most of the largest stocks have been at low levels during the most recent decades. Only deep-sea $S$. mentella on the shelf seem to rebuild slowly. The capelin stock is considered to be at a relatively high level of stock biomass. The Greenland halibut stock has been declining for more than a decade but seems now to have stabilised at a low level and starting to rebuild slowly. Both saithe and haddock are considered to be at a low level. The Icelandic summer-spawning herring has been increasing steadily during the last two decades and is at a higher level of stock size than observed in previous periods. Further information on the demersal stocks at Greenland and Iceland are given in a later section of this overview.

## Other issues

The resources in the area have generally been managed on the basis of fairly long and detailed time series of data. There are well known difficulties with the assessments, for example age readings of slow growing species such as redfish and Greenland halibut. The problems are the same in these areas as elsewhere. Greenland halibut, pelagic redfish stocks in the Irminger Sea (Sub-areas XII and XIV) and deep-sea $S$. mentella on the shelf (Sub-areas V, XII and XIV) are the stocks with the most apparent need for improvements in data analysis and in the gathering of auxiliary information. Such auxiliary information required is trawl abundance or acoustic stock indices. Comprehensive assessment of these large and widely distributed stocks is a challenging task, which requires full scale international cooperation.

Interaction between commercially valuable species is frequently observed but appears to be most pronounced for few species. The most important predator-prey relationships are the cod-capelin and cod-Pandalus interactions. Cod growth depends of capelin abundance and cod predation influences the recruitment of Pandalus. The high abundance of deep-water Pandalus in Icelandic waters in recent years is considered to be a result of this interaction caused by the low of the cod stock. Baleen whales have not been harvested commercially for some time and a continued increase in
the abundance of cetaceans is likely to result in increased natural mortality on stocks such as cod in Division Va.

## Demersal stocks at Greenland and Iceland

The cod at Greenland and Iceland has four components spawning in different areas: A West Greenland offshore component spawning off South-west Greenland (now virtually non-existing), an inshore component found in various West Greenland fjords, a component spawning off East Greenland and a component spawning off Iceland. Eggs and larvae from the East GreenlandIceland components are carried by the Irminger current to West Greenland. The inflow of larvae varies from year to year but for some year classes, such as those of 1973 and 1984, this $\mathbf{F}_{\text {low }}$ was very important.

Emigration of mature offshore cod from West Greenland is well known and most evident for year classes which were earlier observed as 0 -group drifting from Iceland to Greenland.

The fishery off West Greenland has traditionally consisted of an offshore trawl fishery and an inshore fishery mostly using poundnets. The catches have fluctuated substantially, but declined dramatically after 1989 and the offshore fishery has now ceased.

Cod catches off East Greenland have also fluctuated widely and decreased sharply in 1993 when the directed cod fishery failed totally due to very low catch rates.

All available information confirms the severely depleted state of the cod stock off Greenland. The offshore stock may be considered to be almost non-existent at the present time. Strong year classes observed at Iceland as 0-group in 1997-1999 only appeared as moderate at age

1 in bottom trawl surveys in Greenland waters. A rise in water temperatures at East- and West Greenland may provide the basis for a higher recruitment to the West Greenland area.

The inshore stock component has historically been small and available information indicates that recruitment will be low during the next few years.

In Icelandic waters, the cod stock has not shown sign of recovery and is still at a low level due to poor recruitment since 1986 and due to a high and increasing fishing pressure. The management regime adopted in 1995 of harvesting $25 \%$ of the available biomass is previously considered likely to ensure rebuilding of the stock, but this harvesting regime has resulted in fishing mortalities well above what expected. The most recent year classes are somewhat below average size.

The Icelandic saithe stock is considered to be outside safe biological limits. Saithe is taken in mixed fisheries with cod.

The Icelandic haddock has for more than a decade been exploited at a very high fishing mortality. The stock is close to record low. Several strong year classes enter or are expected to enter the fishery.

The fishery for Greenland halibut in Sub-areas V and XIV is conducted by various nations but is still dominated by Icelandic trawlers in Division Va. The fishery in Divisions XIVb and Vb constitutes now about a third of the total fishery for Greenland halibut within Sub-areas V and XIV. Surveys have only recently been initiated for Greenland halibut. All indices, surveys as well as commercial CPUE's suggest that the stock has stabilised and may be rebuilding slowly.

### 3.2.2

Cod

### 3.2.2.a Greenland cod (ICES Sub-area XIV and NAFO Sub-area 1)

State of stock/exploitation: The stock is outside safe biological limits. The offshore component is severely depleted since 1990 with a very small recovery potential as derived from recent survey indices. The dramatic decrease in stock abundance was associated with changes in environmental conditions, emigration and high fishing mortalities. Inshore catches and CPUE are presently low and both have declined continuously since 1991. Recruitment to the inshore component has been poor since the 1993 year class and indices indicate that the inshore stock is still declining. Only the offshore catches in Greenland are subject to a TAC regulation. The inshore fishery is unregulated. This may give cause for concern about the exploitation rate of the inshore component.

Management objectives: Greenland and EU established an agreement on fisheries valid from 2001 to 2006. A variable TAC regulation has been agreed, with annual TACs adjusted to take account of ICES advice on stock status. The agreement also provides for a transfer of catches into future years, should a rapid increase in stock occur.

No reference points have been proposed for this stock, so the Agreement cannot be evaluated relative to the Precautionary Approach. However, TAC for 2002 is not consistent with the current ICES advice, and ICES stresses that any multi-year management plan should ensure that fisheries do not expand until a substantial increase in biomass and recruitment is evident.

Advice on management: ICES recommends that no fishery should take place until a substantial increase in biomass and recruitment is evident. A recovery plan for both the inshore and offshore components should be developed in order to take advantage of strong year classes when they occur and to protect all inshore spawning components.

Comparison with previous assessment and advice: An analytical assessment was performed in 1996,
covering only the offshore component for the period 1955-1992. The most recent information available is based on a German groundfish survey, a Greenland trawl survey directed towards shrimp, and a Greenland inshore gillnet survey.

Medium- and long-term projections: Not updated, last version from 1996.

Elaboration and special comment: The historic fishery was mainly targeted at cod with some redfish as a by-catch. The fishery was international until the declaration of EEZs in the 1970s. During the 1980 s EU vessels, mainly freezer trawlers, dominated the offshore fishery. During the late 1980 s the offshore fishery was based almost exclusively on the 1984 and 1985 year classes. Thereafter, a total failure of the directed cod fishery indicated a stock collapse. Cod by-catch in the shrimp fishery is expected to be substantially reduced due to the mandatory use of sorting grids since October 2000.

In Greenland waters there are inshore fjord stocks and offshore stocks. Given suitable climatic conditions (water temperature) and prudent management, sustained production of offshore cod is possible. However, interaction between the East Greenland and Irminger currents during the early 1970s and 1980s has apparently rendered climatic conditions unsuitable for offshore cod in some years. Combined with high fishing mortality, this caused the offshore cod stock to be severely depleted. In order to take advantage of suitable climatic conditions, when they occur, it is necessary to protect the remaining biomass of offshore cod.

### 3.2.2.b Icelandic cod (Division Va)

State of stock/exploitation: SSB is currently estimated to be about 240000 t , near its historic low of 220000 t (1993) is currently below long term average and the current $F$ of 0.77 exceeds $F_{\text {med }}$. Recruitment was poor or below average for the year classes 1985-1996. The 1997 to 1999 year classes are estimated at about average size, and the first signs of the 2000 year class suggest that it is at least average. Fishing mortality dropped markedly in 1994 and 1995 in accordance with the measures taken by Iceland to reduce fishing effort against cod, but has increased since then. The very poor 1996 year class entered the fishable biomass in year 2000 and accelerated the decline in stock biomass and catch.

Management objectives: A formal Harvest Control Rule was implemented for this stock in 1995. The TAC for a fishing year is set as a fraction (25\%) of the "available biomass" which is computed as the biomass of age 4 and older fish, $-B(4+)$-averaged over the two adjacent calendar years. In the long term, this corresponds to a fishing mortality of about 0.4 . That harvest control rule was considered to be in accordance with the precautionary approach.

Last year the government introduced an amendment to the catch rule limiting interannual changes in catches to 30 kT . Limited studies, using a similar approach as when the initial catch rule was adopted were the basis for this amendment. ICES has not evaluated this amendment relative to the precautionary approach.

Advice on management: ICES advises to apply the Harvest Control Rule, which takes $25 \%$ of the $4+$ biomass, corresponding to a projected catch of 164000 t in 2002.

Relevant factors to be considered in management: Safe biological limits have not been defined for this stock.

The catch consistent with the application of the Harvest Control Rule results in an estimated $F$ of 0.50 in 2002, which is well above the $F$ expected from the Harvest Control Rule, as has been the case since the Harvest Control Rule was adopted.

The stock has been consistently overestimated in recent years and retrospective patterns indicate that the overestimation of the stock may not be fully accounted for in the current assessment. The overestimations have led to higher realized fishing mortality than intended when applying the Harvest Control Rule.

Evaluations of catch rules need to consider the effect of recurrent overestimations of stock size, which would result in the realized exploitation rate being consistently higher than the rate intended. Occurrence of a series of poor year classes in succession should also be considered. These and other potentially autocorrelated factors have to be taken into account when adopting a catch rule, particularly one with an interamual constraint on variation in TAC. If the real assessment and implementation errors are greater and more auto-correlated than those assumed in the simulations, then the catch rule may not be precautionary.

At present fishing mortality is high, and age 4 and younger fish account for most of the stock biomass. This situation makes discards (and possibly hidden mortality due to mesh penetration) a major concern as high fishing effort will be directed towards the small fish.

The amended Harvest Control Rule corresponds to a catch of 190000 t in 2002 , which would result in exploitation higher than what ICES would advise.

Catch forecast for 2002：
Assuming a catch in 2001 of 205000 t （TAC－based），the following catch options were derived for 2002 （assuming catch＝landings in all years）：
Basis：Landings $(2001)=205 ; \mathrm{B}(4+, 2001)=623 ; \mathrm{SSB}(2001)=245 ; \mathrm{B}(4+, 2002)=689$ ．

| $\begin{gathered} \mathrm{F}(2002 \\ \text { onwards }) \end{gathered}$ | Basis | Catch $(2002)$ | SSB（2002） | $\begin{gathered} \mathrm{B}(4+) \\ (2003) \end{gathered}$ | $\begin{gathered} \hline \text { SSB } \\ (2003) \end{gathered}$ | Medium－term effect of fishing at given level |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Weights in 000 t ．
Shaded scenarios considered inconsistent with the precautionary approach．
Rule1：Original catch rule applied for advisory years 1996－2000．
Rule2：Amended catch rule applied for 2001.

Elaboration and special comment：In order to protect juvenile fish，fishing is prohibited in areas where the number of small $\operatorname{cod}(<55 \mathrm{~cm})$ in the catches exceeds $25 \%$ ．

From 1977－1983，demersal fishing was limited to a certain number of days each year，but this system，as implemented，failed to meet the objective of limiting fishing mortality and a transferable boat quota system was introduced in 1984．TACs are set for each fishing year，which runs from 1 September through to 31 August in the following year．Catches have exceeded national advice and national TACs considerably for the past decade．ICES

TAC advice on this stock was first given for 1993．In the most recent years catches have been close to the agreed TAC．

Based on extensive simulation work indicating that the biomass would grow under the catch rule，ICES concluded that the $25 \%$ catch rule adopted by Iceland for Icelandic cod was consistent with the precautionary approach．Realised fishing mortalities since the implementation of the catch rule have generally exceeded $\mathbf{F}_{\text {med }}=0.52$ ，while $\mathrm{F}=0.4$ was expected from the long term application of the catch rule．The actual percentage biomass removed has been；

| $1995 / 96$ | $1996 / 97$ | $1997 / 98$ | $1998 / 99$ | $1999 / 2000$ | $2000 / 2001$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $27 \%$ | $27 \%$ | $30 \%$ | $35 \%$ | $39 \%$ | $37 \%$ |

Consequently，the combination of harvest control rules and recent assessments with a substantial retrospective pattern，has resulted in the Harvest Control Rule not achieving the objective of constraining $\mathrm{F}<0.40$ ．

Modelling studies of multispecies interactions indicate that medium－term forecasts should include a higher natural mortality of cod，given the present trends in predator abundance．

In years of high recruitment a larval drift to Greenland is sometimes observed，resulting in a large year class at Greenland as well．In some other years an immigration of adult cod from Greenland has taken place，which has been taken into account in the assessment．

Data and assessment：The analytical assessment is based on catch and survey data using the XSA
programme．An exploratory assessment using the TSA programme gave similar results．Catch－at－age data are considered reliable．

### 3.2.3 Icelandic haddock (Division Va)

State of stock/exploitation: The $\$ \$ B$ has decreased since the early 1990 s and is now the second lowest in the last two decades. Fishing mortality has increased in recent years and is above any candidate values for $\mathbf{F}_{\mathrm{pa}}$. Recruitment and spawning stock fluctuate widely. A strong year class from 1995 began entering the fishery in 1998 and there is evidence from the survey of strong year classes in 1998, 1999 and 2000, but the year class of 1996 is close to a historic low.

Management objectives: There is no explicit management objective for this stock.

Reference points: Work is ongoing to establish a longer data series. Such time series will be the basis for establishing biological reference points,. $\mathbf{F}_{\mathrm{pa}}(=0.47)$ equal to $F_{\text {med }}$ has been provisionally proposed in 2000 .

Advice on management: ICES advises that fishing mortality in 2002 should be reduced to below $\mathrm{F}_{\mathrm{pa}}=$ 0.47 , which corresponds to a catch of less than 30000 t .

Relevant factors to be considered when managing this fishery: The SSB and recruitment are highly variable, and SSB is close to a record low. Fishing mortality is increasing.

Year classes 1998 and 1999 are estimated to be 84 and 72 million, compared to a geometric mean of 47 million from 1978-1999.

Data from 1960 to 2000 indicate that recruitment overfishing has not been a problem. Mortality of haddock slipping through gear meshes is potentially a problem, which, if taken into account, would lower the fishing mortality that maximises yield.

Comparison with previous assessment and advice: The present assessment is largely in line with last year's assessment, but indicates about $10 \%$ Iower SSB estimates in the most recent years.

## Catch forecast for 2002:

Basis: TAC/National estimates, Landings (2001) $=42, \mathrm{~F}(2001)=0.86, \mathrm{SSB}(2002)=64$.

| $F(2002)$ | Basis | Landings (2002) | SSB (2003) |

|  |  | 4\% |  |
|  |  |  | ¢\% |

Weights in ${ }^{4} 000 \mathrm{t}$.
Shaded scenarios considered inconsistent with the precautionary approach.

Elaboration and special comment: Iceland extended its fisheries jurisdiction to 200 miles in 1975 , resulting in a temporary reduction in fishing mortality. In the demersal fisheries, the mesh size in trawls increased from 120 mm to 135 mm in 1976 and to 155 mm the following year. From 1977-1983, demersal fishing was limited by a number of days each year. As this system failed to limit fishing mortality a transferable boat quota system was introduced in 1984. TACs are set for each fishing year ( 1 September to 31 August).

The Icelandic haddock stock is subject to substantial fluctuations in SSB and recruitment, with large year classes dominating the catch in some years. The data from the currently available time series do not indicate reduced recruitment at low SSB.

Data and Assessment: Assessments have reliably estimated stock numbers, but the estimated biomass has been consistently too high due to over-estimated
weights at age. This has led to higher fishing mortalities than intended. A revision of the stock weights should have alleviated this problem.

The analytical assessment is based on catch and sarvey data.

### 3.2.4 Saithe in Icelandic waters (Division Va)

State of stock/exploitation: The stock is at present considered to be outside safe biological limits. SSB is below $\mathbf{B}_{\mathrm{pa}}$ and close to $\mathbf{B}_{\mathrm{lim}}$. Fishing mortality has been substantially above $\mathbf{F}_{\mathrm{pa}}(0.30)$ for all years except two during the last two decades. SSB was at a historic low in 1998 to 2000; less than $50 \%$ of the 1962-1998 average. Recruitment has been below the long-term average since 1989.

Management objectives: There is no explicit management objective for this stock. However, for any management objective to meet precautionary criteria, $F$ should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and spawning stock biomass should be greater than the proposed $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed in 1998 that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is set tentatively at 90000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 150000 t |
| $\mathrm{F}_{\text {lim }}$ is as yet undefined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.3 |

Technical basis:

| $\mathbf{B}_{\text {lin }}: \mathbf{B}_{\text {loss }}$ estimate in 1998 | $\mathbf{B}_{\text {pa }}$ observed low SSB values in 1978-1993 |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ | $\mathbf{F}_{\text {pa }}$ fishing mortality sustained for 3 decades |

Advice on management: ICES advises that no directed fishing for saithe should take place and measures be implemented to keep by-catch of saithe in mixed demersal fisheries as small as possible. Directed fishing for saithe may be prevented by closing appropriate areas.

Relevant factors to be considered by management: Recruitment has been consistently low since 1989. The cause of this is unclear, but the possibility of a regime shift cannot be ruled out. There may be a need for adapting reference points to be in accordance with a
situation with reduced productivity. Preliminary simulations indicate that a fishing mortality of 0.18 is necessary to reach the present $\mathbf{B}_{\mathrm{pa}}$ within 10 years with a more than $80 \%$ probability.

A reduction in fishing mortality is advised both for cod and haddock in Division Va. To the extent that saithe is caught in mixed demersal fisheries, a general effort reduction will help to improve the exploitation also for saithe, but measures need to be taken to keep by-catches of saithe in mixed fisheries as low as possible.

## Catch forecast for 2002:

Basis: National TAC gives $F(2001)=0.35(=0.98 F(2000)$ ); Landings $(2001)=31 ; \operatorname{SSB}(2002)=88$. No discards assumed.

| F (2002 onwards) | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0.00 |  | 0 | 117 |
| 0.07 | $0.2 \mathrm{~F}(2000)$ | 7 | 110 |
| 0.14 | $0.4 \mathrm{~F}(2000)$ | 14 | 104 |
| 0.21 | $0.6 \mathrm{~F}(2000)$ | 20 | 99 |
| 0.27 | $0.75 \mathrm{~F}(2000)$ | 25 | 95 |
|  | K, | \% | §\%だ, |
|  |  |  |  |

Weights in ' 000 t . Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections were done for the stock with input data on selectivity as the average in 1998-2000, and weight at age and maturity predicted with models used in the assessment. Recruitment values were drawn from two periods, from 1980-1998, and from the recent period of lower than long-term average recruitment in 19901998. Yield and SSB under constant fishing mortalities of a number of multipliers of status quo $\mathrm{F}\left(\mathrm{F}_{s q}=0.35\right)$, were brought forward in simulations for 20 years.

The simulations indicate that the probability of SSB reaching $\mathbf{B}_{\mathrm{pa}}$ by 2010 is close to $50 \%$ when tishing at $\mathbf{F}_{\mathrm{sq}}$ on a stock composed of recruitments as in the period $1980-98$, but $80 \%$ when a $25 \%$ reduction in fishing mortality is imposed.

Assuming the recent lower recruitments (1989-1998), a fishing mortality at $0.5 \mathbf{F}_{\text {sq }}(=0.18)$ gives an $80 \%$ probability that $B>B_{p a}$ at 2010 . In order to allow SSB to recover to $\mathbf{B}_{\mathrm{pa}}$ already by $2005-2006$ with $80 \%$
probability, a fishing mortality of 0.12 is required with the lower recruitment level.

Elaboration and special comment: Saithe are taken in a mixed demersal fishery although they may be targeted at certain times, especially in times of high stock abundance. In order to protect juvenile fish, fishing is prohibited in areas where the number of small saithe in the catches exceeds a given percentage.

ICES recommends to evaluate the possibility of imposing closed areas to protect spawning aggregations of saithe.

Time series analysis (TSA) using catch at age data only, with an estimated linear trend in recruitment, was used to estimate fishing mortalities. Migrations from other stocks were included in the stock assessment for the second time.

Exploratory assessments using XSA gave terminal $\mathrm{F}_{4.9}$ values similar to or a bit lower than TSA, in the range of $0.2-0.4$ for both methods.

### 3.2.5 Greenland halibut in Sub-areas V and XIV

State of stock/exploitation: The stock is harvested outside safe biological limits. Recent Fs are estimated to be above the proposed $\boldsymbol{F}_{\mathrm{pa}}$ and close to $\mathbf{F}_{\text {MSY }}$. Even though the recent historical development of SSB and fishing mortality are not well estimated, it is likely that fishing mortality has decreased and biomass increased in recent years. Survey biomass indices have remained relatively stable since 1996.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points: The ASPIC model provides estimates of the biomass relative to $\mathbf{B}_{\text {MSY }}$ and of F relative to $\mathbf{F}_{\text {MSY }}$. The ratio $\mathrm{F} / \mathbf{F}_{\text {MSY }}$ equal to 0.67 is used in the advice as an upper boundary for $F$.

Advice on management: ICES recommends that the ratio $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ in 2002 be reduced to below 0.67, corresponding to catches in 2002 for the total stock of less than 21000 t .

Relevant factors to be considered in management: For a number of years total catches have exceeded the advised TAC. There is no consistent management in the three areas (Divisions $\mathrm{Va}, \mathrm{Vb}$ and XIVb ). At present the fishery in Division Vb is subject to effort limitation and the fisheries in Divisions XIVb and Va are catch limited. The agreed TAC in Division Va has been close to the recommended TAC for the entire area. The combination of different management measures in different Sub-areas mean that there is no control over total fishing mortality for this stock.

Comparison with previous assessment and advice: The previous VPA-based assessment was considered provisional. Advice of this year is based on a production model. According to the results of this model an appropriate $\mathbf{F}_{\mathrm{pa}}$ would be 0.25 , which is $2 / 3$ of the estimated $\mathbf{F}_{\text {msy }}$. This fishing mortality will allow the stock to recover to $\mathbf{B}_{\text {MSY }}$ in the short term.

Medium- and long-term projections: Forward projections of population biomass and fishing mortality were made under three different harvesting regimes, including estimates of uncertainty, assuming a catch in 2001 of 30000 t . Fishing at $\mathbf{F}_{\mathrm{pa}}\left(2 / 3 \mathbf{F}_{\mathrm{MSY}}\right)$, it is expected that the biomass will increase and have a $50 \%$ probability of reaching $\mathbf{B}_{\mathrm{MSY}}$ by 2004. Fishing at $\mathbf{F}_{\mathrm{sq}}$ ( $-\mathbf{F}_{\text {MSY }}$ ), biomass will increase more slowly, and it is expected to have at least a $50 \%$ probability of reaching $\mathbf{B}_{\text {MSY }}$ by 2010, although the confidence interval is wide. Fishing at 30 kt annually is expected have a high probability of $B>\mathbf{B}_{\text {msy }}$ in the medium term, but also implies a considerable risk of a stock collapse.

Elaboration and special comment: Since the nursery grounds are not known and the juveniles therefore not monitored, and as Greenland halibut is a slow-growing species, which first appears in the catches at age 5 , a possible recruitment failure will only be detected in the fishery some $5-10$ years after it occurs.

Source of information: Report of the North-Western Working Group, April/May 2001 (ICES CM 2001/ACFM:20).

### 3.2.6.a Overview

Stocks: There are two main commercial species of redfish in Sub-Areas V, XII, and XIV, Sebastes marinus and $S$. mentella. In Division Va a small fishery has recently developed on the third redfish species, $S$. viviparus. There are indications that $S$. marinus includes a genetically distinct component "giant" $S$. marinus, with a different depth distribution than typical $S$. marinus. The stock structure of $S$. mentella is complex and uncertain, but there are indications that there may be at least "oceanic", "pelagic deep-sea" and "deep-sea" stocks or stock components. Both the "oceanic" and "pelagic deep-sea" forms in the Irminger Sea are sometimes referred to as pelagic redfish, to differentiate them from the redfish associated with the slope and shelf areas. Thus the redfish fisheries in Sub-areas V, XII, and XIV operate on several stocks.

Of these stocks, typical $S$. marinus is mainly distributed in the shallower shelf areas, down to about 500 m depth.

The relationships of the various forms of S. mentella are complex, and not clearly differentiated. "Oceanic" and "pelagic deep-sea" forms of $S$. mentella both have pelagic distributions in the open Irminger Sea, and both can be found in depths from 100 to 1000 m . The "pelagic deep-sea" form is much more common than the "oceanic" form at depths greater than 500 m , and is exploited primarily by pelagic trawls. The "oceanic" form has its highest concentrations at depths less than

500 m , where it is exploited by the same fishing gears as the "pelagic deep-sea" form. The "deep-sea" form has a distribution more closely associated with the continental shelf than either of the other forms, with a depth distribution from below 1000 m up to above 500 m , where it overlaps with typical $S$. marinus. The "deepsea" form is exploited primarily by otter board trawls, although other gears are also used.

Genetic methods suggest that these three forms of $S$. mentella are genetically distinct, and that some types may even have additional substructure. However, in terms of distribution in the sea, there is substantial overlap of "pelagic deep-sea" and "oceanic" forms in the open sea. The distribution of the "pelagic deep-sea" form extends northward close enough to the continental shelf to overlap with the "deep-sea" form, and there may be exchange between the "oceanic" form and the "deep-sea" form at depths around 500 m near the continental slope as well. The figure below illustrates the complexities and uncertainties of the distributions of the species and forms of Sebastes in the Northwest area. Research continues to clarify the genetic relationships among the various forms, but regardless of future advances in that area, the morphological similarities among species and forms, and the overlapping distributions among them will continue to present difficulties for assessment and management of these resources.

Historic development of the fishery: Redfish in Division Va are mainly caught by trawlers using demersal and pelagic trawl. S. marinus is the predominant species down to depths of about 500 m , whereas deep-sea $S$. mentella contributes mostly to the catches at greater depths. The Icelandic fleet takes the major part of the catches, but vessels from Germany and Faroe Islands also fish in Division Va. In recent years the Icelandic fleet has also caught pelagic $S$. mentella in the deeper parts of Division Va using pelagic trawl.

In Division Vb, redfish are mainly caught by trawlers using demersal trawls. Down to about $500 \mathrm{~m}, S$. marinus is the most important redfish species, and pair-trawlers are the most important fleet. Deeper than about 500 m , redfish catches consist almost exclusively of deep-sea $S$. mentella taken mostly by otter-board trawlers larger than 1000 HP . The Faroese catches constitute more than $90 \%$ of the redfish catches in this division. Otter-board trawlers from Germany and France occasionally target these stocks. The remainder of the total catches is mainly by-catch in other demersal fisheries.

Redfish catches taken by several countries in Sub-area VI are considered to be mainly by-catch in demersal fisheries. These catches are negligible in comparison with redfish catches in Sub-areas V, XII and XIV.

Catches in Sub-area XII are mainly pelagic $S$. mentella and are taken by trawlers using pelagic trawls. At least 13 fleets have joined this fishery mainly from Russia, Germany, Iceland, Faroe Islands and Norway.

In Sub-area XIV both $S$. marinus and all $S$. mentella stocks are exploited. On the Greenland shelf and slopes, $S$. marinus dominates the trawl catches above 500 m , whereas deep-sea $S$. mentella dominates below 500 m . Most of the catches are taken by German freezer trawiers. In 1982 a pelagic trawl fishery started exploiting the oceanic $S$. mentella in the deeper parts of Sub-area XIV. Since 1990 the main fleets are from Russia, Norway, Iceland and Germany. In recent years, vessels from several other countries have joined this fishery, mainly outside the EEZs of Iceland and Greenland.

In Sub-areas Va, XII and XIV, a pelagic fishery has developed at depths greater than 500 m to target $S$. mentella. In 2000 a substantial proportion of the pelagic $S$. mentella catch was taken below 500 m depth. For the first time, there was significant fishing effort extended from ICES Division XII into NAFO Sub-area $1 F$ in the autumn of 2000 .

Landings: The total landings from the redfish stock complex (i.e. redfish in all sub-areas) are given in Tables 3.2.6.a.1-5.

### 3.2.6.b $\quad$ Sebastes marinus in Sub-areas V, VI, XII and XIV

State of stock/fishery: The stock is considered to be outside safe biological limits. According to survey information, the stock in Division Va has fluctuated between $\mathbf{U}_{\mathrm{pa}}$ and $\mathbf{U}_{\mathrm{lim}}$ since 1990 (Figure 3.2.6.b.1). In Sub-area XIV the German groundfish survey has shown an almost continuous decrease in biomass indices by more than $90 \%$ since 1986 , and $S$. marinus at East-Greenland has been nearly depleted in the most recent six years (Figure 3.2.6.b.2). In Division Vb
catches have declined since 1985 to a low level in recent years, which is also reflected in the commercial CPUE (Figure 3.2.6.b.4). Research surveys indicate that the 1990/91 year class is the only year class likely to recruit as average or strong in the near future, but its size is uncertain.

Management objectives: There is no explicit management objective for this stock.

Precautionary Approach reference points (unchanged since 1999):
ICES suggests that the relative state of the stock be assessed through survey CPUE index series (U).

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathrm{U}_{\mathrm{ijn}}=20 \%$ of highest observed survey index. | $\mathbf{U}_{\mathrm{pa}}$ be set at $60 \%$ of highest observed survey index. |

Technical basis:
The basis for the catculation of the $\mathbf{U}_{\mathrm{pa}}$ is a survey index series starting in 1985 (Figure 3.2.6.b.1). Since 1990 the average $U$ has been aromd half of $U_{m a x}$. This has not resulted in any strong year classes compared to higher U's. A precautionary $\mathrm{U}_{\mathrm{pa}}$ is therefore proposed at $\mathrm{U}_{\mathrm{max}} * 0.6$, corresponding to the U's associated with the most recent strong year class.

Advice on management: ICES advises that effort should be reduced by $25 \%$, corresponding to catches not exceeding a total of $29000 \mathbf{t}$ in ICES Divisions Va and Vb. As the fishable stock of S. marinus in Sub-area XIV is depleted, ICES advises that there be no direct fishery for $S$. marinus in that Sub-area. Fishing effort should not be allowed to expand on the incoming 1990/91 year class to keep the stock from decreasing in the near future.

Relevant factors to be considered in management: Apart from the 1990/1991 year class, no strong recruitment is expected for the stock for several years.

The effort in Division Va seems to have been reduced considerably since 1995 , and a catch of 29000 t corresponds to a $25 \%$ reduction in 2000 effort. In Subarea XIV the fishable stock of $S$. marinus is depleted.

Comparison with previous assessment and advice: The assessment and advice are in line with those given last year.

Catch forecast for 2002: Catch in 2002 was estimated as a function of the average survey index 1999-2001 and the effort in 2000.

Elaboration and special comment: S. marinus are mainly taken by trawlers in depths down to 500 m . In Division Va the catch is mainly taken by Icelandic trawlers, while in Division Vb Faroese trawlers predominate. In Sub-area XIV the catches are mainly by-catch in shrimp fisheries. Total catches decreased almost continuously from 1983-1996, but have increased slightly since then. The decline occurred in all sub-areas. In order to reduce the catches of $S$. marinus in Division Va, an area closure was imposed in 1994 and the quotas have been reduced in the most. recent years.

Icelandic survey data, data from a German groundtish survey in Sub-area XIV, and from the Faroes groundfish survey in Division Vb are used as indicators of the stock size in the respective areas.

### 3.2.6.c Deep-sea Sebastes mentella on the continental shelf in Sub-areas V, VI and XIV

State of stock/exploitation: The stock as whole is considered to be inside safe biological limits although status varies among regions. All CPUE indices show a substantial reduction from a high in the late 1980 s , but from the mid-1990s the CPUE index from the Icelandic bottom fishery has remained relatively stable, slightly above $\mathrm{U}_{\mathrm{pa}}$.

Since 1994 total catches have declined by about $50 \%$, although the decline is not completely the consequence of declining stock status. Some of the decline is due to
catch restrictions which have substantially reduced effort since 1994.

Based on survey results the SSB of deep-sea S. mentella on the continental shelf in Sub-area XIV remains severely depleted (Figure 3.2.6.c.2).

Management objectives: There is no explicit management objective for this stock. However, for any management objectives to meet precautionary criteria $U$ should be greater than $\mathbf{U}_{\mathrm{pa}}$.

Precautionary Approach reference points:

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| The maximum index in the CPUE series from the <br> Icelandic commercial bottom trawl fishery set as $\mathbf{U}_{\mathrm{max}}$. | $\mathbf{U}_{\mathrm{pa}}=\mathrm{U}_{\max } / 2$. <br> $\mathbf{U}_{\mathrm{lima}}=\mathbf{U}_{\max } / 5$. |

Technical basis:
The basis for the calculation of the $\mathbf{U}_{p a}$ is a CPUE data series from the commercial fishery in Division Va starting in 1985 (Figure 3.2.6.c.1).

Advice on management: ICES advises that the effort should not increase above the current level. Accordingly, the catch for the total stock should not exceed 36000 t . As the fishable stock of $S$. mentella in Sub-area XIV is depleted ICES advises that there should be no direct fishery for $S$. mentella in that Sub-area.

Relevant factors to be considered in management: The German surveys in East Greenland cover nursery grounds for $S$. mentella. The survey observed strong cohorts in 1995-1998, with record high catches in 1997. The cohorts have emigrated from the survey area and coincide with strong incoming cohorts in both pelagic deep-sea $S$. mentella and oceanic $S$. mentella. Therefore, the nursery grounds of $S$. mentella on the continental shelf in Sub-area XIV probably supply recruits to both the pelagic redfish stocks in the Irminger Sea and the shelf stock in Divisions Va and Vb . The possible strong cohorts observed in the survey could enter the fishable stock $5-10$ years after appearing in the surveys.

Comparison with previous assessment and advice: The CPUE series, which is the basis for the advice has been revised. This has changed the perception of the state of the stock from being somewhat below $\mathrm{U}_{\mathrm{pa}}$ to being slightly above $\mathrm{U}_{\mathrm{pa}}$. The advice given for 2001 ( 22000 t ) was for Division Va, but the advice for 2002 ( 36000 t ) is for the entire stock.

Catch forecast for 2002: Catch in 2002 was estimated as a function of an average standardized CPUE series 1998-2000 and the effort in 2000.

Elaboration and special comment: In Division Va deep-sea $S$. mentella are taken mainly by Icelandic trawlers in depths greater than 500 m . In Division Vb the fishery is carried out mainly by Faroese trawlers, though some by-catch is taken by other countries fishing demersal species. In Sub-area XIV the catch is taken largely by German freezer trawlers. The annual catches almost doubled in the early 1990 s , but since then have decreased to the level of the 1980s. The increase was mainly caused by an increase in Division Va, both in the demersal and a temporarily developed pelagic fishery, and by an increase in Sub-area XIV in 1993-1994.

Data and assessment: No data were available to make an analytical assessment. CPUE data are available from Icelandic trawlers in Division Va (1986-2000), the Faroese fishery in Division Vb (1985-2000), and from the German groundfish survey in Sub-area XIV (19822000).

Figure 3.2.6.c. 1 CPUE, relative to 1986, from the Icelandic bottom trawl fishery for deep-sea S. mentella on the continental shelf, based on a GLIM model (a) and based on simple mean (b). The GLIM model shows the modeled development using GLIM, including hauls where redfish deeper than 500 m compose $50 \%$ or more of the total catch in each haul. Simple mean means CPUE calculated on hauls where redfish deeper than 500 m compose $10 \%$ ( 50,70 , or $90 \%$ lines are also shown) or more of the total catch in each haul.

### 3.2.6.d Pelagic fishery for Sebastes mentella in the Irminger Sea

The stock structure of deep-sea redfish $S$. mentella in Sub-area XII, Division Va and Sub-area XIV and NAFO Div. 1F remains generally uncertain. There is a difference in the depth distribution of the two pelagic redfish types, namely the 'oceanic $S$. mentella', mainly above 500 meters, and the 'pelagic deep-sea $S$. mentella', mainly below.

State of stock/exploitation: The stock appears to be at or below $50 \%$ of the biomass in the early the 1980 s, which was estimated to be around 3 million tons, although stock indicators are uncertain. The 1999 survey indicated a continued reduction in the stock abundance and biomass above 500 m , with a major portion of the stock found in the NAFO Div. 1F for the first time. The survey estimated an additional biomass index of around 500000 t below 500 m .

A negative trend is seen in the CPUE shallower than 500 m . A recruitment pulse to the fishable stock was observed in 1999, both below and above 500 m . The recent catches might be above the $5 \%$ exploitation rate considered sustainable.

Management objectives: There is no explicit management objective for this stock. However, for any management objective to meet precautionary criteria, U (index for trawl-acoustic surveys) should be greater than the proposed $\mathrm{U}_{\mathrm{p}}$.

Advice on management: ICES again advises a reduction of catches in 2002 to below 85000 t (including NAFO Div. 1F). In addition, ICES advises that management measures are required to ensure that the possible stock components in the pelagic fishery in the Irminger Sea will not be overexploited. These measures are necessary hecause of the large decline in biomasses and CPUE during the 1990s, the low productivity of the stock, and the need to prevent further declines in the stock.

Comparison with previous assessment and advice: The most recent survey information is derived from 1999. The next international hydroacoustic survey is planned for June/July 2001.

## Special requests:

NEAFC has requested ICES as follows:

- There are uncertainties about the stock structure of pelagic redfish in the Irminger Sea. Genetic studies suggest that Sebastes mentella in this area, like many other species of Sebastes, has a complex stock structure. However, the number of separable units, and the degree of exchange
among them, both genetically and in terms of their population dynamics, is largely unknown. Moreover, their relative productivities are also unknown, but may not be equal. In light of these sources of uncertainty and the risk of local depletions of populations, which would recover very slowly, if at all, management should emphasize distributing effort widely, and monitoring local units for evidence of depletion. Associated risks in overexploitation of the different stock components managed under a common TAC cannot be quantified.
- Since 1998 a) the fisheries in the northeastern area in the first half of the year occurred at depths greater than 500 m and catching larger fish, and b) the fisheries in the southwestern area in the second half of the year occurred mainly at depths shallower than 500 m catching smaller fish.

Relevant factors to be considered in management: The advised catch of 85000 t is $75 \%$ of the 1997-99 average, a period when catches were unsustainable.

The estimated biomass in the 1999 acoustic survey was between 10 and $20 \%$ of that estimated in the early 1990s. However, the 1999 acoustic survey estimate is considered an underestimate due to significant changes in horizontal and vertical stock distribution patterns.

Changes in fishery patterns in recent years forming 2 almost distinct fishing grounds in terms of geographic distribution and trawling depth, and unknown stock structure provide further cause for concern. In 2000, substantial catches were taken for the first time from the pelagic $S$. mentella aggregations discovered recently in NAFO Div. $1 F$. There are, as of yet, no indications that the pelagic $S$. mentella in NAFO Div. 1 F are distinct from the stock(s) or components in the adjacent Irminger Sea, so these catches may represent an increase in exploitation of the stock that has supported the fishery in the Irminger Sea.

There may be a relationship between the demersal deep-sea S. mentella on the continental shelves of the Faroe Islands, Iceland, Greenland and the pelagic $S$. mentella components in the Irminger Sea and this should be kept in mind in the management of these components.

Management action should be taken to prevent a disproportional high exploitation rate of any one component.

Since this is a relatively new fishery on a long-lived, slow-growing species, ICES notes that monitoring of the stock is essential in order to keep track of biomass
changes as they occur. Similarly, it is important to gather the information needed to evaluate the productivity of the stock. This includes information on recruitment, nursery areas, stock identification and biomass estimation.

Nursery areas for both of the pelagic stock components are likely to be found at the continental slope off East Greenland. The juvenile redfish in these areas should, therefore, be protected and appropriate measures to reduce the by-catches in the shrimp fishery need to be taken.

Elaboration and special comment: The pelagic fishery in the Irminger Sea is conducted only on the mature part (approximately $95 \%$ mature) of the stock. The fishery started in 1982. After decteasing from 1988-1991, landings increased. The decrease was mostly due to a reduction in Russian effort. The increase in the catches from 1991-1996 is a direct consequence of increased fishing effort due to new fleets entering the fishery. However, the catches have
been significantly lower during the last 4 years; at the same time the fishery has expanded into deeper water and the season has expanded from March to December.

New survey information will be available after the June/July 2001 survey has been carried out.

Given the technical, seasonal, geographical and depth changes of the fishing activities, the relevance of the estimated reduction in CPUE as indicator of stock abundance remains difficult to assess both above and below 500 m .

Data on maturity at length, and at weight and some age-reading experiments were available from both the survey and from the fishery. CPUE series are available for some fleets (Figures 3.2.6.d.1-2).

Source of information: Report of the North-Western Working Group, April/May 2001 (ICES CM 2001/ACFM:20).

Figure 3.2.6.d. 2 Trends in CPUE of pelagic S. mentella fishery in the Irminger Sea, deeper than 500 m , and estimated acoustic biomass from surveys.

### 3.2.7 Icelandic summer-spawning herring (Division Va)

State of stock/exploitation: The stock is considered to be inside safe biological limits. The spawning stock biomass (SSB) in 2000 is estimated at its observed maximum ( 627000 t ). The current fishing mortality of 0.18 is well below the $\mathbf{F}_{\mathrm{pa}}$.

Management objectives: The practice has been to manage this stock at $\mathrm{F}=\mathrm{F}_{0.1}$ for more than 20 years. This fishing mortality is equal to $\mathbf{F}_{\mathrm{pa}}$. However, no formal management strategy has been adopted.

Precautionary Approach reference points (proposed by ICES in 1999):

| ICES considers that: | ICES proposed in 1998 that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 200000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 300000 t |
| $\mathbf{F}_{\text {lim }}$ not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.22 |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ SSB with a high probability of impaired <br> rectuitment | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} \mathrm{e}^{1.645 \sigma} \sigma=0.25$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lm}}:-$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{0.1}=0.22$ (based on a weighted average) |

Advice on management: ICES recommends that this stock should be continued to be harvested at a fishing mortality rate of $\mathbf{F}_{0.1}=\mathbf{0 . 2 2}$.

Relevant factors to be considered in management: Icelandic TACs apply to 1 September to 31 August. The TAC for the quota year 2001/2002 corresponding to the recommendation is 125000 t . The 1992,1993 and 1995 year classes are estimated to be below
average, but the 1994 and 1996-1999 year classes are all estimated to be above average. In 2001/2002 it is expected that the 1996 year class will have the largest contribution to the catch in numbers.

Comparison with previous assessment and advice: There has been a general trend to overestimate SSB and underestimate $F$.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathbf{F}_{0.1}=0.22$; Landings $(2001)=125 ; \mathrm{SSB}(2002)=725$.

| F(2002) | Basis | $\begin{aligned} & \text { Catch } \\ & (2002) \end{aligned}$ | Landings (2002) | SSB (2003) | Medium term effect of fishing at given level (calculated in 1995) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.18 | $\mathrm{F}_{2000}$ | 113 | 113 | 820 | Sustainable fishery |
| 0.22 | $\mathrm{F}_{0.1}=\mathrm{F}_{\mathrm{pa}}$ | 139 | 139 | 795 | " |
|  | \% \% Weme | \% \% \% | 15 | \%. |  |

Weights in 000 t .
Shaded scenarios considered inconsistent with the precautionary approach. For 2001 the fishing mortality $\mathbf{F}_{0.1}=0.22$ is assumed.

Medium- and long-term projections: Medium-term forecasts in 1995 showed that there was a low probability that the current harvest strategy will reduce the stock to below $\mathbf{B}_{\mathrm{pa}}$.

Elaboration and special comment: The catches of Icelandic summer-spawning herring increased rapidly in the early 1960s due to the development of the purse seine fishery off the south coast of Iceland. This resulted in a rapidly increasing exploitation rate until the stock collapsed in the late 1960 s . A fishing ban was enforced during 1972-1975. Thereafter the catches have increased gradually to over 100000 t. Previously
the fleet consisted of multi-purpose vessels, mostly below 300 GRT, operating purse seines and drift nets. In recent years, larger vessels (up to 1500 GRT) have entered the fishery. These are combination purse seiners and pelagic trawlers operating in both the herring and capelin fisheries. In the past four seasons a considerable proportion of the catch has been taken with pelagic trawls.

Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, April 2001 (ICES CM 2000/ACFM: 17).

### 3.2.8 Capelin in the Iceland-East Greenland-Jan Mayen area (Sub-areas $V$ and XIV and Division IIa west of $5^{\circ} \mathrm{W}$ )

State of stock/exploitation: The stock is considered to be inside safe biological limits. SSB is highly variable due to dependency on only 2 age groups.

Management objectives: The fishery is managed according to a two-part harvest control rule which allows for a minimum spawning stock biomass of 400000 t by the end of the fishing season. ICES considers that the two-part harvest control rule is in accordance with the precautionary approach.

Advice on management: In order to ensure a spawning stock biomass of $400000 t$ in March 2002, ICES advises in conformity with the harvest control rule, that the preliminary TAC for the first half of the $2001 / 2002$ season should not exceed 700000 t . This is two thirds of the total catch of $1050000 t$ predicted for the whole season and is designed to reduce the risk of overexploitation. ICES advises that the data from the surveys in October-November 2001 and/or January-February 2002 be used when the final TAC is set for the 2001/2002 season. ICES advises that, while the 2001 summer/autumn season could be opened on 20 June, areas of high juvenile abundance should be closed to commercial fishery in order to prevent harvesting a high proportion of juveniles. The authorities responsible for the management of this stock should make provisions for a quick and efficient process to close such areas to the fishery.

Kelevant factors to be considered in management: In recent years, large capelin have dominated the catches in July and the first half of August. From the second half of August, the average weight in the catches has declined drastically due to the presence of juvenile fish and not increased again until late autumn.

The spawning stock fell below the minimum safe level of 400000 t in the 1989/90 and 1990/91 seasons. The stock recovered quickly due to good recruitment and appears to be fairly strong at present.

Catch forecast: The basis for the forecast is acoustic surveys and a regression-based prediction model. The model gives a predictive figure for the maturing 2 group capelin of 78.1 billion. For the maturing 3 year olds the predictive value is 16.9 billion individuals. From these predictions a catch of 1050000 t for the 2001/2002 season is expected to leave 400000 t for spawning.

Elaboration and special comment: The fishery is mainly an industrial fishery based on maturing capelin, i.e., the 2-and 3-group in the autumn, which spawn at ages 3 and 4 in March of the following year. After being low in the 1989/90 and 1990/91 seasons, catches have increased and have in recent years been more than 1 million $t$. A record catch of 1571000 t was taken during the $1996 / 97$ fishing season.

Preliminary TAC computations are based on a method which involves the use of 1-group $\left(N_{l}\right)$ indices from the October-November survey for predicting the mature 2group ( $N_{2 \text { mal }}$ ) in the following year. The total 2 -group ( $N_{2 \text { too }}$ ) abundance from the same survey and the relationship between maturation ratios and year class abundance are used for predicting numbers of capelin in the 3-group ( $N_{3 \text { mat }}$ ).

Since 1989, the weight at age shows a significant negative correlation with the adult stock in number. A regression-based predictive model using data from the period 1989-1997 results in predicted mean weights of 16.1 and 22.4 g for age groups 2 and 3 respectively.

The stock size is assessed using acoustic survey data.
Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, April 2001 (ICES CM 2001/ACFM:17).

Catch data (Tables 3.2.8.1-2):

${ }^{17} \mathrm{TAC}$ advised for July-December part of the season. ${ }^{2)}$ Final TAC recommended by national scientists for whole season, ${ }^{3)}$ July March of following year. (Weights in ' 000 t ).
*All surveys of fishable stock abundance during the 1989/1990 season were unsuccessful.

### 3.2.9 <br> Answer to Special Request on Redfish

NEAFC requested detailed information on a) stock identity, b) horizontal and vertical distribution of pelagic redfish stock components in the Irminger Sea and adjacent waters and as c) about the development of the pelagic redfish fishery for redfish with respect to seasonal and area distributions.

## Greenland asked for information on the effectiveness of the "Redfish" box in Division XIV.

## NEAFC a) On further information on stock identity of redfish

The answer to the request is presented as part of the introduction section 3.2.6.a.

NEAFC b) On the possible relationship between pelagic Sebastes mentella and the Sebastes mentella fished in demersal fisheries on the continental shelf and slope.

There are substantial uncertainties in the stock structure of $S$. mentella in this area. This causes concern about the current situation in the fishery related to the possible existence of more than one stock of $S$. mentella.

Prior to 1994, the stock mixing was considered minor as only a small proportion of the catches was taken at depths below $500-600 \mathrm{~m}$. During the last few years as the fishery has shifted towards greater depths, a greater proportion of the catch might have originated from the deeper stock (deeper than 500 m ). The difficulties of separating catches has increased as the oceanic type $S$. mentella also occurs deeper than 500 m in recent years. The problem of distinguishing between stock components increased even further, as the Icelandic oceanic fishery since 1998 was extended very close to the areas where the traditional shelf fishery has been ongoing for years.

Therefore, the future development of the stock(s) and catches are uncertain because it is at present not known how much of each component is actually caught. An attempt to improve the situation has been made by some nations to report the catches by depth and one country also by "stock".

Pretiminary results from ongoing research on the stock structure of $S$. mentella have been evaluated by ICES Working Group on the Application of Genetics in Fisheries and Mariculture (ICES CM 2001/F:3). The results indicate that oceanic $S$. mentella and pelagic deep-sea $S$. mentella "represent separate genetic stocks". Also, "differences between Icelandic and Irminger Sea deep-sea $S$. mentella are less, but significant, indicating also probably distinct genetic stocks".

Strong year classes in $S$. mentella on the continental shelves seem to have recruited both to oceanic $S$. mentella and to pelagic deep-sea $S$. mentella. This is significant new information on the understanding of recruitment processes for the various redfish stocks.

Based on the information given above, ICES stresses that there are still uncertainties in the stock structure of $S$. mentella in ICES Divisions V, XII and XIV.

NEAFC c): Update information on the development of the pelagic fishery for redfish with respect to seasonal and area distribution to allow NEAFC to further consider the appropriateness of area and seasonal closures.

Observations indicate that in the last three years a) the fisheries in the northeastern area in the first half of the year are occurring at depths deeper than 500 m and catching larger fish, and b) the fisheries in the southwestern area in the second half of the year are mainly occurring at depths shallower than 500 m catching smaller fish. The following paragraphs give a detailed description of the fishery.

The geographical distribution of the catches by periods and years since 1995 are given in Figure 3.2.6a.5. The fishery of these four nations (Germany (1995-2000), Iceland (1989-2000), Norway (1990-1999) and Greenland (1999-2000)) indicate that there was a similar pattern in the fishery during the last three years. Fishing usually started in early April and up to the end of June it was prosecuted in areas east of $32^{\circ} \mathrm{W}$ and north of $61^{\circ} \mathrm{N}$. In July and August, the fleet moves about $400-500$ nautical miles to areas south of $60^{\circ} \mathrm{N}$ and west of about $34^{\circ} \mathrm{W}$, where the fishery continues until October. There is very little fishing activity from November until late March. Figure 3.2.6a.6 gives the locations of part of the Spanish activity in the Irminger Sea, and it shows that they had a similar pattern in 2000 as the above-mentioned fleets. The same applies for the Russian fleet in 2000 (Figure 3.2.6a.7). In the third quarter of the year the fishing has, in general, moved towards the southern part of the area, fishing mostly at depths shallower than 500 m , within area XII as well as in NAFO area $1 F$, and both outside and inside the Greenlandic EEZ. However, it is important to note that the described fishing pattern of the fleet has changed significantly in the most recent 5 years, mainly in terms of area and depth expansion. The changes in the fishing pattern as described above does not necessarily reflect changes in stock distribution, maybe due to commercial reasons.

Although there is limited information on fishing depth, except for the Icelandic and the Greenlandic fisheries, the general pattern is that the fishing in the first and second quarter of the year is mostly conducted deeper than 500 m . The mean trawling depth (depth of the
headline) of the Icelandic fleet in April-June 2001 was 656 m , with $8 \%$ of the hauls shallower than 500 m depth. Further, although there are no haul-by-haul data available for the German catches, the available information shows that the fishery in the first two quarters was characterised by a fishery deeper than 450 m , and at shallower depths during the third and fourth quarters in 1995-2000. There is similar pattern in the Spanish fishery. They were fishing deeper than 500 m in the second quarter of the year, and in the third quarter fishery continued at depths shallower than 500 m . The Greenland vessel participating in this fishery also report all its catches above 400 m after July, and show the same pattern as the Icelandic fleet in the first 2 quarters of the year.

Over $95 \%$ of all the fish caught in the pelagic redfish fishery are mature. The mean length of the redfish caught in the southwestern area is smaller than the fish caught in the northeastern area (Figure 3.2.6a.8).

As has been reported in earlier reports of the working group, Iceland has classified its pelagic catches between oceanic and pelagic deep-sea redfish according to a contentious method. The results of this classification have shown that the proportion of fish classified as oceanic type redfish has been very low during recent years, and only about $5 \%$ of the Icelandic catches were classified as oceanic type. Based on the samples, the results also indicate that shallower than $500-600 \mathrm{~m}$ depth, the proportion "oceanic" is between $85-100 \%$, as the proportion deeper than 600 m is usually between $0-$ $20 \%$.

ICES recommends that NEAFC asks all nations participating in the pelagic redfish fishery to provide ICES with information on the trawling depth (headtine depth for each haul as a log-book data), so ICES can have more detailed description of the fishery by season and areas as a basis for giving its advice on the resource.

## Answer to Special request on the Effects of the Redfish-Box

ICES considered the following request from Denmark in respect of Greenland on regulatory measures on bottom trawling off the east coast of Greenland:
'Denmark (in respect of Greenland and Faroe Islands) requests ICES to provide advice on requirement on redfish regulatory measures in ICES Div. XIVb*
'The so-called "Redfish-box" on the East Greenland shelf was established in 1978 after a recommendation from ICES in order to protect nursery grounds for juvenile redfish. The box was based on high catch rates of small redfish in East Greenland waters as observed from bycatches in cod fisheries from the 1950s until the regulation. According to later occasional trial fishery in
the box-area, there is a large variation in the by-catch inside as well as outside the box. The composition of the fisheries in East Greenland has changed since then, currently only comprising a directed Greenlarid halibut fishery (minimum meshsize 140 mm ) and a shrimp fishery. The closure of such a large area for bottom trawl activity constitutes a management problem, if redfish by-catch from time to time is insignificant.
'The Greenland Home Rule Government has from 1 October 2000 introduced mandatory use of 22 mm sorting grids into the full geographic range of the Greenland shrimp fishery in order to minimise by-catch of fish.
'Greenland therefore requests ICES to provide information on the following: Is there a biological justification for maintaining an area within Sub-area XIV where bottom trawl activity is prohibited to protect redfish nursery grounds (the so-called "Redfish-Box"). Special emphasis must be put on:
'1) The present mandatory use of grids in the shrimp fishery.
'2) Influence of trawling activity on the nursery habitat, i.e. the ecosystem effect.'

The following sources of information were considered: a report on a recent experiment carried out in East Greenland waters to measure the effect of sorting grids on the performance of a shrimp trawl; data from German bottom-trawl surveys off East Greenland from 1985 through 2000. It was also noted that German bottom-trawl surveys and the Greenland shrimp survey alike show that small redfish are widely distributed and that the redfish box does not correspond to exceptional densities.

Most of the redfish, of all sizes, caught by the German bottom-trawl survey in the neighbourhood of the redfish box were caught east of the box, between it and the 400 m isobath (Figure 3.2.6a.9). This was true even of redfish shorter than 17 cm . However, the distribution of survey stations within the redfish box was somewhat limited (Figure 3.2.6a.9). Furthermore, in experimental shrimp fisheries in East Greenland in 1992 and 1998, mean by-catch rates within the box were no higher than elsewhere on the East Greenland shrimp grounds, which now stretch some $5^{\circ}$ further to the south than they did when the redfish box was drawn in the early 1980s. The redfish box does not appear to correspond to the current distribution of small redfish, and there is no biological justification for maintaining it.

The results of experimental fishing showed that sorting grids gave nearly complete protection to redfish larger than about 20 cm , but only about $1 / 3$ protection of a numerous class of $11-12 \mathrm{~cm}$ redfish. Qualitatively similar results-i.e. poor protection of the smallest fish-were obtained with other finfish. In spite of this,
sorting grids significantly reduced the lifetime risk to a redfish that it would be by-caught.

There is a risk that large year classes of redfish could appear as significant by-catch in the shrimp fishery for as long as they are shorter than about 15 cm . Greenland shrimp trawling regulations already require ships to change grounds by at least 5 miles as soon as by-catch exceeds more than $10 \%$ the total catch in haul. In addition to this measure, ICES recommends that standard regulatory measures of flexible and
temporary area closures be applied when, and also where, large year classes of redfish generate by-catch problems.

ICES was not able to answer the question of whether the ecosystem effect of bottom trawling per se on redfish nursery habitats would justify closing the area permanently. In order to answer this question, information is needed on nursery habitats and what effect bottom trawling has on these.

### 3.3.1 Overview

The fisheries and management measures: In 1977 an EEZ was introduced in the Faroe area. The demersal fishery by foreign nations has since decreased and Faroese vessels now take most of the catches. The fishery may be considered a multi-fleet and multispecies fishery. The longliners fish mainly cod and haddock; in addition, some longliners fish in deep water for ling and tusk. Most of the trawlers fish cod, haddock and saithe, while some large trawlers fish in deeper waters for redfish, blue ling, Greenland halibut, and occasionally grenadier and black scabbardfish. The jiggers fish mainly saithe and cod. Recently, gill net fisheries for Greenland halibut and anglerfish and a directed pair trawler fishery for Argentines have been introduced. The total demersal catches decreased from 120000 t in 1985 to 65000 t in 1993, but have since increased again to about 100000 t in 1997-1999. The decrease was mainly due to lower catches of cod, haddock and saithe. The cod catches (Faroe Plateau cod and Faroe Bank cod combined) increased considerably from 6000 t in 1993 to more than 42000 t in 1996 but have since declined, and were in 2000 around 24000 t . The catches of haddock also increased considerably from 4000 t in 1993 to 22000 t in 1998, but have since decreased to 16000 t in 2000 . The catches of saithe decreased from 33000 t in 1993-1994 to 20000 t in 1996, but have since increased again to 39000 t in 2000.

During the 1980s and 1990s the Faroese authorities have regulated the fishery and the investment in fishing vessels. In 1987 a system of fishing licences was introduced. The demersal fishery at the Faroe Islands has been regulated by technical measures (minimum mesh sizes and closed areas). In order to protect juveniles and young fish, fishing is temporatily prohibited in areas where the number of small cod, haddock and saithe exceeds $30 \%$ in the catches; after $1-2$ weeks the areas are again opened for fishing. A reduction of effort has been attempted through banning of new licences and buy-back of old licences.

A new quota system, based on individual quotas, was introduced in 1994. The fishing year started on 1 September and ended on 31 August the following year. The aim of the quota system was, through restrictive TACs for the period 1994-1998, to increase the SSBs of Faroe Plateau cod and haddock to 52000 t and 40000 t , respectively. The TAC for saithe was set higher than recommended scientifically. It should be noted that cod, haddock and saithe are caught in a mixed fishery and any management measure should account for this. Species under the quota system were Faroe Plateau cod, haddock, saithe, redfish and Faroe Bank cod.

The catch quota management system introduced in the Faroese fisheries in 1994 was met with considerable criticism and resulted in discarding and in misreportings of substantial portions of the catches. Reorganisation of enforcement and control did not solve the problems. As a result of the dissatisfaction with the catch quota management system, the Faroese Parliament discontinued the system as from 31 May 1996. In close cooperation with the fishing industry, the Faroese government has developed a new system based on individual transferable effort quotas in days within fleet categories. The new system entered into force on 1 June 1996. The fishing year from 1 - September to 31 August, as introduced under the catch quota system, has been maintained.

The individual transferable effort quotas apply to 1) the longliners less than 100 GRT, the jiggers, and the single trawlers less than $400 \mathrm{HP}, 2$ ) the pair trawlers and 3) the longliners greater than 100 GRT. The single trawlers greater than 400 HP do not have effort limitations, but they are not allowed to fish within the 12 nautical mile limit and the areas closed to them, as well as to the pair trawlers, have increased in area and time. Their catch of cod and haddock is limited by maximum by-catch allocation. The single trawlers less than 400 HP are given special licences to fish inside 12 nautical miles with a by-catch allocation of $30 \%$ cod and $10 \%$ haddock. In addition, they are obliged to use sorting devices in their trawls. One fishing day by longliners less than 100 GRT is considered equivalent to two fishing days for jiggers in the same gear category. Longliners less than 100 GRT could therefore double their allocation by converting to jigging. Table 3.3.1.1 shows the number of fishing days used by fleet category for 1985-1995 and 1998-1999 and Table 3.3.1.2 shows the number of allocated days inside the outer thick line in Figure 3.3.1.1. Hoiders of individual transferable effort quotas who fish outside this line can fish for 3 days for each day allocated inside the line. Trawlers are generally not allowed to fish inside the 12 nautical mile limit. Inside the innermost thick line only longliners less than 100 GRT and jiggers less than 100 GRT are allowed to fish. The Faroe Bank shallower than 200 m is closed to trawling.

The effort quotas are transferable within gear categories. The allocations of number of fishing days by fleet categories was made such that together with other regulations of the fishery they should result in average fishing mortalities on each of the 3 stocks of 0.45 , corresponding to average annual catches of $33 \%$ of the exploitable stocks in numbers. Built into the system is also an assumption that the day system is selfregulatory, because the fishery will move between
stocks according to the relative availability of each of them and no stock will be overexploited.

In addition to the number of days allocated in the law, it is also stated in the law what percentage of total
catches of cod, haddock, saithe and redfish, each fleet category on average is allowed to fish. These percentages are as follows:

| Fleet category | Cod | Haddock | Saithe | Redfish |
| :--- | :---: | :---: | :---: | :---: |
|  |  |  |  |  |
| Longliners $<110 \mathrm{GRT}$, jiggers, single trawl. $<400 \mathrm{HP}$ | $51 \%$ | $58 \%$ | $17.5 \%$ | $1 \%$ |
| Longliners $>110 \mathrm{GRT}$ | $23 \%$ | $28 \%$ |  |  |
| Pairtrawlers | $21 \%$ | $10.25 \%$ | $69 \%$ | $8.5 \%$ |
| Single trawlers $>400 \mathrm{HP}$ | $4 \%$ | $1.75 \%$ | $13 \%$ | $90.5 \%$ |
| Others | $1 \%$ | $2 \%$ | $0.5 \%$ | $0.5 \%$ |

Technical measures such as area closures during the spawning periods, to protect juveniles and young fish and mesh size regulations as mentioned above are still in effect.

The marine environment: The waters around the Faroe Islands are in the upper 500 m dominated by the North Atlantic current, which to the north of the islands meets the East Icelandic current. Clockwise current systems create retention areas on the Faroe Plateau and on the Faroe Bank. In deeper waters to the north and east is deep Norwegian Sea water, and to the south and west is Atlantic water. From the late 1980s the intensity of the North Atlantic current passing the Faroe area decreased, but it has increased again in the most recent years. The productivity of the Faroese waters has been very low since the middle of the 1980 s . This applies also to the recraitment of many fish stocks, and the growth of the fish has been poor as well. Measurements of phyto- and zooplankton production show that the situation has gradually improved since 1991. Since 1992 the recruitment of important prey such as sandeels and Norway pout has been good and the growth of fish such as cod, haddock and saithe has improved considerably. The 1992-1993 year classes of
cod and the 1993-1994 year classes of haddock are estimated to be well above the long-term average.

State of stocks: As a result of the combined effect of poor recruitment in the last decade and high fishing effort, the SSBs of Faroe Plateau cod and Faroe haddock were reduced to low levels. In the period 1993-1995 ICES considered them to be well below minimum biologically acceptable levels and consequently advised no fishing. Both stocks have since increased due to improved recruitment and growth with SSB above the precautionary SSB levels ( $\mathbf{B}_{\mathrm{p} 3}$ ). In this years assessment, the SSB of Faroes haddock has, however, decreased to the $B_{\text {lim }}$ level. The fishing mortality on both Faroe Plateau cod and Faroe haddock has been estimated to be well above the precautionary level ( $\mathbf{F}_{\mathrm{pa}}$ ) since 1996. The Faroe Bank cod stock seems to be at or slightly above average. The SSB of Faroe saithe has been increasing from the record low in 1992 to above the $\mathbf{B}_{\mathrm{pa}}$ in 1998-2000. The fishing mortality is well above the precautionary level ( $\mathbf{F}_{\mathrm{p}}$ ).

Table 3.3.1.1 Number of fishing days used by various fleet groups in Vb1 1985-1995 and 1998-2000. For other Fleets there are no effort limitations. Catches of saithe and redfish are regulated by the by-catch Percentages given in Section 2.1.1. In addition there are special fisheries regulated by license. (This is the real number of days fishing not affected by doubling or tripling of days by changing areas/gears).

Fishing area regulations in Division Vb. Allocation of fishing days applies to the area inside the outer thick line on the Faroe Plateau. Holders of effort quotas who fish outside this line can triple their numbers of days. Longliners larger than 110 GRT are not allowed to fish inside the inner thick line on the Faroe Plateau. If longliners change from longline to jigging, they can double their number of days. The Faroe Bank shallower than 200 m depths ( a , aa) is regulated separate from the Faroe Plateau. It is closed to trawhing and the longline fishery is regulated by individual day quotas.

### 3.3.2 Cod

### 3.3.2.a Faroe Plateau cod (Sub-division Vb $_{1}$ )

State of stock/exploitation: The stock is harvested outside safe biological limits. The spawning biomass in 2001 is estimated to be above $\mathbf{B}_{\mathrm{pa}}$, but the 2000 fishing mortality is well above $\mathbf{F}_{\mathrm{pa}}$ and close to $\mathbf{F}_{\text {lim. }}$. The 1997 and 1998 year classes are above average strength.

Management objectives: The effort management system implemented in the Faroese demersal fisheries in Division Vb since 1996 aims at harvesting on average $33 \%$ in numbers of the cod exploitable stock. This translates into an average $F$ of 0.45 . This is inconsistent with the precautionary approach with the $\mathbf{F}_{\mathrm{pa}}$ of 0.35 .

Precautionary Approach reference points (established in 1998).

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 21000 t, the lowest observed biomass | $\mathbf{B}_{\mathrm{pa}}$ be set at 40000 t |
| $\mathbf{F}_{\text {lim }}$ is 0.68 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.35 |

Technical basis:

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}(98)$ | $\boldsymbol{B}_{\mathrm{pa}}: \quad \boldsymbol{B}_{\mathrm{pa}}=$ Blime1 $^{.645 \sigma}$ assuming a $\sigma$ of about 0.40 to account for the relatively large uncertainties in the assessment. |
| :---: | :---: |
| $\mathbf{F}_{\text {liin: }}: \mathbf{F}_{\text {lim }}=$ Fpael $^{1.6450}$.. assuming a $\sigma$ of about 0.40 to account for the relatively large uncertainties in the assessment | $\mathbf{F}_{\mathrm{pa}}$ : Close to $\mathbf{F}_{\mathrm{max}}(0.34)$ and $\mathbf{F}_{\text {med }}(0.38)$ values from 1998 assessment |

Advice on management: ICES advises that fishing mortality in 2002 should be reduced by at least $25 \%$ towards the $F_{p a}$, corresponding to landings of no more than $22000 t$.

Relevant factors to be considered in management: Current fishing mortality is far above the $\mathrm{F}_{\mathrm{pa}}$, but the basis for $\mathbf{F}_{\mathrm{pa}}$ is under revision. Therefore a gradual reduction of the fishing mortality is suggested.

Close monitoring should be carried out in order to evaluate the effect of the effort regulation, in particular the possible changes in catchability and target species. Effort regulation systems may lead to investment aimed at increasing fishing efficiency in order to obtain the greatest benefits from the effort allocated. Management
authorities should monitor vessel characteristics in order to evaluate potential increases in capacity as a result of technological changes.

Cod are taken in a mixed fishery with saithe and haddock. Given that Faroe saithe and haddock are outside safe biological limits, measures to minimise the mortality inflicted on these species while fishing for cod should be implemented.

Comparison with previous assessment and advice: The mean weights-at-age were higher than expected last year and the incoming year classes were adjusted up. It leads to slightly higher estimates of biomass in 2001-2002 and that allows for increase of catches relative to the catches corresponding to advice last year.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}(2000)=0.61$; Landings $(2001)=26200 ; \mathrm{SSB}(2001)=59000 ; \mathrm{SSB}(2002)=60600$.

(Weights in 000 t )
Shaded scenarios considered inconsistent with the precautionary approach.
A short-term prediction of catches is given in the table above. The status quo F assumes the same fleet allocation as in 1999.

Medium- and long-term projections: Medium-term projections were made using the same input parameters as the short-term predictions and making alternative assumptions about recruitment. The results indicate a high probability that $\operatorname{SSB}$ will be less than $\mathbf{B}_{\mathrm{pa}}$ at current fishing mortality, particularly if future recruitment follows a distribution similar to past observations. The results suggest that fishing mortality should indeed be reduced to $F_{p a}$ to keep $B$ above $B_{p a}$ in the medium-term.

Elaboration and special comment: Due to the combined effect of high fishing mortality and poor recruitment of the 1984 to 1991 year classes, the SSB reached record lows in the early 1990s. SSB increased in 1994-1996/1997 due to the recruitment of the 1992 and 1993 year classes, which are estimated to be well above the long-term average. High fishing mortality in 1997 resulted in a $35 \%$ decrease in SSB between 1997 and 1998, and the SSB declined further by over $20 \%$ from 1998 to 1999.

Cod are taken in a mixed demersal fishery which was initially international. Following the declaration of EEZs in 1977, the fishery became largely Faroese. Most of the vessels involved are trawlers and longliners. Fishing mortality declined through the 1960 s and was variable with an increasing trend until 1990. After a sharp decline from 1990 to 1994, F increased again in 1996/1997 to 0.66 , and although lower during 19982000 , it remains too high.

In 1995-1997 catch per unit effort increased considerably, both in the survey and for most fleets in the fishery. The CPUE increased for many age-groups compared to 1994, which suggests that the availability
of the stock to both the fishery and the survey may have increased in 1995-1997, possibly because of a change in the behaviour or distribution of the stock. Such changes make analytical assessments difficult and uncertain. However, the two CPUE series used in the current assessment are not strongly affected by this.

In this analytical assessment catch at age data are tuned with two commercial CPUE series. The growth rate of fish in the stock has shown a declining trend over the last three decades, with a short-term increase in the mid-1990s. After a drop in 1998 the growth rate has increased again.

The survey database is being re-constructed and two survey indices will be evaluated for inclusion in the assessment next year. Medium-term projections and the updated spawners per recruit calculations suggest that the proposed $\mathbf{F}_{\mathrm{pa}}$ may be too conservative. This will be more thoroughly evaluated in the 2002 assessment using the survey indices.

### 3.3.2.b Faroe Bank cod (Sub-division $\mathbf{V b}_{\mathbf{2}}$ )

State of stock/exploitation: Although stock biomass is not known, it appears to be at or above average based on survey indices. The surveys indicate a steep increase of the stock in 1996-1998 compared with previous years, followed by a decline to average biomass in 1999-2000 (Figure 3.3.2.b.1). In 2001, the stock seems to have increased again and length distributions suggest strong incoming year classes.

Management objectives: There are no explicit management objectives for this stock and biological reference points have not been established.

Advice on management: ICES advises that fishing effort on the Faroe Bank should not exceed that exerted annually in recent years (1996-2000).

Relevant factors to be considered in management: The directed fishery is by a longline fleet that has been stable in size since 1996. The fleet is regulated by effort restrictions, so advice is provided in terms of effort.

The landing estimates are uncertain because since 1996 the vessels have been allowed to fish both on the Plateau and on the Faroe Bank during the same trip, making it difficult to assign landings to area. Given the relative size of the two fisheries, this causes greater uncertainty regarding catches for Faroe Bank cod than for Faroe Plateau cod, but the magnitude remains unquantified for both. The ability to provide advice depends on the reliability of input data. Because the cod
landings from Faroe Bank are not known, it is not possible to provide catch advice on management. If the fishery management agency intends to manage the two fisheries to protect the productive capacity of each individual unit, then it is necessary to monitor and regulate the catch removed from each stock.

Comparison with previous assessment and advice: The advice is similar to advice from last year.

Elaboration and special comment: This fishery was an international fishery until the declaration of EEZs. Thereafter, primarily Faroese vessels have exploited the stock. The stock was the subject of a summer trawl fishery, but trawling inside the 200 m contour is now banned. The fishery is mainly carried out by longliners, and by trawlers, which are allowed to fish outside the 200 m contour.

The tentative analytical assessment presented last year could not be updated this year because the catches were poorly sampled. Exploratory analyses with a production model failed to produce reliable results.

Survey indices in the spring 2001 are most likely too optimistic, since the total catch was dominated by one very large haul.

Source of information: Report of the North-Western Working Group, April/May 2001 (ICES CM 2001/ACFM: 20).

## Faroe Bank cod

Figure 3.3.2.b.1 Faroe Bank (Sub-division $\mathrm{Vb}_{2}$ ) COD. Catch per unit effort in the spring and autumn groundfish survey.

### 3.3.3 Faroe haddock (Division Vb)

State of stock/exploitation: The stock is outside safe biological limits. SSB in 2001 is estimated to be below $\mathbf{B}_{\mathrm{pa}}$ and close to $\mathbf{B}_{\text {lim }}$. Fishing mortality in 2000 is estimated to be above the $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{F}_{\text {linn }}$. The SSB increased significantly in 1996-1998 due to the recruitment of the very strong 1993 year class and the above average 1994 year class. The subsequent year classes have all been weak and SSB is expected to decline below $\mathbf{B}_{\text {lim }}$ in the short term, even with no fishery.

Management objectives: The effort management system implemented in the Faroese demersal fisheries in Vb since 1996 aims at harvesting on average $33 \%$ of the haddock exploitable stock. This translates into an average $F$ of 0.45 , higher than the proposed $F_{p a}$ of 0.25 . The harvest regime is expected to maintain fishing mortalities substantially in excess of $\mathbf{F}_{\text {lim }}$ in the medium term, resulting in a high probability that SSB will be less than $\mathbf{B}_{\text {lim }}$. ICES therefore considers this regime as inconsistent with the Precautionary Approach.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 40000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 55000 t |
| $\mathrm{F}_{\text {lim }}$ is 0.40 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.25 |

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Former MBAL | $\mathbf{B}_{\mathrm{pa}}: 2$ st. dev. above $\mathbf{B}_{\text {lim }}$ but reduced based on inspection <br> of the SSB-R scatter plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: 2 *_{\text {std. Dev. above }} \mathbf{F}_{\mathrm{pa}}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\mathrm{med}}(1998)=0.25$ |

Advice on management: ICES recommends that there be no fishing in 2002 on this stock. ICES recommends that a rebuilding plan is developed, aiming at preventing a further decline in SSB below $B_{\text {lim. }}$. The rebuilding plan should take into account technical interactions with other gadoids and ensure that fisheries do not expand when good year classes do occur, until SSB has increased above $B_{p a}$.

Relevant factors to be considered in management: The effect of the effort regulation should be closely monitored, in particular the possible changes in catchability and target species. Haddock are taken in a
mixed fishery together with saithe and cod. Measures to minimise the mortality inflicted on haddock, while fishing for saithe and cod should be implemented.

Comparison with previous assessment and advice: In recent years the assessment has overestimated stock abundance and underestimated fishing mortality. This, together with a strong increase in fishing mortality has changed the perception of the state of the stock. Consequently, the stock has moved from being within safe biological limits to being outside safe biological limits both regarding biomass and harvest rate.

## Catch forecast for 2002:

Basis: $F(2001)=\operatorname{avgF}(98-00)=0.48$; Landings $(2001)=20 ; \operatorname{SSB}(2002)=40$.

| $\mathrm{F}(2002$ onwards) | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 34 |
| 4.1\% | 9.434.290\% | 3\% | \%3 |
|  |  | \$ | YS |
|  | \$/. | \% | \&\% |
|  |  | \$ |  |
|  | \%.2. | 10 | \# |
| $\text { y, } 1$ |  |  | 発\% |
|  |  |  |  |

[^17]Medium- and long-term projections: Medium-term projections are not presented. They indicate that the average and above average year classes are less frequent since 1980 than in the previous 20 years. This suggests that medium term predictions may overestimate future SSBs at the chosen fishing mortality options.

Elaboration and special comment: The estimate of the recruiting year classes is poor as the survey indices were not available in the assessment.

The mean weights at age, which have been decreasing since the middle of the 1990 s, have now increased again for most ages.

Haddock is mainly fished by longliners and pairtrawlers. At present there are closed areas to trawling, and this combined with the large minimum meshsize in the codend ( 145 mm ) effectively reduces catches of
juvenile and young haddock in trawl fisheries, whereas this is not the case for longliners.

Data and Assessment: The analytical assessment was performed using commercial trawl and longline CPUE data. No recruitment indices are available this year.

### 3.3.4 Faroe saithe (Division Vb)

State of stock/exploitation: The stock is at present harvested outside safe biological limits. SSB is above $\mathbf{B}_{\mathrm{pa}}$ due to above average recruitment in the second half of the 1990s, but fishing mortality is high ( $\mathrm{F}_{2000}=0.41$ ), well above $\mathbf{F}_{\mathrm{pa}}(=0.28)$ and also above $\mathrm{F}_{\text {iim }}(=0.40)$. Although there has been high recruitment in the late 1990 s, the stock is expected to decline in the medium term with the present exploitation pattern.

Management objectives: The effort management systern implemented in the Faroese demersal fisheries (Division Vb ) since 1996 aims at harvesting on average $33 \%$ of the saithe stock in numbers. This translates into an average $F$ of 0.45 , higher than $F_{p a}$ of 0.28 and even above $\mathbf{F}_{\text {lim }}$. The harvest regime is expected to produce fishing mortalities substantially in excess of $\mathbf{F}_{\text {lim }}$ in the medium term. ICES considers this regime to be inconsistent with the precautionary approach.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 60000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 85000 t |
| $\mathbf{F}_{\text {lium }}$ is 0.40 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.28 |

Technical basis:

| $\mathbf{B}_{\text {lin: }}$ lowest observed $S S B$ | $\mathbf{B}_{\mathrm{pa}}$ : former MBAL |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ :consistent with $\mathbf{B}_{\text {lim }}$ of 60000 t | $\mathbf{F}_{\mathrm{pa}}:$ consistent with $\mathbf{F}_{\text {lim }}$ and $\mathbf{F}_{\text {med }}$ |

Advice on management: ICES advises that fishing effort in 2002 be reduced to correspond to fishing mortality below $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings less than 28000 t . Current practice under the effort management system, to increase the number of fishing days allowed when moving into deeper waters, should be suspended until fishing mortality has decreased such that saithe is harvested within safe biological limits. The present spawning closures should be maintained.

Relevant factors to be considered in management: The effect of the effort regulations should be closely
monitored, in particular the possible changes in catchability and target species. In addition, it should be noted that saithe are partly caught in a mixed trawl fishery together with haddock and cod. Hence management measures taken in 2000/2001 for cod and haddock should also ensure protection for the saithe stock.

Comparison with previous assessment and advice: This year's assessments show higher estimates of SSB than last year's assessment. This is due to higher estimates of 1995-1998 year classes. However, these year classes are still poorly estimated.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}(2000)=0.41$; Landings $(2001)=39.0 ; \operatorname{SSB}(2002)=92.9$.

(Weights in '000 t)
Shaded scenarios considered inconsistent with the precautionary approach.

If the number of fishing days allocated is maintained, there is a high probability that fishing mortality will exceed $\mathbf{F}_{\mathrm{pa}}=0.28$ in 2002 and 2003.

Medium- and long-term projections: Medium-term projections are not presented. They were made using the same input parameters as the short-term predictions. The results indicate a high probability that SSB will be less than the proposed $\mathbf{B}_{\mathrm{p}^{2}}$ at current fishing mortality, particularly if future recruitment follows a distribution similar to past observations.

Elaboration and special comment: Saithe are taken in a mixed trawl fishery although they may be targeted with a small by-catch of other demersal species. The fishery was originally international, but for all practical purposes saithe has been fished only by Faroese vessels since the introduction of the 200 nm EEZ in 1977. The principal fleet consisting of large pair trawlers with engines larger than 1000 HP , accounted for $60 \%$ of the catches in 1994-2000. In the same period the smaller pair trawlers ( $<1000 \mathrm{HP}$ ) caught $20 \%$, jiggers $9 \%$ and large single trawlers $9 \%$. All other vessels had only
small catches of saithe as by-catch. Growth rates have increased from the low level observed in 1990-1991 to higher values in 1994-1996 and have decreased again since 1997.

The assessment was tuned with commercial pair trawler catch and effort data from logbooks. No recruitment indices are available.

The Faroese Government has requested ICES as follows:
for cod, haddock and saithe in Division Vb, where an effort control management system is in effect, estimate the probability profile of fishing mortalities which would be generated under the current effort control scheme and provide effort options which have a high probability ( $>80 \%$ ) that the realised fishing mortalities in 2002 would correspond to the fishing morality identified as being within safe biological limits;

The probability profile of fishing mortalities presented in the 1999 report could not be provided in this years report.

In recent reports, the fishing mortality on cod, haddock and saithe that could be generated in the upcoming fishing year, given the number of fishing days allocated to each fishing fleet, was estimated, using partial fishing mortalities by age ( 3 to 7 ) and by year ( 1985 to 1995) to calculate catchability coefficients. Probability profiles for various combinations of effort allocations were then constructed from the effort allocated and the estimated catchabilities. Based on the 1999 assessment and the observed effort allocation, there was a high probability for all 3 stocks that fishing mortality was in excess of the proposed $\mathbf{F}_{\mathrm{pa}}$ 's.

The number of fishing days reported for 1996 to 1997 are not believed to be reliable because the number of days fished in trips landed at multiple landing sites were recorded at each landing site. This problem is believed to have been resolved from 1998 onwards. With the implementation of the fishing days system, it is expected that the mortality exerted by a single fishing day for the various fleet categories will have changed and therefore the basis for the calculation of the expected fishing mortality is probably no longer valid. Another problem is that the fleet definitions have changed since the introduction of the day system, and this makes comparisons back in time difficult. And the existing recent time-series is too short to be used in reliable evaluations.

However, the recent history and the present assessment indicate that fishing mortality on all three stocks is expected to be above the proposed $\mathbf{F}_{\text {pa }}$, unless the number of days are reduced substantially. Furthermore, medium-term projections indicate that with present fishing mortalities there is a high probability that SSB for all three stocks will be below $\mathbf{B}_{\mathrm{pa}}$, for haddock even below $\mathbf{B}_{\text {lim }}$.

### 3.4.1 Overview

## Description of fisheries

The fleets operating in the Skagerrak and Kattegat (Division IIIa) include vessels targeting species for human consumption as well as vessels engaged in fisheries for reduction purposes. The human consumption fleets are diverse including gill netters and Danish seiners exploiting flatfish and cod and demersal trawlers involved in various human consumption fisheries (roundfish, flatfish, Pandalus and Nephrops). Demersal trawling is also used in the fisheries for Norway pout and sandeel which are landed for reduction purposes. Pelagic trawlers and purse seiners exploit herring, mackerel, horse mackerel and sprat.

The roundfish, flatfish and Nephrops stocks are mainly exploited by Danish and Swedish fleets consisting of bottom trawlers (Nephrops trawls with $>70 \mathrm{~mm}$ meshes and bottom trawls with $>90 \mathrm{~mm}$ mesh size), gill netters and Danish seiners. The number of vessels operating in Division IIIla has decreased in recent years. This is partly an effect of the EU withdrawal programme which until now has affected the Danish fleets only, but these fleets still dominate the fishery in Division IIIa. Pandalus is exploited by Danish, Swedish and Norwegian shrimp trawlers.

The industrial fisheries are carried out by trawlers mainly of a size above 20 m using small-mesh trawl. The main target species are sandeel, Norway pout, sprat and blue whiting. By-catches in these fisheries have decreased since 1996 mainly due to enforcement of bycatch regulations. Landings in the industrial fisheries in Division IIIa are given in Table 3.4.1.1.

There are important technical interactions between the fleets.

Misreporting and non-reporting of catches have occurred mainly in the cod fisheries. The amount is, however, not known. There are no discard data available for assessments. The time series of age samples from landings for industrial purposes is short.

## Overview of resources

The Skagerrak-Kattegat area is to a large extent a transition area between the North Sea and the Baltic both in terms of hydrography and topography and the identity of stocks. The exchange of water between the North Sea and the Baltic is the main hydrographic feature of the area.

When assessed as separate stocks, several of the stocks in the Skagerrak show close affinities to the North Sea stocks, in terms of both population dynamics (similar trends in recruitment and $S S B$ ) and biological indicators such as parasites or genetics. Tagging experiments have demonstrated extensive migration between the two areas for several species. Species with no clear stock boundary between the North Sea and Skagerrak include saithe, hake, cod (except for coastal populations in fjords), haddock, whiting and Norway pout. Sandeel in the North Sea and Skagerrak is probably a complex of several local populations rather than separate populations in the two areas. The landings of sandeel from the Skagerrak area have had a different composition of sandeel species from that in the North Sea.

The main herring stocks exploited in the area are the North Sea autumn spawners and the stock of springspawners spawning in the western Baltic and the southern part of Division IIIa. Both stocks have important components migrating into Division IIIa at some time during their life cycle. The juvenile herring in Division IIIa are mainly of North Sea stock origin while the mature fish are predominantly springspawners. The major part of the Western Baltic spring spawners migrates into Division IIIa outside the spawning season and is found in the Skagerrak in summer.

Cod in the Kattegat and Belt area are also associated with the western Baltic stock. The structure and extent of migrations is, however, not clear.

Most of the species are now assessed in conjunction with the stocks in the neighbouring areas - cod in the Skagerrak, haddock, saithe, Norway pout and autumnspawning herring are assessed as part of the North Sea stocks, spring spawning-herring as part of the western Baltic stock. The state of these stocks is considered in the sections concerning the North Sea and Baltic respectively.

The cod in Skagerrak is assessed together with cod in the North Sea and the Eastern Channel. The stock is outside safe biological limits (see Section 3.5.2). The landings of cod in the Skagerrak in 2000 were 9300 t in the human consumption fishery. No by-catch was observed in the small meshed industrial fisheries. Denmark and Sweden took the majority of catches.

The cod in Kattegat is outside safe biological limits. Landings in 2000 were 4900 t , which is the lowest in the time series.

Haddock in Division IIIa is assessed together with haddock in the North Sea. The stock is outside safe biological limits. The landings of haddock in Division IIla in the human consumption fisheries amounted to 1485 t in 2000 . By-catches in the industrial fisheries were estimated at 600 t . Most of the catches are taken in the Skagerrak.

Assessment of the state of the whiting in Division Illa was not possible. The landings of whiting in Division IIIa were 600 t in 2000 and the major part was taken in the industrial fisheries. Most of the landings are taken in the Skagerrak.

The plaice in Division IIIa is harvested outside biological limits, as fishing mortality is higher than $\mathbf{F}_{\mathrm{pa}}$ Landings amount to 8800 t in 2000 . About $75 \%$ of the landings were taken in the Skagerrak.

Sole in Division IIIa is harvested outside safe biological limits. Landings in 2000 were 780 t , substantially lower than the 1300 t in 1995.

The industrial fisheries yielded a total catch of 72000 t in 2000, well below the mean catches of 120000 t (1989-2000). Most of the catches consisted of sandeel, sprat and herring with smaller catches of Norway pout and blue whiting (Table 3.4.1.1) By-catches of cod, haddock and whiting in the industrial fisheries were all much reduced from 1996.

The landings of Nephrops and Pandalus in 2000 from Division IIIa amounted to 4700 t and 7300 t respectively. The stocks seem to be able to sustain the present fishing mortality.

Table 3.4.1.1 Catches of the most important species in the industrial fisheries in Division IIIa (000 t), 1974 $1999^{1}$.

| Year | Sandeel | Sprat ${ }^{2}$ | Herring ${ }^{3}$ | Norway pout | Blue whiting | Total |

[^20]
## 3．4．2 Cod in the Kattegat

State of the stock／exploitation：The stock is at present considered to be outside safe biological limits．The present fishing mortality is above $\mathbf{F}_{\mathrm{pa}}$ and even above $\mathbf{F}_{\text {lim．}}$ ．The estimated SSB of 6500 t in 2001 is close to the $\mathbf{B}_{\mathrm{imm}}$ ．

The spawning stock declined steadily from 35000 t in the early 1970 s to about 10000 t in the 1990 s ，with a concurrent drop in recruitment from $20-30$ million in the 1970 s to around 10 millions in the 1990 s ．The fishing mortality exceeded 1.0 during most of the 1980 s
and 1990s．In the present state the fishery is dependent on the strength of incoming year classes．The present assessment indicates that recruitment is low for the 1999 and 2000 year classes and close to the lowest． observed．

Management objectives：There is no explicit management objective for this stock．However，for any management objective to meet the proposed precautionary criteria，$F$ should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and spawning stock biomass should be maintained above the proposed $\mathbf{B}_{\mathrm{pa}}$ ．

Precautionary Approach reference points（unchanged since 1999）：

| ICES considers that： | ICES proposes that： |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{lim}}$ is 6400 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 10500 t |
| $\mathbf{F}_{\mathrm{lin}}$ is 1.0 | $\mathrm{~F}_{\mathrm{pa}}$ be set at 0.6 |

## Technical basis：

| $\mathbf{B}_{\text {lini }}$ ：lowest observed SSB | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{lim}} * \exp (1.645 * 0.3)$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ The spawning stock has declined steadily since <br> the early 1970s at fishing mortality rates averaging | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} * \exp (-1.645 * 0.3)$ |
| $\mathrm{F}=1.0 . \mathbf{F}_{\text {lim }}$ is tentatively set equal to $\mathrm{F}=1.0$. |  |

#### Abstract

Advice on management：ICES advises that there be no fishing on this stock in 2002 and a rebuilding plan should be implemented in order to rebuild SSB above $B_{p a}$ ．

Rebuilding plan：The fishery should not be re－opened until a rebuilding plan is established，which aims at rebuilding the SSB to above $\mathbf{B}_{\mathrm{pa}}$ ．Because a large part of cod is taken as by－catch in fisheries for flatfish and Nephrops，the necessary reduction in fishing mortality on cod cannot be achieved by a reduction in TAC alone．

The rebuilding plan should include measures to improve the selectivity in the directed fishery such as a significant increase of the legal minimum mesh size of 90 mm ．By－catches in the fisheries directed to Nephrops and flatfish could be reduced by measures which improve species selectivity，e．g．，escape windows or grids．The rebuilding plan could also include seasonal and area closures．

Relevant factors to be considered in management： The economically most important species in the Kattegat are cod，Nephrops and sole，which each account for about $25 \%$ of the value of the total annual landings．By－catches of cod occur in the fisheries targeting sole and Nephrops．Management measures in the Kattegat need to take account of technical
interactions in the area．Changes in mesh regulations may be introduced with the aim of protecting mainly young cod．

Comparison with previous assessment and advice： The present assessment estimates last years SSB to be $10 \%$ lower than last years assessment．

Catch forecast for 2002：
Basis：$F(2001)=F_{s q}=F(1998-2000)=1.21$ ；Landings $(2001)=5680 ; \mathrm{SSB}(2002)=5168$.

Weights in t ．
Shaded scenarios considered inconsistent with the precautionary approach．

Medium－and long－term projections：Medium－term projections use spreadsheet－based Monte Carlo simulations with stochastic noise associated with recruitment，weights at age，and maturities．

Recruitment is generated from a Ricker Stockrecruitment model.

The medium-term projections suggest that fishing at $\mathbf{F}_{\mathrm{pa}}$ leads to a more that $75 \%$ probability of the stock exceeding $\mathbf{B}_{\text {lim }}$ in 2005.

Elaboration and special comment: Landings have decreased from 15000 t in the 1970 s to about 7000 t in the 1990s. During the years 1991-1994 an unknown, but probably substantial amount has been either
unreported or allocated to other areas. The quality of catch data from 1994 onward has improved, leading to improved reliability of the assessment.

The stock recruitment plot indicates that strong recruitment requires large spawning biomass, which
will not occur at present exploitation rates, particularly on younger ages $(1-3)$. There is evidence that the stock interacts with neighbouring cod stocks in the Skagerrak and the Baltic Sea by way of migrations. These interactions add uncertainty to the assessment.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 3-5 | Yield/R | SSB/R |

### 3.4.3 Whiting in Division IШa (Skagerrak - Kattegat)

State of stock/exploitation: Based on the available information it was not possible to assess the status of the stock or identify safe biological limits. It is likely that this stock is linked to the North Sea stock for which the assessment is very uncertain, but which is likely to be outside safe biological limits.

Management objectives: There are no specific management objectives for this stock.

Advice on management: ICES advises landings of 1500 t in 2002 as a precautionary value to restrict the potential for re-expansion of the fishery and misreporting from other regions.

Elaboration and special comment: The major part of the catch is taken as a by-catch in small-mesh fisheries. Total landings in 2000 were the lowest historically observed. The landings value advised for 2002 is consistent with ICES advice provided in 2000, and is based on the average of the catch during 1996-1998.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

| 1980 |  | Total |  |  | 65 | 1,516 | 3 |

Preliminary: Norway 1997-1999.

### 3.4.4 Plaice in Division IIa (Skagerrak - Kattegat)

State of stock/exploitation: The stock is harvested outside safe biological limits. The estimated SSB in 2001 is above $\mathbf{B}_{\mathrm{pa}}$.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ cannot be accurately defined | $\mathbf{B}_{\mathrm{pa}}=24000 \mathrm{t}$ |
| $\mathbf{F}_{\text {lim }}$ cannot be accurately defined | $\mathbf{F}_{\mathrm{pa}}=0.73$ |

Technical basis:

|  | $\mathbf{B}_{\mathrm{pa}}=$ smoothed $\mathbf{B}_{\text {loss }}$ (no sign of impairment) |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\mathrm{nned}}$ |

Advice on management: ICES recommends that fishing mortality should be less than the proposed $\mathrm{F}_{\mathrm{pa}}$ ( 0.73 ), corresponding to landings in 2002 of less than 8500 t .

Comparison with previous assessment and advice: The perception of the state of this stock with regard to
safe biological limits can change from year to year due to the uncertainty and variability in the estimates of fishing mortality in the most recent year. Successive assessments are consistent in estimating $\$ S B$ to be above the proposed $\mathbf{B}_{\mathrm{pa}}$.

Catch forecast for 2002:
Basis: $\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(98-00)$ scaled to $\mathrm{F}(00)=0.82$; Landings $(2001)=8.6 ; \operatorname{SSB}(2002)=33.2$.

| F (2002) | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 44.3 |
| 0.16 | $0.2 * \mathbf{F}_{\text {sq }}$ | 2.3 | 41.7 |
| 0.33 | $0.4 * \mathbf{F}_{\text {sq }}$ | 4.3 | 39.5 |
| 0.49 | $0.6 * \mathbf{F}_{\text {sq }}$ | 6.2 | 37.6 |
| 0.73 | $0.89 * \mathrm{~F}_{\mathrm{sq}}=\mathbf{F}_{\mathrm{pa}}$ | 8.5 | 35.1 |

|  |  |  | , \% \% \% |

Weights in '000t.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Status quo projections show a low probability of SSB falling below the proposed $\mathrm{B}_{\mathrm{pa}}$ in the medium-term.

Elaboration and special comment: The estimates of fishing mortality and proposed $\mathrm{F}_{\mathrm{p}}$ for plaice in Division ILIa are substantally higher than the corresponding estimates for plaice in the North Sea (Sub-area IV). The difference may be caused by a difference in the exploitation pattern, with the fishing mortality of young ages (2-3) being much higher in the North Sea. It may also be caused by older, mature plaice emigrating from the Skagerrak to the North Sea for spawning, or by higher natural mortality due to possible parasitic infection. Reference points based on the estimated $F$ will still be appropriate for use with this stock, but the values are not comparable to reference points for other plaice stocks.

The major plaice catches are taken in fisheries using Danish seine, trawl, and gillnet, targeting mixed species for human consumption. The fishery is more directed at older fish than for most other plaice fisheries. As noted above, the proportion of plaice younger than 3 years in the catches is lower than in the North Sea, which might partly explain the relative robustness of the stock to high fishing mortality levels.

The short-term predictions, and in particular those dealing with SSB, should be interpreted cautiously, as a result of the high contribution of recruitment in 2001 and 2002 , which have been extrapolated using the geometric mean average.

The analytical assessment uses information from Danish commercial fleets and one survey series and is considered to be uncertain.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

### 3.4.5 Sole in Division IIa

State of the stock/exploitation: The stock is harvested outside safe biological limits. Fishing mortality in 2000 was above $\mathrm{F}_{\mathrm{pa}}$ and landings increased by $20 \%$ in 2000 compared to 1999. Spawning biomass is estimated still to be well above $\mathbf{B}_{\text {pa }}$. The stock size was exceptionally high in the period 1992-1996 due to strong recruitment in the period 1989-1993. Recruitment has been near or below average since 1994.

Management objectives: There are no explicit management objectives for this stock. However, for any management objective to meet the proposed precautionary criteria, $F$ should be less than the proposed $F_{p a}$ and spawning stock biomass should be maintained above the proposed $\mathbf{B}_{\text {pa }}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 770 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 1060 t |
| $\mathrm{F}_{\text {livi }}$ is 0.47 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30 |

Technical basis:

| $\mathbf{B}_{\text {lima }}: \mathbf{B}_{\mathrm{pa}} * \exp (-1.645 * 0.2)$ | $\mathbf{B}_{\mathrm{pa}}: \mathrm{MBAL}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim: }}: \mathbf{F}_{\text {med }} 98$ excluding the abnormal years around 1990 | $\mathbf{F}_{\mathrm{pa}}:$ consistent with $\mathbf{F}_{\text {lim }}$ |

## Advice on management: ICES advises that current

 fishing mortality should be reduced to below $F_{p a}$ corresponding to landings in 2002 of less than 500 t .Relevant factors to be considered in management: This stock supported catches at $250-450 \mathrm{t}$ for 35 years, prior to the occurrence of strong recruitments in the period of 1989 to 1993. These recruitments led to large increases in SSB, yield and fishing effort, with a decline in $F$ through the 1990s. Since 1995, recruitment has returned to the earlier low values.

Regardless of short-term management measures, biomass and yield will decline over the next few years under the lower recruitment regime. Recruitments appear to have periods of generally high or low yearclasses that are not closely tied to the size of the spawning biomass. This suggests that environmental factors might be important for recruitment and therefore contribute uncertainty to medium-term projections and biological reference points.

Comparison with previous assessment and advice: This years analyses are consistent with last years assessment. However, the advice is changed because $F$ now exceeds $\mathbf{F}_{\text {pa }}$.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\overrightarrow{\mathbf{F}}_{\text {sq }}=\mathrm{F}(2000)=0.39$; Landings (2001) $=706 ; \mathrm{SSB}(2002)=2052$.

| F (2002) | Basis | Landings (2002) | $\begin{gathered} \hline \text { SSB } \\ (2003) \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| 0.23 | $0.6 * \mathbf{F}_{\text {sq }}$ | 390 | 2110 |
| 0.30 | $\begin{gathered} 0.8 * \mathbf{F}_{\text {sq }} \\ \left(\mathbf{F}_{\mathrm{pa}}\right) \end{gathered}$ | 500 | 1990 |
| ¢ | H. | 01/3 | 183的 |
| 04s. | U | ก0. | 1䊼 |

Weights in t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections rely heavily on input (e.g. maturity ogive, weights at age) that may be relatively uncertain. It appears that factors other than $\operatorname{SSB}$ contribute significantly to the variability in recruitment.

Elaboration and special comment: The analytical assessment is based on landings data and commercial CPUE series. Official catch statistics are considered unreliable for the early 1990s, but are thought to be fairly accurate since 1994.

### 3.4.6

## Pandalus borealis in Division IIIa and Division IVa East (Skagerrak and Norwegian Deeps)

State of stock/exploitation: The state of the stock is unknown, but the stock in 2001 is around the long-term (1984-2000) average as indicated by survey and commercial CPUE series. Fishing effort has remained relatively stable in recent years. Information on year classes relevant to the stock and exploitation in 2002
will become available from research vessel surveys in November 2001.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (revised in 2001):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| No biological basis for defining $\overline{\mathbf{B}}_{\mathrm{ilim}}$ | No biological basis for defining $\mathbf{B}_{\mathrm{pa}}$ |
| No biological basis for defining $\mathbf{F}_{\mathrm{lim}}$ | No biological basis for defining $\mathbf{F}_{\mathrm{pa}}$ |

ICES withdraws its previously proposed $\mathbf{B}_{\mathrm{pa}}$ of reasons described below.

Advice on management: ICES recommends a TAC of 12600 t in 2002, based on the 1985-2000 average landings. If the CPUE of the October 2001 survey indicates a substantial deviation from the average ICES will provide a revision of the advice.

Relevant factors to be considered in management: In the past, survey CPUE's between 7.5 and $15 \mathrm{~kg} / \mathrm{nm}$ have been associated with approximate long-term average landings. Survey results outside this interval could justify a change in the recommended TAC.

The perception of the state of the stock in 2001 is based on the October survey in 2000 . Catch opportunities in 2002 are to a large extent dependent on 1- and 2-year old shrimps. Over the period 1985-2000 these age groups comprised about $75 \%$ of the landings. The estimates of the abundance of these age groups are imprecise or not known yet. Information on the stock size and age composition in 2002 will become available after the October survey in 2001.

Sorting grids or other means of facilitating the escape of fish should be implemented in this fishery.

Comparison with previous assessment and advice: The previous analytical assessment for this stock is no longer considered reliable. In previous years, analytical assessments (XSA) have been applied in assessing this stock and to provide catch forecasts. However, since the natural mortality of this species most likely is several times higher than the fishing mortality, the methodology of cohort analyses is not well suited for this species. The few age groups in the stock further add to uncertainty of the XSA estimates.

ICES has been aware of these special facts and has in recent years been investigating assessment models, which include predator components (natural mortality).

However, exploratory runs with such models indicate a dramatic shift (increases) in estimated total biomass, and ICES prefers further exploratory assessments by this model, before using its results as a basis for management advice.

Catch forecast: Not available.

Elaboration and special comments: Pandalus borealis is fished by bottom trawls at $150-400 \mathrm{~m}$ depth throughout the year by Danish, Norwegian, and Swedish fleets.

Strong fluctuations in the Pandalus stocks are frequently observed. Predator pressure as well as the low number of age groups in the stock contributes significantly to such fluctuations. The natural mortality for Pandalus is likely to be substantially higher than the fishing mortality and is likely to fluctuate considerable according to the abundance of predators.

Because of the potentially large impact of predation on stock dynamics, the biological consequences of any specific fishing mortality rate can be highly variable. At low predator abundance, even a low fishing mortality ( F ) may be a high proportion of total mortality (Z), whereas at high predator abundance, a higher $F$ may still be a small part of $Z$. It is not yet possible to identify appropriate precautionary fishing mortality reference points ( $\mathbf{F}_{\text {lim }}, \mathbf{F}_{\mathrm{pa}}$ ) for such circumstances, and reference points based on total mortality may be more sound biologically.

ICES withdraws the previously proposed $\mathbf{B}_{\mathrm{pa}}$ of 12000 t for this stock. This PA reference point was based on a XSA type assessment, which is now considered to be unreliable. Alternative production models suggest that population levels may be about 3 times higher than estimated XSA. These alternative estimates have to be confirmed by further analyses.

Exploratory assessments were based on commercial catches, survey indices of available biomass, recruitment and amount of predators, but were not considered sufficiently reliable to base advice on.

### 3.4.7 Herring in Sub-divisions 22-24 and Division III (spring-spawners)

State of stock/exploitation: The state of the stock is uncertain. However, the available information provides reason for concern. Fishing mortalities appear to be stable at a high level during the last 4 years while catches have declined over the same period. An improvement can be expected only if the indications that the year classes 1998 and 1999 are large can be confirmed in future. However, at the present fishing mortality-such an improvement would not be sustained in the long term.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: ICES recommends that the fisheries on herring in Division IIIa should continue to be managed in accordance with the management advice given on autumn-spawning herring in Section 3.5.8. If a catch limit is required in Sub-divisions 2224, ICES advises that it should not exceed recent catches in that area which are of the order of 50000 t .

Relevant factors to be considered in management: A considerable part of the landings of juvenile herring in Division IIIa originates from the North Sea stock. An abundant 1999 year class of North Sea autumn-spawner herring is expected to be present in the area as one-yearolds in the year 2001. Recently, this fishery has been managed to be consistent with the management of the herring in the North Sea. As the North Sea stock recovers, the need for separate assessment of this herring stock increases. Failure to obtain reliable catch data for this area may place this stock at increasing risk of serious overexploitation.

In the Baltic the TACs for herring apply to several herring stocks including the component of this stock in Sub-divisions 22-24, and there is no specific instrument available that allows control over the exploitation of spring-spawning herring in Division IIIa and Subdivisions 22-24. ICES reiterates its previous advice that the herring TAC for the Baltic should be split and individual TACs applied to the stocks, i.e. Sub-divisions 22-24, Sub-divisions $25-29+32$, and Sub-divisions 30, 31.

It should also be stressed that, if fishing mortality for North Sea autumn-spawners is allowed to increase due to an increase in SSB of the North Sea autumn spawners, fishing mortalities on spring-spawners in Division IIIa is likely also to increase due to their being
taken together in several fisheries. This is an additional threat to the stock.

Comparison with previous assessment and advice: The assessment continues to remain uncertain.

Catch forecast: The present assessment was not considered reliable to base a projection on.

Elaboration and special comments: The assessment of this stock is very uncertain and no population analysis was accepted.

Herring of this stock are taken in the Northeastern part of the North Sea, Division IIIa and Sub-divisions 22-24. Division IIIa has directed fisheries by trawlers and purse seiners (fleet C), while Sub-divisions 22-24 have directed trawl, gillnet and trapnet fisheries (fleet F). The herring by-catches taken in Division IIIa in the small mesh trawl fishery for Norway pout, sandeel and sprat (fleet D) are mainly autumn-spawners from the North Sea stock. After a period of high landings in the early 1980 s the combined landings of all fleets have decreased to below the long-term average.

The TACs in Division IIa in 2000 were 1) for the directed fishery 80000 t and 2) for by-catch in the small mesh fisheries 21000 t . The TAC comprises both the autumn- and spring-spawning stocks in the area. The spring-spawners are also fished in the Baltic, under the overall IBSFC herring TAC of 405000 t (Sub-divisions $22-29 \mathrm{~S}$ and 32). The agreed TACs in Div. Illa for 2001 are 80000 t for directed fishery and a total of 21000 t for by-catches in the small mesh fisheries.

The recent attempt to assess the stock gives unreliable results due to the different signals from the diverse sources of information. In order to obtain a reliable assessment, a comprehensive survey covering the whole stock is required. As a new method to calculate the proportion of spring- and autumn-spawners caught in these areas has been implemented by the HAWG, all catch and IBTS data for the period 1991-1999 has been revised. Further application of methods to split the spawning components in the catch data before 1991 should be undertaken to provide a stable set of historical catch at age data.

### 3.4.8 Sprat in Division Ша

State of stock/exploitation: The state of the stock is unknown. Sprat in this area is short-lived with large annual natural fluctuations in stock biomass.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: As sprat is mainly fished together with juvenile herring the exploitation of sprat will be limited by the restrictions imposed on fisheries for juvenile herring.

Relevant factors to be considered in management: Sprat cannot be fished without significant by-catches of herring except in years with high sprat abundance. The most recent period when this occurred was 1994-1995. The available surveys are not reliable indicators of sprat abundance in Division IIIa. Therefore, tishing possibilities in 2002 cannot be projected.

Management of this stock should consider management advice given in Section 3.5 .8 (Herring in Sub-area IV, Division VIId and Division IIIa).

Catch forecast 2002: None.

Elaboration and special comment: The directed sprat fishery serves a very small market. Most sprat catches are taken in an industrial fishery whose catches are limited by herring by-catch restrictions. This combination of factors has limited the expansion of harvests of this sprat stock to fully exploit the occasional strong year classes, which pass quickly through it.

Landings of sprat in Division IIIa averaged about 70000 t in the 1970 s , but since 1982 have typically been in the region of 20000 t , except in 1994-1995.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

### 3.4.9 Sandeel in Division III (Skagerrak - Kattegat)

State of stock/exploitation: Based on the available information it was not possible to assess the status of the stock or identify safe biological limits.

Management objectives: There are no explicit management objectives for this stock.

Elaboration and special comment: ICES notes that this is an unregulated fishery on an important prey species.

The fishery is an extension of the North Sea fishery into Division IIla, but with smaller vessels working closer inshore, mostly along the coast of Jutland.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

Catch data (Table 3.4.1.1):

Weights in ' 000 t .

### 3.4.10 Anglerfish in Division ШII (Skagerrak - Kattegat)

Comments: Landings of anglerfish in Division IIIa are low compared to landings taken from the North Sea and Division VIa. Landings increased in the early 1990s and have since declined. Anglerfish caught in Division IIIa probably form part of the same stock as those in the North Sea and Division VIa. No assessment has been carried out on this stock. Landings from the North Sea are mis-reported into Division IIIa.

If these misteportings compromise the effectiveness of management measures in the North Sea, then a TAC for Division IIIa may be appropriate.

Source of information: Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, August 2001 (ICES CM 2002/ACFM:02).

### 3.5.1 Overview

## Description of the fisheries

The fisheries in the North Sea can be grouped into demersal and pelagic human consumption fisheries and industrial fisheries which land their catch for industrial puposes. Demersal human consumption fisheries usually target a mixture of roundfish species (cod, haddock, whiting), or a mixture of flatfish species (plaice and sole) with a by-catch of roundfish. A fishery directed at saithe exists along the shelf edge. The catch of these fisheries is landed for human consumption. The pelagic fisheries mainly target herring mackerel and horse mackerel. Although most of the landings of these species may be landed for human consumption purposes, part of the landings are used for fishmeal and fishoil. The catch of the industrial fisheries mainly consists of sandeel, Norway pout and sprat. The industrial catches also contain by-catches of other species including herring, haddock and whiting (Table 3.5.1.1). In addition to the finfish fisheries, smaller fleets exist which fish for crustaceans including Nephrops, Pandalus and brown shrimp (Crangon crangon).

Each fishery uses a variety of gears. Demersal fisheries: otter trawls, pair trawls, twin trawls, seines, gill nets, beam trawls. Pelagic fisheries: pelagic trawls and purse seines. Industrial fisheries: small-meshed otter trawls, pelagic trawls and purse seines.

Some major technological developments changed the fisheries in the North Sea during and after the 1960 s such as the development of the beam trawl fishery for flatfish, purse seines in the pelagic fishery and large pelagic trawls to replace driftnets. In recent years twin trawls have been introduced in the fishery for flatfish and roundfish. The introduction of power blocks in the 1960s has enommously increased the possibilities for the purse seiners. Right up to the present further development of electronic equipment such as satellite navigation, fish finders and sonar has increased fishing efficiency of the fleets.

The trends in landings of the most important species landed by these fleets since 1970, together with the total intemational landings, are shown in Table 3.5.1.2 and in Figure 3.5.1.1. The demersal landings have steadily declined over the period. The pelagic landings, dominated by herring, decreased to a minimum in the late 1970 s, when the fishery for herring was closed, but increased again up to over 1 million $t$ in the period 1987-1995. In 1996 they were reduced by about half and remain stable since then. The landings in the industrial fisheries increased to approximately 1.8 million $t$ in the mid 1970 s, and have fluctuated between 1 and 1.5 million $t$ in recent years. These landings show the largest annual variations, due to the
short life span of the species. The total fandings reached 3 million t in 1974, and have been around 2.5 million t since the 1980s.

Most commercial species are managed by TAC/quota regulations that apply to Sub-area IV or a combination of Sub-area IV with an adjacent area. The national management measures with regard to the implementation of the quota in the fisheries differ between species and countries. The industrial fisheries are subject to regulations for the by-catches of protected species.

## Data

The biological data available from scientific sources for the assessment of roundfish, flatfish, herring and mackerel are relatively good. The level of biological sampling of most of the commercial landings has been maintained. Discard data are only used directly in assessments for haddock and whiting, but a historical series exists only for one country. Several countries now collect discard data on a recurrent basis although many of these data are yet to be incorporated in the assessments.

Data on landings, fishing effort and species composition are available from all industrial fisheries. There are catch and effort data available for many fisheries but it is uncertain how reliably these data reflect trends in effective effort, i.e. nominal effort after corrections for technological improvements. Restrictive management measures (TAC's) have also resulted in changes in fishing practice of some fleets and redirected effort to other species. In a number of cases this has lead to abandon the use of time series of commercial CPUE data in the assessments (cod, haddock, whiting, plaice). In some recent years there was misreporting of roundfish landings associated with restrictive quotas. Substantial underreporting of cod landings occurred in 1998.

Several series of research vessel survey indices are available for most species. Quarterly data were available from the International Bottom Trawl Survey for a period of 6 years (1991-1996) and these were used in the assessment of some stocks. This survey covers quarters 1 and 3 since then. For herring and mackerel the spawning stock sizes are estimated by annual larvaeand acoustic surveys (herring) or intermittent egg surveys (mackerel).

Analytical assessments were performed on cod, haddock, whiting, saithe, herring, mackerel, plaice, sole, sandeel and Norway pout.

Multispecies considerations are not incorporated in the assessments or the forecasts for the North Sea stocks. However, average natural mortalities estimated by multispecies assessments are incorporated in the assessments of cod, haddock, whiting, herring, sprat, sandeel and Norway pout.

## Overview of resources

In the past 10 years the state of the stock for most roundfish and flatfish species in the North has further deteriorated. Some of these stocks have reached a historical low within this period. One of the major causes of this deterioration is the continuous very high level of exploitation. This exploitation has lead to a reduction in the number of age groups in the stocks and fishing opportunities have consequently become more dependent on the success of recruitment. Recruitment for most stocks is, however, very variable. For a number of species (cod, whiting, plaice) recruitment in most years has been lower than in previous decades. At the same time it is observed that a number of species (cod, haddock, whiting, sole, plaice) simultaneously show a reduction of growth. On the contrary, other (southern) species like sea bass and red mullet have increased and in some times attracted a fishery. There is considerable speculation on the reasons for the observed changes. The reduction in recruitment can be explained by a reduction in the production of eggs by the reduced spawning stocks, but it cannot be excluded that changes in the environment play a role. In the last 10 years the climate has changed not only on land but also in the sea and mean temperatures in the sea have increased. Also changes in the sea currents have been observed. The changes in environmental conditions may also be responsible for changes in the distribution and abundance of the different species.

In the North Sea all stocks of roundfish and flatfish species have been exposed to high levels of exploitation. The present assessments indicate that the fishing mortality in the last three years has been reduced for whiting and saithe, but not for cod and haddock. The cod stock is at a very low level and is presently in a region where the chance of collapse is high. The stock of whiting has shown a continued decline over time although the recent estimates of biomass are uncertain. It is considered likely that the whiting stock is still outside safe biological limits. The saithe stock is now considered to be within safe biological limits. The stock of haddock presently profits from a good year class recruiting into the spawning stock but the explotation rate is still too high. Plaice is outside safe biological limits and fishing mortality on both plaice and sole are high and unsustainable in the longer term. The spawning stock biomass of sole is decreasing. Norway pout and sandeel are short living species and their biomass show large fluctuations in accordance with large variability of recruitment. The biomass of Norway pout and sandeel in 2001 were high and these stocks are both considered within safe biological limits.

The herring stock in the North Sea collapsed in the mid1970s due to heavy exploitation, but has recovered after a closure of the fisheries between 1977 and 1981. In the mid-1990s it declined again. In 1996, effective management measures have been implemented to reduce the catches in both the human consumption and industrial fishery. These measures resulted in a considerable reduction in the fishing mortality in 19962000. The stock has been outside safe biological limits for a number of years, but is recovering. The spawning stock is expected to be close to safe biological limits in 2002. The herring stock is exploited in the North Sea and the Channel (Downs herring) by human consumption fisheries. Also by-catches of juvenile North Sea herring are taken in the industrial fishery for sprat in the North Sea and Division Illa (Skagerrak). The sprat stock fluctuates considerably between years. The actual state of the sprat stock is not precisely known, but the biomass is thought to be high presently. The North Sea component of the mackerel stock collapsed in the early 1970s and shows no signs of recovery. Most of the mackerel catches taken in the northern North Sea in recent years originate from the western component.

Landings of cod in 1999 were 59000 t . The spawning stock in 2001 has been estimated at 55000 t , which is close to its historical observed level. Recruitment has been below average since 1985 in all years, with the exception of the 1996 year class. The present assessment indicates a constant high tishing mortality in recent years. A recovery plan is required to rebuild to the stock.

The spawning stock of saithe (assessed for the North Sea and West of Scotland combined) is at a low level compared to the 1970 s when it was more lightly exploited and recruitment was higher. In recent years it has increased slightly. Landings in 2000 in the North Sea were 87000 t . Fishing mortality has as almost continuously declined from the 1980s. The proportion of the stock available in area VI has been reduced from the 1980s.

Human consumption landings of haddock in 1999 were 47000 t . Historically, the stock size has shown large variation due to the occasional occurrence of a very strong year class. The spawning stock size in 2001 has increased due to a large 1999 year class. Fishing mortality remains too high.

The assessment of whiting has a much lower precision than the assessment of many other stocks. Total landings have been gradually decreasing since 1976 and the landings in 2000 , at 28000 t , are the lowest observed in the time series. There are indications that the stock has increased in recent years but that it is likely still outside safe biological limits.

The spawning stock of plaice decreased in the early 1990s and in 1997 was at the lowest observed historically. Landings have decreased since 1990 and were 83000 t in 2000 . Fishing mortality has decreased but remains too high. At its present exploitation rate there is a high probability that the stock will remain below the levels observed in the 1970s and 1980s. An abundant 1996 year class was expected to increase the spawning stock but a slower growth of this year class and increased discarding has reduced the its contribution to the spawning stock.

Landings of sole were 23000 t in 2000 . The spawning stock is decreasing. The spawning stock in recent years mainly consisted of a large 1996 year class which has now mostly passed the fishery. Fishing mortality has reduced in recent years but is still too high.

Landings of Norway pout have increased in 2000 to 185000 t . The spawning stock in 2001 was amongst the highest in the time series, due to the large 1999 year class. The 2000 year class, however, was poor and the stock is expected to decline fast. Fishing mortality has generally decreased between 1974-1995 and has fluctuated around a low level since.

Landings of sandeel in 2000 were 700000 t which is close to the average yield over the period 1976-2000. Over the years, the spawning stock has been fluctuating without a trend. The spawning stock in 2001 was also around the long term average. There is insufficient information to forecast the development of the stock in the short term.

The herring has recently recovered from a low but is still considered to be outside safe biological limits. The stock is expected to increase in the short term by a large 1998 year class which matures in 2002. Catches in the human consumption and industrial fisheries in the North Sea remained stable in the last three years and were 330000 t in 2000 . Landings of sprat in 2000 were 196000 t . The state of the sprat stock is not precisely known.

The spawning stock of mackerel in the North Sea remains small. Recruitment to this stock component has been very low for many years. An egg survey in 1999 estimated a spawning stock size of 68000 t . The fisheries for mackerel in the North Sea rely on a much larger stock component, the western mackerel, which spawns outside the North Sea and which is present in the northern North Sea in the second half of the year.

The present state of the North Sea horse mackerel stock is not known. The last estimate from egg surveys in 1989-1991 indicates an SSB of about 240000 t . The age composition of the relative small catches suggests that the exploitation rate of juvenile fish may have increased in recent years.

The stock of Pandalus borealis in Division IVa (Norwegian Deep) and Division IIIa remains stable. The
state of the stocks in Division IVa (Fladen Ground) and Division IVb (Farn Deep) is not known, as only insufficient data for assessments were available. The fishery in the latter two areas is opportunistic, strongly influenced by stock abundance and market prices.

## Management advice

Reductions in fishing mortalities have been advised for several stocks which are outside safe biological levels. Fishing mortality is generally high and reached for most stocks the highest historical values in recent decades. This is in itself a clear indication of excessive effort.

This, and the poor performance of TACs, as implemented, in reducing fishing mortality, leads ICES to reiterate that the required reductions in fishing mortality can only be achieved if reductions in effort are included in management.

Most fisheries on roundfish and flatfish in the North Sea are characterised by extensive discarding. Discarding and high-grading also take place in pelagic fisheries, but little and incomplete information on discarding practices in these fisheries is available. Management measures, which reduce the amount of juveniles caught, would contribute to the recovery of spawning stocks and benefit yields.

Specific advice is presented in the respective stock sections.

## Information provided by fishing industry associations

In August 2001, the preliminary results of a number of assessments of stocks in the North Sea (cod, haddock, whiting, saithe, plaice and sole) were presented at a meeting held at ICES HQ of the North Sea Commission Fisheries Partnership. At this meeting ICES invited representatives from a number of fishing organisations around the North Sea, to provide written comments on the assessment presented and in particular to inform on the degree to which fishermen agree or disagree with the perception of the stock as indicated by the assessments. ICES received comments from the National Federation of Fishermen's Organisation and the Scottish Fishermen Federation in the UK, the Dutch fishermen's representatives and the Danish fishing industry. The comments were based on enquiry surveys among fishermen. They were in different format and it was not clear how representative they are. ICES welcomes the response and realizes that further discussion is needed to improve the quality of the enquiry and uniformity of the format in order to be able to make better use of the information.

## Summary of Comments from the Fishing Industry

Danish Fishermen's Association: Comments were based on interviews with fishermen from the major
fishing harbours in the North Sea. The information was given as a first-hand impression of the abundance of cod, haddock, saithe, whiting, plaice and sole, based on recent developments in catches and landings to a number of fish auctions. DFF offered explanations of some of the reported trends and in particular noted that the Danish information would not be appropriate for an analysis of the state of the whiting stock. A table of the total landings in the period Jan. to Sep. in 2000 and 2001 to four of the major auctions in the North Sea and Skagerrak area was included. DFF pointed out that time constraints had prevented them from making a more thorough analysis of the catch data.

National Federation of Fishermen's Organisations (UK): The NFFO summarised the views of fishermen on the same six species covered by DFF. Similarly, NFFO felt that they would have been able to provide more systematic data if more time had been available. It was also commented that catch trends and CPUE data have been distorted by the restricting TAC allocations.

Scottish Fishemen's Federation: The SFO paper was based on the responses to a questionnaire seeking fishermen's views on abundance, size, size range, and geographical distribution of cod, haddock, whiting and saithe in ICES fishing areas IV and VI during the period January to August 2001 compared to 2000. Respondents were asked to indicate their answers on a scale of 1 to 5 . "1" indicated respectively "much less", "much smaller", "mostly small", and "local clusters". "5" indicated respectively "much more", "much larger", "mostly large", and "widespread". The responses were summarised as a series of histograms (bar charts), and comprised the views of 84 fishermen ( 56 from North Sea ports, 28 from the West of Scotland). This represented $10 \%$ of the white fish fleet.

Dutch Fish Producers Board: The Dutch paper was in the form of a large spreadsheet, summarising the opinions (agree/disagree, with reasons), of 19 fishermen on the scientists preliminary views concerning (i) status of the plaice stock, (ii) discard rates in plaice fisheries, (iii) status of the sole stock, (iv) discard rates in the sole fisheries, (v) reduced biomass of the sole spawning stock, (vi) status of the whiting stock, (vii) discard rates in the whiting fisheries, (viii) existence of two whiting stocks (north and south of the Dogger Bank), (ix) status of the cod stock, ( $x$ ) cod recovery measures, (xi) other comments. The regular fishing area used by the 19 fishermen was also indicated on the spreadsheet.

All four working papers stated an appreciation of the opportunity to make an input.

## ACFM response

It is the policy of ICES to encourage and facilitate this sort of dialogue between scientists and the fishing industry. The documentation at this ACFM meeting is a very encouraging start to that process.

Just as the fishermen's organisations had found, however, ACFM likewise had insufficient time to fully evaluate the documents. Taking into account also that the information provided was mainly of a qualitative nature, ACFM could form only a preliminary view.

The enquiry indicates in some diversity of opinions. Impressions of stocks vary between individual fishermen but also between countries and areas.

The information on the status of fish stocks from the fishermen deals with abundance (in weight?) and with the size distribution in the catches. Comparisons are short term 1-3 years. There is only rarely a reference to the fishing mortality or a proxy thereof. The ICES assessment information is expressed differently, the SSB is often compared to $\mathbf{B}_{\mathrm{pn}}$ or $\mathbf{B}_{\text {lim }}$ while the shortterm trend is mostly not referred to. In order to compare the information these short-term trends have been inferred based on the graphs of SSB presented in the advisory report.

There is general agreement on the poor state of the cod stock, but the stock was considered in a better condition in the Northern North Sea than further south.

There is also general agreement that the stock of haddock has increased considerable over a large area and that fish size has decreased.

On whiting, responses were divided. Most responses indicate a higher stock size than indicated in recent assessments and point to the mismatch between TAC and catch opportunities. Considerable amounts of marketable size whiting were reported as discarded for legal reasons but also low market prices and low weight at length (poor condition) were mentioned as a reason for discarding.

Most responses on saithe indicate a larger stock than indicated in recent (unrealistic) assessments. The saithe is also said to be smaller and present in a wide area.

There was agreement that plaice catches in 2001 were better than in 2000, which was again better than 1999. A reduction in the condition of plaice was mentioned several times. Also small plaice seems to be more abundant in areas where they previously have been scarce. It was confirmed that discarding had increased but not in all areas.

There were only few responses on the sole. In general they report a decrease of larger fish, but a recent increase of small sole in coastal areas.

## Final Comments

The material provided by the industry will be sent to the relevant ICES assessment Working Groups for their consideration in the 2002 round of meetings.

At present, the nature of the data provided means that they cannot be handled in a quantitative way, but the collection and reporting of quantitative data is a goal that both sides should work towards achieving. ACFM
therefore welcomes the suggestion from the North Sea Commission Fisheries Partnership that appropriate methods of collecting and reporting data could be developed through the Partnership.

Figure 3.5.1.1 Landings from North Sea. Data from Table 3.5.1.2.

### 3.5.2 Cod in Sub-area IV (North Sea), Division VHd (Eastern Channel) and Division Шa (Skagerrak)

State of stock/exploitation: The stock is outside safe biological limits. The spawning stock is estimated to have been below $\mathbf{B}_{\mathrm{pa}}$ since 1984 and in the region of $\mathbf{B}_{\text {lim }}$ since 1990. SSB in 2001 is estimated at a new historic low and remains in a region where the risk of stock collapse is high. Fishing mortality has remained at about the historic high and above $\mathbf{F}_{\mathrm{pa}}$ since the early 1980 s and F in 2000 is estimated to be about $\mathrm{F}_{\text {lim }}$. Except for the 1996 year class, recruitment has been below average in all years since 1987. The 1997 and 2000 year classes are estimated to be the poorest on record.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the cod stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $70000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.65 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $150000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 150000 t .
4. In order to reduce discarding and to enhance the spawning biomass of cod, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on $F$ and lower bounds on SSB. and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | YCES proposes that: |
| :---: | :---: |
| $\mathbf{B}_{\text {lim }}$ is 70000 t , the lowest observed spawning stock biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 150000 t . This is the previously agreed MBAL and affords a high probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of assessments. Below this value the probability of below average recruitment increases. |
| $\mathbf{F}_{\text {Iim }}$ is 0.86 , the fishing mortality estimated to lead to potential stock collapse. | $\mathrm{F}_{\mathrm{pa}}$ be set at 0.65. This F is considered to have a $95 \%$ probability of avoiding $\mathbf{F}_{\text {lim }}$, taking into account the uncertainty of assessments. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=$ Rounded $\mathbf{B}_{\text {loss }}=70000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=$ Previous MBAL and signs of impaired recruitment below: 150000 t |
| :---: | :---: |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.86$ | $\mathbf{F}_{\mathrm{pa}}=$ Approx. $5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss; }}$ implies an equilibrium biomass $>\mathbf{B}_{\mathrm{pa}}$ and a less than $10 \%$ probability that (SSBMT $<\mathbf{B}_{\mathrm{pa}}$ ) |

Advice on management: ICES recommends a recovery plan that will ensure a safe and rapid recovery of SSB to a level in excess of 150000 t . If a recovery plan is not implemented ICES recommends that fishing mortality on cod should be reduced to the lowest possible level in 2002. ICES has repeatedly stated that for various reasons, TACs alone are not effective in regulating fishing mortality.

Rebuilding plan: Rebuilding of the cod stock can be obtained by reducing the fishing mortality, by improving the exploitation pattern or by a combination of the two in a way that implies a trade-off between reductions in fishing effort and increases in effective mesh size. The results of simulations that include recent data on discards of cod are available (Anon 2001 ) and these have shown, for example, that a reduction of effort by $30 \%$ or an increase in mesh size
of around 30 mm would yield the same results on the spawning biomass per recruit. (NB. These forecasts use data on both landed and discarded cod. ICES is unable to include discard data in its historical reconstruction of the cod stock size due to the lack of a sufficiently long and representative time-series of cod discard data).

Norway and the EU have agreed on a number of gears and mesh size changes.
reduce exploitation to the level needed to rebuild the cod stock and additional reduction in mortality is needed."

A fishing mortality of zero in 2002 is not expected to rebuild SSB to $\mathbf{B}_{\mathrm{pa}}$ by 2003 , but fishing mortality of less than 0.25 in 2002 and 2003 are expected to rebuild it by 2004 (see text table below). The table also shows the options for rebuilding SSB by 2004, 2005 and 2006.

ICES has not been able to quantify the likely impact of the agreed changes but they will not be sufficient to

| $\begin{aligned} & \mathrm{F}(\mathrm{sq})=\mathrm{F}(98-00) \text { scaled to } \\ & \mathrm{F}(00)=0.83 \end{aligned}$ |  | Options for fishing mortality in 2002-2005 |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $0.3 * \mathbf{F}_{s \mathrm{~s}}=0.25$ | $0.46 * \mathbf{F}_{\text {sq }}=0.38$ | $0.56 * \mathbf{F}_{\text {sa }}=0.46$ |
| SSB in | 2002 | 55.4 | 55.4 | 55.4 |
| ${ }^{\prime} 000 \mathrm{t}$ | 2003 | 100 | 88 | 81 |
|  | 2004 | 150 | 117 | 101 |
|  | 2005 | 208 | 150 | 123 |
|  | 2006 | 276 | 186 | 150 |

Setting the TAC at low level may reduce fishing mortality, but past experience has shown that it is very difficult to control fishing mortality by TACs alone. ICES therefore recommends that in addition to setting the TAC at the lowest possible level, restrictions in effort of fleets exploiting cod should be implemented.

Large closed areas and seasons may contribute to stock recovery, but only if accompanied by major reductions in effort.

At recent exploitation rates, year classes suffer substantial fishing mortality before they mature and spawn. Given the low SSB and the expected poor recruitment, the action needed to rebuild the stock has to be severe in order to have any impact in the short term. Rebuilding of the stock could be accelerated if in the coming years average or above average year classes were generated and appropriate measures were already in place to allow a larger part of these year classes to recruit to the spawning stock.

Relevant factors to be considered in management: The stock is below $\mathbf{B}_{\text {lim. }}$. Strong and efficient measures are needed to ensure a rapid rebuilding of the spawning stock biomass to at least $\mathbf{B}_{\mathrm{pa}}$. Results of medium-term simulations indicate that a reduction in frshing mortality to around 0.25 is needed to ensure a high probability of rebuilding the stock to the agreed $\mathbf{B}_{\mathrm{pa}}$.

Substantial under-reporting of cod landings occurred in 1998. There are no reasons to suspect substantial under-reporting in 1999 or 2000 because the 1999 and 2000 TACs were not restrictive. However, the TAC in 2001 is restrictive and there are indications that underreporting is likely to occur.

The spawning stock in 2001 has remained in a situation where the probability of low recruitment is high and the potential for a recovery has been reduced. The relatively strong 1996 year class has been heavily exploited as juveniles and will not contribute significantly to the spawning stock beyond 2001.

The emergency measures agreed for 2001 and the agreed technical measures for 2002 and beyond should be further developed as soon as possible. The effect of the emergency closure implemented in 2001 has not been evaluated, but the closure is likely to have contributed little to the recovery of the stock. Increases in minimum codend mesh sizes and other gear modifications to be introduced on the 1 January 2002 are unlikely to result in any immediately detectable benefits to the spawning stock, but may result in an improvement in the exploitation pattern and a reduction in the proportion of the catch of 1-year old cod discarded, if implemented effectively.

Continued fishing at current rates is expected to lead to stock collapse (Figure 3.5.2.1). Fishing at $\mathbf{F}_{\mathrm{pa}}$ the stock is expected to remain below $\mathbf{B}_{\mathrm{pa}^{a}}$ after 2002 when the poorest year class (1997) observed so far will mature.

In recent years the growth rate of North Sea cod has declined. The reasons for this are not known, but if growth remains slow, the rate of recovery of SSB will be delayed. Lower growth may also expose juveniles longer to discarding.

The TAC for the portion of the stock in Division VIId incorporates information from the assessment of the stock in Division VIIb-k, and managers should take this advice into account when setting the quota for Division VII.

Comparison with previous assessment and advice： Fishing mortality has consistently been under－estimated and stock size over－estimated in assessments prior to 2000．In addition，weights－at－age in 2000 for age groups 4－6 have been lower than previously assumed．

Compared to previous assessments，the historical consistency of the present assessment appears to have improved．It is thought that this is caused by the exclusion of the commercial CPUE data from the assessment．

Weights in ${ }^{4} 000 \mathrm{t}$ ．
Shaded scenarios considered inconsistent with the precautionary approach．

Landings by Division or Sub－area are obtained by pro－ rating the combind area catch by 0.122 for $\mathrm{IIL}, 0.851$ for IV and 0.027 for VIId．These factors are the ratio of the mean catches by area to the combined area for the period 1992－1996．

Medium－and long－term projections：The current． high fishing mortality（ $\mathrm{F}_{2-8}=0.83$ ）implies a $90 \%$ probability that $\mathbf{B}_{\mathrm{pa}}$ will not be reached by 2010．A reduction in the fishing mortality to $\mathrm{F}_{\mathrm{pa}}(0.65)$ results in a $35 \%$ probability that the SSB will not have reached the $\mathbf{B}_{\mathrm{pa}}$ of 150000 t by 2010 （Figure 3．5．2．2）．

Elaboration and special comment：Using information from the stock－recruit relationship it is possible to construct the expected equilibrium spawning stock biomass for a range of fishing mortality rates（Figure 3．5．2．1）．As $F$ increases the expected equilibrium declines．Also shown on the graph are the observed values of SSB over time（thin line with years indicated）．Where a particular year lies above the solid line，the stock would be expected to decline．Where a point lies below the line，the stock would be expected to increase．Consistent with the analysis ${ }_{t}$ it can be seen that as fishing mortality has increased，the SSB has declined．The diagram shows that the expected equilibrium at the estimated 1999 F is effectively zero， i．e．that the stock will collapse．

It was apparent that commercial CPUE data used in calibrating previous assessments had a strong tendency
to give a much more optimistic estimate of the state of the stock than research vessel survey data．There are a number of reasons for believing that the commercial CPUE data may be biased．For example，there have been substantial changes in the distribution of commercial fleet effort and the nature of vessels in the fleet，which may affect abundance indices derived from these sources．In addition，commercial fleets may target areas of high cod abundance leading to artificially higher abundance estimates．It should be noted that differing signals between commercial CPUE data and survey data affected assessments of some Canadian cod stocks resulting in an over－optimistic decision on the management of these stocks before they collapsed．In view of these problems，the assessment of North Sea cod this year did not use commercial CPUE data from any commercial fleets．

A number of analyses were performed using a variety of different assessment models．All these approaches gave very similar results．While no method is without uncertainty，the fact that a variety of methods give comparable results increases confidence in the current assessment．

Cod are taken by towed gears in mixed roundfish fisheries，which include haddock and whiting．They are also taken in directed fisheries using fixed gears．By－ catches of cod occur in flattish and shrimp fisheries especially in the Southern North Sea and in Nephrops fisheries．

The assessment is based on analysis of catch at age data calibrated with data from three research vessel surveys．

Figure 3.5.2.1 Long-term equilibrium analysis. Top right: SSB as a function of fishing mortality.

Figure 3.5.2.2 Cod in Sub-area IV and Divisions VIID and IIIA (Skagerrak). 10-year medium term projections. Probability of SSB below $B_{p a}(150 \mathrm{kT})$ in any year given fixed mortality rates.

### 3.5.3 Haddock in Sub-area IV (North Sea) and Division IMa (Skagerrak Kattegat)

State of stock/exploitation: The stock is being harvested outside safe biological limits. SSB in 2001 is estimated to be above the $\mathbf{B}_{\text {pa }}$ and fishing mortality in 2000 is estimated to be above the $\mathbf{F}_{\text {pa }}$. The 1999 year class is estimated to be strong and should increase the SSB in the short-term, but it is the only year class above average size for a number of years and dominates both the stock biomass and the catches. The first indications of the 2001 year class suggest that it is poor, and if this is confirmed it means that the expected increase in SSB may be short-lived at the present fishing mortality rates.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the haddock stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $100000 t\left(B_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.70 for appropriate age groups as defined by ICES.
3. Should the $S S B$ fall below a reference point of $140000 t\left(B_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of $S S B$ to a level in excess of $140000 t$.
4. In order to reduce discarding and to enhance the spawning biomass of haddock, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 100000 t , the bootstrapped median estimate of <br> the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 140000 t. This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}, ~ t a k i n g ~ i n t o ~ a c c o u n t ~ t h e ~$ |
| uncertainty of the assessments. |  |

Technical basis:

| $\mathbf{B}_{\mathrm{lim}}=$ Smoothed $\mathbf{B}_{\mathrm{loss}}$ | $\mathbf{B}_{\mathrm{pa}}=1.4^{*} \mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ poorly defined; $1.4 \mathbf{F}_{\mathrm{Fa}}$ which has historically <br> led to decline: 1.0 | $\mathbf{F}_{\mathrm{pa}}=\mathrm{F}_{\mathrm{lpg}}{ }^{1}$ implies an equilibrium biomass $>\mathbf{B}_{\mathrm{pa}}$ and a <br> less than $10 \%$ probability that $\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$. |

${ }^{1} \mathrm{~F}_{\mathrm{lpg}}$ is defined as the F value having a $10 \%$ probability of giving a replacement line above $\mathrm{G}_{10 s s}$, which is the slope in the stock recruitment plot associated with the lowest observed SSB.

Advice on management: Fishing mortality in 2002 should be below $F_{p a}$, corresponding to a human consumption landing of 97000 t . However, due to the mixed nature of the fisheries the fishing mortality for haddock in 2002 may have to be reduced further to achieve consistency with the recovery plan for cod.

Relevant factors to be considered in management: Haddock, while a principal target for some fleets, are
taken in a mixed roundfish fishery. This means it is important to take into account the impact of management of haddock on other stocks, notably cod and whiting. The reverse is, of course, also true. Recent measures to protect North Sea cod, such as the closed area, and agreements to increase mesh size, will affect the haddock fishery. Improvements in selectivity related to measures to protect cod should, if effectively implemented, benefit the haddock fishery by reducing discards and increasing landings in the long-term.

There is frequently debate about the extent to which the cod－haddock－whiting fisheries are linked．This linkage is not one－to－one，but it is also true that they are far from separate．It is possible for fishing vessels to increase their targeting of individual species，but there will always be a significant by－catch of other roundfish． Hence，for example，the need to protect cod will require at least some reduction in the fishing mortality for haddock and vice versa．This means that TACs for the three main roundfish species do need to be set in a way， which acknowledges the fishery linkage，but it remains difficult to judge how close this linkage should be．

The first indication of the strength of the 2001 haddock year class from the August English groundfish survey is that it is extremely poor，possibly the lowest on record． Although this requires confirmation，it implies that as the influence of the very strong 1999 year class diminishes in the haddock stock，the stock could decline very rapidly．

Square mesh panels have been introluced in the UK in 2000 in an attempt to reduce discarding．Further gear measures were introduced in Scotland during 2001．It is still too early to determine whether these have been effective．If implemented effectively，these measures
should help in reducing discarding．
The forecast is extremely sensitive to the estimate of the strength of the 1999 year class，and factors affecting its survival and contribution to the catch and stock．This strong year class has already suffered substantial mortality due to discarding in 2000 ．Indications from observer trips in 2001 indicate continued very high discard rates．

The weight at age of the 1999 year class is below average which means that it has taken longer to reach the minimum landing size and is therefore exposed to discarding for longer．With the present exploitation pattern and fishing mortality rate，the expected catch in weight of discards is likely to be similar to the weight of human consumption landings over the lifetime of the year class．

Comparison with previous assessment and advice： Assessments carried out since 1997 showed a strong tendency to over－estimate SSB and under－estimate fishing mortality．The retrospective analysis of the cument assessment indicates that this problem has been reduced．

Weights in＇ $000 \mathrm{t},{ }^{1}$ North Sea＋IIIa human consumption．${ }^{2}$ Multipliers on $\mathrm{F}_{\mathrm{sq}}$ refer to human consumption and discard partial fishing mortality only．By－catch $F$ is assumed constant at 0.06 ．The landings in Division IIIa are calculated as $3.3 \%$ of the combined area total．The figure $3.3 \%$ is the long－term average of the Division IIIa（human consumption） landings expressed as a percentage of the combined IIIa－IV（human consumption）landings．
Shaded scenarios considered inconsistent with the precautionary approach．

Medium- and long-term projections: At status quo F (0.92), the probability that $S S B$ will be below $\mathbf{B}_{\mathrm{pa}}$ in 10 years time is about 0.35 .

Elaboration and special comment: The large majority of the catch is taken by Scottish trawlers, seiners and pair trawlers. Smaller quantities of haddock are taken by other vessels, including Nephrops trawlers which use 70 mm mesh. In Division IHa, catches are taken by trawl, seine, and gill net in mixed fisheries.

Landings and SSB have varied considerably in response to large variations in year class strength. The 1999 year class is strong, but its current estimate is still not very precise. The observations of the year class by research vessel surveys are outside the range historically observed, and estimates by these surveys are extrapolations. Forecasts suggest that the 1999 year class will contribute to a rapid increase in the spawning stock in 2001-2002, but unless fishing mortality is
reduced in 2002, the probability that SSB will be below $\mathbf{B}_{\mathrm{pa}}$ in 2003 is about 0.3 .

The analytical assessment is based on a long time series of catch-at-age data using CPUE from survey fleets.

### 3.5.4

 Whiting in Sub-area IV (North Sea) and Division VIId (Eastern Channel)State of stock/exploitation: The stock is outside safe biological limits. SSB has declined over the last 20 years, reaching a historic low in 1998. Although the trends in SSB and fishing mortality in the most recent years cannot be determined precisely, the assessment indicates that SSB is now increasing and fishing mortality has
decreased. Recruitment has fluctuated below the average (1980-2000) level since 1990, with the exception of the 1998 year class.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 225000 t, the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 315000 t . This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. Below this value the <br> probability of below-average recruitment increases |
| $\mathrm{F}_{\text {iim }}$ is 0.90, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.65. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathrm{F}_{\text {lim }}$, taking <br> into account the uncertainty of the assessment. |

Technical basis:

| $\mathbf{B}_{\mathrm{lim}}=\mathbf{B}_{\mathrm{loss}}=225000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4 * \mathbf{B}_{\mathrm{lim}}$, apparent impaired recruitment below this <br> value: 315000 t. |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}=\mathbf{F}_{\mathrm{loss}}=0.9$. | $\mathbf{F}_{\mathrm{pa}} \sim 0.7 \mathbf{F}_{\mathrm{lim}}=0.65$. |

Advice on management: To bring SSB above $\mathbf{B}_{\mathrm{pa}}$ in 2003 , fishing mortality in 2002 should be below 0.37 , corresponding to human consumption landings of less than 37000 t . However, due to the mixed nature of the fisheries the fishing mortality for whiting in 2002 may have to be reduced further to achieve consistency with the recovery plan for cod.

Relevant factors to be considered in management: The current assessment is uncertain. However, it is likely that SSB is still well below Bap $_{\text {pa }}$. The SSB is estimated to have increased since 1998, due mainly to lower fishing mortality.

ICES notes that some benefit for whiting may be achieved through implementation of technical conservation measures for cod, because whiting are taken in a mixed fishery with cod. Hence, the rebuilding of whiting SSB could be somewhat greater if the advice on North Sea cod and measures to reduce discarding are implemented effectively.

Because of the observation of a long period of poor recruitment, ICES has expressed concern that the productivity and distribution of this stock may have changed. Although recruitment is still well below average, the year classes 1998 and 1999 appear to be sufficient to rebuild $S S B$ at the current levels of fishing
mortality. Whether the productivity of the stock has changed cannot be determined unless SSB is allowed to rebuild substantiaily.

The recommended reduction in fishing mortality cannot be achieved by TAC management alone, because whiting is caught in mixed demersal fisheries, where discarding of whiting is sometimes high (commonly $60 \%$ by weight). In Nephrops, shrimp, and flattish fisheries nearly all whiting are discarded. A reduction in TAC is likely to result in increased discarding which may counteract the desired reduction in fishing mortality. It is necessary that management plans for all fisheries, which take whiting for human consumption or industrial uses, or as significant amounts of by-catch, include provisions, which ensure lowest possible capture of whiting. For mixed demersal fisheries improvements to gear selectivity, such as increased mesh size or inclusion of square mesh panels, would contribute to this goal.

There is scope for investigating whether the geographical distribution for cod, haddock and whiting, based on surveys, may allow area specific measures to be devised.

Square mesh panels have been introduced in the UK in 2000 in an attempt to reduce discarding. It is still too early to determine whether this has been effective.

## Catch forecast for 2002：

Basis：$F(2001)=F_{s q}=F(98-00$ ，scaled $)=0.46 ; \operatorname{SSB}(2002)=258 ; \mathrm{HC}$ landings $\Gamma \mathrm{V}(2001)=36 ; \mathrm{HC}$ landings VIId（2001） $=5$ ；Discards $(2001)=25$ ；Industrial by－catch $(2001)=12$ ．

Weights in ${ }^{6} 000 \mathrm{t}$ ．The HC landings in Division VId are calculated as $11.5 \%$ of the HC landings forecast for the area combined， $11.5 \%$ being the average of the VIId HC landings relative to the HC landings from the combined area for the years 1992－1996．
Shaded scenarios considered inconsistent with the precautionary approach．

Different assessment methods give different interpretations of the state of this stock．A probabilistic forecast based on continued fishing at status quo implies
a total catch in 2002 of 81000 t at status quo，but with approximate $95 \%$ confidence intervals from 48000 t to 114000 t ．

Comparison with previous assessment and advice： The current assessment employs a different methodology（TSA）compared to last year．This assessment was taken forward to prediction because it characterises the uncertainty in the assessment better than the other approaches．The historic results of the current assessment are，however，generally consistent with last year＇s assessment．

Medium－and long－term projections：No medium－or long－term projections have been carried out．

Elaboration and special comment：At very low stock sizes，as experienced in recent years，catch opportunities in the short－term are very dependent on the strength of incoming year classes．However，the estimates of year class strength for whiting are very imprecise．

Analytical assessment is based on a twenty-one year time-series of catch-at-age data only. There are inconsistencies between information from commercial catch data and survey information. Discard information is available for about $50 \%$ of the catch since 1975, although discard estimates are imprecise due to low sampling effort.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

## Saithe in Sub-area IV (North Sea), Division IIIa (Skagerrak) and Sub-area VI (West of Scotland and Rockall)

State of stock/exploitation: The stock is within safe biological limits. Fishing mortality has declined from 1986 to 2000 , and is estimated below $\mathbf{F}_{\mathrm{pa}}$ in 2000 . SSB has remained near or below $\mathbf{B}_{\mathrm{pa}}$ since 1984, but it has increased in the late 1990s and is estimated to be above B $_{\text {Pa }}$ in 2001.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the saithe stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $106000 \mathrm{t}\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.40 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $200000 t\left(B_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of $S S B$ to a level in excess of 200000 t .
4. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on $F$ and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 106000 t | $\mathbf{B}_{\mathrm{pa}^{\mathrm{a}}}$ be set at 200000 t |
| $\mathrm{F}_{\text {lim }}$ is 0.60 | $\mathbf{F}_{\mathrm{p}^{\mathrm{a}}}$ be set at 0.40 |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=106000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Impaired recruitment at SSB less than 200 000 t. <br> This affords a high probability of maintaining SSB |
| :--- | :--- |
| above $\mathbf{B}_{\text {lim, }}$ taking into account the uncertainty of |  |
| assessments. Below this value the probability of below |  |
| average recruitment increases. |  |,

Advice on management: ICES advises that fishing mortality in 2002 should be below $\mathrm{F}_{\mathrm{p} \text { a }}$ corresponding to landings in 2002 of less than 148000 t.

Relevant factors to be considered in management: The assessment is considered to be uncertain as it is very sensitive to the addition of a single year's data and there are no survey data to confirm the stock trends as calibrated by commercial CPUE. The catch forecast is mainly driven by the assumption of average recruitment, with about one third of the forecast 2002
landings and 2003 SSB originating from this assumption. This means that the forecasts may not track fluctuations in the stock particularly well. Fishing at $F_{p a}$ will at current recruitment levels make SSB fluctuate around $\mathbf{B}_{\mathrm{p}}$, and therefore the stock will in some years be slightly below $\mathbf{B}_{\mathrm{pa}}$ and in other years, such as in 2001, be slightly above. Therefore, the ICES assessment of the state of the stock will move in and out of safe biological limits. Medium-term considerations indicate that continued fishing at $\mathbf{F}_{\mathrm{sq}}$ implies low probability of falling below $\mathbf{B}_{\mathrm{pa}}$.

The following table illustrates the proportional contribution of landings by area over different periods.

|  |  |  |
| :---: | :---: | :---: |
| Pekkik |  | Musky |
| 1982-1998 | 86 | 14 |
| 1988-1998 | 87 | 13 |
| 1993-1998 | 91 | 9 |

Comparison with previous assessment and advice: The perception of the state of the stock is different from last year when the stock was considered to be outside safe biological limits. The general tendency of this assessment to overestimate F and underestimate SSB has persisted, and the current assessment indicates that the stock is within safe biological limits.

Catch forecast for 2002:
Basis: $\mathrm{F}_{\mathrm{sq}}=\mathrm{F}(98-00$ scaled $)=0.29$; Landings $(2001)=110 ; \mathrm{SSB}(2002)=233$.

| $F$ (2001 onwards) | Basis | Total Landings | Landings IIIa \& IV ${ }^{*}$ (2002) | $\begin{gathered} {\text { Landings } \mathrm{VI}^{*}}^{(2002)} \end{gathered}$ | SSB(2003) |

Weights in ${ }^{+} 000 \mathrm{t}$.
Shaded scenarios considered inconsistent with the precautionary approach.
*Landings split according to average in 1993-1998.

Medium- and long-term projections: Results of the medium-term analysis indicate that under the status quo fishing mortality there is a low probability of falling below $B_{p a}$ in the medium-term.

Elaboration and special comment: Saithe in the North Sea are mainly taken in a direct trawl fishery in deep water near the Northern Shelf edge and the Norwegian deeps. Norwegian, French and German trawlers take the majority of the catches. In the first half of the year the fishery is directed towards mature fish, while immature fish dominate in the catches the rest of the year. The main fishery was developed in the beginning of 1970s. In later years, the trawlers have also exploited deep-water fish. The fishery in Sub-area VI consists largely of a directed French, German and Norwegian deep-water fishery operating on the shelf edge, and a Scottish fishery operating inshore.

Analytical assessment is based on catch-at-age analysis using CPUE information from commercial fisheries. Lack of recruitrment indices for recent and incoming year classes makes catch predictions imprecise.

Before 1999, saithe in Sub-area VI and saithe in Subarea IV and Division HIa were assessed as two separate stocks. The ICES advice applies to the combined areas IIIa, IV, and VI.

${ }^{1}$ GM 1989-1998.
${ }^{2}$ Based on 1998-2000 mean weight at age.

State of stock/exploitation: The stock is considered to be outside safe biological limits. SSB in 2001 is below $\mathbf{B}_{\mathrm{pa}}$ and fishing mortality in 2000 was above $\mathbf{F}_{\mathrm{pa}}$. Spawning stock biomass has declined from 1989 to 1997, where it reached its historical minimum. Fishing mortality increased from the 1960 s to the 1990 s, reaching a record high in 1997. Except for the 1996 year class, recruitment since 1993 has been below average. Surveys indicate that the 2001 year class measured as 0group is strong.

Management objectives: In 1999, the EU and Norway have "agreed to implement a long-term management plan for the plaice stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $210000 t\left(B_{i m}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality of 0.3 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $300000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 300000 t .
4. In order to reduce discarding and to enhance the spawning biomass of plaice, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.

The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on $F$ and lower bounds on SSB, and not as targets.

Precautionary approach reference points (unchanged since 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 210000 t , the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 300000 t. This is the previously agreed <br> MBAL and affords a bigh probability of maintaining SSB <br> above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of <br> assessments. |
| $\mathrm{F}_{\text {lim }}$ is 0.6. | $\mathbf{F}_{\text {pa }}$ be set at 0.30. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathrm{F}_{\text {lim }}$, taking <br> into account the uncertainty of the assessment. |

## Technical basis:

| $\mathbf{B}_{\text {limim }}=\mathbf{B}_{\text {loss }}=210000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Approximately $1.4 \mathrm{~B}_{\mathrm{lim}}$, previous MBAL. |
| :---: | :---: |
| $\mathrm{F}_{\mathrm{lim}}=\mathbf{F}_{\text {loss }}=0.6$. | $\mathbf{F}_{\mathrm{pa}}=5^{\text {tii }} \%$ of $\mathbf{F}_{\text {loss }}(0.6)$ is 0.36 , which implies that $\mathbf{B}_{\text {eq }}<$ $\mathbf{B}_{\text {pa }}$. Therefore a lower value is required. $\mathbf{F}=0.3$ implies $\mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}$ and a less than $10 \%$ probability that $\mathbf{S S B}_{\mathrm{MT}}<$ B $_{\mathrm{pa}}$. |

NB: As F increases above 0.3, $\mathrm{P}\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$ increases rapidly.

Advice on management: ICES recommends that the fishing mortality be less than $F_{p a}=0.3$, corresponding to landings of less than 77000 t in 2002.

Relevant factors to be considered in management: In this stock, SSB is persistently over-estimated and F under-estimated, possibly as a result of not including discards in the assessment. The bias of the assessment suggests that the TAC for 2002 should be set lower than the 77000 t .

The impact of the cod emergency measures in 2001 and of the agreed technical measures that will be implemented from 2002 onwards have not been evaluated. It has been observed that the closed area in 2001 has induced a change in the spatial distribution of the fleets. The implementation of a square mesh panel for beam trawl gears, which will be mandatory from 2002 onwards, is not expected to affect the exploitation of plaice.

Comparison with previous assessments：The assessment has changed because of a revision of the age compositions in the landings and because commercial CPUE series have been excluded．The new assessment gives a higher estimate of spawning biomass in recent
years and also a higher estimate of fishing mortality compared to the previous assessment，but it has not resolved the retrospective bias，which is thought to originate from the catch data．

Catch forecast for 2002：

|  |  |  |  |
|  |  |  |  |

Weights in＇ 000 t ．
Shaded scenarios considered inconsistent with the precautionary approach．

Medium－and long－term projections：Medium－term analysis indicates that fishing at $\mathbf{F}_{\mathrm{pa}}(=0.3)$ would give a very low probability that $S S B$ is below $\mathbf{B}_{\mathrm{pa}^{4}}$ in year 2005.

A fishing mortality rate of 0.25 would give a low probability of SSB still being below $\boldsymbol{B}_{\mathrm{pa}}$ in 2003.

Elaboration and special comment：Due to the minimum mesh size（ 80 mm ）in the mixed beam trawl fishery，south of $55^{\circ} \mathrm{N}$ ，or $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$ ，large numbers of（undersized）plaice are discarded．Estimates of discards are not included in the assessment since time series of discards are not available．Because discards are not included in the assessment the fishing mortality on juveniles is underestimated．Ongoing sampling programmes indicate that discarding in recent years has
increased from about $50 \%$ in numbers historically to 70 － $80 \%$ in 2000 and 2001．The high estimates of discards in recent years may be caused by a reduction in growth， which extends the time the fish is undersized and subject to discarding．There is a need for continuous monitoring of discards and special attention should be given to reconstructing recent discard trends so as to improve the assessment of this stock．

Commercial CPUE series have been excluded from the assessment this year. There was accumulating evidence that the CPUE series may be biased by restrictive TACs and may thus not reflect the trends in the stock.

The strong 1996 year class has started to recruit to the fishery in the summer of 1999 . The 1996 year class has increased the SSB less than expected. First indications of the 2001 year class are that it is also strong. If this year class follows a similar pattern of growth and maturation as the 1996 year class, it implies that it too may show delayed recruitment to the fishery and high discard rates over an extended period.

The stock-recruitment plot suggests that in recent years recruitment has declined at lower SSB. However, recruitment surveys at age zero do not indicate such a reduction, and it is possible that the lower estimated recruitment in the assessment may be explained by an increase in discarding.

Around 9\% of the total cod landings in 1999 in the North Sea were taken by beam trawlers fishing for plaice and sole (Anon 2001).

North Sea plaice is taken mainly in a mixed flatfish fishery by beam trawlers in the southern and southeastern North Sea. Directed fisheries are also carried out with seine and gillnet, and by beam trawlers in the central North Sea.

Since 1989, an area with high concentrations of small plaice ("Plaice Box") was closed to beam trawl fisheries
with vessels $>300 \mathrm{hp}$ during the second and third quarter and, since 1994, during the fourth quarter as well. Since 1995, the plaice box has been closed for the whole year. Beam trawlers $<300 \mathrm{hp}$ are allowed to fish inside the box. Effort reductions have mainly been effective since 1994 when the fourth quarter was closed and when effort levels in the box decreased to around $10 \%$ of the pre-box level.

Analytical assessment uses catch-at-age and CPUE data from surveys only. Forecasts use indices from research vessel surveys, including one from 2001 surveys. No discards are used in the assessment.

### 3.5.7 Sole in Sub-area IV (North Sea)

State of stock/exploitation: The stock is being harvested outside safe biological limits. SSB in 2001 is above the proposed $\mathbf{B}_{\mathrm{pa}}$ but fishing mortality in 2000 remains above $\mathbf{F}_{\text {pa }}$. The spawning stock reached an historic low in 1998 below $\mathbf{B}_{\text {lim }}$. It increased sharply following recruitment of the strong 1996 year class, but has since declined as this
year class has passed through the fishery. Subsequent year classes have been about average.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{lim}}$ is 25000 t, the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 35000 t. This affords a high probability of <br> matntaining SSB above $\mathbf{B}_{\text {lim, }}$ taking into account the <br> uncertainty of assessments. |
| $\mathrm{F}_{\mathrm{lim}}$ is undefined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. This F is considered to provide a greater <br> than $95 \%$ probability of avoiding $\mathbf{B}_{\text {lim, taking }}$ <br> account the uncertainty of the assessment. |

Technical basis:

| $\mathbf{B}_{\text {limi }}=\mathbf{B}_{\text {loss }}=25000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4 * \mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}} 5^{\mathrm{th}}$ percentile $(0.49)$ of $\mathbf{F}_{\text {loss }}$ implies $\mathrm{B}_{\mathrm{eq}}<\sim \mathbf{B}_{\mathrm{pa}}, \mathrm{F}=$ |
|  | 0.4 implies $\mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}$ and $\mathrm{P}\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<10 \%$. |

Advice on management: ICES recommends that fishing mortality on North Sea sole be reduced to below 0.37 corresponding to catches of less than $14300 t$ in 2002 in order to maintain SSB at $B_{p a}$ in the medium-term.

Relevant factors to be considered in management: The toend in SSB of this stock is heavily dependent on the occasionally occurring strong year classes. The SSB and landings in recent years has been dominated by the abundant 1996 year class which is no longer dominating in the stock and following year classes are of average strength. Consequently, the stock is decreasing and is expected to decrease further in 2003 below $\mathbf{B}_{\mathrm{pa}}$, even if fishing mortality is reduced to $F_{p a}$. A reduction in fishing mortality to well below $F_{p a}$ is required to maintain SSB above $\mathbf{B}_{\mathrm{pa}}$ in 2003. TACs in recent years have been agreed above the recommended $\mathbf{F}_{\mathrm{pa}}$.

Two surveys indicate that the 2001 year class may be strong, but this year class will not affect SSB before 2004 and will not affect the short-term prediction. The size of this year class will be more precisely estimated by directed 0 -group surveys. These results will become available in November 2001. The strength of the 2001 year class will affect medium-term prospects significantly.

Sole is mainly caught in a mixed beam trawl fishery with plaice using 80 mm mesh in the southern Norch Sea. This means it is important to take into account the impact of management measures for plaice when considering sole. There is not a simple one-to-one link between the catch of sole and plaice when considering effort reduction. The proposed reduction in fishing
mortality for plaice is $30 \%$, while the advice given above indicates a reduction of around $20 \%$. These reductions are not considered to conflict.

Management measures, which produced a reduction in the mortality on juvenile sole would benefit the stock. The continued use of 80 mm mesh together with the minimum landing size of 24 cm results in a high proportion of sole being landed which are immature. The maintenance of the plaice box is a measure, which probably benefits sole by protecting juveniles in the main continental nursery areas.

The closed area in spring 2001 under the North Sea cod emergency regulations resulted in a redistribution of fishing activity for flatfish. The flatfish fishery was probably more impacted by this measure than the roundfish fishery. The consequences of these measures are not assessed or accounted for in the projections. Around $6 \%$ of the total cod landings in 1999 in the North Sea were taken by beam trawlers fishing for sole.

In relation to this, technical measures introduced in January 2000 may affect the exploitation of the sole and plaice. The area where fishing with 80 mm is allowed has extended from $55^{\circ} \mathrm{N}$ to $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$. ICES is not able to assess the impact of this measure, but it is considered unlikely to have an impact on sole.

Comparison with previous assessment and advice: The assessment of North Sea sole appears to be relatively stable from year to year and comparison of the historical trends in $F$ and $S S B$ between this year and last show a close similarity.

Catch forecast for 2002:
Basis: $F(2001)=F_{s q}=F(1998-2000$, scaled $)=0.46$; Landings $(2001)=19.8 ; S S B(2002)=35.5$.

| F (2002) | Basis | $\begin{gathered} \text { Landings } \\ (2002) \end{gathered}$ | SSB 2003) |

| (1) if |  |  | $4$ |
|  |  |  |  |

Weights in " 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium and long-term projections: At $\mathrm{F}_{\text {sq }}(0.46)$, there is around $50 \%$ probability of the SSB falling below $B_{p a}$ in the medium-term ( 10 years). A reduction of fishing
mortality to $F_{p a}$ will reduce the probability of falling below $B_{p a}$ to around $25 \%$.

Elaboration and special comment: Sole is mainly taken by beam trawl fleets in a mixed fishery for sole and plaice in the southern part of the North Sea. The minimum mesh size permitted when fishing for sole is 80 mm . Beam trawl fleets started to develop in the mid1960s, and have expanded up to the 1990s. A relatively small part of the catch is taken in a directed fishery by gill-netters in coastal areas, mostly in the 2nd quarter of the year. Since 1989, the distribution pattern of the beam trawl ffeets $>300 \mathrm{HP}$ has changed due to the introduction of the 'Plaice Box' in the south-eastern part of the North Sea.

| 2001 | $67000^{1}$ | $39600^{2}$ |  | 0.4600 |
| Average | 133178 | 61605 | 22661 | 0.4032 |

State of stock/exploitation: The stock is outside safe biological limits. $\mathrm{S} S \mathrm{~B}$ in 2000 was 772000 t , which is below the $\mathbf{B}_{\mathrm{lira}}$ of 800000 t . SSB decreased slightly after the gradual increase since 1993. In 1996 the fishing mortality for the adult part of the stock was reduced to 0.45. It has fluctuated at that level in the subsequent years, being 0.42 in 2000 . For juveniles the fishing mortality remained below 0.1 since 1996 . The 1996 year class appears to be smaller than previously assumed, but is still above average. The 1997 year class is below average. The 1998 year class appears to be strong in all surveys and is already showing up in the catches. Early indications of the 1999 year class show that it may also be well above average.

Management objectives: According to the EU-Norway agreement (December 1997):

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the Minimum Biological Acceptable level (MBAL) of 800.000 tonnes.
2. A medium-term management strategy, by which annual quotas shall be set for the directed fishery and for by-catches in other fisheries as defined by ICES, reflecting a fishing mortality rate of 0.25 for 2 -ringers and older and 0.12 for 0 -1-ringers, shall be implemented.
3. Should the SSB fall below a reference point of 1.3 million tonnes, the fishing mortality rates referred to under paragraph 2, will be adapted in the light of scientific estimates of precise conditions then
prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.
The recovery plan referred to above may, inter alia, include additional limitations on effort in the form of special licensing of vessels, restrictions on fishing days, closing of areas and/or seasons, special reporting requirements or appropriate control measures.
4. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
5. The allocation of the TAC for the directed fishery for herring shall be $29 \%$ to Norway and $71 \%$ to the Community. The by-catch quota for herring shall be allocated to the Community.
6. The Parties shall, if appropriate, consult and adjust management measures and strategies on the basis of any new advice provided by ICES including that from the assessment of the abundance of the most recent year class.
7. A review of this agreement shall take place no later than 3I December 2001.
8. This agreement shall enter into force on I January 1998.

ICES considers the agreement to be consistent with the precautionary approach.

| ICES considers that: | ICES proposed that: |
| :--- | :--- |
| $\mathbf{B}_{\text {limt }}$ is 800000 t | $\mathbf{B}_{\mathrm{p}^{\mathrm{a}}}$ be set at 1.3 mill t |
| $\mathrm{F}_{\text {lim }}$ is not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathrm{F}_{\text {ages } 0-1}=0.12 ;$ at $\mathrm{F}_{\text {ages 2-6 }}=0.25$ |

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ below this value poor recruitment has been <br> experienced | $\mathbf{B}_{\mathrm{pa}}$ : part of a harvest control rule based on simulations |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ : Not defined | $\mathbf{F}_{\mathrm{pa}}$ : part of a harvest control rule based on simulations |

Advice on management: ICES advises that catches in 2002 should be within the constraints on fishing mortality agreed by EC and Norway, i.e. $F_{2-6}<0.2$ and $F_{0.1}<0.1$. Several such options are presented in the Management Option table. Fishing mortality inrecent years is well in excess of the specified targets and ICES advises that additional measures to
control the catches and ensure accurate reporting will be required to restrict catches.

Rebuilding plan: Management has in recent years intended to reduce the $\mathbf{F}_{26}$ to 0.2 and an $\mathbf{F}_{0-1}$ to $<0.1$. These targets serve as a rebuilding plan.

Relevant factors to be considered in management: Overly optimistic assessments have contributed significantly to TACs that in retrospect have delayed stock rebuilding. There is no assurance that the revised assessment presented this year does not suffer also from being overly optimistic. Catches on adult herring have in recent years consistently exceeded the agreed TAC, partly due to misreporting from other ICES areas into and out of the North Sea; this gives rise to overshooting of the TAC.

Short-term forecasts indicate that a low fishing mortality (0.2) is necessary for the objective of attaining a high probability of SSB being above $\mathbf{B}_{\text {lim }}$.

The 1998 year class is strong and will comprise almost all the increase in SSB expected in 2002. In the past large year classes have tended to have a lower maturation rate than the long-term average. Different plausible assumptions about the maturation rate of the 1998 year class can produce forecasts of SSB in 2002 from slightly above $\mathbf{B}_{\text {lim }}$ to above $\mathbf{B}_{\mathrm{p}}$ at the advised fishing mortalities.

Continued fishing at status quo fishing mortality (Scenario I below) leads to a smaller increase in SSB in 2002 compared to other scenarios where adult mortality is reduced.

The ICES advice is based on the projected SSB in 2001 being below 1.3 million t . SSB in 2002 depends on the fisheries in 2001 and that part in 2002 that takes place
before spawning. About $2 / 3$ of the total mortality is expected to be realised before spawning each year.

The increase in SSB expected in 2002 depends strongly on the incoming 1998 year class. Observations from different surveys indicate that this year class is strong. However, historically the assessments have tended to overestimate the current stock abundance. The rebuilding regime should therefore be maintained until the SSB is clearly above 1.3 million $t$.

Comparison with previous assessment and advice: Assessments show a tendency to overestimate stock size and underestimate fishing mortality. Similarly, advice has the tendency to be too optimistic concerning stock status.

Catch Forecast for 2002: Catch options are given for 2002, for limits on the fishing mortality rate which reflect both the ICES recommendation and the EUNorway agreement. Catch forecasts for 2002 assume $\mathbf{F}$ status quo (=F2000).

There are many possible permutations of catches by the four fleets that could result in the desired values of $F_{0}$. ${ }_{1}$ and $\mathbf{F}_{2-6}$. Hence, there is some liberty within the framework set by the fishing mortalities for managers to decide the ratio of the total catch to be allocated to each of the fleets. This method is the same as that used last year, but other combinations are possible and can be evaluated using the spreadsheet prediction program.

Shaded scenarios considered inconsistent with the precautionary approach.
Fleet definitions:
A: Directed herring fisheries with purse seiners and trawlers in the North Sea;
B: All other vessels, which take herring as by-catch in the North Sea;

C: $\quad$ Directed fisheries with purse seiners and trawlers in Division IIIa;
D: Vessels fishing in Division IIa for herring and sprat and other vessels participating in fisheries where herring is taken as by-catch in Division IIIa.
The following bullet points apply for all options (I-V) presented above:

- Catches of 3-ringers and older autumn-spawners in Division IIIa are assumed to be of North Sea origin and are included in projections;
- $F_{A, 2-6}$ is the $F$ for fleet $A$, averaged over 2-6-ringers;
- $F_{B-D, 0-1}$ is the average $F$ for 0-1-ringers, fleets $B, C, D$.
- The 1997 agreement between EU and Norway operates with a single TAC for small mesh fisheries in Division IIIa. Prior to 1999 this was termed Fleets D \& E, but is now termed Fleet D.

Medium- and long-term projections: The projections are heavily dependent on the stock-recruitment relationship. The currently estimated parameters for the Beverton and Holt stock-recruitment tend to give very optimistic trends in SSB. However, when geometric mean recruitment is used the projections indicate that the stock is expected to remain approximately stable around $\mathbf{B}_{\text {lim }}$ at current fishing mortality.

Elaboration and special comment: The harvest control law, which forms the basis for advice, separates the mortality for adults and juveniles. Fleet A catches adults, fleets $B$ and $D$ catch juveniles, and fleet $C$ catches both. Therefore, the harvest control law does not determine the catches uniquely, but offers some flexibility to the share of the catch between the fleets.

To obtain catch forecasts, projections by fleet are performed separately by area for juveniles. Such projections are complicated by year-to-year changes in the proportions of North Sea 0- and 1-ringers that occur in Division IIIa. These fluctuations depend on the relative year class strength of North Sea and Western Baltic spring-spawning herring.

The stock is exploited by two groups of fleets: one harvesting mainly the adult part of the stock in a human consumption fishery (fleets $A$ and $C$ ) and the other exploiting the juvenile part of the stock as bycatch in the small mesh industrial fishery (fleets B and D). The by-catch of herring in the small mesh fishery has been low since 1998.

Stock depletion in the 1970s resulted in a four-year closure of the directed fishery. The stock recovered during the 1980s. Following the re-opening of the fishery, the fishing mortality rate steadily increased. By the 1990 s this rate was no longer sustainable and the SSB fell below the MBAL of 800000 t . Emergency regulations were introduced to reduce TACs which reduced the fishing mortality rate substantially.

The total catch of North Sea autumn-spawners, taken in all areas in 2000, comprises around $50 \%$ immature fish (in numbers), which is more than in recent years, but
significantly lower than the $80 \%$ in 1995 and earlier years.

The directed fisheries (fleet $A$ in the North Sea and fleet $C$ in the Skagerrak/Kattegat area) have been managed by TACs since the re-opening of the North Sea herring fisheries in 1981. Fleet D, landing herring as by-catch, has also previously been managed by TAC. It has been managed by a by-catch ceiling since 1996. The catch of fleet $A$ has been higher than the agreed TAC and in 2000 was about 1.2 times the agreed TAC of 265000 t .

This stock complex also includes Downs herring (herring in Divisions IVc and VIId) which has shown independent trends in exploitation rate and recruitment, but cannot be assessed separately. Abundance indices from larvae and trawl surveys indicate that since 1995 the SSB has increased. The Downs fishery is concentrated on the spawning aggregations in a restricted area, which makes this stock component particularly vulnerable to excessive fishing pressure. EU splits its share of the total TAC (Sub-area IV and Division VIId) into TACs for Divisions IVa +IVb and for Divisions $\mathrm{IV} \mathrm{C}+\mathrm{VIId}$. In response to ICES advice in May 1996 the IVc+VIId TAC was reduced by $50 \%$ in line with reductions for the whole North Sea. The TAC for Downs berring was reduced from 50000 t to 25000 t and has remained there since. TACs for this component have been significantly exceeded in all years. At current stock sizes there is no biological basis for not adjusting the TAC for Downs herring in harmony with overall adjustments of the total stock TAC.

Catches for recent years from Divisions IVc and VIId are found in Table 3.5.8.5.

Age-based assessment is based on landings and surveys. Incomplete discard data are available.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

### 3.5.9 Sprat in the North Sea (Sub-area IV)

State of stock/exploitation: The state of the stock is uncertain. Sprat in this area is short-lived with large annual natural fluctuations in stock biomass. The IBTS surveys (February) are a good indicator of the availability of the stock to the fishery for the year of the survey. The total IBTS (February) 2001-index decreased from last year but is still among the highest in the series.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: For this stock only in-year advice is available. Based on the historic relationship between survey and catch, the 2001 survey value indicates that a catch of 225000 t in 2001 would allow the SSB to remain stable or increase.

Relevant factors to be considered in management: The TAC has in recent years been set (for the EU zone) on the basis of considerations for herring and on the state of the sprat stock. Relevant biological information on the abundance of sprat becomes available early in the TAC year from the IBTS.

As the sprat fishery has a by-catch of juvenile herring, the exploitation of sprat will in some periods be limited by the restrictions imposed on fisheries catching juvenile herring, particularly if sprat abundance is low. In years of high abundance sprat can normally be caught with small herring by-catch.

Information from the fishery has shown that in recent years about $90 \%$ of the catch has been sprat and the percentage of herring by-catch about $6 \%$.

It is important that existing by-catch restrictions are maintained.

Comparison with previous assessment and advice:
State of stock similar.
Catch forecast: No reliable catch forecast is available for 2002.

Elaboration and special comment: The catches of sprat are mostly composed of young fish, particularly those of age one. This means that catch prognoses under the present assessment and TAC-setting regime, which requires a two-year forecast, are not realistic. However, abundance indices from surveys in February each year are reasonable predictors of the catch in the same year (Figure 3.5.9.1). It would be possible to provide information early in the year on which a TAC for the remainder of the year could be based. For example a provisional TAC could be set for the period January-March which is then updated at the beginning of April, based on contemporary survey data. Alternatively, the TAC year could run April-March, with an annual TAC being set in April of the year in question using the survey data. This might require some change in the process of setting TACs for sprat but would overcome the problem of the absence of appropriate data at the time ICES advice is given and would provide TACs, which more adequately reflected the true size of the sprat stock.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

## IBTS Index and Catch

Figure 3.5.9.1 Prediction of sprat catch from survey results.

Evaluation of the North Sea mackerel component is given in Section 3.12 .3 dealing with the combined mackerel assessment.

### 3.5.11 North Sea horse mackerel (Trachurus trachurus) (Division III (eastern part), Divisions IVb,c, VIId)

State of stock/exploitation: The state of the stock is not known. There is no recent quantitative information on stock size. Egg surveys from 1989 to 1991 indicated a spawning stock biomass of about 240000 t . The age composition of the relatively small catches until 1997 and the past biomass estimates suggest that the exploitation rate may have been low in the early 1990s. However, the catch increased from a long-term level of 18000 t to the historic high in 2000 of 48425 t , and the present level of exploitation is therefore uncertain, but may be increasing.

Management objectives: No explicit management objectives have been established for this stock.

Reference points: There is not sufficient information to estimate appropriate reference points.

Advice on management: ICES recommends that catches in 2002 be no more than the 1982-1997 average of 18000 t in order to avoid an expansion of the fishery until there is more information about the structure of horse mackerel stocks, and sufficient information to facilitate an adequate assessment.

Relevant factors to be considered in management: These fish migrate out of the North Sea to areas where they mix with the Western horse mackerel. The present agreed TAC is for the North Sea and Division IIa and this area does not correspond to the distribution area of the stock. The TAC should apply to all those areas where the North Sea horse mackerel are fished, i.e. Divisions IIIa, IVb,c and VIId.

Over the later years there has been a change in exploitation pattern of this stock. In 1998 about $55 \%$, in $199940 \%$ and in $200041 \%$ of the catch in numbers
were fish 1-4 years old, which represents a large increase since 1996 and 1997 (about $28 \%$ ). Since it is not known how abundant recent year classes are, concern is expressed about this high exploitation of juvenile fish.

Comparison with previous assessment and advice: Advice in 1999 was to constrain expansion of the fishery until there was a scientific basis for advice. This was expressed due to concerns about unrestricted expansion on pelagic stocks in which high catch rates can be maintained even when the stock is in decline. The way in which the 1999 advice was framed failed to prevent catches of this stock increasing by $1 / 3$, from 37 kt in 1999 to 48 kt in 2000 . Consequently, ICES has revised its advice for this stock to reflect more closely its concern over the potential impact of the recent expansion of the fishery.

Elaboration and special comment: In earlier years the majority of the catch was taken as by-catch in the smallmesh industrial fishery. Only a small proportion of the catch was sampled. In recent years the fishery for human consumption has increased, and these catches are better sampled. A first attempt at exploratory assessments was made this year. In order to assess the state of the stock, adequate sampling for determination of catches-at-age, as well as new egg surveys are needed. The allocation of catches to the different horse mackerel stocks is based on the temporal and spatial distribution of the fishery. It is therefore important that the fishing nations report their catches by ICES rectangle and by quarter.

Source of information: Report of the Working Group on the Assessment of Mackerel, Horse Mackerel, Sardine and Anchovy, September 2001 (ICES CM 2002/ACFM:06).

### 3.5.12 and Kattegat

State of stock/exploitation: The stock is within safe biological limits. Spawning stock biomass is currently above $\mathbf{B}_{\mathrm{pa}}$, but is expected to decrease significantly during 2001 and 2002. Recruitment is highly variable and influences stock biomass rapidly due to the short life span of the species. Recruitment in 2001 is unknown at the time of the assessment. Fishing mortality has generally been lower than natural mortality and has decreased in recent years below the long-term average. The yield doubled in 2000
compared to 1999 due to exploitation of the strong 1999 year class in 2000 and in the $1^{\text {st }}$ quarter of 2001.

Management objectives: There are no management objectives set for this stock. With present fishing mortality levels the status of the stock is more determined by natural processes and less by the fishery. However, there is a need to ensure that the stock remains high enough to provide food for a variety of predator species.

Precautionary Approach reference points (unchanged since 1997):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {iim }}$ is 90000 t , the lowest observed biomass | $\mathbf{B}_{\text {pa }}$ be established at 150000 t. This affords a high <br> probability of maintaining SSB above $\boldsymbol{B}_{\text {tin }}$ taking into <br> account the uncertainty of assessments. Below this <br> value the probability of below average recruitment <br> increases. |

Note: With present fishing mortality levels the status of the stock is more determined by natural processes and less by the fishery. It may be more appropriate to formulate reference points based on total mortality, recruitment and stock biomass for use within management procedures using surveys (and real time monitoring of catches),

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=90000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Below-average recruitment below: 150000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {liim }}$ None advised. | $\mathbf{F}_{\mathrm{pa}}$ None advised. |

## Advice on management: None.

Relevant factors to be considered in management: The stock can on average sustain current fishing mortality. The fishery targets both Norway pout and blue whiting. In managing this fishery, by-catches of haddock, whiting, and blue whiting should be taken into account and existing measures to protect the bycatch species should be maintained. Management should be implemented to regulate the catch of blue whiting in the directed Norway pout fishery, in accordance with the ICES advice for blue whiting. This fishery is mainly by Danish and Norwegian vessels using small mesh trawls in the northern North Sea.

The estimated fishing mortality for Norway pout is lower than the estimated natural mortality. This stock is important as a food source for other species, which means that the population dynamics for Norway pout in the North Sea and in the Skagerrak are very dependent on changes caused by recruitment variation and predation mortality (or other natural mortality causes) and less by the fishery.

The assessment indicates a high SSB in 2000. However, recruitment of the weak 2000 year class is expected to result in a decline in SSB in 2001. The size
of the 2001 year class cannot be estimated with the precision required for a reliable catch prediction.

Comparison with previous assessment and advice: The assessment and advice are consistent with those from previous years.

Catch forecast for 2002: No forecast is possible for this stock, because catches in 2002 will consist primarily of recruiting year classes whose abundance cannot currently be estimated.

Medium- and long-term projections: No mediumterm projections are given for this stock.

Elaboration and special comment: The assessment is analytical using catch-at-age analysis based on quarterly catch and CPUE data. The assessment is considered appropriate to indicate trends in the stock and immediate changes in the stock because of the seasonal assessment taking into account the seasonality in fishery.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

3.12.3.a Mackerel (combined Southern, Western and North Sea spawning components) ..... 590
3.12.4 Western horse mackerel (Trachurus trachurus) (Divisions IIa, IVa, Vb, VIa, VIIa-c, e-k, VIIIa,b,d,e) ..... 608
3.12.5 Blue whiting combined stock (Sub-areas I-IX, XII and XIV ..... 618

## ACFM REPORT 2001 PART 2 OF 3

### 3.5.13.a Sandeel in Sub-area IV

Catches for the total North Sea are given by country in Table 3.5.13.1 and by the Sub-areas shown in Figure 3.5.13.1 and Table 3.5.13.2.

State of stock/exploitation: The stock is within safe biological limits. SSB in 2001 is estimated to be above the proposed $\mathbf{B}_{\mathrm{pa}} . \operatorname{SSB}$ has declined since the historical high SSB in 1998.

Management objectives: There are no management objectives set for this stock. There is a need to develop management objectives that ensure that the stock remains high enough to provide food for a variety of predator species.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{lim}}$ is 430000 t | $\mathbf{B}_{\mathrm{pa}}$ is 600000 t |

Technical basis:

| $\mathbf{B}_{\text {lim }}$ is $430000 t$, the lowest observed biomass | $\mathbf{B}_{\mathrm{pa}}$ is set to $1.4^{*} \mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lial }}$ None advised | $\mathbf{F}_{\mathrm{pa}}$ None proposed |

## Advice on Management: None.

Relevant factors to be considered in management: The stock can sustain current fishing mortality. Sandeels are important prey for many marine predators. Fishing mortality should not be allowed to increase because the consequences of removing a larger fraction of the food-biomass for other biota are unknown. Management of fisheries should try to prevent local depletion of sandeel aggregations, particularly in areas where predators congregate.

Comparison with previous assessment and advice: The assessment and advice is consistent with those from previous years.

Catch forecast for 2002: No forecast is possible for this stock, because catches in 2002 will consist primarily of recruiting year classes whose abundance cannot currently be estimated.

Elaboration and special comment: Sandeel is taken by trawlers using small mesh gear. The fishery is seasonal, taking place mostly in the spring and summer. Most of the catch consists of Ammodytes marinus and there is little by-catch of TAC species. Sandeels are largely stationary after settlement and the North Sea sandeel must be considered as a complex of local populations. Rectuitment to local areas may not only be related to the local stock, as interchange between areas seems to take place during the carly phases of life before settlement. The Shetland sandeel stock is assessed as a separate unit.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

Figure 3.5.13.1 North Sea sandeel. Sampling areas and assessments area used by ICES.

### 3.5.13.b $\quad$ Sandeel in the Shetland area

State of stock/exploitation: Safe biological limits have not been defined for this stock. An assessment based on survey data alone suggests that the SSB in 2000 is close to its lowest observed value and that recent recruitment has been weak. It is believed that fishing mortality is well below natural mortality. This means that natural processes largely drive stock variations. Landings in 2000 were 4871 t , slightly higher than in 1999 , but below the TAC of 7000 t .

Management objectives: The Shetland sandeel fishery re-opened in 1995 subject to a multi-annual management regime. This was revised for the 1998 fishing season onwards. The new regime consists of an annual TAC of 7000 t and a closure during the months of June and July. The seasonal closure is to avoid any possibility of direct competition between the fishery and seabirds during the chick-rearing season. There is also a limit on vessel size to boats of 20 m or less. These arrangements were renewed in 2001 for another three years.

## Advice on management: None.

Relevant factors to be considered in management: Due to the low SSB and recent poor recruitment, ICES considers that it is appropriate to review the carrent management agreement before 2004.

Fishing grounds are close inshore and often adjacent to large colonies of seabirds for which the sandeel population is an important food supply, especially during the breeding season. For some seabird species the availability of 0 -group sandeel as prey is very important.

In some years most of the recruitment comes from spawning areas away from Shetland. The availability of 0 -group sandeel is, therefore, not closely linked to the local spawning population. The sandeel population is also an important food source for other predator species in the Shetland area.

Elaboration and special comment: The previous assessment was undertaken in 1997 and was based on survey and commercial age composition data. Because fishing mortality appears to be very low compared with natural mortality, the current assessment uses a model, which only attempts to estimate total mortality. The model calculates age-dependent total mortality from survey data alone. This assessment is consistent with the 1997 assessment, but is subject to high uncertainty. It indicates that SSB has declined recently and that recent recruitment has been poor. If these indications are correct then the SSB is likely to decline further in the short-term.

The sandeel population at Shetland is not a separate stock, but forms part of a larger complex of subpopulations. Estimates of the consumption of sandeel by seabirds and other predators greatly exceed the quantities taken by the fishery in recent years.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

Catches in the total North Sea are given in Table 3.5.13.1. For the Shetland Area see Table 3.5.13.2.

Weights in '000 t.

Sandeel in the Shetland Area

### 3.5.14.a Pandalus borealis in Division IVa (Fladen Ground)

State of stock/exploitation: The current state of the stock is unknown. During the last 10 years total landings fluctuated between a low of around 500 t to a high of about 6000 t . Total effort has been at a relatively low level in 1999 and 2000.

Relevant factors to be considered in management: The fishery is highly dependent on year class strength. Only age groups 2 and 3 at the beginning of the year and age groups 1 and 2 at the end of the year are caught. There is no basis for defining biological reference points for this stock.

Elaboration and special comment: No assessment was conducted in 2001.

A main characteristic of the Fladen stock of Pandalus is that the catches consist of mainly 2 age groups.

During the first two quarters of the year age groups 2 and 3 normally dominate the catches. During quarter 4 age group 3 usually disappears from the catches, while age group 1 adds to the catches. Because of the few age groups constituting this stock predictions for the Fladen fishery are possible only if very reliable information on recruitment is available.

The Fladen stock is mainly exploited by Danish and UK trawlers normally using 35 mm cod-end mesh size. It is a targeted fishery on Pandalus with low by-catches of other species. In recent years the by-catch in the Danish fishery of other species was estimated to be $11 \%$ of the total landings.

Source of information: Report of the Pandalus Assessment Working Group, Charlottenlund, Denmark, August 2001 (ICES CM 2002/ACFM:04).

## 3．5．14．b Pandalus borealis in Division IVb（Farn Deeps）

State of stock／exploitation：The state of the stock is unknown．

In recent years this fishery has yielded very Iow annual landings（ $0-5$ t）and in 2000 no landings were reported．

There is no basis for defining biological reference points for this stock．

Source of information：Report of the Pandalus Assessment Working Group，CharlottenIund，Denmark， August 2001 （ICES CM 2002／ACFM：04）．

Elaboration and special comment：ICES has never assessed the stock．

Anglerfish was previously assessed separately for the North Sea (Sub-area IV) and the area west of Scotland
(Sub-area VI). These components have now been combined and the assessment is presented in Section 3.7.7.

### 3.6.1 Overview

## Major fleets

A large proportion of the Eastern Channel is in the coastal zones ( 12 miles zone) which are exploited by small-scale fisheries. The major fleets operating in this area are: a French inshore fleet, mainly comprising small vessels using various gears, an English inshore fleet using fixed gear, English and Belgian offshore beam trawlers and French offshore otter trawlers.

Both beam trawl fleets mainly target sole and take a significant amount of plaice as a by-catch. Sole is also taken in directed inshore UK fisheries using trammels and in French fisheries using trammels and otter trawl. The major part of the plaice landings originates from a seasonal fishery in winter by French offshore otter trawlers taking sole as by-catch. The major part of the cod landings originates from French offshore trawlers and inshore gill-netters. Cod is also taken as a by-catch in other fisheries. Whiting are caught by inshore and offshore French trawlers in the Channel in mixed fisheries.

A pelagic trawl fishery takes place in the winter during the herring spawning season.

Effort directed at flatfish increased consistently and considerably in all fleets from 1975 and reached a peak during 1989-1990, after which it has remained at that level.

There are no separate TACs for cod and whiting in Division VIId but they are part of a total TAC for the whole of Sub-area VII excluding Division VIIa. Sole is managed by a TAC for the Division VIId and plaice is managed by a TAC for VIId and VIIe combined. TACs for cod, whiting, plaice and sole in recent years have generally not been restrictive.

Cod and whiting are assessed together with the North Sea stocks; reference is made to Sections 3.5.1, 3.5.2 and 3.5.4.

In plaice, the spawning stock has been fairly constant since 1992 although the estimates of fishing mortality are rather variable. The stock is harvested outside of safe biological limits. Although the spawning biomass of the sole stock is above the proposed $\mathbf{B a p}_{\mathrm{pa}}$, the exploitation rate is high and unsustainable.

Pelagic species caught in Division VId are herring (Downs herring), horse mackerel, mackerel, and sprat. These species are subject to TACs set over larger areas. There are no separate estimates of the state of the stocks in this area. Also no separate statistics on catches and landings are available.

### 3.6.2 Sole in Division VIId (Eastern Channel)

State of stock/exploitation: The stock is within sate biological limits. The SSB in 2001 is above $\mathbf{B}_{\mathrm{pa}}$, and the fishing mortality in 2000 was below $\mathbf{F}_{\mathrm{pa}}$.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| There is currently no biological basis for defining $\mathbf{B}_{\text {lin }}$ | $\mathbf{B}_{\text {pa }}$ be set at 8000 t . This is the lowest observed <br> biomass, at which there is no indication of impaired <br> recruitment. |
| $\mathrm{F}_{\text {yim }}$ is 0.55. This is a fishing mortality at or above which <br> the stock has shown continued decline, | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathrm{F}_{\text {lim }}$ |

## Technical basis:

| $\mathbf{B}_{\text {lin: }}:$ Poor biological basis for definition. | $\mathbf{B}_{\mathrm{pa}}:$ Smoothed $\mathbf{B}_{\mathrm{loss}}$ (no sign of impairment): 8000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is set equal to $\mathbf{F}_{\text {loss }}$ but poorly defined; analogy to <br> North Sea and setting of $1.4 \mathbf{F}_{\mathrm{pa}}=0.55$. | $\mathbf{F}_{\mathrm{pa}}:$ Between $\mathbf{F}_{\mathrm{med}}$ and $5 \mathrm{th} \%$ of $\mathbf{F}_{\text {loss }} ; \mathbf{S S B}>\mathbf{B}_{\mathrm{pa}}$ and <br> probability $(\mathbf{S S B}$ |

Advice on management: ICES recommends that fishing mortality should be maintained below the proposed $F_{p a}$, corresponding to landings in 2002 of less than 5200 t.

Relevant factors to be considered in management: Due to the large 1998 year class, SSB is expected to remain above the proposed $\mathbf{B a}_{\mathrm{pa}}$ in the short-term, providing fishing mortality does not exceed $\mathbf{F}_{\mathrm{pa}}$ -

Fishing mortality for this stock has recently tended to tluctuate around the proposed $\mathbf{F}_{\mathrm{pa}}$. For this reason, the state of the stock with respect to the proposed $\mathrm{F}_{\mathrm{pa}}$ fluctuates correspondingly.

Comparison with previous assessment and advice: The 2001 assessment is consistent with previous assessments.

Catch forecast for 2002:
Basis: $F(s q)=F(98-00$, scaled $)=0.34 ;$ Landings $(2001)=4.43 ; \operatorname{SSB}(2002)=13.1$.

## Weights in '000 t

Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: There is a low probability of SSB falling below the proposed $\mathbf{B}_{\mathrm{Pa}}(8 \mathrm{kt})$ if fished at $\mathbf{F}_{\mathrm{sq}}(0.34)$ in the medium-term.

Elaboration and special comment: There are 5 main commercial fleets fishing for sole in Division VIId. Beigian and English offshore beam trawlers ( $>300 \mathrm{HP}$ ) fish mainly for sole, but can switch to scallops or move to adjacent areas. French offshore trawlers target roundfish and take sole as by-catch. Numerous inshore (under 10 m vessels) on the English and French coasts using mainly fixed nets target sole in the spring and autumn. The inshore vessels take over half the reported
landings and sole forms their main source of income. The minimum mesh size in the sole fishery with towed gears is 80 mm and in the fishery with static gears 90 mm .

Analytical assessment using catch-at-age and CPUE data from commercial fleets and surveys. Underreporting from the inshore fleet and mis-reporting by beam trawlers, fishing in adjacent management areas is thought to be significant. The lack of information on this phenomenon contributes to the uncertainty of the stock assessment and forecasts.

About $50 \%$ of the predicted SSB in 2003 consists of year classes whose strength is poorly defined．

### 3.6.3 Plaice in Division VIId (Eastern Channel)

State of stock/exploitation: The stock is harvested outside safe biological limits. SSB in 2001 is estimated to be above the proposed $\mathbf{B}_{\mathrm{pa}}$, and has fluctuated near this level since 1992. However, fishing mortality in 2000 is estimated to have been well above the proposed $\mathrm{F}_{\mathrm{p}}$.

Management objectives: No explicit management objectives are set for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to reduce or maintain $F$ below the proposed $\mathbf{F}_{\mathrm{pa}}$ and to increase or maintain the spawning stock biomass above the proposed $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 5600 t, the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 8000 t . This affords a high probability of <br> maintaining $S S B$ above $\mathbf{B}_{\text {lim, }}$ taking into account the <br> uncertainty of the assessment. |
| $\mathbf{F}_{\text {lim }}$ is 0.54, the fishing mortality estimated to lead to <br> stock collapse. | $\mathbf{F}_{\text {pa }}$ be set at 0.45. This $F$ is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathbf{F}_{\text {lim, }}$, <br> into account the uncertainty of the assessment. |

Technical basis:

| $\mathrm{B}_{\text {lim }}$ : $\mathrm{B}_{\text {loss }} \mathbf{5 6 0 0} \mathrm{t}$. |  |
| :---: | :---: |
| $\mathrm{F}_{\text {lim }}: \mathrm{F}_{\text {loss }}$ : 0.54 | $\mathrm{F}_{\mathrm{pa}}$ : $\mathbf{5}^{\text {th }}$ \% of $^{\mathrm{F}_{\text {loss }} ; \text { B }^{*}>\mathrm{B}_{\mathrm{pa}}}$ and $\mathrm{P}\left(\mathrm{SSB}_{\mathrm{MT}}<\mathrm{B}_{\mathrm{pa}}\right)<10 \%: 0.45$ |

$\mathbf{B}^{*}$ is equilibrium SSB at $\mathbf{F}_{\mathrm{pa}}$.

Advice on management: ICES recommends that fishing mortality in 2002 be reduced to less than the proposed $\mathrm{F}_{\mathrm{pa}}$ ( 0.45 ), corresponding to landings in 2002 of less than 5800 t .

Relevant factors to be considered in management: The TAC is set for Divisions VIld and VIIe combined. The plaice stock in Division VIIe is also harvested outside
safe biological limits and the advice for the two stocks is consistent.

Comparison with previous assessment and advice: The current assessment is consistent with previous assessments. The increase in the forecast landings for 2002 corresponding to the proposed $\mathbf{F}_{\mathrm{pa}}$ compared to the advice last year, is attributable to the projected increase in stock size in 2002.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}_{\text {sy }}(98-00$, scaled $)=0.52 ; \operatorname{Landings}(2001)=6.37 ; \operatorname{SSB}(2002)=9.85$.

| $\mathrm{F}(2002$ onwards) | Basis | Catch (2002) | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: | :---: |
| 0.31 | $0.6 \mathbf{F}_{\text {sf }}$ | 4.3 | 4.3 | 11.9 |
| 0.42 | $0.8 \mathbf{F}_{84}$ | 5.5 | 5.5 | 10.8 |
| 0.45 | $\mathbf{F}_{\mathrm{pa}}=\left(0.87 * \mathrm{~F}_{\mathrm{sq}}\right)$ | 5.8 | 5.8 | 10.5 |
|  |  | K, | ¢ |  |
|  |  |  | § |  |

## Weights in " 000 t .

Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: At status quo fishing mortality or lower, there is a high probability of remaining above $B_{p a}$ in the medium-term.

Elaboration and special comments: In the Channel, plaice are taken mainly in a mixed flatfish fishery by otter and beam trawlers. There is a directed fishery in winter by French offshore otter trawlers. Large numbers of plaice are discarded.

The analytical assessment uses CPUE data from 3 commercial fleets and 3 surveys. The time series is short and data prior to 1985 are considered to be unreliable. The estimates of fishing mortality and SSB are not very precise. Discards are not included in the assessment. Anecdotal information from the fishery suggests that catch rates in 2001 have been lower than in 2000 , which may indicate that the assessment may be too optimistic.

Unfortunately, the information from the fishery was not substantiated or verifiable.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

### 3.7.1 Overview

## Fisheries

To a large extent, the roundfish fishery in Division VIa is an extension of the similar fishery in the North Sea. The demersal fisheries in Division Vla are predominantly conducted by otter-trawlers fishing for cod, baddock, anglerfish and whiting, with by-catches of saithe, megrim and lemon sole. These trawlers use mesh sizes of $80-100 \mathrm{~mm}$ depending on area and may at times discard considerable amounts of young haddock and whiting. The majority of these vessels are locallybased Scottish trawlers using 'light-trawls', but trawlers from Ireland, Northern Ireland, England, France and Germany also participate in this fishery. The importance of Scottish seiners essentially targeted at haddock has been declining in recent years as many of these vessels have been converted to trawlers. A part of the fleet of light trawlers has diversified into a fishery for anglerfish that has been expanding into deeper water off the northern coast of Scotland. By-catches in this fishery include megrim and cod.

The larger Scotish trawlers and Irish trawlers fish for haddock at Rockall when opportunities arise for good catches from the Division Vlb stock. Although young saithe are caught by coastal trawlers, the fishery for saithe essentially takes place on the shelf edge to the west and northwest of Scotland. Traditionally, this fishery has largely been operated by the larger deep-sea French trawlers. However, the number of these vessels has declined in recent years. Since the late 1980s, some of these vessels diverted their activity toward deep-sea species, notably orange roughy and some medium-sized trawlers also participate in the fishery for deep-sea species during summer in some years.

Some 200 Scottish trawlers also take part in fisheries for Nephrops on inshore grounds. Some use 70 mm mesh with 80 mm square mesh panel, but others use 100 mm mesh to avoid the by-catch limitations associated with the smaller mesh size. These boats also land small quantities of haddock, cod, whiting and small saithe, but discard large amounts of whiting and haddock.

The pelagic fishery for herring is mainly operated by UK vessels in the north, and by Irish vessels in a roe fishery in the south. Substantial misreporting of catches from the North Sea and between the northern and southern stocks occurred in the past, but UK licensing regulations are thought to have reduced misreporting since 1997. The Clyde herring fishery has declined sharply in recent years as the stock has suffered from a series of low recruitments. Recent TACs have not been taken and the catches have been less than 1000 t since 1991.

There is a directed trawl fishery for mackerel and horse mackerel in the area. The mackerel fishery mainly takes place in the fourth and first quarter of the year, when the mackerel is returning from the feeding area to the spawning area. The horse mackerel is mainly fished in the second half of the year. In addition, there are fisheries for blue whiting in the area.

The industrial fisheries in Division Vla are much smaller than in the North Sea. The Scottish sandeel fishery statted in the early 1980s, peaking in 1986 and 1988. It is irregular, depending on the availability of the resource and of processing facilities at Shetland, Denmark and Faroe. By-catches in this fishery are very small. The Norway pout fishery is conducted mainly by Danish vessels.

## State of stocks

The assessments of demersal and herring stocks in Subarea VI continued to be hampered by the poor quality of catch data due to misreporting, although this has become less of a problem for roundfish species in recent years. Quantities misreported during 1992-1995 were estimated for Division VIa cod, and estimates of area misreporting since 1987 were made for anglerfish and megrim. The distribution of reported catch data were also examined to estimate the likely extent of misreporting of herring between the North Sea and Division Vla North.

It is likely that the stocks of haddock, saithe, anglerfish and megrim in Division VIa are closely related to those of the same species in the North Sea. The saithe stock is now assessed as part of the North Sea stock, and the pattern of haddock recruitment in the two areas is very similar.

All roundfish stocks in Sub-area VI are outside safe biological limits and ICES advice points to the need of reducing fishing mortality in the relevant fisheries.

The stock of cod is outside safe biological limits and the spawning stock size in 2000 is at a record low. Analysis indicates that with current rates of exploitation it is very unlikely to achieve safe limits in the medium-term. Due to the poor state of the cod in Division Vla, emergency measures were enacted by the EU for 2001 prior to the agreement and implementation of a five year cod recovery plan to start in 2002. The principal regulatory measure for 2001 other than the TAC, was the
establishment of three controlled areas from 6 March 30 April 2001. The regulations sought to minimise cod catches but also to minimise the effect of the measures on certain pelagic and shellfish fisheries. Consequently, derogations existed for: purse seine and pelagic trawls targeting pelagic fish species; dredges, pots and creels; and for the inner Clyde area, Nephrops trawls. The aim of the controlled areas was to allow as many cod as possible to spawn before the end of April 2001 when the spawning season finishes (Commission Regulation (EC) No. 456/2001). Consequently, the regulation targeted areas where high catch rates of cod are usually experienced during March and April. The controlled areas were not defined for the purposes of regulating fishing effort on the cod stock in this area. No measures were applied to regulate effort displaced during the period of the control.

The haddock spawning stock in Division VIa is above $\mathbf{B}_{\text {pa }}$, but fishing mortality is above $\mathbf{F}_{\mathrm{pa}}$. The spawning biomass in Division VIb is below $\mathbf{B}_{\mathrm{pa}}$ for this stock, and fishing mortality is in excess of $\mathbf{F}_{\mathrm{pa}}$.

The whiting stock in Division Vla is outside safe biological limits, with spawning biomass in 2001 below $\mathbf{B}_{\mathrm{pa}}$ and fishing mortality above $\mathbf{F}_{\mathrm{pa}}$.

Concerns that catch-rates of megrim and anglerfish are being sustained by continual expansion into new areas mean that assessments of these species are not considered sufficiently reliable to be used as the basis of advice. However, there are indications that fishing mortality on anglerfish may not be sustainable in the long term. The fish are exploited at an early age due to their size and shape, and are subject to considerable fishing mortality prior to first maturity. The expansion of this fishery has been further accelerated by diversion of fishing effort from other stocks subject to more restrictive quotas in recent years and by market opportunities. Fishing mortality on megrim appears to be sustainable. However, this may not remain the case if the fishery expands further into deeper water.

The assessment of the stock of herring in Division VIa North has been impossible due to low precision in the data on catches, acoustic surveys and larvae surveys. The state of the stock is uncertain and it has not been possible to assess the status of this stock with respect to safe biological limits. The catches from this stock have been stable since 1991. The state of the herring stock in Division VIa South is also uncertain and the fishery appears to be dependent on occasional strong year classes. There are indications that this stock may have declined considerably in recent years, and that levels of fishing mortality may be comparatively high. There is evidence that the Clyde herring stock remains low.

When last assessed (in 1996) the level of exploitation on sandeel was moderate and the SSB of this stock appears to be high. The stock is, however, subject to large variations depending on recruitment. Precautionary management has been put in place on a three-year basis, including a TAC and fishery closures after 31 July each year, in order to reduce the interaction with breeding seabirds.

The fisheries for mackerel and horse mackerel exploit the southern and western components of mackerel and the western horse mackerel stock. Information on these widely distributed stocks is presented in Section 3.12. The mackerel stock is considered to be inside safe biological limits: the spawning biomass is above $\mathbf{B}_{\mathrm{pa}}$, and fishing mortality is just below $\mathbf{F}_{\mathrm{pa}}$. Following the outstanding 1982 year class, which for more than a decade contributed a significant part of the catches, recruitment of horse mackerel has been weak. SSB is bound to be low as this year class is fished out and the sustainable yield is unlikely to be higher than about 130 000 t per year.

The Nephrops stocks are assessed every two years. The overall catches of Nephrops from Division VIa North have remained stable since the mid 1980s, and catchrates of the different stocks have fluctuated without trend.

### 3.7.2.a Cod in Division VIa (West of Scotland)

State of stock/exploitation: The stock remains outside safe biological limits. SSB has been declining since the early 1980s and is currently at a record low, well below $\mathbf{B}_{\mathrm{pa}}$ and $\mathbf{B}_{\mathrm{lim}}$. Fishing mortality in 2000 was far above $F_{p a}$ and $F_{\text {lim }}$, and at the current rate of exploitation the chance of a stock collapse is high. Fishing mortality increased progressively over the period 1966 to 1987 , rising significantly between 1982 and 1985, and has since remained high. In the last ten years, only one year
class has been above average and the 3 poorest year classes have been recruited since 1995.

Management objectives: Due to the poor state of the cod stock in Division VIa, emergency measures were enacted by the EU for 2001 prior to the agreement and implementation of a five-year cod recovery plan to start in 2002.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :---: | :---: |
| $\mathbf{B}_{1 \mathrm{im}}$ is 14000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 22000 t . This is considered to be the minimum SSB required to ensure a high probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of assessments. This also corresponds with the lowest range of SSB during the earlier, more productive, historical period. |
| $\mathrm{F}_{\text {tim }}$ is 0.8 . Fishing mortalities above this have historically led to stock decline. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.60 . This F is considered to have a high probability of avoiding $\mathbf{F}_{\text {lim }}$. |

## Technical basis:

$\mathbf{B}_{\text {lim }}=$ smoothed estimate of $\mathbf{B}_{\text {loss }}$ (as enumerated in $\mathbf{B}_{\mathrm{pa}}=$ previously set at 25000 t at which good 1998) recruitment is probable. Reduced to 22000 t due to an extended period of stock decline
$\mathbf{F}_{\text {lim }}=\mathrm{F}^{\prime} \mathrm{s}$ above 0.8 have led to stock decline in early $\mathbf{F}_{\mathrm{pa}}$ consistent with $\mathbf{B}_{\mathrm{pa}}$ 1980's

Advice on management: ICES recommends a rebuilding plan that will ensure a safe and rapid recovery of SSB to a level in excess of 22000 tons. If a rebuilding plan is not implemented, ICES recommends that fishing mortality on cod should be reduced to the lowest possible level in 2002. ICES has repeatedly stated that for various reasons, TACs alone are not effective in regulating fishing mortality.

Relevant factors to be considered in management: The EC regulation No. 456/2001 of the Commission targeted areas where high catch rates of cod are usually experienced during March and April. The controlled areas were not defined for the purposes of regulating fishing effort on the cod stock in this area. No measure was applied to regulate effort displaced during the period of the control. It is unlikely that the controlled areas in Division VIa will significantly have affected fishing mortality on cod in 2001. Up until 1999, discard rates have been low, but have increased in 2000.

Even with no directed harvest or by-catch of cod in 2002, SSB is forecast in the short-term to remain below $\mathbf{B}_{\mathrm{pa}}$ and close to $\mathbf{B}_{\mathrm{lim}}$. All possible measures should be considered for implementation in the recovery plan. Fishing effort displaced due to the cod rebuilding plan in Division VIIa, should not be permitted to target cod in Division VIa, or any other stocks considered to be outside safe biological limits.

Cod is taken with whiting and haddock in a mixed demersal fishery. Scottish Nephrops trawlers take a bycatch of cod. A by-catch of cod is taken by French vessels fishing for saithe. Management needs to take this into account.

Comparison with previous assessment and advice: Retrospective analysis indicates that the overestimation of the stock may not be fully accounted for in the current assessment and catch forecast. There are substantial changes in the assessment compared to that of last year; however, the status of the stock has remained unchanged.

${ }^{1} \mathbf{F}_{\mathrm{pa}}=0.60$
Weights in＇000 t
Shaded scenarios considered inconsistent with a precautionary approach．

Medium－and long－term projections：Although the short－term forecast suggests some improvement in SSB， medium－term analyses indicates that with current rates of exploitation，this improvement is very unlikely ever to be sufficient to achieve $\mathbf{B}_{\mathrm{pa}}$ ．

Elaboration and special comment：The directed fishery consists mainly of Scottish vessels using towed gears．Since 1976，effort by Scottish heavy trawl and seine effort has decreased，whilst that of light trawlers has generally increased，particularly in more offshore areas．

Immature cod in Division VIa are subject to high fishing mortality．The fish are not fully mature until age group 4 ，increasing the susceptibility of the stock to collapse．

Analytical assessment is based on landings－at－age and survey CPUE data．Discard rates have been low for about 20 years and the data are variable．Discards of one year old fish increased significantly in 2000. Because discard data are noisy there is a need to
carefully examine the sensitivity on the assessment before these data can be included．Discard data have not been taken into account in the assessment model and the youngest age groups are therefore likely underestimated．The quantities of fish mis－reported during 1992－1995 are estimated in the assessment，but the true quantities caught in those years remain uncertain．

### 3.7.2.b Cod in Division VIb (Rockall)

Catch data are given in Table 3.7.2.b.1.

Special comments: There is no information on the status of cod in Division VIb. Official catch data are incomplete. To set a TAC for this Division compatible with management measures for Division VIa cod, it is proposed to adopt the most recent recorded landings. The average recorded catch over 1997-1999 is 760 t . 2000 data are incomplete.

Relevant factors to be considered in management: TAC set for Division VIb cod should not jeopardise a rebuilding plan for cod in Division VIa.

Source of information: Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, August 2001 (ICES CM 2002/ACFM:02).

* Preliminary.

## 3．7．3．a Haddock in Division VIa（West of Scotland）

State of stock／exploitation：This stock is harvested outside safe biological limits．SSB in 2001 is above $\mathbf{B}_{\text {pa }}$ ， and the fishing mortality in 2001 was above $\mathbf{F}_{\mathrm{p} a}$ ．The recruitment estimate of the 1999 year class is greater than twice the average based on the last four years．

Management objectives：No explicit management objectives are set for this stock．

Precautionary Approach reference points（established in 1998）：

| ICES considers that： | ICES proposes that： |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{lim}}=22000 \mathrm{t}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 30000 t |
| $\mathbf{F}_{\text {lin }}=$ not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.50 |

Technical basis：

| $\mathbf{B}_{\mathrm{lim}}=$ lowest observed SSB | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ not defined | $\mathbf{F}_{\mathrm{pa}}=$ high probability of avoiding $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ in long term |

Advice on management：Advice on management： Fishing mortality in 2002 should be below $F_{p a}$ corresponding to a human consumption landing of 14100 t ．However，due to the mixed nature of the fisheries the fishing mortality for haddock in 2002 may have to be reduced further to achieve consistency with the recovery plan for cod．

Relevant factors to be considered in management： Haddock are taken with cod and whiting in a mixed demersal fishery．The area closures for cod in Division VIa in 2001 have had no measurable impact on the haddock fishery in Division VIa．

A high proportion（up to $42 \%$ in weight，1991－2000）of the total haddock catch is discarded．The amount of discard of the large 1999 year class（ 51 mill．）is already around the estimated recruitment in the immediately preceding years．The proposed mesh size increases that are part of the cod recovery plan are likely to reduce
discards．Square mesh panels have been introduced in the UK in 2000 in an attempt to reduce discarding． Further gear measures were introduced in Scotland during 2001．It is still too early to determine whether these have been effective．If implemented effectively， these measures should help in reducing discarding． Measures to control by－catch and discarding of cod should be implemented within a directed haddock fishery．

Comparison with previous assessment and advice： The estimates of fishing mortality in 1999 is $22 \%$ higher and SSB in $200038 \%$ lower in this year＇s assessment compared to last year＇s assessment．The principal change to the catch forecast compared with that of last year is in part due to $65 \%$ higher estimates of the 1999 year class in the current assessment compared to the previous assessment．The basis for a single stock fishery advice is the same as last year．

Catch forecast for 2002：
Basis：$F(2001)=F_{s q}=F(98-00)=0.72 ; \operatorname{Catch}(2001)=31.7 ;$ Landings $(2001)=16.4 ; \operatorname{SSB}(2002)=53.1$ ．

| $\begin{gathered} \mathrm{F}(2002 \\ \text { onwards }^{1} \end{gathered}$ | Basis | Catch （2002） | Discards $(2002)$ | $\begin{aligned} & \text { Landings } \\ & (2002) \\ & \hline \end{aligned}$ | SSB（2003） | Medium term（10 year） <br> Probability（\％）of $\mathrm{SSB}<\mathbf{B}_{\mathrm{pz}}$ |

Weights in＇000 t．
Shaded scenarios considered inconsistent with the precautionary approach．

Elaboration and special comment: The fishery is dominated by Scottish light trawlers. Effort by Scottish seiners and heavy trawlers has declined since 1976. Haddock in Division VIa are fully exploited by age group 3, and also reach full maturity at that age. Immature fish are subject to comparatively high fishing mortality, and comprise a large fraction of the discarded catch. High fishing mortality on immature haddock increases the susceptibility of the stock to over-exploitation.

Analytical age-based assessment uses landings-at-age data, discard-at-age data, and indices from research vessel surveys. Some misreporting of landings has occurred in recent years, but this is not considered to have significantly affected the results of the current assessment.

Source of information: Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, August 2001 (ICES CM 2002/ACFM:02).

### 3.7.3.b Haddock in Division VIb (Rockall)

State of stock/exploitation: The stock remains outside safe biological limits. Fishing mortality in 2000 was above $\mathbf{F}_{\mathrm{pa}}$, and SSB is below $\mathbf{B}_{\mathrm{pa}}$ in 2001 .

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (established in 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 6000 t, the lowest observed spawning stock. | $\mathbf{B}_{\mathrm{pa}}$ be set at 9000 t . This is considered to be the <br> minimum SSB required to have a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. |
| $\mathrm{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. This F provides a small probability that <br> SSB will fall below $\mathbf{B}_{\mathrm{pa}}$ in the long term. |

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ as estimated in a previous assessment | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ could not be defined, due to uninformative stock <br> recruitment data | $\mathbf{F}_{\mathrm{pa}}=$ adopted by analogy with other haddock stocks. |

Advice on management: ICES recommends that fishing mortality in 2002 should be reduced to below 0.2, corresponding to landings of less than $1300 t$ in 2002 in order to rebuild the SSB to $B_{p a}$ within 4 years.

Relevant factors to be considered in management: The TAC applies to Sub-area VI, with a limit on how much of the catch may be taken in Division VIa, but no such limit for Division VIb. In addition, part of Division VIb now falls within international waters where non EU-vessels are not subject to TAC. This allows for an unregulated fishery in that area. A separate TAC applicable only to Division VIb, including international waters, would ensure sustainable fishery in Division VIb.

Following the NEAFC agreement in March 2001, an area of the NEAFC zone around Rockall was closed to haddock. It is too early to quantify the effect this closure has on the fishery on the stock.

It is difficult to predict actual fishing mortality as fleet behaviour will depend on fishing opportunities elsewhere.

Comparison with previous assessment and advice: The estimates of fishing mortality in 1999 is $27 \%$ lower and SSB in $200015 \%$ higher in this years assessment compared to last years assessment.

Catch forecast for 2002:
Basis $\mathrm{F}(2001)=\mathrm{F}(98-00)=0.39 ;$ Landings $(2001)=2.7 ; \mathrm{SSB}(2002)=4.9$.

| F(2002) | Basis | $\begin{aligned} & \text { Catch } \\ & (2002) \\ & \hline \end{aligned}$ | Landings (2002) | $\begin{gathered} \text { SSB } \\ (2003) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.16 | $0.4 \mathrm{~F}(98-00)$ | 1.1 | 1.1 | 6.9 |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Elaboration and special comment: The Rockall fishery is dominated by Scottish vessels and until recently has taken place largely in the summer if fishing at Rockall is more profitable than in the North Sea or West of Scotland. A few Irish vessels exploit this
stock on a more regular basis. It is largely a haddock fishery, with relatively little catch of other species.

During 1999 a substantial spring fishery developed for the first time, fishing on concentrations of haddock in a
different area of the Rockall bank than previously. An unregulated fishery on part of the bank which now falls outside of the EU EEZ also started during 1999 and has led to opportunities for other nations to exploit the fishery, notably Russia. The table on official statistics has included Russian catches from the Rockall area for the last two years.

The analytical, age-based assessment uses landings-atage data and research vessel survey data. Although no discard data are available, there is likely to be substantial discarding of younger fish. The short time
series, variable fishing effort and mis-reporting of landings limit the precision of the assessment. The time series is too short to estimate the stock recruitment relationship for medium-term projections and estimation of fishing mortality reference points. Maturity is assumed to be attained at age 3, but information from surveys in 2001 indicates that fish may be maturing at an earlier age.

Terms of reference of the meeting:
To evaluate the spatial distribution of the fishery, the spawning stock and the juvenile fish of the stock of haddock around Rockall, to allow NEAFC to consider the appropriateness of area and seasonal closures among other measures. Evaluation of the consequences of fishing with larger mesh sizes (within a range considered appropriate by ICES) is also requested.

Dates of meeting: 30 January to 1 February 2001
Venue:
FRS Marine Laboratory, Victoria Road, Aberdeen.

## Participants

Mike Armstrong (UK, Northern Ireland;
Rick Officer
Phil Kunzlik
Vladimir Vinnichenko
Nikolai Timoshenko

Chair)
(Ireland)
(UK, Scotland)
(Russia)
(Russia)

The meeting was also attended by Tore Jakobsen (Norway, ACFM Chair), Coby Needle (FRS, Scotland), Robin Cook (FRS, Scotland) and Dick Ferro (FRS, Scotland).

The following Working Documents were submitted to the meeting, and are appended to this report:

WD1. Vinnichenko, V.I., Gorchinskiy, K.V., Lisovsky, S.F., Khlivnoy, V.N., Gerber, E.M. The Russian haddock fishery (Melanogrammus aeglefinus) on Rockall Bank (Division VIb). 7pp.

WD2. Vinnichenko, V.I., Gorchinskiy, K.V., Khlivnoy, V.N., Timoshenko, N.M. Russian researches of haddock (Melanogrammus aeglefinus L.) on Rockall Bank. 26pp.

## 1 <br> INTRODUCTION

### 1.1 Structure of the Report

This report is divided into two sections: the first dealing with spatial and temporal patterns in the fishery and stock of haddock on Rockall, the second with the consequences of fishing with different mesh sizes. Information was available from the three main countries presently exploiting haddock at Rockall: UK(Scotland), Russia and Ireland. Fishing activities by Russian vessels recommenced at Rockall in 1999 following the change in fisheries jurisdiction to include the southwestern region of Rockall in international waters.

The recent patterns in the fisheries are described in terms of officially reported landings and fishing effort by month, and where available, by ICES rectangle. Information on discarding was available for only a few Irish and Scottish trips and was considered inadequate for inclusion in any analyses. Data on Russian landings in 1999, and provisional figures for 2000 , were available by month for the total area of the Russian fishery, which operated mainly within four ICES rectangles beyond the 200 mile EU EEZ at southwest Rockall. Information on distribution of juvenile and adult haddock was available only from the Scottish groundfish survey carried out annually in September, and from Russian surveys of SW Rockall carried out in March and August-September 2000. Catch-rates of adults in the surveys were specified as catches per hour for fish of 30 cm and above. This length also corresponds to the minimum landing size for haddock in EU legislation.

The ability to make forecasts of catch and spawning biomass under a range of mesh-size scenarios was limited by the paucity of data on discards at Rockall. Hence, analyses were carried out using composite data from the Division VIa and Rockall stocks. Selection ogives were estimated for two fleet sectors with different mesh-size and net construction. Selection ogives from Russian mesh selection experiments were also used. Vectors of population numbers, partial fishing mortality and mean weight and length at age in landings were obtained from data files and assessment results from the June 2000 ICES assessment of the VTa and Rockall haddock stocks (ICES CM 2001/ACFM: 01 ). Short-term changes in yield and $S S B$, and in longterm yield per recruit (YPR) and spawning biomass per recruit (SPR) were computed for a range of mesh sizes and combination of mesh sizes.

### 1.1 State of stock

The ICES ACFM view is that the haddock stock in Division Vlb (Rockall) is outside safe biological limits (ACFM Report: November 2000). Fishing mortality in 1999 ( $\mathrm{F}=0.52$ ) was above the proposed precautionary fishing mortality ( $\mathrm{F}_{\mathrm{pa}}$ ) of 0.40 . Spawning stock biomass (SSB) has declined since 1996 to $7,000 \mathrm{t}$ in 2000 and is now below the proposed precautionary biomass reference point ( $\mathbf{B}_{\mathrm{pa}}$ ) of $9,000 \mathrm{t}$. Total international landings in 1999 were estimated at 5,400 t. Reported landings have been relatively stable since 1997. No explicit management objectives are set for this stock. The ICES recommendation in 2000 was for fishing mortality in 2001 to be reduced below the proposed $\mathrm{F}_{\mathrm{pa}}$. This corresponded to landings in 2001 of less than 2,700 t . The TAC covers ICES Sub-Area VI, with a limit on how much of the catch may be taken in Division VIa. No such limit is set for Division VIb within the TAC for Sub-Area VI. In addition, part of Division VIb now falls
within international waters where non-EU vessels are not subject to TAC. This allows for an unregulated fishery in that area. It is difficult to make short-term forecasts of fishing mortality Rockall, as the activities of fleets in this area can be unpredictable depending on fishing opportunities elsewhere.

## 2 SPATIAL AND SEASONAL PATTERNS IN FISHING ACTIVITY AND HADDOCK STOCK

### 2.1 Development of fishing activities at Rockall

The sea area at Rockall within which fishing activities were recorded in 1998 to 2000 is shown in Figure 1.

## Russian fleets

The first Russian (Soviet) scouting/research expeditions to the Rockall area were undertaken in 1958-1959, and made commercial catches of blue whiting, haddock, argentine and other species. Scouting/research investigations were repeated in June 1966. In the latter period, catches consisted mostly of blue whiting, argentine and ling. Haddock was caught in small quantities.

Strong haddock year classes in 1968 and 1972 provided the basis for a directed haddock fishery from 1972 to 1976. The fishery was carried out in the area $56-58^{\circ} \mathrm{N}$ and $13^{\circ} 30^{\prime}$ to $15^{\circ} 00^{\circ} \mathrm{W}$, mainly at depths of $140-250 \mathrm{~m}$. Dense concentrations of haddock were frequently observed over hard bottom (corals, rocks), where bottom trawl fishing was hampered or impossible.

In 1972 the fishing season at Rockall started late in April. During the first ten days of May the average catch rate of haddock was 25.2 t live weight per vessel per day. The haddock concentrations then dispersed and the fishing fleet left the area. In August the haddock fishery was more successful, with catch rates of about 39 t per vessel day. In 1972 the total catch at Rockall was $8,800 \mathrm{t}$, of which haddock comprised $7,300 \mathrm{t}$.

In 1973 fishing operations at Rockall were carried out for a short period around the middle of April before the haddock concentrations were dispersed. Average catch rate was 6 t per vessel day. Total catch was $3,400 \mathrm{t}$, including 3,300 thaddock.

In 1974 the fishery took place from August to December. The catches were stable and catch rates were $34-50 \mathrm{t}$ per vessel day. Haddock made up $48,900 \mathrm{t}$ of a total catch of $50,200 \mathrm{t}$.

The Russian haddock fishery peaked in 1975 with a catch of $49,800 \mathrm{t}$. The fishery took place in March-April and August-September. The fishing was stopped in September because of large by-catches of small haddock.

In 1976 the fishing took place in July-October on mixed concentrations of haddock, saithe and cod. The total catch of $45,300 \mathrm{t}$ included $40,700 \mathrm{t}$ haddock.

During 1977-1998 Russian fishing operations on the Rockall Bank were not carried out because of the introduction of 200 -mile exclusive economic zones.

In 1999 the Russian trawl fleet was fishing in international waters at south-west Rockall. Fishing operations started with one vessel during 26 May - 24 June. Most of the catch was small redfish (Sebastes viviparus) and haddock. From late July to the middle of August, two trawlers were fishing on mixed concentrations of small redfish, haddock and blue whiting. From the middle of August to October one or two vessels operated at Rockall. The catches were dominated by grey gumard, and haddock were caught only in small numbers. The catch of haddock taken by Russian vessels at Rockall in 1999 was 458 t , representing only $3.6 \%$ of the total Russian catch of all species from the area.

In 2000 the Russian fleet continued to trawl in international waters at south-west Rockall. Fishing operations started with one vessel in late March, and in April one to four trawlers were fishing. Along with haddock, blue whiting made up an important share (up to $50 \%$ ) of the catches. By the middle of April catch rates were declining, but four to seven trawlers were fishing until June. In July, five to ten vessels were operating and at the beginning of the month took mixed catches of small redfish, haddock and blue whiting. At the end of the month grey gurnard dominated the catches, attaining a share of $80-100 \%$. This species continued to dominate the catches during the rest of the year.

Total catch of haddock by Russian trawlers from Rockall in 2000 was 1,811 t (provisional figures), corresponding to $3 \%$ of the total Russian catch of all species from the area.

## UK fteets

The Scottish haddock fishery at Rockall commenced in the early 1980 s . Until the early 1990 s, the fishery was opportunistic and targeted occasional strong year classes of haddock in relatively shallow water in the northern region of Rockall. The dominant fishing gear was single-vessel otter trawl and the fishery was considered a mid to late-summer operation in waters less than 200 m deep. With the adoption of restrictive TACs in the early 1990 s, some vessels began targeting monkfish and megrim as well as haddock at Rockall. During 1994 to1996, two designs of trawl net were used at Rockall, both constructed with heavy rock-hopper ground gear. Some vessels fished so-called scraper trawls with long wings, low headline and short tapered body panels to target monkfish and megrim, whereas haddock was targeted using so-called hopper trawls with short wings,
high headline and long tapered body panels. From 1996 onwards many of the vessels fishing at Rockall were replaced by new, more powerful ones. Because of the success of the twin rig for monktish and megrim, the new vessels entering the fleet were also being rigged for twin trawling. By 1999, the twin-rig trawl had become the main fishing method at Rockall. Trawl nets used during this period combined the design characteristics of both scraper and hopper nets to enable haddock, monkfish and megrim to be targeted at the same time. Double 6mm twine was used in the cod-end construction. The current minimum mesh size in the fishery is 100 mm stretched-mesh.

In 1997, a few vessels began developing the haddock fishery in deeper water to the west of Rockall, at depths between 200 m and 400 m . This fishery is believed to operate below the 200 m isobath in ICES rectangles 43D5, 44D5 and 42D4. In 1998 and 1999, more vessels joined this late spring to early summer fishery, indicating a substantial shift in effort both seasonally and spatially. Anecdotal evidence from the fishery is that high catch rates were obtained in 1997 and 1998. The catch rates then declined but were still good in 1999. However, catch rates in 2000 were reported to be poor in the deeper water. Further anecdotal evidence is that increased discarding has been associated with the deeper-water fishery compared to the more traditional fishery at northern Rockall. The average fish size is reported to be smaller in the deeper water, even though fish aggregating at this time may well include spawning fish.

## Irish fleets

Otter trawlers from Killybegs, and Greencastle have traditionally carried out the Irish haddock fishery at Rockall. This is generally a mixed fishery targeting haddock, megrim and monkfish. Irish vessels are now exploiting this stock on a more regular basis and take about $19 \%$ of the reported European landings of haddock from Rockall. The fishery is extremely important to the larger whitefish vessels operating out of Killybegs and Greencastle in County Donegal. In 1999. Ireland took about $1,020 \mathrm{t}$ of the total reported international landings of Rockall haddock of $5,400 \mathrm{t}$. This represented an increase of 316 t from the landings reported in 1998. Irish landings of Rockall haddock appear to have been relatively stable since 1997. There have been substantial changes in targeting practices in the fishery in recent years. In 1999, peak landings of both the Irish and Scottish fleets were recorded in April from deeper water to the west of Rockall. The fishery, which in earlier years took place almost exclusively in summer, now takes place throughout the year.

Between 10 and 14 Irish vessels participated in the fishery between 1997 and 2000. Twin-rig otter trawlers using rock-hopper ground gear now take the bulk of the catch. A few vessels use high-opening, single rock-
hopper nets. The most common cod-end mesh size is 100 mm . The recent addition of new, larger vessels to the Irish fleet has increased the ability of Ireland to participate in the fishery.

### 2.2 Seasonal patterns of fishing

Data on monthly total catch and catch per unit of effort of Russian trawlers were available for 1999-2000. Monthly landings and landings per unit of effort were available for the Irish fleet in 1998 - 2000. UK (Scotland) provided only landings data by month for 1998-2000, as not all Scottish vessels record fishing effort. All data for 2000 are provisional.

The Russian fishery in 1999 (Table 2.1) lasted from May to November. Most of the catch and effort was from June to October with a peak in August. Catch rates, however, were highest from May to August, declining markedly in the rest of the season.

The Russian fishery in 2000 (Table 2.2) lasted from March to December. The effort was lowest in March and December and highest from August to September. The catches, however, were highest from April to July, peaking in April. Catches were very low between August and December (only 3 t out of a total of 1811 t). Consequently, catch rates were also highest from March to July, although they declined markedly after April.

The Scottish fishery in 1998-2000 (Table 2.3) was conducted throughout the year. Landings were lowest in the period December to February. Peak landings were reported in April, May in August.

The Irish fishery in 1998-2000 (Table 2.4) was conducted throughout most of the year. Catch and effort were generally highest between May and August. In 1998 and 1999 catch rates show peaks in April and July, the former clearly the highest. The corresponding peaks seem to have occurred in May and August in 2000, but the highest values occurred in January and February. Relatively high catch rates were also reported towards the end of the year.

The drop in Russian catches and catch rates after August is not reflected in the other fleets, but the Russian fleet operates in intemational waters and is therefore more restricted. There was a shift in the fishing strategy of Russian vessels midway through the season. The target species changed from haddock, redfish and blue whiting to grey gurnard. However, there also seemed to be reduced abundance of haddock in the area on the southwestem part of the bank where the Russian fleet was fishing.

Both the Irish and the Scottish fishery indicate a peak in availability in April/May, possibly connected with spawning aggregations, and another less marked peak in July/August.

Data on the spatial distribution of catches, by ICES rectangles and quarter (Tables 2.5-2.7), were available for 1999-2000 from Russia and for 1998-2000 from U.K. (Scotland) and Ireland. Data for 2000 are provisional. Russia also provided monthly maps of the distribution of catches (Figure 2.1). For the purposes of discussion, the "Bank" at Rockall is defined as the area shallower than 200 m .

There are clear differences in the spatial distribution of the catches between the three fleets.

The Russian fishery was conducted in international waters at south-west Rockall. The Irish fishery also mostly took place on the Rockall Bank, but to a larger extent in the European waters farther northeast. The Scottish fishery had the widest distribution. Most of the landings by Scottish vessels were from the Bank. The fishing area extended further northeast and further west than the Irish fishery, with a higher proportion of the catches from depths greater than 200 m . Overall, the landings from the six rectangles covering virtually all of the area shallower than 200 m were $59 \%$ of the total for 1998-2000.

There were some differences in the spatial distribution of catches between seasons. The Russian fishery moved slightly to the southeast in the $3^{\text {rd }}$ quarter. The Irish fishing area expanded in the $2^{\text {nd }}$ quarter, was more restricted again in the $3^{\text {rd }}$ quarter and moved towards northeast in the $3^{\text {rd }}$ and $4^{\text {th }}$ quarters. The Scottish fishery started more to the northeast than the other fisheries. In the $2^{\text {nd }}$ quarter the spatial extent of the fishery expanded and the centre of activities moved southwest. In the $3^{\text {rd }}$ and $4^{\text {th }}$ quarter the fishery moved back northeast.

Over the period examined there was no clear frend in the spatial distribution in the Irish fishery. In the Scottish fishery, however, there was a tendency towards a more southwesterly distribution of the activity.

### 2.3 Size and age compositions of catches

### 2.3.1 Length and age compositions of Russian landings in 2000

Data were available from observers on board Russian vessels at Rockall in March, April and June 2000 (Fig. 2.2 ), and represent all haddock caught. The vessels sampled fished with cod-end meshes ranging from 40 mm to 100 mm stretched mesh (mainly 70 mm ). The 70 mm and 100 mm mesh nets retained haddock down to $25-26 \mathrm{~cm}$, with modal length around $30-31 \mathrm{~cm}$ in spring and 32.34 cm in June. The net with 40 mm cod-end retained baddock down to around 22 cm , with modal length 28 cm . Age compositions were available only for April 2000 and are given below as percentage by number:

Length and age compositions of Scottish landings in 1998 and 1999

No data were available for discards. Scottish landings rarely included fish below the minimum legal size of 30 cm . The length distribution of Scottish landings was similar in the first quarters of 1998 and 1999 (Fig. 2.3). Age compositions are shown in Table 2.8 and show considerable variation from quarter to quarter, and between years.

### 2.3.3 Length and age compositions of Irish landings in 1998 and 1999

Insufficient data were available to examine length composition of discards. The length distribution of Irish landings was much broader than the Scottish length distribution despite the use of 100 mm mesh cod-ends in both fleets, and indicates differences in discarding practices. Quarterly age compositions are shown in Table 2.9.

### 2.4 Spatial patterns of distribution from survey data <br> 2.4.1 Scottish groundfish survey

A groundfish survey of Rockall is carried out by UK(Scotland) in autumn. The survey was annual up to 1997 and was carried out using the old R.V. Scotia deploying an Aberdeen 48 -foot trawl fitted with a finemesh cover on the cod-end. Subsequent surveys are every two years, and are carried out using a GOV trawl with ground-gear deployed from the new R.V. Scotia. Most stations are within the 200 m depth contour (Fig. 2.5). During 1999 , some additional stations were fished in deeper water to the west of the Bank. Catch rates of haddock are shown in Figures 2.5 and 2.6 as tish less than 30 cm in length, and 30 cm and longer. A cut-off point of 30 cm was chosen as this approximately separates mature fish of three years and older from younger, immature fish, and also corresponds to the EU minimum landing size for haddock. The highest catch rates of haddock $<30 \mathrm{~cm}$ were on the shallowest regions of the Bank at NE Rockall (Figure 2.5). Very high catch rates up to 16,500 fish per hour were recorded, comprising mainly fish of the 1999 year-class. The highest catch rates of adult haddock were also towards the northern part of Rockall, but farther west than the area of highest juvenile concentrations (Figure 2.6). Very few haddock were caught at the deep-water stations to the west of Rockall. This was surprising in view of anecdotal evidence for heavy discarding of small haddock by vessels extending their range into deeper water. It is possible that there are localised high densities of haddock in deep-water areas not covered by the survey, or that there is a movement of haddock into deeper water at other times of year. The survey may not provide an accurate picture of the full distribution of haddock at Rockall throughout the year.

## 2.4 .2 <br> Russian groundfish survey

A Russian survey of SW Rockall was carried out in spring and autumn 2000. The surveys were carried out at random stations using a bottom trawl with 25 m ground-rope and 20 mm cod-end mesh. The opening shape of the trawl was rectangular with 17 m width and 6 m height. Data on catch-rates per station were available only for the autumn survey. The spring survey data were available only as species and sample length compositions. The data from the autumn survey are shown in Figures 2.7 and 2.8 as numbers of haddock caught per tow in the length categories $<30 \mathrm{~cm}$ and $30 \mathrm{~cm}+$. Tow duration was mostly half an hour. The highest concentrations of haddock $<30 \mathrm{~cm}$ in autumn were recorded in the shallower regions of the survey area, at depths of around 200 m or less (Fig. 2.7). Juvenile haddock of recent year classes appeared comparatively abundant in the survey area. Adult haddock were located in two patches, one at the northwest boundary of the survey area, and the other in deeper water in the southwest region (Fig. 2.8).

Hauls made in the deeper regions of the survey area in autumn tended to have the lowest contribution of haddock by weight (Fig. 2.9). During spring, hauls made between the 200 m and 500 m isobaths at southwest Rockall had large quantities of haddock relative to other species (Fig. 2.10). It is not clear if this represents a movement of haddock into deeper water in spring. The
share of haddock and red-fish in the survey catches in spring and autumn was higher than recorded in Russian surveys in the 1960s and 1970 s , whilst the relative contribution of argentine has decreased. Much of the haddock was found on coral grounds, which are difficult to trawl. The total area covered by coral appears to have increased in comparison with the 1970s, and some locations where the seabed was suitable for trawling have now become colonised by corals.

Both spring and autumn surveys demonstrated full sexually maturity of haddock (males and females) by 25 cm total length (see WD2). Half of specimens investigated were mature by length 22 cm .

## 3 ANALYSIS OF SHORT AND MEDIUM-TERM EFFECT OF CHANGES IN MESH SIZE ON HADDOCK CATCHES AND SSB

### 3.1 Theoretical selectivity curves of gears used at Rockall

Experimental work in Scotland over the period 19921998 has led to the formulation of a general model of haddock selectivity (Ferro and Graham 1998), the components of which are as follows. Building on this work, the length at which $50 \%$ of haddock will be retained by a given gear configuration can be expressed as:

$$
\begin{equation*}
L_{50}=N F \times L F \times P F \times(13.55+0.3343 M S-0.1193 M R-1.576 T D) \tag{1}
\end{equation*}
$$

where

$$
\begin{aligned}
& \text { Nylon factor } N F= \begin{cases}1.2 & \text { if nylon twine is used } \\
1.0 & \text { if polyethylene twine is used }\end{cases} \\
& \text { Lifting - bag factor } L F= \begin{cases}0.895 & \text { if a lifting bag is used } \\
1.0 & \text { if a lifting bag is not used }\end{cases}
\end{aligned}
$$

Panel factor $P F=1.0$ for analyses discussed here

$$
M S=\text { wedge }- \text { measured mesh size in mm }=1.04 \times \text { ICES } \text { mesh size }
$$

$M R=$ number of meshes around the circumference of the codend
$T D=$ nominal twine diameter $=1.13 \times$ actual wine diameter

Model settings for typical current Scottish and Russian (Working Document 1) vessels are given in Table 3.1. The Scottish settings can also be applied to Irish vessels as a first approximation.

Observed selection ogives for haddock caught with Russian gear types with measured inside-mesh of 82.4 and 107.7 mm were presented by Vinnichenko et al (Working Document 2). These ogives were obtained from covered-codend experiments carried out by Russia
in spring 1972 on the shelf to the east of Rockall. Figure 3.1 compares these empirical results with theoretical ogives derived from the application of the Scottish model of selection (Equation 1) to typical gear types in current use by Scottish and Russian vessels, while Table 3.2 gives modelled values of $L_{50}$ for each of these analyses. Note that the model used assumes that selection range is fixed at 5 cm ; there is no statistical evidence that selection range is affected by codend design (Ferro and Graham 1998). Both survey and
theoretical results suggest that the Russian gear is considerably more selective for haddock than the Scottish equivalent, possibly due to the use of relatively thin nylon twine in cod-ends.

### 3.2 Mesh change simulations

The ICES assessment of the Rockall haddock stock is undertaken using landings-at-age data that are implicitly assumed to correspond to the true catch-at-age. However, it is known that in recent years at least, haddock have been discarded from European member State vessels fishing at Rockall, sometimes in considerable quantities. However, due to the relatively low probability of fishing trips to Rockall being selected for observation, insufficient data on rates of discarding of haddock by size or age were available for this meeting. Consequently, the necessary age distributions or length distributions of the Rockall catches required to evaluate the effects of changing gear selectivity were also unavailable. Information provided by other nations on catches in international waters at Rockall was also insufficient to permit an evaluation of the effects of changing fishing gear selectivity.

Due to these problems, two approaches were considered:
(i) examination of an earlier ICES evaluation of gear selectivity changes for haddock in both the North Sea and in ICES Division VIa;
(ii) evaluation of the potential effects of gear selectivity changes on a haddock stock adjacent to Rockall, for which a catch-at-age analysis and age distributions of landings and discards were available (ie haddock in Division VIa).

### 3.2.1 Previous ICES studies

The ICES Roundfish Working Group of 1990 (ICES CM 1991/Assess:4) had, as a term of reference, to assess the short term effects of an increase in the minimum mesh size to $100 \mathrm{~mm}, 110 \mathrm{~mm}$ and 120 mm in the North Sea roundfish fishery taking into account all available information on the 1990 year classes. In fact, that working group broadened the scope of its activities to include Division Vla roundfish stocks as well, and to address other issues that also contribute to fishing gear selectivity, for example, the number of meshes around the circumference of the cod end. In doing so, the working group evaluated the short term catch and stock development for five mesh sizes ( $90,100,110,120$ and 130 mm ) and three values for number of meshes around the codend ( 120,100 and 75). The evaluation of 90 mm mesh with 120 meshes around the codend was considered the baseline result, and gains or losses from other combinations were expressed relative to this. The analysis was highly fleet disaggregated, and used experimental selectivity data and models developed at
the Aberdeen Marine Laboratory. The results for mesh sizes in excess of 100 mm were based on extrapolation of the experimental results, which at that time were only available for meshes up to 100 mm .

Fleet specific results are not available in the working group report of that meeting although summaries of the overall results are available. For haddock, these are presented in Tables 3.3 and 3.4. Medium term and long term results were not presented so it is not possible to draw inferences for the optimum mesh size and gear configuration. However, the analysis indicates the overall direction of short-term changes when varying the gear configuration, and these can be compared with the results presented in the following section.

### 3.2.2 The current fishery at Rockall and in Division VIa

Because insufficient data are available to evaluate the effects of changes in fishing gear selectivity at Rockall, a composite analysis has been undertaken that includes elements from the current fisheries at Rockall and in Division VIa. This sought to combine stock number and mortality estimates from Division VIa haddock with the biological characteristics of Rockall haddock (eg, weights-at-age and maturity ogive). The values used were taken from the inputs to prediction table from the 2000 meeting of the Northern Shelf assessment Working Group (ICES CM 2001/ACFM:01)

Similarities between the stocks are illustrated in Figure 3.2. Recruitment in the two stocks is positively correlated if an outlying value for the 1984 year-class is disregarded. The age compositions of the stocks in 2000 (Fig 3.2b), from the ICES assessment, will differ due to the absence of discards in the Rockall assessment, and the assumption of geometric mean recruitment in 1999 for the Rockall stock. The correlation in recruitment between the two regions suggests that the strong 1999 year-class estimated for VIa, which will strongly affect the short-term forecast for this region, could also be reflected in recruitment at Rockall. Mean weights at age in the landings are similar in VIa and Rockall up to age 3, but diverge from age 4 (Fig. 3.2c). The patterns of fishing mortality attributed to landings in both stocks are very similar over 1997-1999 (Fig. 3.2d).

For a given set of fishing gear characteristics, the population numbers and partial fishing mortality at age (landings and discards) from the most recent assessment of the haddock stock in Division VIa were used to generate short term catch and stock trajectories in numbers. As the most recent assessment using Extended Survivors Analysis gives numbers at age surviving to the start of 2000 , any changes in mesh size were imposed from the start of that year. (It is emphasized that this exercise was carried out to illustrate the potential short-term effect of a change in mesh size in a haddock fishery with similar characteristics of that at Rockall, given a specified starting population, rather than to give an actual forecast.) Equilibrium ("per
recruit') estimates were calculated using the VIa partial fishing mortality values assuming no changes in growth.

The mean weight-at-age of landed fish was taken from the Division Vlb assessment because older haddock in this area are smaller than fish of the corresponding age in Division VIa. The mean weight-at-age of discarded fish was taken as the landings mean-weight-at-age from Division VIb multiplied by the ratio of the discard to landings mean weights-at-age from Division VIa. The weighted mean of landings and discard weights-at-age were used as stock weights-at-age and catch weights-atage. The maturity ogive was taken from inputs to the Division VIb assessment. These biological characteristics were then applied to the catch in number and stock in number estimates from the catch forecasts to convert the outputs to yield and biomass estimates.

The mesh assessment method used here is an elaboration of an age-based mesh change analysis of the sort illustrated in, for example, Sparre, P., and Venema, S.C. (1992. Introduction to tropical fish stock assessment. Part 1 - manual. FAO Fisheries Technical Paper 306, Rev 1. 376 p.) The method was modified to account for fleet-specific partial fishing mortality values.

The raised, recent fishing mortality at each age from the Division: Vla haddock assessment was partitioned between a nominal "European" 100 mm mesh fleet and a nominal "International" 70 mm fleet for carrying out the forecast. This was done arbitrarily on the basis of, eg a 80:20 split or $70: 30$ split (the sensitivity of the results to this choice was evaluated). (Whilst varying mesh sizes from 40 mm to 100 mm have been used by Russian vessels fishing haddock at Rockall, the majority of the vessels used 70 mm mesh.) Partial F values for the European fleet were further partitioned between landings and discards on the basis of rates of discarding at age estimated from the Scottish discard sampling scheme in Division VIa. Such a split is also possible for the International fleet, but for this analysis it was assumed that all the catch of that fleet was retained. The partial Fs-at-age for the International fleet were further adjusted according to the relative values of the selection coefficient at age for 100 mm mesh (using European selectivity values) and 70 mm mesh (using the theoretical Russian selectivity values shown in Table 3.2). This was done to modify the exploitation pattern imposed on the International fleet to correspond to its current gear characteristics.

For the results presented here, only mesh size was varied in the simulations. Other important gear configuration parameters, for example, meshes around the circumference and cod-end twine diameter, were kept constant at values typical of the Scottish trawl fleet for the case of the European fleet. For the International fleet, the Scottish model of gear selectivity for haddock was used to calculate selectivity at age using gear characteristics typical of the Russian fleet. This means that for a given mesh size, the selectivity characteristics
of the European and International fleets will differ considerably (see Table 3.2). It was further assumed that all vessels catching haddock are trawlers to which the applied selectivity values are appropriate.

Baseline calculations were made assuming a European 100 mm mesh fleet and an International 70 mm mesh fleet. Simulations were then undertaken that assumed both fleets changed to:

- 70 mm mesh
- 100 mm mesh
- 110 mm mesh
- 120 mm mesh

It must be borne in mind that although the mesh sizes changes were applied to both the European and the International fleets concurrently, for a given mesh size the selectivity of their respective fishing gears will differ markedly due to the different construction of the nets.

Results are illustrated as percentage changes in the expected landings and discards of the European fleet, the expected catch of the international fleets, total landings (European landings plus Intemational catch), total discards (equal to European discards in this context) and spawning stock biomass. The percentage change was calculated as: [New Value x 100 /Baseline] -100 .

Simulation results for an initial split of partial fishing mortality at age of $70 \%$ European and $30 \%$ are presented in Figures 3.3-3.8. Changing the initial split of fishing mortality of the European 100 mm and International 70mm fleet from 70:30 to 80:20 and 60:40 did not affect the results in terms of directions or patterns of change, only the magnitude of change was affected, and in general such changes were small.

Because of the deficiencies in the data required for these simulations, all results should be considered only as indicative of the direction of change likely as a result of the change in mesh size. The magnitude of these changes will be subject to considerable uncertainty.

Where gains or losses to yield are discussed, it is well known that they must be considered in the context of competing fleets. In isolation, an individual fleet may well be advantaged by increasing the selectivity of its fishing gear, and on that basis its expected yield would increase. However, due to technical interactions with other fleets, such an advantage may not accrue. Indeed, other fleets using less selective gear may be placed at a competitive advantage by the actions of an individual fleet improving its selection pattern. Similarly, if all fleets change their gear selectivity in some way, it does not follow that all fleets would be similarly advantaged. Some may experience gains whilst others may incur Iosses having been placed at a competitive disadvantage.

## 70 mm mesh

Changing the mesh size of both fleets to 70 mm gave short and long term increases in discarding in the European fleet (Figure 3.3). This is not unexpected and is offset by a decrease in the expected European landings, International catch and spawning stock biomass. The order of magnitude of changes after the first year is around $15 \%-20 \%$ and at equilibrium, around $20 \%-30 \%$. Although this result is not meaningful in the sense that a 70 mm mesh size for the European fleet is unrealistic, it does indicate a potential benefit in not fishing with that mesh size in the European fleet.

## 100 mm mesh

Simulations in which both fleets used 100 mm mesh gave increases in both landings and discards of the European fleet and spawning biomass, but considerable losses for the International fleet using more selective fishing gear $(40 \%-50 \%$ losses in catch in the short term, and $40 \%$ at equilibrium). (Fig. 3.4)

A bigger difference was exhibited if empirical information on the selectivity of the International fleet provided by early Russian selectivity experiments is incorporated in the simulations. The results from this simulation are presented in Figure 3.5. Much more severe short and long term reductions in the International catch of the order of $60 \%-70 \%$ are indicated, along with positive enhancement of European landings ( $20 \%-40 \%$ ) and a lesser increase in European discarding. The spawning stock biomass also shows positive change associated with this.

If the change to 100 mm mesh was made using gear characteristics in the International fleet corresponding to those in the European fleet (i.e. as shown in the top
panel of Figure 3.1), then only marginal changes occur. In this case the International fleet makes small gains to its catch whilst the European fleet and spawning biomass suffer small losses (Figure 3.6).

These three sets of results for a move to 100 mm mesh size are given to provide an indication of the sensitivity of these results to the assumption of selectivity in the International fleet. The incorporation of Scottish selectivity parameters, theoretical Russian selectivity parameters or empirical Russian selectivity ogives in the simulations has major implications for interpreting the results.

## 110 mm mesh

Changing the mesh size of both fleets to 110 mm gave improved landings in the European fleet, and an increase in SSB, after a short transitional period (40$60 \%$ after the second year). However, there was a considerable reduction of $50-60 \%$ in the Intemational catch after the second year (Fig. 3.7).

## 120 mm mesh

Similar results to the 110 mm simulation were found for increasing mesh size in both fleets to 120 mm . Again, after a short transitional period, landings of the European fleet were significantly enhanced, as was the SSB. However, this was offset by considerable losses in the International fleet catch (Fig. 3.8).

# Some comments of Russian delegation to Report of ICES Expert group on Rockall haddock 

Results of the Russian research and fishery of Rockall haddock in 2000 allow to do some following provisional conclusions:

1. Length composition of haddock caught on Rockall Bank by trawls with mesh minimum size of 70 mm to 100 mm did not considerably differ. However, with larger mesh size the fishing efficiency substantially decreased. At the same time, traumatism and mortality of escapes will probably increase. Therefore, it shall not be indisputable to increase mesh minimum size as a measure for protecting haddock stock. It is required that additional studies are undertaken to obtain more detailed data on different mesh selectivity and on haddock escapes survival.
2. Majority of haddock individuals shall attain sexual maturity being of 25 cm in length and at the age of 2 years. Immature fish share in catches by trawlers with 70 mm to 100 mm mesh minimum size was not large, not exceeding $2 \%$ ( $0.8 \%$ at an average). Thus, catching with this mesh shall not considerably affect reproductive potential of population provided observation of catch limits.
3. Existence of vast areas useless for bottom trawl fishing in the southern bank and spatial-temporal separation of fishing grounds from young fish habitat are major factors providing for safe exploitation to haddock stocks.
4. Results of research carried out in 2000 are the basis for making an assumption that haddock stock state on Rockall Bank is satisfactory. It is expedient that an additional trawl survey is carried out within the whole bank water area during haddock spawning season to obtain more detailed data.

### 3.7.4.a Whiting in Division VIa (West of Scotland)

State of stock/exploitation: The stock remains outside safe biological limits. Fishing mortality exceeds $\mathbf{F}_{\mathrm{pa}}$ and is estimated to be close to $\mathbf{F}_{\text {lim }}$ in the last two years. Spawning stock is below $\mathbf{B}_{\mathrm{pa}}$. There has been no trend in recruitment during the 1990 s, but a gradual increase in $F$ has reduced $S S B$, which has been below $\mathbf{B}_{\text {lim }}$ since
1998. Although the estimate of the discards is uncertain, discard of the 1999 year class was high.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 16000 t, the lowest observed spawning stock <br> estimated in previous assessments. | $\mathbf{B}_{\text {pa }}$ be set at 22000 t. This is considered to be the <br> minimum SSB required to have a high probability of <br> maintaining $S S B$ above $\mathbf{B}_{\text {lim }}$ taking into account the <br> uncertainty of assessments. |
| $\mathbf{F}_{\text {lim }}$ is 1.0, above which stock decline has been observed. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.6. This $F$ is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim. }}$. |

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {lim }}(1998)=16000 \mathrm{t}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}=$ see above | $\mathbf{F}_{\mathrm{pa}}=0.6 * \mathbf{F}_{\mathrm{lim}}$ |

Advice on management: To bring SSB above $B_{p a}$ in 2003 , fishing mortality in 2002 should be below 0.29 , corresponding to a human consumption landing of less than 2000 t. However, due to the mixed nature of the fisheries the fishing mortality for whiting in 2002 may have to be reduced further to achieve consistency with the recovery plan for cod.

Relevant factors to be considered in management: Whiting are taken as a by-catch with cod and haddock in a mixed demersal fishery. The rebuilding plan for cod in Division Vla has had no measurable effect on the stock and fishery for whiting in Division VIa. A reduced whiting fishery should have a positive impact on the rebuilding of the cod stock in Division VIa.

Over $80 \%$ of the SSB in 2003 is comprised of the 2000 and 2001 year classes for which short-term geometric mean recruitment has been assumed. Retrospective analysis indicates that the over-estimation of the stock
may not be fully accounted for in the current assessment and catch forecast.

Fishing effort displaced due to the cod rebuilding plan in Division VIIa, should not be permitted to target whiting in Division VIa, or any other stocks considered to be outside safe biological limits.

The proportion of fish discarded is very high and appears to have increased in recent years. Measures to improve the exploitation pattern would be beneficial to the stock and to the fishery. National technical measures introduced to help protect the 1999 year class of haddock may also be beneficial to the whiting.

Comparison with previous assessment and advice: The estimates of fishing mortality in 1999 is $5 \%$ higher and SSB in $200035 \%$ lower in this years assessment compared to last years assessment. The basis for the single stock fishery advice is the same as last year.

Catch forecast for 2002：
Basis $F(2001)=F_{s q}=F(2000)=0.95 ;$ Catch $(2001)=8.82 ;$ Landings $(2001)=4.44 ; \operatorname{SSB}(2002)=13.9$ ．

| F （2001 onwards） | Basis | $\begin{aligned} & \text { Catch } \\ & (2002) \end{aligned}$ | Discards （2002） | Landings （2002） | SSB（2003） |

Weights in＇000 t．
Shaded scenarios considered inconsistent with the precautionary approach．

Elaboration and special comment：Whiting in Division VIa are caught mainly by Scottish trawlers． Since 1976，Scottish heavy trawl and seine effort has declined，whilst that of light trawlers has generally increased．Approximately $50 \%$ of the total catch in weight is discarded，so restricted landings alone will not achieve the necessary increase in SSB．Analytical age－based assessment uses landings－at－age data， discard－at－age data and indices from research vessel surveys．

Source of information：Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks， August 2001 （ICES CM 2002／ACFM：02）．

Saithe in Sub-area VI has previously been assessed as a separate stock. This component has now been combined with saithe in the North Sea (Sub-area IV) and saithe in

Skagerrak and Kattegat (Division IIIa), see Section 3.5.5.

### 3.7.6 Megrim in Sub-area VI (West of Scotland and Rockall)

State of stock/exploitation: When last assessed (1999) the stock was within safe biological limits. The historical perspective of SSB, fishing mortality and recruitment is not well estimated, although it is likely that fishing mortality has increased since the 1980s as the fishery for anglerfish, (in which megrim is taken as a by-catch) has expanded into progressively deeper water.

Management objectives: No explicit management objectives are set for this stock.

Reference points: There is not sufficient information to estimate appropriate reference points.

Advice on management: ICES advises that catches in $\mathbf{2 0 0 2}$ be no more than the recent TAC.

Relevant factors to be considered in management: Megrim are caught as part of a targeted anglerfish fishery, which has expanded rapidly in recent years. Maintenance of the existing megrim TAC should help to prevent expansion of the fishery for anglerfish that is considered to be outside safe biological limits. The megrim in Sub-area VI consists of two species, Lepidorhombus whiffiagonis and L. boscii. The large majority of the landings are $L$ whiffiagonis. Although total landings are less than the TAC, some national quotas are restrictive and this has led to mis-reporting. Previously, the adjacent fishery in the North Sea was
not subject to a TAC for megrim, and catch controls on anglerfish in Sub-area VI have led to mis-reporting of landings, including the megrim component, into the North Sea.

The landings from Division VIa showed a marked increase from 1991 to 1996 (4 400 t), but have subsequently fallen to the recent low of 1780 t in 2000.

Elaboration and special comment: Until recently, megrim was taken mainly as a by-catch in bottom trawl groundfish fisheries. The expansion of the fishery for anglerfish has led to increased fishing pressure on megrim in the area, where they are now caught as a bycatch in the targeted anglerfish fishery. Previous analyses have indicated that megrim are more robust to exploitation than anglerfish, hence management of the fishery should primarily reflect concerns for the anglerfish stock.

Length frequency and age composition data are only available for 1992-1999. Incomplete data were available for 1990 and 1991. Preliminary assessments have previously indicated that $F$ may be rather low, but this impression may be due to the expansion of the area fished.

Source of information: Report of the Working Group on the Assessment of Northern Shelf Demersal Stocks, August 2001 (ICES CM 2002/ACFM:02).

| 1999 | 2567 |
| 2000 | 2146 |
| Average | 3794 |

State of stock/exploitation: The stock is harvested outside of safe biological limits. Although highly uncertain, an assessment for the combined area indicates that the recent $F$ 's have been well above $\mathbf{F}_{\text {pa* }}$ Even though the historical perspective of SSB, fishing mortality and recruitment is not well estimated, it is likely that fishing mortality has increased since the 1980s as the fishery has expanded into deeper water with an associated increase in catches, although these have shown a sharp drop over 1997-1999. The fishery
has expanded into areas, which are believed to have been refugia for adult anglerfish, increasing the vulnerability of the stock to over-exploitation. Immature fish are subjected to exploitation for a number of years prior to first maturity.

Management objectives: No explicit management objectives are set for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to reduce or maintain $F$ below $F_{p a}$.

Precautionary Approach reference points (unchanged since 1998):

| ICES considers that: | ICES proposes that: |
| :---: | :---: |
| There is currently no biological basis for defining $\mathbf{B}_{\text {lin }}$ or $F_{\text {fiim }}$ | $\mathrm{F}_{35 \% \mathrm{SPR}}=0.30$ be chosen as $\mathrm{F}_{\mathrm{pa}}$. This fishing mortality corresponds to $35 \%$ of the unfished SSB/R. It is considered to be an approximation of $\mathbf{F}_{\text {MSY }}$. |

Advice on management: The highest catch that may have been sustainable was around $15000 t$ and occurred in the period 1973-1990, before the recent expansion in the fisheries. The stock has since been depleted and the sustainable catch at present is likely to be lower. The assessment is too imprecise to give exact guidance on what the reduction in fishing should be. ICES continues to recommend catches no higher than $2 / 3$ of the sustainable catches identified in the period 1973-1990. This corresponds to landings no greater than 10000 t in 2002.

Relevant factors to be considered in management: Catches for the combined area are believed to be adequately estimated. However, due to a long history of mis-reporting, the correct allocation of catches to Subareas IV and VI is not possible. Estimates which take into account mis-reporting indicate that the percentage of the catch taken in Sub-area VI in the years 1992 2000 (the period used in the assessment) has ranged between $25 \%-36 \%$, with a mean of $30 \%$. These values may be used as a basis to allocate the 2002 TAC between the management units.

The lack of TAC regulation in the adjacent Sub-area IV before 1998 encouraged mis-reporting of landings into that area and undermined management for Sub-area VI. The agreed TACs in 1998 and 1999 for Sub-area IV were based on recent landings reported from that area. Because those landings included misreporting in the preceding years these TACs are unlikely to have prevented further mis-reporting or to have improved conservation in either area.

Anglerfish are subject to significant fishing mortality before attaining full maturity, and this means the stock is particularly vulnerable to depletion of the spawning component. Their body shape means that at a young
age they are easily retained by the minimum mesh size currently in force. They are known to be discarded, although no routine discard sampling is undertaken. There is also a by-catch of small anglerfish associated with scallop dredging.

In past assessments the existence of a large unexploited reservoir of mature females was assumed to exist in deep waters. In recent years, surveys and fisheries have explored deep water areas widely, without locating any such aggregations of mature anglerfish.

Two species occur, Lophius piscatorius and $L$ budegassa, although catches are almost exclusively of the former.

Elaboration and special comment: The fishery for anglerfish in the North Sea is closely associated with the fishery to the West of Scotland, and catch trends from the two areas are similar, with a steady increase from around 1984 due to the development of a directed Scottish fishery, and a sharp decline from 1997 to 2000. It is likely that catches from two areas come from the same biological stock.

The sharp reduction in landings since 1996, and the scarcity of mature females in the catches may indicate that the stock is heavily over-exploited.

Until the mid-1980s, anglerfish was taken mainly as a by-catch in bottom trawl groundfish fisheries. Restrictive TACs for other species in Division VIa have led to increased fishing pressure on anglerfish in that area, where they are now caught in a targeted anglerfish fishery. Species such as cod, haddock and saithe form a significant by-catch in the anglerfish fishery.

The North Sea catch at length distribution is derived solely from Scottish market sampling. Information for catch composition is unavailable from other countries and this contributes to the imprecision of the assessment.

### 3.7.8 Herring West of Scotland

### 3.7.8.a Herring in Division VIa (North)

State of stock/exploitation: It has not been possible to access the status of this stock with respect to safe biological limits. $F$ is at present considered to be low and close to the value of $\mathbf{F}_{0.2}$. The stock has remained stable and fishing mortality has decreased in recent years.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: ICES recommends catches in 2002 should not exceed the 1991-2000 average of 30000 t .

Relevant factors to be considered in management: In recent years TACs have not been restrictive, presumably because of low effort and a weak market. There has been substantial misreporting of catches into this area from the North Sea and Division VIa(S).

Comparison with previous assessment and advice: The perception of stock status and management advice has not changed.

Catch forecast for 2002: No projections were carried out given the uncertainty in the assessment.

Elaboration and special comment: There are three main fleets operating, 1) the Scottish inshore paired midwater trawl fleet, which operates in the Minches and around the Isle of Barra in the southern part of the area, 2) the Scottish purse-seine fleet, which operates in the northern part of VIa, and 3) the offshore (mainly Dutch and German freezer trawlers) fleet, which operates in the deeper waters near the edge of the continental shelf.

Information on misreporting in the catches has improved, but biological sampling of catches has deteriorated and the assessment remains uncertain. Satellite data has improved knowledge of vessel behaviour. The assessment is uncertain based on uncertain catches and a noisy survey series, but analyses in recent years have consistently pointed towards the stock being exploited at a sustainable rate. Acoustic surveys and the assessment indicate that spawning biomass is reasonably stable or may be increasing. Yield per recruit analysis with geometric mean recruitment suggests that an $F$ of 0.25 would provide a yield of 32000 t .

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

### 3.7.8.b

State of stock/exploitation: In the absence of surveys, and no stock separation of catches, little is currently known about the state of the Clyde spring-spawning stock or the immigrant autumn-spawning component from elsewhere within Division VIa. The fishing mortality is not known. The catch in 2000 was the lowest on record.

## Advice on management: ICES recommends that until

 new evidence is obtained on the state of the stock, existing time and area restrictions on the fishery should be continued in 2002.Relevant factors to be considered in management: Traditionally, the fishery has taken place in October and November. In 2000 there was no fishery. The absence of a fishery might be explained by the low price of herring in 2000 compared to other pelagic
species available to the vessels to which the quota is assigned.

Elaboration and special comments: There are two stock components present on the fishing grounds, resident spring-spawners and immigrant autumnspawners. The spring-spawning stock supported a strong and locally important fishery from 1955-1974 at catch levels ranging from 4000 to 15000 t . Since 1988 catches have been below the TAC.

No assessment possible. No independent survey data are available for recent years.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

### 3.7.9 Norway pout in Division VIa (West of Scotland)

State of the stock/exploitation: There is no current information on which to evaluate the state of the stock.

Management objectives: There are no specific management objectives for the fisheries exploiting this stock.

Elaboration and special comment: The fishery is a small mesh trawl fishery operated by Danish vessels.

Catches are highly variable. The only data available are official landings statistics. There is no information available on which to base scientific advice. By-catches in this fishery should be quantified and made available to ICES.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001 (ICES CM 2002/ACFM:01).

|  |  |

State of the stock/exploitation: There is no current information on which to evaluate the state of the stock.

Management objectives: The current management regime uses a multi-annual TAC of 12000 t per year with the fishery closed from 31 July. Access is limited to vessels with a track record. These arrangements took effect in 1998 for a period of three years and were renewed in 2001.

Relevant factors to be considered in management: Fishing grounds are close inshore and often adjacent to large colonies of seabirds for which the sandeel
population is an important food supply, especially during the breeding season.

Elaboration and special comment: The stock was last assessed in 1996 and a new assessment has not been made. At that time it was considered to be within safe biological limits.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2001, Hamburg, Germany (ICES CM 2002/ACFM: 01).

### 3.8.1 <br> Overview

## Fisheries

The roundfish fisheries in the Irish Sea are conducted primarily by vessels from the bordering countries (UK and Ireland). The majority of vessels are otter-trawlers fishing for cod, whiting and plaice, with by-catches of haddock, anglerfish, hake and sole. The mesh size is 80 mm and 80 mm square mesh panels have been mandatory for UK otter-trawlers since 1993, and for Irish trawlers since 1994. The number of Irish vessels operating in this region has declined in recent years. Fishing effort in the England and Wales fleet of vessels longer than 12.2 m declined rapidly after 1989 , and over 1992-1995 was about $40 \%$ of the effort reported in the 1980s, although it has increased again in recent years. Since the early 1980 s there has been a development of semi-pelagic trawling for cod and whiting, predominantly by vessels from Northern Ireland. Some of these vessels switch between pelagic trawling and twin-trawl fishing for Nephrops depending on fishing opportunities and market demands.

Although some of the otter-trawlers also take part in the fishery for sole, there has been a growing number of beam-trawlers, particularly from southern England and from Belgium, exploiting this stock. The most important by-catches of this fleet are plaice, rays, brill, turbot and anglerfish. The fishiag effort of the Belgian beam-trawl fleet varies according to the catch-rates of sole in the Irish Sea compared with other areas in which the fleet operates. Fishing effort peaked in the late 1980s following a series of strong year classes of sole, but is presently only about $60 \%$ of the peak value.

A fleet of vessels, primarily from Ireland and Northem Ireland, takes part in a targeted Nephrops fishery using 70 mm nets and 75 mm square-mesh panels. The larger vessels, including some that normally target roundfish, may use twin trawls with 80 mm mesh. Decommissioning has reduced the size of the Northern Ireland fleet in recent years. All boats take a considerable by-catch of whiting, much of which is discarded. Discards comprise mainly juveniles because the distribution of Nephrops coincides with the main nursery grounds for whiting. In this fishery as well as in the roundfish fishery in the western Irish Sea, the bycatch of haddock has increased substantially in recent years because of strong year classes in the 1990s.

The other gears employed to catch demersal species are gill-nets, notably by inshore boats targeting cod, bass, grey mullet, sole and plaice.

The main pelagic fishery in the Irish Sea is for herring. In recent years, it has been predominantly operated by pair-trawlers from Northem Ireland. The size of this fleet has declined to a very low level in recent years.

## State of the Stocks

The stock of cod is outside safe biological limits and at risk of collapse: The spawning biomass is below $\mathbf{B}_{\text {lim }}$ and fishing mortality is close to $\mathbf{F}_{\text {lim }}$. Fishing mortality on cod increased progressively throughout the 1980 s . During the early 1990s, the spawning stock declined rapidly and is presently dominated by one age class. As a consequence, it is sensitive to variations in recruitment and in 1995 reached a historical low following entry of the very weak 1992 year class. The 1997 and 1998 year classes are very weak and the 1999 year class is estimated to be about average. In 2000 , the EU introduced a recovery plan for Irish Sea cod (Council Regulation (EC) No. 304/2000) and subsequently established technical measures for the recovery of the stock of cod in the Irish Sea (Council Regulation (EC) No. 2549/2000). This recovery plan consisted of spawning box closures from 14 February to 30 April 2000. Within the closure it was prohibited to use any demersal trawl, seine or similar towed net, any gill net, trammel net, tangle net or similar static net or any fishing gear incorporating hooks. Derogations were permitted for certain demersal otter trawls and for certain beam trawls. The closure was continued in 2001, but was restricted to the western Irish Sea west of $4^{\circ} 50^{\prime} \mathrm{W}$ on the evidence that the abundance of adult cod in the eastern Irish Sea was too low to justify the restrictions on fishing for other species.

The stock of whiting is also outside safe biological limits, both in terms of biomass (below $\mathbf{B}_{\text {lim }}$ since 1997) and of fishing mortality (above $\mathrm{F}_{\mathrm{pa}}$ since 1980). The Irish Sea whiting fishery has been characterised by high levels of fishing mortality throughout the 1980s and 1990s. At such high fishing mortalities, the spawning stock contains few age classes and is vulnerable to poor recruitment, and the stock has been in more or less continuous decline since the early 1980s. Discarding of whiting is considered a major problem in the Nephrops directed fishery.

A notable phenomenon in the Irish Sea, and also in the Celtic Sea, during the 1990s has been a substantial growth in the stock of haddock, particularly following the recruitment of above-average 1991 and 1993 year classes and a very strong 1994 year class. The 1996 year class is confirmed to be still stronger and will result in increased catches in the short term. The fish are confined mainly to the western Irish Sea where established roundfish and Nephrops fisheries take place. Due to the present TAC arrangements, some national quotas have proved limiting, causing substantial misreporting. To alleviate this problem, a separate TAC allocation for Irish Sea haddock has operated since 1999.

The stock of plaice is within safe biological limits. The landings declined in the 1990s, and in 1998 were close to the lowest recorded. This resulted from a combination of declining fishing effort and a succession of below-average year classes recruited since 1987. The spawning stock in currently above $\mathbf{B}_{\mathrm{pa}}$ and fishing mortality in 2000 was below $\mathbf{F}_{\mathrm{pa}}$. The stock is expected to increase and will have a low probability of falling outside safe biological limits in the medium-term.

The sole stock is within safe biological limits. It has benefited several times since 1970 from very strong year classes, and as a consequence has sustained fishing mortalities that are considered high for a sole stock. In 2000 , fishing mortality was at $\mathbf{F}_{\mathrm{p}}$. The frequency of strong year classes has decreased since the mid-1980s, leading to a decline in spawning stock to a historical
low in 1996. The stocks of Nephrops in the Irish Sea are considered to be fully exploited. There is some concern that fishing mortality may rise from the current high level if the use of twin trawls expands. Account should also be taken of the impact of this fishery on the stocks of protected species. There has been no assessment in recent years of the effects on Nephrops of predation by cod, but the low abundance of the latter has probably reduced its impact.

The stock of Irish Sea herring is presently sabject to low fishing mortality exerted by a small fleet of trawlers from Northem Jreland. The stock has recovered from the collapse which followed high fishing mortalities in the 1970s. However its present state is uncertain because the series of survey estimates remains too short to establish the recent trends in biomass.

## 3．8．2 Cod in Division VIIa（Irish Sea）

State of stock／exploitation：The stock remains outside of safe biological limits．Fishing mortality in 2000 was estimated to be close to $\mathbf{F}_{\text {lim }}$ ，and SSB in 2000 to below $\mathbf{B}_{\text {lim }}$ ．For the past ten years $F$ has been in the region of $\mathbf{F}_{\text {lim }}$ ，whilst SSB has remained in the region of $\mathbf{B}_{\mathrm{jmm}}$ ．The probability of good recruitment appears to have been reduced at the SSBs observed in the 1990 s．

Management objectives：To rebuild the SSB of the stock，a spawning closure was introduced in 2000 for ten weeks from mid－February to maximize the reproductive output of the stock（EU Regulations 304／2000 and 2549／2000）．The measures were revised in 2001，involving a continued，but smaller spawning ground closure，coupled with protection of juvenile fish．

Precautionary Approach reference points（established in 1998）：

| ICES considers that： | ICES proposes that： |
| :---: | :---: |
| $\mathrm{B}_{\mathrm{lim}}$ is 6000 t （agreed by ACFM in 1998） | $\mathbf{B}_{\mathrm{pa}}$ be set at 10000 t ．This is the previously agreed MBAL and affords a high probability of maintaining the SSB above $B_{\text {lin，}}$ ，taking into account the uncertainty of assessments．Below this value the probability of below average recruitment increases． |
| $\mathbf{F}_{\text {lim }}$ is 1.0 ．This is the fishing mortality above which there is a reduced probability that the stock can sustain itself． | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.72 ．This F is considered to have a high probability of avoiding $F_{\text {lin }}$ ．Fishing mortalities above $\mathbf{F}_{\mathrm{pa}}$ have been associated with observed stock decline． |

Technical basis：

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{p}^{\mathrm{a}}}=$ Previous MBAL and signs of reduced recruitment |
| :--- | :--- |
| $\mathbf{F}_{\text {lin }}=\mathbf{F}_{\mathrm{med}}$ | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\mathrm{med}} * 0.72$ |

Advice on management：ICES recommends a recovery plan that will ensure a safe and rapid recovery of SSB to a level in excess of 10000 t ．If a recovery plan is not implemented ICES recommends that fishing mortality on cod should be reduced to the lowest possible level in 2002.

Relevant factors to be considered in management： The lower TAC and the closure of spawning ground appear to have resulted in a reduced fishing mortality on older age groups in 2000 ．It is not possible to identify the relative contribution of these measures． There is also an indication that fishing mortality on two－year－olds in 2000 may have increased．The average $F$ in Table 3．8．2．2 does not show these effects．It is
important that management action being taken to reduce fishing mortality on the adult component of the stock is not compensated for by an increase in fishing mortality on the juveniles．

In view of the state of the cod stock in Division VIIa， diversion of effort from the cod spawning grounds to other vulnerable stocks should also be prevented．

Comparison with previous assessment and advice： The estimates of fishing mortality in 1999 is $15 \%$ lower and SSB in 2000 the same in this years assessment compared to last years assessment．The basis for the advice is the same as last year．

## Catch forecast for 2002：

Basis：$F(2001)=F(98-00)=0.97$ ；Landings $(2001)=5.9 ; \operatorname{SSB}(2002)=5.8$ ．

| 乡\＃\＃ |  | K | 4\％ |  |
|  |  |  |  |  |
|  |  | \} |  |  |

Weights in＇ 000 t ．
Shaded scenarios are considered inconsistent with the precautionary approach．

The catch forecast is made on the assumption of an average exploitation pattern 1998-2000, due to a poorly determined exploitation pattern in the last year of the assessment.

Elaboration and special comment: The cod fishery has traditionally been carried out by otter trawlers targeting spawning cod in spring and juvenile cod in autumn and winter. Activities of these vessels have decreased in recent years, whilst a fishery for cod and hake using large pelagic trawis increased substantially during the 1980s. In recent years the pelagic fishery has also targeted cod during the summer. Cod are also taken as a by-catch in fisheries for Nephrops, plaice and sole

Analytical assessment is based on landings-at-age and recruitment indices from surveys in Division VIIa. Estimates of mis-reported landings are included from 1991 onwards. Successive assessments have revised the estimates of recent fishing mortality upwards.

Although landings in 2000 were half those in 1999, the fishing mortality still remains high, due in part to the lowest observed year class passing through the fishery.

## 3．8．3 Haddock in Division VHa（Irish Sea）

State of stock／exploitation：The stock continues to be harvested outside safe biological limits．Fishing mortality has been well above $\mathrm{F}_{\mathrm{pa}}$ since 1993. Occasional pulses of strong recruitment have resulted in opportunistic fisheries lasting only for relatively short periods．In the 1990s a more sustained population
existed，with strong year classes in 1994 and 1996 causing an increase in both spawning biomass and catches．Subsequently，the SSB has declined．

Management objectives：No explicit management objectives are set for this stock．

Precautionary Approach reference points（established in 1998）：

| ICES considers that： | ICES proposes that： |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ not defined | $\mathbf{B}_{\mathrm{p}^{\mathrm{a}}}$ not set |
| $\mathbf{F}_{\text {lim }}$ not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.5 |

Technical basis：

| $\mathbf{B}_{\text {limu }}=$ not defined | $\mathbf{B}_{\mathrm{pa}}=$ not set |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ not defined | $\mathbf{F}_{\mathrm{pa}}$ set by in analogy with other haddock stocks |

Advice on management：ICES recommends that fishing mortality in $\mathbf{2 0 0 2}$ should be reduced to below $F_{p a}$ ，corresponding to a catch of less than $1200 t$ in 2002.

Relevant factors to be considered in management：A TAC is set for haddock for the whole of Sub－areas VII， VIII，IX and X．The present high availability of haddock in Division VIIa has resulted in substantial mis－reporting and／or discarding due to large by－catches of haddock taken by fleets with restrictive allocations available to them．To alleviate this problem，a separate TAC allocation has been made for Division VIIa since 1999.

The haddock stock in the Irish Sea could be sustained if recent strong year classes are allowed to realise their potential for growth，and contribute to SSB．This would only occur if fishing mortality were reduced substantially．

The haddock stock is mainly confined to the western Irish Sea where important mixed－species fisheries for Nephrops，whiting and cod take place．A directed fishery has developed for haddock during the 1990s． Large catches of haddock are taken in the Nephrops fishery during periods of high haddock abundance．

The current directed fishery for haddock in the Irish Sea is likely to generate by－catches of cod in the same area．

Comparison with previous assessment and advice： The estimates of fishing mortality in 1999 is $53 \%$ higher and SSB in $200048 \%$ lower in this years assessment compared to last years assessment．The basis for a single stock fishery advice is the same as last year．

Catch forecast for 2002：
Basis： $\mathrm{F}(2001)=\mathrm{F}_{\mathrm{sa}}=\mathrm{F}(98-00)=1.45 ; \operatorname{Catch}(2001)=2.29 ;$ Landings $(2001)=2.29 ; \mathrm{SSB}(2002)=2.15$ ．

|  |  |  | そ．．．． |  |
|  | 4－4wnexack |  |  |  |

[^33]Elaboration and special comment: Haddock production in the Irish Sea has been irregular, with one productive period in the late 1950 s, two in the early 1970s, and a recent one in the latter half of the 1990 s . Production in the 1990s has exceeded that in the earlier periods and also coincides with increased abundance of haddock in the Celtic Sea. Previous productive periods, other than the recent one, are believed to have coincided with strong year classes in Sub-Area VI, Whilst the 1994 year class was relatively strong in Divisions VIa, VIIa and VIIb-k, patterns of recruitment in subsequent years have differed markedly between areas. Growth rates of individual haddock also differ between areas, and haddock grow fastest in the Irish Sea.

Analytical age-based assessment uses landings at age and indices from research surveys. The time series of
data is short and recent $F$ is likely to be poorly estimated.

### 3.8.4 Whiting in Division VIIa (Irish Sea)

State of stock/exploitation: The stock remains outside safe biological limits. The current assessment indicates that fishing mortality has been above $\mathbf{F}_{\mathrm{pa}}$ since 1980. SSB has declined since 1980 to a very low level, and has been below $\mathbf{B}_{\text {lim }}$ since 1997. Catches have declined progressively since the early 1980s, but the proportion discarded has increased. Estimates for 2000 indicate that three quarters of the catch was discarded.

Management objectives: No explicit management objectives are set for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to reduce or maintain $F$ below $F_{p a}$ and to increase or maintain spawning stock biomass above $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 5000 t , the lowest observed spawning stock <br> biomass as estimated in previous assessment. There is no <br> clear evidence of reduced recruitment at the lowest <br> observed SSB's. | $\mathbf{B}_{\mathrm{pa}}$ be set at 7000 t , which is considered to be the <br> minimum SSB required to ensure a high probability of <br> maintaining SSB above its lowest observed value, taking <br> mato account the uncertainty of assessments. |
| $\mathbf{F}_{\text {lim }}$ is 0.95. This is the fishing mortality estimated to lead <br> to a potential stock collapse. | $\mathbf{F}_{\text {pa }}$ be set at 0.65. This $F$ is considered to have a high <br> probability of avoiding $F_{\text {tim }}$ and is consistent with a high <br> probability of remaining above $\mathbf{B}_{\mathrm{pa}}$ in the long run. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ as estimated in an earlier assessment | $\mathbf{F}_{\mathrm{P}^{\mathrm{a}}}=0.65$, implies an equilibrium SSB of 10.6 kt, and a <br> relatively low probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}(=7 \mathrm{kt})$, and is <br> within the range of historic Fs. |

Advice on management: ICES recommends that fishing mortality on whiting should be reduced to the lowest possible level in 2002. A rebuilding plan, including provisions to effectively reduce directed harvest, discards and by-catch in other fisheries should be developed and implemented in order to rebuild SSB above $B_{p a}$.

Relevant factors to be considered in management: $A$ Nephrops directed fishery operates on the main whiting nursery areas in the Irish Sea. Recent levels of discards in this Nephrops directed fishery during the late 1990 s have been at around $43 \%$ by weight of the estimated catch of whiting, rising to approximately $73 \%$ in the most recent assessment year 2000. This means that the fishing mortality on whiting cannot be effectively controlled by restrictions on landings alone, but would also require measures to reduce discards. Square mesh panels have been mandatory for all UK trawlers (excluding beam trawlers) in the Irish Sea since 1993,
and for Irish trawlers since 1994. While the effects of this technical measure have not been formally evaluated, the Nephrops fishery still generates substantial quantities of whiting discards, indicating that further measures are necessary. Management measures for the Nephrops fishery should also take into account the effect on whiting.

Over $80 \%$ of the SSB in 2003 is comprised of the 2000 and 2001 year classes, which are poorly determined. Recruitment and SSB have been over-estimated in recent years. Retrospective analysis indicates that the over-estimation of the stock may not be fully accounted for in the current assessment and catch forecast.

Comparison with previous assessment and advice: The estimates of fishing mortality in 1999 is $27 \%$ higher and SSB in 2000 the same in this year's assessment compared to last year's assessment. The basis for the advice is the same as last year.

Weights in＇ 000 t ．
${ }^{\mathrm{I}} \mathrm{F}$ multipliers applied to human consumption fishery only．
${ }^{2} \mathbf{F}_{\mathrm{pa}}=0.65$ ．
Shaded scenarios are considered inconsistent with the precautionary approach．

Elaboration and special comment：Whiting is taken mainly as a by－catch in mixed species otter trawl fisheries for Nephrops，cod and other demersal species， and in the pelagic fishery for cod．

Analytical assessment is based on catch－at－age， commercial CPUE and indices from surveys in Division VIIa．Estimates of discards in the Nephrops fisheries are included in the assessment，and estimates of mis－reported landings have been included since 1991．Discarding by whitefish fleets is presently being studied，but there are insufficient data for inclusion in the assessment．

Uncertainties in the assessment are related to a strong conflict between the indices from the Eastern and Western Irish Sea．Reconciling the conflicting signals
in the assessment will necessitate understanding dispersal of whiting between the two areas．This will require spatially disaggregated catch and survey data．

### 3.8.5 Plaice in Division VIIa (Irish Sea)

State of stock/exploitation: The stock remains within safe biological limits. SSB in 2001 is above $B_{p a}$, and fishing mortality in 2000 was below $\mathbf{F}_{\mathrm{pa}}$. Consistent with an overall decline in fishing effort on flatfish in the Irish Sea, the exploitation rate on this stock has declined in recent years.

Recruitment has been below average since the mid1980s, but this period of reduced recruitment started at a time of relatively high $S S B$, and there is no indication that it has resulted from reduced spawning biomass.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| There is no biological basis for defining $\mathbf{B}_{\text {lim }}$ or $\mathbf{F}_{\text {lim }}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 3100 t. There is evidence of high <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ can <br> therefore be set equal to the lowest observed SSB |
|  | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.45. This is considered to provide a high <br> probability that $S S B$ remains above $B_{\mathrm{ps}}$ in the long term. |

## Technical basis:

| $\mathbf{B}_{\text {lim }}$ and $\mathbf{F}_{\text {lim: }}$ stock-recruitment data uninformative; $\mathbf{F}_{\text {loss }}$ <br> poorly defined | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }}$ |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }}$ in a previous assessment, and long term <br> considerations |

Advice on management: ICES recommends that fishing mortality on plaice in 2002 should be maintained below the proposed $\mathrm{F}_{\mathrm{pa}}$, corresponding to landings of less than 2800 t in 2002 .

Comparison with previous assessment and advice: The current assessment is in accordance with last year's assessment. The basis for a single stock fishery advice is the same as last year.

## Catch forecast for 2002:

Basis: $F(2001)=\mathbf{F}_{s q}=F(98-00)=0.31$; Landings $(2001)=2.0 ; \operatorname{SSB}(2002)=5.7$.

| $\mathrm{F}(2002)$ <br> onwards | Basis | Catch <br> $(2002)$ | Landings <br> $(2002)$ | $\mathrm{SSB}(2003)$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.31 | $1.0 * \mathrm{~F}(00)$ | 2.0 | 2.0 | 5.7 |
| 0.37 | $1.2 * \mathrm{~F}(00)$ | 2.4 | 2.4 | 5.4 |
| 0.45 | $\mathbf{F}_{\mathrm{ga}}\left(=1.45 * \mathbf{F}_{\mathrm{sq}}\right)$ | 2.8 | 2.8 | 5.0 |

Weights in ${ }^{4} 000 \mathrm{t}$.

Elaboration and special comment: Plaice are taken mainly in long-established UK and Irish otter trawl fisheries for demersal fish. They are also taken as a bycatch in the beam trawl fishery for sole. The main fishery is concentrated in the North-east Irish Sea. Effort in the UK and Belgian beam trawl fleets increased in the late 1980s, but declined in the early 1990s.

The analytical assessment is based on a tuned catch-atage analysis with CPUE data from two commercial fleets and two surveys, which does not include discard information.

The assumed average recruitment of the 1999 year class may be conservative, but indices from two autumn surveys will only be available later in the year.

Reported landings in recent years are likely to be more accurate than in the past.

| 2001 | 9862 | 5654 |  | 0.310 |
| Average | 14775 | 6081 | 3555 | 0.555 |

[^34]State of stock/exploitation: The stock is within safe biological limits. The fishing mortality in 2000 is at $\mathbf{F}_{\mathrm{pa}}$ (0.3). SSB has recently increased from the historic low in 1997 and in 2001 is above $\mathbf{B}_{\text {pa }}$.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lin }}$ is 2800 t . The lowest observed spawning stock in an <br> earlier assessment. | $\mathbf{B}_{\mathrm{pa}}$ be set at be set at 3800 t , which is considered to be <br> the minimum SSB required to ensure a high probability <br> of maintaining SSB above its lowest observed value, <br> taking into account the uncertainty of assessments. |
| $\mathbf{F}_{\text {lim }}$ is 0.4. Although poorly defined, there is evidence <br> that fishing mortality in excess of 0.4 has led to a general <br> stock decline and is only sustainable during periods of <br> above average recruitment. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30. This F is considered to have a high <br> probability of avoiding $\mathrm{F}_{\text {liim. }}$ |

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}} \sim \mathbf{B}_{\text {lim }} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ poorly defined; based on historical <br> considerations | $\mathbf{F}_{\mathrm{pa}}=$ see above |

Advice on management: ICES recommends that fishing mortality in 2002 remains below the proposed $F_{p a}$, corresponding to landings of less than 1100 t in 2002.

Relevant factors to be considered in management: Discarding of sole increased in 1998 and 1999 with the bulk of the discards coming from the 1996 year class,
and to a lesser extent from the 1997 year class. No data are available for discarding in 2000.

Comparison with previous assessment and advice: The estimates of fishing mortality in 1999 is $\mathbf{1 7 \%}$ lower and SSB in $20007 \%$ higher in this years assessment compared to last years assessment. The basis for a single stock fishery advice is the same as last year.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00) ;, \mathrm{F}_{\mathrm{sq}}=0.30 ;$ Landings(2001) $=1.13 ; \mathrm{SSB}(2002)=4.58$.

| $F(2002)$ onwards | Basis | Landings (2002) | SSB (2003) | Medium term (10 year) probability (\%) of $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.24 | $0.8 \mathrm{~F}(98-00)$ | 0.90 | 4.84 | $<25$ |
| 0.27 | $0.9 \mathrm{~F}(98-00)$ | 1.00 | 4.74 | $<25$ |
| 0.30 | $1.0 \mathrm{~F}(98-00)=\mathbf{F}_{\mathrm{pa}}$ | 1.10 | 4.65 | $<25$ |
| 0.3s) |  | 1. S | 4, 紬 | 43 |
|  |  |  |  | \% |

Weights in 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: There is a low probability of SSB falling below $\mathbf{B}_{\mathrm{pa}}$ at the current fishing mortality of $\mathbf{F}_{\mathrm{pa}}$.

Elaboration and special comment: Sole are taken mainly in a beam trawl fishery and are also taken as a by-catch in otter trawl fisheries. In recent years, catch rates of sole have been low in the Irish Sea, and part of the beam trawl fleet has moved to sole fishing grounds in other areas. The analytical assessment is based on a tuned catch at age analysis with CPUE data from two commercial beam trawl fleets and two surveys.

### 3.8.7 Irish Sea herring (Division VIIa)

State of the stock/exploitation: The state of the stock is uncertain. SSB declined through the 1980s, and may have been stable in the 1990s but cannot be estimated in relation to precautionary reference points. $\mathbf{F}_{\mathrm{pa}}$ has not been proposed, but the fishing mortality in 2000 is likely to be below any candidate value for $\mathbf{F}_{\mathrm{pa}}$.

Management objectives: There are no explicit management objectives for this stock. However, for any management objective to meet precautionary criteria, spawning stock biomass should be greater than the proposed $\mathbf{B}_{\mathrm{pa}}$

Precautionary Approach reference points (established in 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |

## Advice on management: ICES advises that landings

 should not exceed the average catch of the last 5 years, corresponding to $\mathbf{4 , 8 0 0 t}$.Relevant factors to be considered in management: Areas closed to herring fishing around the east coast of Ireland and west coast of Britain were put in place to protect juveniles when an industrial fishery operated. A closed area exists to the east of the Isle of Man to protect the spawning aggregations.

These closed areas should be maintained. The catch in 1998 to 2000 is uncertain.

Comparison with previous assessment and advice: The update of the assessment gave $20 \%$ lower estimates of SSB for the last 15 years. Until this change in the perception of the stock size is explained it will not be possible to use the assessment for a quantitative catch advice.

Catch forecast for 2002: The assessment is not certain enough to be used as basis for a catch forecast.

Elaboration and special comment: Fishing mortality was high during the 1970 s due to a transfer of effort from other closed herring fisheries and the operation of an industrial fleet. Since 1981 the size of the exploiting fleets in this area has declined and the industrial fishery has closed.

Survey indices have been revised and the new assessments are based on the same catches with additional survey data series providing more information on recruitment and the age structure of the stock. Further exploratory analyses are required before the current assessment can be regarded as stable.

In 2000, the catch was lower because some quota holders did not participate in the fishery.

Many aspects of the biology and fisheries data changed rapidly in the mid-1980s, affecting assessment results. These changes require further investigations and depending on the causes of the changes, reference points may be affected. If the changes are a result of stock components being exploited by the fishery, any similar changes in the future could cause serious problems for producing reliable assessments.

### 3.9.1 Overview

## Fleets and fisheries

Most of the demersal fisheries in this area have a mixed catch. Although it is possible to associate specific target species with particular fleets, various quantities of cod, whiting, hake, anglerfish, megrim, sole, plaice and Nephrops are taken together, depending on gear type.

In the Celtic Sea and Western Channel, fisheries for demersal species, mainly cod, whiting, sole and plaice, are conducted by Belgium, France, Ireland and the UK. The principal gears used are otter trawls and beam trawls. The targeting of sole and plaice using beam trawls became prevalent during the mid-1970s, leading to an increase in the landings of these two species. The gradual replacement of otter trawls by beam trawls has occurred in the Belgian and UK fleets. In the Bay of Biscay there has been a substantial replacement of inshore trawling by gill-net fisheries targeting sole.

A trawl fishery for anglerfish by Spanish and French vessels developed in the Celtic Sea and Bay of Biscay in the 1970s and expanded until 1990. In addition, a gill net fishery has developed in the Celtic Sea in the 1990 s. Selectivity is known to be poor for these species.

Nephrops are an important component of the fisheries in this area. These fisheries developed in the 1970s and 1980s. Fishing effort has decreased continuously since the early 1990s. However, gear efficiency has increased in recent years and this may have helped maintaining LPUE at relatively high levels. In the Bay of Biscay, since $1^{\text {st }}$ January 2000, the mesh size used when firshing for Nephrops has increased and is now similar to the one used for other demersal fish ( 70 mm ). Management of these fisheries needs to be sensitive to by-catches of stocks requiring protection such as Celtic Sea cod and Northern hake.

There are separate trawl fisheries targeting herring in the Celtic Sea and mackerel and horse mackerel in the whole area. The herring fishery is principally a "roe" fishery and discard rates have at times reached very high levels, but not in the most recent two years. There is also a small directed fishery for sprat in the Channel.

## Management measures

The assessment units used for many of the demersal stocks in this area are small and catches deriving from them are generally in the region of 10000 t or less. However, the TACs set for the stocks often cover many assessment units. In addition, for some units, there are
still insufficient data for adequate assessments. This means that TACs comprise a summation across units of analytical forecasts and average catches which may offer no effective management control of the exploitation rate. Since a number of stocks affected by this problem are close to or outside safe biological limits, there is a need to reconsider the areas on which TACs are set if management is to improve.

A notable feature of the demersal fisheries in this area is their mixed nature. The effectiveness of single species TACs is likely to be diminished unless this is taken into account. Use of measures to reduce fishing mortality directly, such as effort reductions in fleets, is likely to avoid a number of the disadvantages of catch controls in regulating the exploitation rate.

The fisheries in the Celtic Sea are very similar to the fisheries in the Bay of Biscay and some of the same fleets operate in both areas. However, the technical measures in the two areas differ. Despite the revision by the European Commission Technical Conservation Regulation of existing technical measures in $1^{\text {se }}$ January 2000, the minimum mesh sizes in the Celtic Sea are still often different from those in the Bay of Biscay. These differences make enforcement more difficult.

The catch includes a large amount of juveniles of some late-maturing species (anglerfish, hake). While improving selectivity to prevent any catch of hake less than 55 cm (length of maturity for females) seems to be difficult, some selective devices such as rigid grids should be promoted to protect juveniles of the incoming strong year-classes of white anglerfish.

## State of the stocks

The majority of fish stocks which are assessed in this area are harvested outside safe biological limits. They are characterised by low spawning stock biomass and recent high fishing mortality rates. Of particular concern are Celtic Sea (VIIf,g) and Western Channel (VIIe) sole and plaice, Celtic Sea (VIle-k) cod and Bay of Biscay (VIIIabd) sole. These stocks exhibit high F, low SSB and low recruitments in most recent years.

The Celtic Sea whiting stock has been fluctuating within safe biological limits, following period of low and high recruitment.

The assessment of Celtic Sea haddock was considered preliminary due to the short time series. Recruitment
seems to be highly variable influencing the variation in the stock size. This is also reflected in the landings.

Anglerfish and megrim are close to safe biological limits Recent recruitment of L. piscatorias (1998-1999 year classes) are well above average.

The Northern hake stock is discussed fully in Section 3.12.2. It is important to note that this species is taken by most of the demersal fleets in this area. This hake stock is outside safe biological limits, and a rebuilding plan is needed in order to rebuild the SSB.

There are no major concerns about the Nephrops stock in the Celtic Sea.

The Nephrops stock in the Bay of Biscay has been declined since the early 1990s. A strong reduction in the fishing mortality and an improvement of the selection pattern is required. The recent increase (from 55 mm to 70 mm ) which occurred in 2000 is unlikely to have improved selectivity significantly.

The abundance of anchovy varies considerably according to fluctuations in recruitment which is likely to be strongly dependent on environmental factors. In 2001 , the stock is inside safe biological limit.

The mackerel caught in the area belong to the Southern and Western spawning components. The Western horse mackerel has declined rapidly since the mid 1980s and is estimated to continue to decline.

### 3.9.2 Cod in Divisions VIIe-k

State of stock/exploitation: The stock is outside safe biological limits. SSB has decreased since 1996, is currently below $\mathbf{B}_{\mathrm{pa}}$, at $\mathbf{B}_{\text {lim }}$, and close to a historical low estimate. Recruitment is highly variable. The 1997 and 1998 year classes are well below average and the 1999 year class is estimated to be above. Fishing mortality
shows a generally increasing trend since the early 1980s and has fluctuated well above $\mathbf{F}_{\mathrm{pa}}$ since 1989. Fishing mortality has been above $\boldsymbol{F}_{\text {lim }}$ since 1998.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (established in 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 5400 t, the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\text {pa }}$ be set at 10000 t . Biomass above this affords a high <br> probability of maintaining $S S B$ above $B_{\text {lim, taking into }}$ <br> account the uncertainty in assessments. |
| $\mathbf{F}_{\text {lim }}$ is 0.90, the fishing mortality estimated to lead to <br> potential collapse. | $\mathbf{F}_{\text {pa }}$ be set at 0.68. This $F$ is considered to have a high <br> probability of avoiding $F_{\text {lim }}$ and maintaining $S S B$ above <br> $\mathbf{B}_{\text {pa }}$ in the medium term, taking into account the <br> uncertainty assessments. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}_{\mathrm{a}}}=$ historical development of the stock |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ based on historical response of the stock | $\mathbf{F}_{\mathrm{pa}}=5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}$ |

Advice on management: ICES recommends that fishing mortality should be reduced to less than 0.55 which is below $\mathrm{F}_{\mathrm{p}}$, corresponding to landings of less than 5300 t in 2002. This represents a reduction in $F$ of $45 \%$ and this would allow SSB to reach $B_{p a}$ in the short-term.

Comparison with previous assessment and advice: The current assessment estimates are very similar to those obtained last year. This year's advice is stronger than the one provided last year because of the further decline in the stock size, the uncertainty in the strength of the 1999 year class and high contribution of assumed 2000-2001 year classes to SSB in 2003. Mean weights at age have been revised for years prior to 1980.

## Relevant factors to be considered in management:

Even though advised reduction in fishing mortality is
higher than last year, the catch corresponding to present advice is higher than the catch advised last year due to recruitment of the strong 1999 year class. This year class contributes about $50 \%$ to the catch in 2002 .

The assessment area was expanded in 1997 to cover Divisions VIle-k. The TAC for cod is set for all of Subarea VII (excluding Division VIIa) and Division VIII. In order to protect cod in Divisions Vחe-k, the TAC should be allocated on a stock basis. If setting an overall TAC for Sub-areas VII(excl. Division VIIa) and VIII, the state of cod in Division VIId that is assessed as part of the North Sea stock should be considered.

The yield-per-recruit model suggests that a reduction in F to $\mathbf{F}_{\text {max }}$ ( $=0.29$ ) will increase the long-term yield.

## Catch forecast for 2002:

Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)=1.00 ;$ Landings $(2001)=8.1 ; \mathrm{SSB}(2002)=7.9$.

| $\mathrm{F}(2002)$ onwards | Basis | Catch(2002) | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: | :---: |
| 0.4 | $0.4 \mathrm{~F}_{98-90}$ |  | 4.1 | 11.4 |
| 0.5 | $0.5 \mathrm{~F}_{98-00}$ |  | 5.0 | 10.4 |
| 0.55 | $0.55 \mathrm{~F}_{98-60}$ |  | 5.3 | 10.0 |
|  |  |  | , \#\#, | 9\%走 |
|  | \%ikn |  |  |  |
| $\%$ | 318ines. |  |  |  |

[^35]Catch and SSB are sensitive to the strength of the 1999 yeat-class, which still needs to be confirmed. Also about $60 \%$ of SSB in 2003 (ages 2-3) is based on long-term geometric mean recruitment.

Medium- and long-term projections: Assuming the current selection pattern, fishing at $\mathbf{F}_{\text {max }}$ would require a $71 \%$ reduction in F .

Elaboration and special comment: Cod in Divisions VIIe-k are taken as a component of catches in mixed trawl fisheries. Landings are made mainly by French gadoid trawlers, which prior to 1980 were mainly fishing for hake in the Celtic Sea. Landings of cod by French Nephrops trawlers have fluctuated between $10 \%$ and $20 \%$ of the total French cod landings from this stock in recent years. UK (England and Wales) accounts for about $10 \%$ and Ireland for $15 \%$, while Belgian vessels take about $5 \%$. Landings are made throughout the year, but mainly in the winter months during November to April.

Analysis of landings trip by trip for the French gadoid trawlers for the period 1996-1999 showed that on a trip basis, cod and whiting were mixed. Information from the fishery indicates that on a haul basis, these two species are rather well separated. This means that fishermen seem to be able, for each trawl operation, to target cod and whiting separately. In Ireland in recent years, cod has increasingly been the target, using gillnet rather than trawl.

Most cod spawning in the Celtic Sea occurs off northern Conwall in mid to late March. There is also some spawning off south-east Ireland and a little in the

Western Channel. Tagging studies have given no evidence of cod movement out of Division VIIe, where there appears to be a simple inshore-offshore migration between deep-water wrecks and reefs in the summer and inshore spawning areas in the winter. Recent tagging work in the Irish Sea suggest that only a small component of cod landings from the Celtic Sea are fish which spawn in the Irish Sea. Furthermore, no cod tagged in the Celtic Sea were recaptured in the Irish Sea.

The analytical assessment was based on landing data and CPUE data for four commercial fleets and one survey. Landing data prior to 1988 are not available for Divisions VIIe,j and $k$ and have been estimated assuming the same relative area distribution of landings as observed in the period 1988-1998. Landings for France in 1999 and 2000 are based on official landings for the TAC area and log book data.

### 3.9.3 Whiting in Divisions VIIe-k

State of stock/exploitation: The stock is within safe biological limits. SSB reached high levels in 1995 and 1996, and has decreased until 1999 though remaining well above $\mathbf{B}_{\mathrm{pa}}$. In 2001 SSB reaches a record high mainly due to the outstanding 1999 year class. Fishing mortality was very high during the 1980 s, decreased in
the early 1990s and is currently estimated to be around 0.5 .

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 15000 t, the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 21 000 t . Biomass above this affords a high <br> probability of maintaing SSB above $\mathbf{B}_{\text {lim }}$, taking into <br> account the uncertainty of the assessment. |
| $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ not proposed. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.4$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{iim}}$ not proposed. | $\mathbf{F}_{\mathrm{pa}}$ not proposed. |

Advice on management: There is no $F_{p a}$ defined for this stock, but there is no long-term gain in increasing fishing mortality. Therefore, ICES recommends that fishing mortality should not increase, corresponding to landings of at most 27700 t in 2002.

Comparison with previous assessment and advice: Last year there was not enough information to confirm the strength of the 1999 year class and ICES used a geometric mean of past recruitment for prediction purposes. This outstanding year class is now consistently estimated in two surveys and verified by one commercial fleet. There was a slight downward revision
of $F$ and an upward revision of $S S B$ in the current assessment. Addition of new tuning fleets contributed further to the revision of SSB.

Relevant factors to be considered in management: The assessment area was expanded in 1997 to cover Divisions VIIe-k. The TAC for whiting is set for all of Sub-area VII (excluding Division VIIa). In order to protect whiting in Divisions VIIe-k, the TAC should be allocated to Divisions and catches in the other parts of Sub-area VII be accounted against such TACs. The state of whiting in Division VIId should be considered, if setting an overall TAC for Sub-area VII.

## Catch forecast for 2002:

Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)=0.49 ;$ Landing $s(2001)=23.4 ; \mathrm{SSB}(2002)=73.7$.

Weights in "000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: $\mathbf{F}_{\text {max }}$ is not well estimated due to a flat-topped Y/R curve.

Elaboration and special comment: The landings in 2001 are predicted to be considerably higher than the advised TAC because of the contribution of the outstanding 1999 year class. In $200346 \%$ of SSB is predicted to consist of fish from this year class.

Celtic Sea whiting are taken in mixed species (cod, whiting, hake, Nephrops) fisheries. French trawlers account for about $60 \%$ of the total landings, Ireland $30 \%$ and the UK (England and Wales) 7\%, while Belgian vessels take less than $1 \%$. The French Nephrops trawlers have for several years adopted a larger mesh, following by-catch restrictions and market demand for larger Nephrops. Landings for France in

2000 are based on official landings for the TAC area and computed log books.

Analysis of landings trip by trip by the French gadoid trawlers for the period 1996-1998 showed that on a trip basis, cod and whiting were mixed. Information from the fishery indicates that on a haul basis, these two species are rather well separated. This means that fishermen seem to be able, for each trawl operation, to target cod and whiting separately.

The main Irish fleets in Divisions VIIf,g,h are inshore and offshore otter trawlers and seiners based in Dunmore East and Kilmore Quay. However, in recent years there has been an increase in the number of Irish beamers ( +6 vessels) targeting anglerfish and megrim with whiting as by-catch, offshore in Division VHg. Division VII-k whiting are taken in a mixed species fisheries (cod/whiting/anglerfish/megrim and Nephrops). The main gears used are otter trawl and seiners, and landings are taken by Ireland ( $90 \%$ ) and France ( $7 \%$ ).

The main Irish fleet in Divisions $\mathrm{VIIj}, \mathrm{k}$ are otter trawlers that target mixed gadoids and account for $10 \%$ of landings of whiting in Divisions VIle-k. The main UK fisheries in Divisions VHe,f,g,h are inshore between Newlyn and Salcombe and off the north Cornish coast, the bulk of the landings ( $>60 \%$ ) being made in the winter months between November and March. UK landings in the 1950s were 4-5 times higher than at present, though landings overall have generally increased during the period since 1982, with peaks in 1989 (16540 t) and in 1995 (22680 t). The main gears used in the Western Channel are otter-trawls targeting
a wide range of species, and beam-trawls targeting sole, anglerfish and plaice.

The main spawning areas of whiting in the Western Channel and Celtic Sea are off Start Point (VIIe), off Trevose Head (VIIf), and south-east of Ireland (VIIg). Returns of adult whiting tagged in the Western Chamel indicated more movement into the Celtic Sea than between the Western and Eastern Channel. Whiting released in the Bristol Channel moved south and west towards the two spawning grounds off Trevose Head and south-east of Ireland. There was no evidence of emigration out of the Celtic Sea area. The results of returns of whiting tagged and released in the County Down spawning area show that a greater proportion of Irish Sea whiting move south into the Celtic Sea than north towards the west of Scotland.

Analytical assessment is based on landings, commercial CPUE, and surveys data. Some information on discards indicates that they may be substantial,

Source of information: Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, September 2001 (ICES CM 2002/ACFM:05).

Yield and spawning biomass per Recruit F-reference points:

### 3.9.4 Celtic Sea plaice (Divisions VHf and g)

State of stock/exploitation: The stock is outside safe biological limits. SSB decreased sharply from 1988 to 1997 when it fell below $B_{p a}$. Since then SSB has continued to decline at a lower rate. Fishing mortality has
fluctuated around the average. Most recent year classes have been below average.

Management objectives: There are no explicit. management objectives for this stock.

Precautionary Approach reference points (established in 1998, modified in 2001):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 1100 t, the lowest observed spawning stock <br> biomass $\mathbf{B}_{\text {losss }}$ | $\mathbf{B}_{\text {pa }}$ be set at 1800 t . Biomass above this affords a high <br> probability of maintaining SSB above $\mathbf{B}_{\text {iim }}$ taking into <br> account the uncertainty assessments. |
| $\mathbf{F}_{\text {lim }}$ not defined. | $\mathbf{F}_{\mathrm{pa}}$ not defined |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} * 1.64$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Not defined | $\mathbf{F}_{\mathrm{pa}}$ not defined |

Advice on management: ICES recommends a reduction in $F$ of at least $35 \%$ relative to $F_{s q}$, corresponding to landings of less than 680 t in 2002. This is consistent with the reduction in $F$ recommended for sole, which is the target species for the flatfish fishery in this area. This is expected to result in an increase in $\operatorname{SSB}$ to $\mathbf{B}_{\mathrm{pa}}$ in the short-term.

Comparison with previous assessment and advice: Results of this assessment are very close to the previous one. As previously, advice has been based on Sole,

Previously adopted $\boldsymbol{F}_{\mathrm{pa}}\left(\mathbf{F}_{\text {met }}\right)$ is no more relevant. The fishing mortality has been fluctuating around the previously adopted $\mathbf{F}_{\mathrm{pa}}$ during the assessment period, and this has not prevented the stock from declining below $\mathbf{B}_{\mathrm{pa}}$. However, a new proposal for $\mathbf{F}_{\mathrm{pa}}$ is postponed until a new basis is found.

Relevant factors to be considered in management: Given the apparent low recruitment since 1989, SSB is unlikely to increase at current fishing mortality.

Catch forecast for 2002:
Basis: TAC constraint; Landings $(2001)=0.76 ; \mathrm{F}(2001)=0.50 ; \mathrm{SSB}(2002)=1.57$.

| F(2002) onwards | Basis | Landings (2002) | SSB(2003) |
| :---: | :---: | :---: | :---: |
| 0.37 | $0.6 \mathrm{~F}_{98-00}$ | 0.63 | 1.84 |
| 0.40 | $0.65 \mathrm{~F}_{98-100}$ | 0.68 | 1.80 |
|  |  |  |  |
| $\overline{7}$ |  |  |  |
|  |  | \%191月 | 气. |
|  |  | $\frac{10}{20}$ | $3$ |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Assuming the current selection pattenn, $\mathbf{F}_{\text {max }}$ is estimated to be $0.36 \mathbf{F}_{\text {sq }}$. Assuming status quo F in 2001, results of the mediumterm analysis indicate that the probability of SSB falling below $\mathbf{B}_{\mathrm{pa}}$ after 10 years is less than $5 \%$ when fishing mortality is reduced by $35 \%$ in 2002 onwards.

Elaboration and special comment: The fisheries that catch plaice in the Celtic Sea mainly involve vessels from France and Belgium: Total landings are split among France ( $39 \%$ ), Belgium ( $30 \%$ ), England and Wales (24\%), and Ireland (the remaining 7\%).

In the 1970s, the Divisions VIIf,g plaice fishery was mainly carried out by Belgian beam trawlers and Belgian and UK otter trawlers. Effort in the UK and Belgian beam-trawl fleets increased in the late 1980s, but has since declined. Recently, many otter trawlers have been replaced by beam trawlers, which target sole. Landings gradually increased until 1989, then declined rapidly in 1991. The main fishery occurs in the spawning area off the north Cornish coast, at depths greater than 40 m , about 20 to 25 miles offshore. Although plaice are taken throughout the year, the larger landings occur during

March after the peak of spawning, and again in September.

There is some evidence from tagging that plaice from the south and west coasts of Wales move southwards to join the adult population off the north Comish coast during spawning.

Analytical age-based assessment using landings, survey, and commercial CPUE data.

### 3.9.5 Sole in Divisions VIIf and g (Celtic Sea)

State of stock/exploitation: The stock is outside safe biological limits. Fishing mortality has increased since the late 1970s, exceeding $\mathbf{F}_{\mathrm{pa}}$ since the early 1980s, and sometimes has even exceeded $\mathbf{F}_{\text {lim }}$. SSB has declined steadily since the early 1970s. SSB fell below $\mathbf{B}_{\mathrm{pa}}$ in 1995 and has remained low since then. Recruitment has
fluctuated with some peaks: the 1970, 1989 and 1998 year classes are the strongest.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not defined | $\mathbf{B}_{\mathrm{pa}}$ be set at 2200 t. There is no evidence of reduced <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ can <br> therefore be set equal to the lowest observed SSB. |
| $\mathbf{F}_{\text {lim }}$ is 0.52, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\text {pa }}$ be set at 0.37. This $F$ <br> probability of avoiding $\mathbf{F}_{\text {lim }}$ and maintaining SSB above <br> $\mathbf{B}_{\mathrm{pa}}$ in 10 years, taking into account the uncertainty of <br> assessments. |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Not defined | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\text {loss }}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim: }}: \mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} \times 0.72 ;$ implies a less than 5\% probability that <br> $\left(S S B_{M T}<\boldsymbol{B}_{p a}\right)$ |

Advice on management: ICES recommends that the fishing mortality should be reduced to below $\mathrm{F}_{\mathrm{pa}}$ corresponding to landings of less than 1000 t in 2002. This corresponds to a reduction of $\mathbf{3 5 \%}$ from status $q u o \mathrm{~F}$, and will promote an increase in SSB above $B_{\mathrm{pa}}$ in the short-term.

Comparison with previous assessment and advice: Results are very close to those of the previous assessment.

Relevant factors to be considered in management: The assessment indicates a large 1998 year class, and SSB is
expected to increase in the short-term. However, outstanding year classes have only been produced at long intervals and the stock increase is therefore likely to be temporary. The 1998 year class contributes $36 \%$ to the landings in 2002 . This year class will not be fully mature until 2003, and the high exploitation before 2003 will reduce the potential for this year class to contribute to the SSB.

Sole is taken manly in a directed beam-trawl fishery with plaice as a by-catch, and to a lesser extent in otter trawl fisheries. Management should take account of the mix of Celtic Sea sole and plaice.

Catch forecast for 2002:
Basis: $\operatorname{TAC}$ constraint; Landings $(2001)=1.02 ; F(2001)=0.43 ; \operatorname{SSB}(2002)=2.40$.

| F(2002) | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0.34 | $0.6 \mathrm{~F}_{98-90}$ | 0.94 | 2.71 |
| 0.37 | $0.65 \mathrm{~F}_{98-00}=\mathrm{F}_{\mathrm{pa}}$ | 1.00 | 2.64 |
|  |  |  |  |
|  |  |  |  |
|  |  | $4$ | 啮的 |

Weights in " 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Assuming status quo $F$ in 2001, results of the medium-term analysis indicate that the probability of $S S B$ falling below $B_{p a}$ after $5-10$ years is less than $5 \%$ when fishing mortality is reduced below $\mathbf{F}_{\mathrm{pa}}$ from 2002 onwards. Assuming the current selection pattern, $\mathbf{F}_{\text {max }}$ is $0.46^{*} \mathbf{F}_{\text {sq }}$.

Elaboration and special comment: The fisheries for sole in the Celtic Sea and Bristol Channel involve vessels from Belgium, taking $2 / 3$, the UK $1 / 4$, and France and Ireland taking minimal amounts of the total landings. The sole fishery is concentrated on the north Comish coast off Trevose Head and around Lands End.

Sole are taken mainly in a beam trawl fishery that started in the early 1960 s and，to a lesser extent，in the longer established otter－trawl fisheries．In the 1970s， the fishery was mainly carried out by Belgian beam trawlers and Belgian and UK otter trawlers．The use of beam trawls（to target sole and plaice）increased during the mid 1970s，and the Belgian otter trawlers have now been almost entirely replaced by beam trawlers．Effort in the Belgium beam－trawl fleet increased in the late 1980s as vessels normally operating in the North Sea were attracted to the west by improved fishing opportunities．Beam－trawling by UK vessels increased substantially from 1986，reaching a peak in 1990 and decreased thereafter．In the Celtic Sea，the beam and otter trawl fleets also take plaice，rays，brill，turbot and anglerfish．

The main spawning areas for sole in the Celtic Sea are in waters $40-75 \mathrm{~m}$ deep，off Trevose Head，and spawning usually takes place between February and April．Juvenile sole are found in relatively high abundance in depths up to 40 m ，and adult sole（fish
aged 3 plus）are generally found in deeper water． Spawning and nursery grounds are well defined．

The results of recent tagging experiments suggest that there is only limited movement of sole between the Bristol Channel and adjacent areas．

Age－based analytical assessment using catch－per－unit effort data from two commercial fleets and one survey．

| 1998 | 5271 | 1586 | 875 | 0.669 |
| 1999 | 8787 | 1659 | 1012 | 0.630 |
| 2000 | 5668 | 1605 | 1091 | 0.424 |
| 2001 | 4551 | 2001 |  | 0.426 |
| Average | 4893 | 2998 | 1148 | 0.442 |

State of stock/exploitation: The stock is outside safe biological limits. SSB peaked in 1988-1990, following a series of good year classes in the mid-1980s, but has declined rapidly to well below $\mathbf{B}_{\mathrm{pa}}$ until 1995 and has remained low since then. Fishing mortality increased in the 1980 s and has fluctuated well above $\mathbf{F}_{\mathrm{pa}}$ in the 1990 s.

In recent years recruitment has been mostly below average.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 1300 t, the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\text {pa }}$ be set at 2500 t. This is the previously proposed <br> MBAL. <br> Biomass above this affords a high probability of <br> maintaining $S S B$ above $B_{\text {im, }}$ <br> uncertainty in assessments. |
| $\mathbf{F}_{\text {lim }}$ not defined into account the |  |$\quad$| $\mathbf{F}_{\text {pa }}$ be set at 0.45. This $F$ is considered to have a high |
| :--- |
| probability of maintaining SSB above $B_{p a}$ in the medium |
| term, taking into account the uncertainty in assessments. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathrm{MBAL}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Not defined | $\mathbf{F}_{\mathrm{Pa}}=$ low probability that $\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$ |

Advice on management: ICES recommends that fishing mortality should be reduced to below $F_{\text {pa }}$ corresponding to catches of less than 890 t in 2002. This represents a reduction in $F$ of around $25 \%$ and will allow SSB to reach $\mathrm{B}_{\mathrm{p} 1}$ in three years with $\mathbf{5 0 \%}$ probability.

Comparison with previous assessment and advice: The current assessment estimates are very similar to those obtained last year.

Relevant factors to be considered in management: $A$ reduction in F of at least $70 \%$, corresponding to a catch of less than 400 t , would be required to promote $S \$ B$ above $\mathbf{B}_{\mathrm{pa}}$ in the short-term. If the advice for sole is followed, it will imply an approximate $40 \%$ reduction in F for plaice.

The TAC for plaice in the Channel is set for Divisions VIId, e combined, so the results from this assessment need to be considered along with those for the much larger Division VIId stock. Given that the Division VIId component dominates the TAC, a catch control does not guarantee that fishing mortality in Division VIle is constrained. To achieve a decrease in fishing mortality, a direct reduction in fishing effort in Division VПe, or a separate catch control, is necessary.

Plaice are taken in a mixed demersal species otter trawl fishery, and as a by-catch in the sole beam trawl fishery. Management measures should therefore be considered in conjunction with those for Division VIIe sole. There is anecdotal evidence of strategic mis-reporting of landings.

## Catch forecast for 2002:

Basis: $F(2001)=F(98-00)=0.61 ;$ Landings $(2001)=1.09 ; \operatorname{SSB}(2002)=1.77$.

| F(2002) | Basis | Landings (2002) | SSB(2003) |
| :---: | :---: | :---: | :---: |
| 0.18 | $0.3 * \mathbf{F}_{\text {sq }}$ | 0.40 | 2.50 |
| 0.25 | $\mathbf{F}_{\text {max }}$ | 0.53 | 2.38 |
| 0.37 | $0.6 * \mathrm{~F}_{\text {sq }}$ | 0.75 | 2.17 |
| 0.43 | $0.7 * \mathbf{F}_{s q}$ | 0.85 | 2.08 |
| 0.45 | $\mathrm{F}_{\mathrm{pa}}$ | 0.89 | 2.04 |
|  |  | §た |  |
|  |  |  |  |

Weights in '000 t.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Assuming the current selection pattern, $\mathbf{F}_{\text {max }}$ is $41 \%$ of $\mathbf{F}_{\text {sq. }}$

Elaboration and special comment: The fisheries taking plaice in the Western Channel mainly involve vessels from the bordering countries: The total landings are split among UK vessels ( $75 \%$ ), France ( $22 \%$ ) and Belgium (the remaining 3\%), Landings of plaice in the Western Channel were low and stable between 1950 and the mid1970s, and increased rapidly during 1976 to 1988 as beam-trawls began to replace otter-trawls, although plaice are taken mainly as a by-catch in beam-trawling directed at sole and anglerfish. Reported landings have been declining throughout the 1990s. The main fishery is south and west of Start Point. Although plaice are taken throughout the year, the larger landings are made during February, March, October and November.

Most plaice tagged whilst spawning during December to March around Start Point in the western Channel migrated into the eastem Channel and the North Sea after spawning, whilst few plaice tagged there during

April and May were recaptured outside the Channel. This suggests there is both a resident stock and one, which migrates to the North Sea after spawning in the Channel.

Analytical age-based assessment based on landings, survey, and commercial CPUE data. Mis-reporting of landings is known to occur.

### 3.9.7 Sole in Division VHe (Western Channel)

State of stock/exploitation: The stock is outside safe biological limits. SSB has declined since 1980 and has been estimated to be at its historic lowest level in 2001, well below $\mathbf{B}_{\mathrm{pa}}$. Although fishing mortality in the 1990s has been lower than in the 1980s, it is still estimated to be well above $\mathbf{F}_{\mathrm{pa}}$ and even above $\mathbf{F}_{\text {linn }}$. Since 1990 all year classes have been below average.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (changed in 2001): The age range used in this year's assessment has been extended from 10 to 12 years old, because historically the old age groups have been a significant part of the stock. This has resulted in a general downward revision of fishing mortality and upward revision of $\$ S B$. Therefore, the PA reference points needed to be re-evaluated.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 2000 t the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 2800 t. |
| Fim <br> potential stock collapse. |  |

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}:$ historical development: Biomass below this has <br> increased risk of reduced recruitment. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} \times 0.72$ |

Advice on management: ICES reconmends that $F$ should be reduced to below $\mathbf{F}_{\mathrm{pa}}$ corresponding to catches of less than 450 t in 2002.

Comparison with previous assessment and advice: For most recent years the assessment is similar to last year's assessment. In general, the trends in biomass and fishing mortality are similar to the previous assessment.

Relevant factors to be considered in management: Fisheries for sole also take plaice as a by-catch. This needs to be taken into account in management.

The advice represents a reduction in F of around $40 \%$ and will allow SSB to rebuild above $\mathbf{B}_{\mathrm{pa}}$ in 2004. In order to increase SSB above $B_{p a}$ in 2003 a reduction in $F$ of more than $95 \%$ would be required. This corresponds to catches of less than 40 t .

Catch forecast in 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)=0.32 ; \operatorname{Landings}(2001)=0.66 ; \operatorname{SSB}(2002)=2.10$.

| F(2002) onwards | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0.02 | $0.05 * \mathrm{~F}_{98-00}$ | 0.04 | 2.80 |
| 0.13 | $\mathbf{F}_{0.1}$ | 0.31 | 2.55 |
| 0.19 | 0.6* $\mathrm{F}_{98-00}$ | 0.43 | 2.43 |
| 0.20 | $\mathbf{F}_{\text {pa }}$ | 0.45 | 2.41 |
|  |  |  | \# |
|  |  |  |  |
|  |  |  |  |
| Ifs. | Nikyky |  |  |

Weights in ${ }^{\circ} 000 \mathrm{t}$.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: $F_{\text {max }}$ is poorly determined (yield per recruit curve flat-topped).

Elaboration and special comment: In recent years, UK vessels have accounted for around $60 \%$ of the total landings, with France taking approximately a third and

Belgian vessels the remainder. UK landings were low and stable between 1950 and the mid-1970s, but increased rapidly after 1978 due to the replacement of otter trawlers by beam trawlers. The principal gears used are otter-trawls and beam-trawls, and sole tends to be the target species of an offshore beam-trawl fleet,
which is concentrated off the south Comish coast，and also takes plaice and anglerfish and at times cuttlefish．

In the Westem Channel the peak spawning period of sole is April and May．The main spawning areas are to the west of the Isle of Wight and in the vicinity of Hurd Deep．The nurseries are in estuaries，tidal inlets and shallow，sandy bays．Adult sole in the Western Channel may recruit from local nurseries and from those in the Eastern Channel，but there is no evidence of subsequent emigration from the Westerm Channel．Coupled with the localised spawning areas in the western Channel，this suggests that adult sole are largely isolated from those found in northern Biscay，the eastern Celtic Sea，and the Eastern Channel．

Analytical assessment based on landings，survey，and commercial CPUE data．There is anecdotal evidence of strategic mis－reporting of landings from this stock，which
may compromise the assessment．Biological sampling data are good．Variations in effort and fleet catchability may occur as vessels move in and out of the fishery dependent on prevailing catch rates of sole．

|  |  |  |  |  |
|  |  |  |  |  |

State of stock/exploitation: The stock is outside safe biological limits. Fishing mortality has been variable, but with an increasing trend since 1984 and in 2000 is $70 \%$ above $\mathrm{F}_{\mathrm{pa}}$. SSB has remained relatively stable up to

1994, but has decreased sharply since then. Since 1994 recruitment has also decreased to the lowest on record.

Management objectives: There is no explicit management objective for this stock.

Precautionary Approach reference points (changed in 2001):
Revised assessment and new maturity ogive resulted in new estimates of reference points.

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ not defined. | $\mathbf{B}_{\mathrm{pa}}$ be set at 13000 t. The probability of reduced <br> recruitment increases when SSB is below 13 000 t. |
| $\mathbf{F}_{\text {lim }}=0.5$, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}=0.36$ |

## Technical basis:

| $\mathbf{B}_{\mathrm{lima}}=$ Not defined. | $\mathbf{B}_{\mathrm{pa}} \sim$ historical development of the stock [lowest <br> observed for the converged part of the VPA, i.e. the most <br> recent years are not included] |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ : based on historical response of the stock | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\mathrm{lim}} * 0.72$ |

Advice on management: In the light of the sharp decrease in SSB and recruitment since 1995, ICES recommends a recovery plan that will ensure a safe and rapid recovery of SSB to a level in excess of 13000 t . If a recovery plan is not implemented, ICES recommends that the fishing mortality should be reduced to the lowest possible level in 2002.

Rebuilding plan: Rebuilding of the sole stock can be obtained by reducing the fishing mortality, by improving the exploitation pattern, or by a combination of the two.

Setting the TAC at a low level may reduce fishing mortality, but past experience has shown that it is very difficult to control fishing mortality by TACs alone. ICES, therefore, recommends that in addition to a TAC, restrictions in effort of fleets exploiting sole should be implemented. Large closed areas and seasons may contribute to stock recovery, but only if accompanied by major reductions in effort.

The selection pattern improved in the late 1980 s when the gill net fishery expended. More than half of the sole is caught by gill net, and strong regulation of this fishery (limitation of number and length of nets) should be implemented, since no or small further improvement of selectivity of these nets is expected. However, improvement of selection pattern for the trawl fishery would contribute to stock recovery in the mediurn-term. It has to be noted that the stock of sole may benefit from the effort measures taken for the rebuilding of the hake stock.

A fishing mortality of zero in 2002 would allow SSB to almost reach $\mathbf{B}_{\mathrm{pa}}$ by 2003. However, a rebuilding plan could achieve this goal in 4-5 years. Fishing mortality
less than 0.24 ( $\mathrm{F}_{98-90}$ reduced by $60 \%$ ) in 2002, 2003 and 2004 is expected to rebuild it by 2004 with close to $50 \%$ probability (see text table below). The table also shows that a weaker reduction in $\mathrm{F}(50 \%)$ would require two years more to rebuild SSB above $\mathbf{B}_{\mathrm{pa}}$ with the same probability. Given the state of the stock, and the risk of impaired recruitment, this is not in accordance with precautionary approach.

Medium-term projections: Presented below from 2002-2006. The stock-recruitment relationship is assumed to have a flat asymptote for large SSB, (a Beverton and Holt $S-R$ ) The basis for the simulations is: $F(2001)=F_{s q}=F_{(98-00)}=0.59$.
$\mathbf{F}(\mathbf{2 0 0 2})$ onwards $=1.0 * F_{\text {sq }}:$ Catches $2002=4.2$.

| 2005 | 11.6 | 12.4 | 13.4 |
| 2006 | 12.2 | 13.2 | 14.3 |

Comparison with previous assessment and advice： The previous assessment was not considered reliable， because some landings and effort data were missing．This year＇s assessment gives a perception of a more rapid decline of the stock．

Relevant factors to be considered in management： Even though the exploitation pattern of this stock has improved in the past due to the development of the gillnet fishery（in the mid－1980s），fishing mortality is too high to allow a sustainable exploitation of this stock．

Catch forecast for 2002：
Basis： $\mathrm{F}(2001)=\mathrm{F}(98-00)=0.59$ ；Landings $(2001)=4.05 ; \mathrm{SSB}(2002)=7.78$ ．

Weights in ${ }^{6} 000 \mathrm{~L}$
Shaded scenarios considered inconsistent with the precautionary approach．

About $70 \%$ of the projected SSB in 2003 is based on recruitment of yearclasses the strength of which has not been verified neither by commercial fisheries nor by abundance surveys．The calculations are done assuming that these yearclasses have a strength equal to the geometric mean of past recruitment．

Elaboration and special comment：A succession of weak recruitments in recent years gives concern on the further development of the state of this stock if fishing mortality remains at this high level．

Catches have increased continuously until a maximum was reached in 1994 （ 7400 t ）．They decreased to 6300 t in 1995 and remained for 4 years between 6000 t and 6300 t ．They decreased again to 5400 t in 1999 and 5100 t in 2000 ．Since 1984，catches of sole by French small－mesh shrimp trawlers decreased markedly．The gill－net and trammel－net fisheries have expanded and account for more than half of the French landings in the last years．

Landings by Belgium beam trawlers increased rapidly in the late 1980 s and，since 1991，have been relatively constant at $6-9 \%$ of the total landings．Since 1996，an increase in effort of this fleet is associated with a decrease of its CPUE．

Analytical assessment based on landings，available discards information，and CPUE data series from 1984 to 2000．No recruitment indices are available for this stock． Data prior to 1984 are not considered reliable．A maturity ogive based on females has been applied instead of knife－ edge at age 3.

Unailocated landings may account for more than $25 \%$ of estimated landings．

## 3.9 .9 Celtic Sea and Division VIIj herring

State of the stock/exploitation: The stock status is unknown.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathrm{B}_{\text {lim }}$ is 26000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 44 000 t |
| $\mathrm{F}_{\text {lin }}$ : not defined | $\mathrm{F}_{\mathrm{pa}}$ : not defined |

Technical basis:

| $\mathbf{B}_{\text {lim: }}:$ The lowest stock observed | $\mathbf{B}_{\mathrm{pa}}:$ Low probability of low recruitment |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ not defined | $\mathbf{F}_{\mathrm{p}:}:$ not defined |

Advice on management: ICES recommends that catches be restricted to $6000 t$ for the first half of 2002, which is about $2 / 3$ of current landings during the $1^{\text {st }}$ half year. Advice for the second half of 2002 will be given in June 2002.

Relevant factors to be considered in management: It is difficult to give appropriate management advice for 2002 because of the uncertainty about the current stock size. A scientific program aimed at collecting additional biological information (including the age composition and distribution of the adult stocks throughout the Celtic Sea and Division VIIj) was organized by the local management committee and was carried out by the Irish Marine Institute during the period June to October 2001. This programme also included two acoustic surveys. Preliminary information from this program was presented to ICES in October 2001.

These data together with new data from the 2001/2002 fishery will be used by ICES in May 2002 to provide management advice for the second half of 2002.

Catches from this fishery in recent years have been taken almost exclusively by Ireland. The management of the Irish fishery is on a seasonal basis in which about $50 \%$ of the national quota is allocated to the January to February period, while the remainder is allocated to the mid-October to December period. A new management committee is currently monitoring the catches and if the fishery in the fourth quarter of 2001 is dominated by catches of small herring then the fishery will be closed immediately.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM: 12).

${ }^{1)}$ Preliminary.

### 3.9.10 Sprat in Divisions VIId,e

State of stock/exploitation: The state of the stock is not known.

Management objectives: There are no specific management objectives for this stock.

Elaboration and special comment: Insufficient data are available to carry out an assessment. Sprat catches are very low and are mainly taken in the second half of
the year by the Lyme Bay sprat fishery. The 2000 catch has decreased to 1710 t ; the catch has thus been lower than average since 1984.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

Catch data (Table 3.9.10.1):

## 3．9．11 Megrim（L．whiffiagonis）in Sub－area VII and Divisions VIUa，b，d

State of stock／exploitation：The stock is harvested outside safe biological limits．SSB was high from 1984 to 1988，then declined until 1990 and has been above $\mathbf{B}_{\mathrm{pa}}$ since then．The fishing mortality has declined from the 1991 peak until 1997 and has increased since then to above $\mathrm{F}_{\mathrm{pa}}$ ．Recruitment at age 1 has been relatively stable
with a peak in 1998．However，the strength of this 1997 year class needs to be contirmed．

Management objectives：There are no explicit management objectives for this stock．

Precautionary Approach reference points（established in 1998）：

| ICES considers that： | ICES proposes that： |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not defined | $\mathbf{B}_{\mathrm{pa}}$ be set at 55000 t ．There is no evidence of reduced <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ was <br> therefore set equal to the lowest observed SSB． |
| $\mathbf{F}_{\text {limu }}$ is 0．44，the fishing mortality above which stock <br> dynamics are unknown | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30, the estimated $\mathbf{F}_{\text {med }}$. This $F$ <br> with the proposed $\mathbf{B}_{\mathrm{pa}}$ and it approximates $\mathbf{F}_{\mathrm{MSY}}$. |

Technical basis：

| $\mathbf{B}_{\text {lim }}=$ | $\mathbf{B}_{\mathrm{Pa}}=\mathbf{B}_{\text {loss }}$ <br> $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }} ;$ implies a less than 5\％probability that <br> $\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$ |  |

## Advice on management：ICES recommends that

 fishing mortality should be reduced to below $F_{p a}$ ， corresponding to landings of less than 12400 t in 2002．Including a $5 \%$ contribution of $L$ ．bosciï in the landings，the equivalent TAC for the two species combined would be 13000 t ．Comparison with previous assessment and advice： Historical trends in F and SSB are similar to those in the previous assessment，with a slight downward revision in F and upward revision in SSB．The estimated high 1997
year class was out of the scope of the previous（two years ago）assessment．

Relevant factors to be considered in management： Until 1999，the minimum landing size of Lepidorhombus spp．in this area was 25 cm length． From $1^{\text {st }}$ January 2000 the minimum landing size for these species was reduced to 20 cm ．Technical measures such as increases in mesh size to reduce the catches of small fish should be investigated for this stock．

Catch forecast for 2002：
Basis：$F(2001)=F(98-00)$ scaled to $F_{00}=0.39 ;$ Landings $(2001)=16.4 ; \operatorname{Catch}(2001)=21.9 ; \operatorname{SSB}(2002)=62.6$ ．

| F（2002） | Basis | Catch（2002） | Landings （2002） | SSB（2003） |
| :---: | :---: | :---: | :---: | :---: |
| 0.16 | $0.4 \mathrm{~F}_{00}$ | 9.2 | 7.0 | 72.8 |
| 0.18 | $\mathrm{F}_{\text {max }}$ | 10.6 | 8.1 | 71.0 |
| 0.24 | $0.6 \mathrm{~F}_{60}$ | 13.2 | 10.1 | 67.8 |
| 0.30 | $\mathrm{F}_{\mathrm{pa}}$ | 16.3 | 12.4 | 64.2 |
| 3，部 |  | ， |  |  |
| $\hat{\vartheta}$ | Wivik |  | 步娄 |  |
| Yenk |  |  | \#1in |  |

Weights in＇ 000 t ．
Shaded scenarios considered inconsistent with the precautionary approach．

Projection of biomass and landings are sensitive to the strength of the 1997 year class．This 1997 year class contributes $33 \%$ to landings in 2002 and $20 \%$ to SSB in 2003.

Medium－and long－term projections：Assuming the current selection pattern， $\mathbf{F}_{\max }$ is $0.47 \mathrm{~F}_{\mathrm{sq}}$ ．

Elaboration and special comment：Estimates of recruitment are very dependant on discards information． Since discard data are available for some years only， derivations were carried out for years without information．In 1998，high discard estimates from France resulted in a large estimate of recruitment coming into the spawning stock biomass in 2000 ．No French discard data
for 1999 were available, and the data available on Spanish discards in 1999 indicated a large change in the discard pattern. For 2001 no discard estimates from France and Spain are expected.

Megrim in the Celtic sea, west of Ireland and in the Bay of Biscay are caught predominantly by Spanish and French vessels, which together have reported more than $60 \%$ of the total landings, and by Irish and UK demersal trawlers. For most fleets, megrim is taken in mixed fisheries for hake, anglerfish, Nephrops, cod and whiting. Most UK landings of megrim are made by beam trawlers fishing in Divisions VIe,f,g,h. Otter trawlers account for the majority of Spanish landings from Sub-area VII, the remainder being taken by gill netters prosecuting a mixed firshery for anglerfish, hake and megrim on the shelf edge around the 200 m contour to the south and west of Ireland. Irish megrim landings are largely made by multi-purpose vessels fishing in Divisions VIIb,c,g for gadoids as well as plaice, sole and anglerfish. Megrim landings have remained fairly stable over the period 1986-2000. Discards are estimated to be about $14 \%$ ( $27 \%$ in 1998) of the total catches by weight and comprise fish over a large range of sizes.

Megrim are widely distributed over the whole of Subareas VII and VIII and are most abundant in the deeper
waters of the continental shelf, Spawning takes place between January and April along the edge of the continental shelf to the southwest and west of the British Isles, and research vessel trawling surveys indicate that 0 -group megrim do not move far from the spawning grounds on the shelf edge during their first year.

Age-based analytical assessment using catch-per-unit effort from three commercial fleets and one survey. Discard estimates were used but were considered incomplete.

Source of information: Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, September 2001 (ICES CM 2002/ACFM:05).

Yield and spawning biomass per Recruit F-reference points:

State of stocks/exploitation: The stock of $L$ piscatorius is outside safe biological limits, and the stock of $L$. budegassa is inside safe biological limit. The SSB of both stocks decreased from 1986 until 1993, then increased up to 1995-1996 and are presently decreasing. For both stocks, fishing mortality in most years has been above $\mathbf{F}_{\mathrm{pa}}$. In 2000 fishing mortality is estimated to be about $\mathbf{F}_{\mathrm{pa}}$. Recent recruitments of $L$ piscatorius (1998 and 1999 year classes) are well above average, while those of $L$.
budegassa have decreased steadily in 1993-1998, and remained low in 1999-2000.

Management objectives: There are no explicit management objectives for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to reduce or maintain $F$ below $F_{p a}$, and to increase or maintain spawning stock biomass above $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (changed in 2000):
L. piscatorius:

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not defined | $\mathbf{B}_{\mathrm{pa}}$ be set at 31000 t . There is no evidence of reduced <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ can <br> therefore be set equal to the lowest observed $S S B$. |
| $\mathbf{F}_{\text {lim }}$ is 0.33, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.24. This F is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim }}$ taking into account the <br> uncertainty in assessments. |

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Not defined | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\text {loss }}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} \times 0.72$ |

## L. budegassa:

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}$ be set at 16600 t . There is no evidence of reduced <br> recruitment at the lowest biomass observed and $\mathbf{B}_{\mathrm{pa}}$ can <br> therefore be set equal to the lowest observed SSB, |
| $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathbf{F}_{\mathrm{med}}=0.23$. This F is consistent with the <br> proposed $\mathbf{B}_{\mathrm{pa}}$. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=$ Not defined | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Not defined | $\mathbf{F}_{\mathrm{pa}}=$ see above. |

Advice on management: ICES recommends that $F$ should be kept below $F_{p a}$. This corresponds to landings of less than $19900 t$ in 2002 for both species combined ( 14300 t L. piscatorius, and 5600 t L. budegassa). For Le piscatorius, this will allow SSB to rebuild above $B_{p a}$ in the short-term.

Comparison with previous assessment and advice: This assessment is quite different from the assessment performed in 2000 (using the 1999 data set). For $L$ piscatorius the inclusion of new survey and data from 1999-2000 resulted in a big upwards revision in F and downwards revision in SSB estimates for the most recent 5 years. In the case of assessment for $L_{\text {. }}$ budegassa no major changes have occurred. The recruitment estimates in the most recent years have changed substantially for both species. The status of $L$. piscatorius has been revised compared to last year.

Relevant factors to be considered in management: $L$ piscatorius and $L$ budegassa are both caught on the same grounds by the same fleets, and are usually not separated by species in landings; therefore, management measures for both species must be considered together and in conjunction with other species caught in these fisheries (sole, cod, rays, megrim, and hake). The management area for this stock also includes Division VIIa, where catches in recent years have been between 500 and 1300 t .

The fishery may become heavily dependant on two strong year classes ( $L$ piscatorius 1998-1999) entering in the fishery. In order to protect juveniles of these yearclasses the use of selective devices, such as rigid grids, should be promoted.

Catch forecast for 2002：
Basis：L piscatorius： $\mathrm{F}_{2001}=\mathrm{F}(98-00)=0.29$ ；Landings $(2001)=16.3 ; \operatorname{SSB}(2002)=28.3$ ．
Basis：$L$ budegassa： $\mathrm{F}_{2001}=\mathrm{F}(98-(00)=0.24$ ；Landings $(2001)=7.2 ; \operatorname{SSB}(2002)=20.1$ ．

Weights in＇ 000 t ．
Shaded scenarios considered inconsistent with the precautionary approach．

Medium－and long－term projections：Assuming the current selection pattern， $\mathbf{F}_{\max }$ is 0.32 and $0.58 \mathbf{F}_{\mathrm{sq}}$ for $L$ ． piscatorius and $L$. budegassa respectively．

Elaboration and special comment；Anglerfish landings from the west of the British Isles and down to the northern Bay of Biscay comprise two species－$L$ ． piscatorius and $L$ budegassa．$L$ piscatorius has a wide distribution in waters from the south－western Barents Sea to the Adlantic coast of Spain，whereas $L$ budegassa has a more southerly distribution，ranging from the British Isles in the north to Senegal in the south．Large specimens of both species are found in deep waters． Juvenile anglerfish have been caught both in deep water and along the shoreline，and discrete nursery areas have not been identified．

Anglerfish are an important component of mixed fisheries taking hake，megrim，sole，cod，plaice，and Nephrops．A trawl fishery by Spanish and French vessels developed in the Celtic Sea and Bay of Biscay in the 1970 s，and overall annual landings may have attained $35-40000 \mathrm{t}$ by the early 1980 s ．Even though fishing effort increased until 1990，landings decreased between 1986 and 1993，but returned to the original level 10 years ago，when France and Spain together reported more than $75 \%$ of the total landings of both species combined．The remainder is taken by the UK and Ireland（around $10 \%$ each）and Belgium（less than 5\％）．Otter－trawls（the main gear used by French，Spanish and Irish vessels） currently take about $80 \%$ of the total landings of $L$ ． piscatorius，while around $60 \%$ of UK landings are by beam trawlers and gill netters．Over $95 \%$ of total international landings of $L$ budegassa are taken by otter trawlers．There has been an expansion of the French gill net fishery in the last decade in the Celtic Sea and in the north of the Bay of Biscay，mainly by vessels based in Spain and fishing in medium to deep waters．Otter－ trawling in medium and deep water in ICES Sub－area VII appears to have declined，even though the
increasing use of twin trawls by French vessels may have increased significantly the overall efficiency of the French fleet．Fishing activity by UK gill netters and beam trawlers has remained relatively stable over the period 1986－1995．Belgium landings of anglerfish are exclusively by beam trawlers．

The analytical age－based assessment is based on landings， survey and commercial CPUE data．The catch－at－age matrix covers ages to $13+$ for $L$ piscatorius and to $14+$ for $L$ budegassa．Short－term predictions of landings and SSB are not sensitive to recent assumed recruitment．

### 3.10.1 Overview

## Fleet and Fisheries

The fishery in Divisions Vlib.c is mainly a trawl fishery although some gill netting is carried out. The fishery in Divisions VIIh-k is also a trawl fishery but gill netting is increasing in importance in the area. These are mixed fisheries for cod, haddock, whiting, hake, monk, megrim, sole and plaice; and cod and whiting are taken as by-catch in the Nephrops fishery. In recent years, there has been an increase in the number of seiners operating in the Irish fleet in Division VIIg, , targeting whiting and haddock .

Landing figures for these ICES Divisions are difficult to interpret as several countries differ in the manner in which they report their landings data for the various ICES Divisions.

Other species taken in the area are herring, mackerel and blue whiting (See Sections 3.9.9, 3.10.3, 3.12.3 and 3.12.5).

## Management Measures

There are single cod and whiting TACs covering the whole of Divisions VIIb-k so that assessment areas do not correspond to management areas. In 1997, the assessment areas for Celtic Sea cod and whiting were extended to include Divisions VIIj,k. The assessment areas now cover Divisions VIIe-k. There are separate plaice and sole TAC's for Division VIfbc and for Division VIIjk.

## State of the Stocks

Since stock monitoring programmes and annual groundfish and young fish surveys have been in place since 1993, assessments were carried out in 2001 for the stocks of sole and plaice in Division VIIbc and for Division VIIjk. Given the short time series, the preliminary assessments of the state of these stocks are considered only indicative of recent stock development.

SSB of Plaice in West of Ireland has declined steadily since 1994 and being below the average since 1998. SSB in 2000 is estimated at 164 t . Fishing mortality has fluctuated, thought with an increasing trend over the time series, although it decreased in 2000.

Recruitment has steadily declined, with values below the average since 1997, with exception in 2000, where recruitment is estimated higher than average, and above 1996 level.

SSB of Plaice in Southwest of Ireland has declined steadily, following a series of declining recruitment, and being below the average since 1998. SSB in 2000 is estimated at 599 t . Fishing mortality has decreased until 1996 and again in 1999 , being the lowest value in the time series, thought 2000 presented the second highest value. Recruitment has steadily declined, with values below the average since 1997.

SSB of Sole in West of Ireland has been constant in recent years, being above the average only in 1994 and 1996. SSB in 2000 is estimated at 248 t. Fishing mortality decreased until 1996, increased until 1999, bur decreased again in 2000. Recruitment has steadily increased, with the exception of 1995.

SSB of Sole in Southwest of Ireland has declined steadily, since 1996. SSB in 2000 is estimated at 609 t . Fishing mortality presents an increasing trend, thought in 2000 has a strong decrease. Recruitment has been variable, with a high value in 2000.

Fish in this area may only be components of larger stock complexes. It is still not clear if these stocks should be assessed with the stocks in the Celtic Sea or with the stocks off the West of Scotland.

There is a directed fishery for hake mainly in Divisions VIIh-k and an overview of hake is provided in Section 3.12.2.

Anglerfish and megrim are important species in this area, but are assessed for Sub-areas VII and VIII combined. An overview is provided in Sections 3.9.11 and 3.9.12.

Nephrops fisheries take place in Functional units $16-19$ (see Section 3.10.4 in the 1999 ACFM report). Catch per unit of effort is fluctuating without trend. There is a TAC for all of Sub-area VII. An overview of Nephrops stocks is provided in Section 2.4 in the 2001 ACFM report.

### 3.10.2

Demersal Stocks

### 3.10.2.a Haddock in Divisions VIIb-k

State of stock/exploitation: The state of the stock is unknown. A preliminary assessment of the state of this stock is considered only indicative of recent stock development. Recruitment seems to be highly variable. This is also reflected in the landings. There are some indications from surveys of good 1999-2000 year classes.

## Management objectives: none.

Precautionary Approach reference points: not defined.

Advice on management: ICES recommends not to increase landings above the average of the last four years of 8000 t . ICES recommends that a management plan, including monitoring of the development of the stock and of the fishery should be developed and implemented.

Relevant factors to be considered in management: This stock is presently managed by means of a TAC set
for the whole of Sub-areas VII, VIII, IX and X. The TAC currently includes an additional allocation for Division VIIa. The current TAC is not restrictive on catches from Divisions VIIb-k and creates the opportunity for mis-reporting from other areas.

Elaboration and special comment: Assessment of the state of this stock is difficult due to a short time series of assessment data. Catches of haddock are recorded along the entire western seaboard of the British Isles, with concentrations off the west coast of Scotland, off the NW coast of Ireland, in the Celtic Sea, and in the western Irish Sea. The extent of mixing between these areas is not presently known. However, recent patterns of recruitment and growth differ between areas.

Some information on discards indicates that they may be substantial.

Source of information: Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, September 2001 (ICES CM 2002/ACFM:05).

Catch data (Table 3.10.2.a.1):

${ }^{1}$ Applies to Sub-areas VII, VIII, IX and X. ${ }^{2}$ Possible underestimates due to misreporting. ${ }^{3}$ Increased in-year to 14000 t . ${ }^{4}$ Incomplete official statistics. ${ }^{5}$ Includes separate Division VIIa allocation of 4990 t . ${ }^{6}$ Includes separate Division VIIa allocation of 3400 t . Weights in 000 ' tonnes.

Haddock in Divisions VIIb-k

### 3.10.3 Herring in Divisions VIa (South) and VIIb,c

State of the stock/exploitation: The stock is considered to be outside safe biological limits. The SSB is likely to be below the proposed $\mathbf{B}_{\mathrm{pa}}$. Fishing mortality has decreased from a very high level, but is still in excess of the $\mathrm{F}_{\mathrm{pa}}$.

Management objectives: A local Irish management committee has been established for this stock. One of its aims is to rebuild the stock to above $\mathbf{B}_{\mathrm{pa}}$ over a threeyear period.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 81000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 110000 t |
| $\mathbf{F}_{\text {lim }}$ is 0.33 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.22 |

Technical basis:

| $\mathbf{B}_{\text {lim: }}:$ Lowest reliable estimated SSB | $\mathbf{B}_{\text {pa }}:$ Approximately $1.4 \mathbf{B}_{\text {lim }}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\text {pa }}:=$ Fmed 98 |

Advice on management: ICES recommends that the catches in 2002 should not exceed the 2001 TAC of 14000 t-

Rebuilding plan: A management and rebuilding plan for this stock is currently in place. A continuation of this should ensure that catches do not exceed the TAC and that the stock is rebuilt to $\mathbf{B}_{\mathrm{pa}}$ in the medium term.

Relevant factors to be considered in management: Recent changes to the management of the fisheries on this stock are likely to have greatly reduced the impact of misreporting and under-reporting of catches in this area. These changes to the reliability and composition of the catch data could have great impacts on the assessment, which is solely based on catch-at-age data. A few more years of consistent data under the current management regime will be necessary before it will be possible to produce reliable estimates of SSB and review the appropriateness of the reference points.

The management plan currently in place has led to a closure of this fishery in mid-February 2001, and it will not be re-opened until October 2001.

The high stock levels observed from 1984 to 1992 are the result of two high year classes in 1982 and 1986. No other year classes of this magnitude have been observed over the time series from 1970 to 2000 .

Comparison with previous assessment and advice: Perception of the stock is more uncertain this year, particularly with respect to being below $\mathbf{B}_{\text {lim }}$. The
provisional SSB was revised downwards and F revised upwards in this year's assessment.

Catch forecast for 2002: No forecast available.
Elaboration and special comments: In the absence of tuning data the assessment in recent years was carried out by assuming various terminal $F$ values on the catch at age data. These assessments appear to have poorly estimated F and this year some exploratory work was carried out in an effort to objectively select a terminal F. Dramatic changes to the age composition of the catch since 1998 make it impossible to reliably estimate terminal F .

Total catches have decreased and are in 2001 in line with the TAC since 1998. An acoustic survey has been resumed on the stock and commercial vessels have been equipped with data loggers to obtain information on the distribution of the stocks.

The fishery exploits a mixture of autumn- and winter/spring-spawning fish, which spawn from October to March. The winter/spring-spawning component is distributed in the northern part of the area. The main decline in the overall stock appears to have taken place on the autumn-spawning component, and this is particularly evident on the traditional spawning grounds in the southern part of the area.

Source of information: ACFM Working Document and Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2001 (ICES CM 2001/ACFM:12).

### 3.11

### 3.11.1 Overview

## The fisheries

The Iberian Region along the eastern Atlantic shelf is considered an upwelling area with high productivity; this phenomenon takes place during late spring and summer. The region is characterized by a large number of commercial and non-commercial fish species.

The fisheries are of a typical mixed nature. Different kinds of Spanish and Portuguese fleets operate: one is the mixed trawl fleet (single, pair and crustacean trawlers) fishing for hake, blue whiting, horse mackerel, megrim, anglerfish, mackerel, Nephrops, bib and cephalopods as the main species. Other fisheries are longliners fishing for hake and hand-line fishing for mackerel, fixed nets used for hake, anglerfish and mackerel and purse seiners which mainly target sardine and anchovy, but also horse mackerel and mackerel.

Many bottom trawlers are fishing in the southern part of Division IXa (Gulf of Cadiz); these trawlers are smaller than those operating in the northern parts of the Iberian Region. The composition of their catches is also different. They are fishing for hake as well as crustaceans, molluscs and cephalopods (Octopus etc.).

The number of trawlers has decreased since the early 1980 s, resulting in a decreasing trend in the overall effort in the Portuguese and Spanish fleets. The number ofo boats in fleets operating gillnets and long lines has also declined in recent years. Spanish boats using trawl, longline or fixed nets are currently subjected to a restricted entry system.

Two stocks of anchovy are considered in the Iberian Region, one in Sub-area VIII and one in Division IXa. The Spanish and French fleets fishing for anchovy in Sub-area VIII are well separated geographically and in time (the Spanish fleet operates mainly in Division VIIIc and VIIIb in spring and the French fleets in Division VIIIa in summer and autumn and in Division VIIIb in winter and summer). Changes in the catch-atage composition between the 1984-1996 period and the earlier years could be related to a higher dependence of catches on recruitment in recent years and a change in the seasonality in this fishery. The number of Spanish purse seiners for anchovy has remained stable since 1990 and a slight increase in the number of French purse seiners has been observed in the last five years. A sharp increase in fishing effort for anchovy in the Bay of Biscay has occurred since 1987 mainly due to the increased effort in the French pelagic trawl fleet.

Traditionally the anchovy fishery in Division IXa is located in the Gulf of Cadiz (Sub-division IXa South). However, in 1995 the bulk of the fishery was located to the North of Portugal and to the West of Galicia (SubDivision IXa North) and was very reduced in the Gulf of Cadiz, owing to exceptional availability of anchovy in the Northern part of the Division IXa. In recent years the bulk of the anchovy fishery in IXa is again located in the Gulf of Cadiz.

In Divisions VIIIc (East) and VIIIb the target species for the purse seine fleet change with the season anchovy in spring and tuna in the summer. This fleet changes gear and uses trolling and bait boats to catch tuna.

The catches of horse mackerel in Divisions VIIIc and LXa have been relatively stable over the last ten years. The proportion of landings by different gears has changed, i.e., trawl catches are decreasing while the purse seine catches are increasing.

During the 1990s the purse seine fleets in Divisions VIIIc West usually directed to sardine redirected the effort to horse mackerel because of lower availability of sardine in VIIIc West than during the 1980s.

Mackerel is a target species for the hand line fleet during the spawning season in Division VIIIc, during which about one third of the total catches are taken. It is taken as by-catch by the trawl fleets in Division VIIIc and IXa. The highest catches ( $80 \%$ ) from the Southern component are taken in the first half of the yearmainly from Division VIIIc and consist of adult fish. In the second half of the year, catches consist of juveniles and are mainly taken in Division IXa, as by-catches of the trawl fisheries. Catches from the southern component have been increasing in recent years and in 1998 and 1999 reached a maximum of 44000 t each year.

## Management measures

The fisheries in the Iberian Region are managed by a TAC system and technical measures. In 2000 a new EU regulation was established. Common mesh sizes for trawls are 55 mm , except for trawlers targeting blue whiting or horse mackerel ( 40 mm ) and these can only operate in depths $+-\leq 2000 \mathrm{~m}$. Other measures are minimum landing sizes and seasonal closures to protect juvenile hake.

At national level there are management measures enforced in the sardine fishery for restriction of days of absence from the ports, number of purse-seiners in activity, annual catch restrictions and seasonal closures. A minimum landing size is enforced at the international level,

A TAC for southern mackerel is in place, as a part of the Northeast Atlantic mackerel TAC.

In recent years data quality has improved including landing statistics and length composition, notably in the Gulf of Cadiz. Routine estimates of discards are only available for Northern Spanish waters in 1994, and 1999. For most of the stocks the sampling level of the landings is considered adequate for assessment purposes. The low level of samples of discards, particularly of undersized hake, is considered a problem.

The Iberian Region is an important nursery ground for hake, sardine, horse mackerel and blue whiting. Catches of fleets operating gears with low selectivity therefore contain significant quantities of juvenile fish.

## State of stocks

The stock of hake is outside safe biological limits. SSB decreased very sharply between 1982 and 1986 and gradually decreased thereafter. Recruitment has declined steadily in 1984-1991. However, the 1996 year class is estimated to be above average and comparable to year classes produced consistently in early 1980 s. Although there are indications that fishing effort has decreased since the early 1990 s, the estimate of a sharp decrease in fishing mortality on hake last three years was considered unreliable.

The anglerfish stocks ( $L$ piscatorius and $L$ budegassa) are outside safe biological limits. The biomass in recent years is estimated to be below $\mathrm{B}_{\mathrm{pa}}$ for both species.

The megrim stocks ( $L$. boscii and $L$. whiffiagonis) are outside safe biological limits. SSB of both species has decreased over most of the assessment period, Recruitment in both species appears to be falling. Fishing mortality has fluctuated with no clear trend.

Two stocks of Nephrops are considered in Division VIIIc and five in Division IXa. The landings are slightly decreasing in Division VIIIc while the catches fluctuate without a clear trend in Division IXa. The fishing mortality is low and stable for this area.

The southern horse mackerel (Trachurus trachurus) stock is harvested outside safe biological limits. Although the spawning stock is estimated to be above the proposed $\mathrm{B}_{\mathrm{pa}}$, fishing mortality in is still below $\mathrm{F}_{\mathrm{p} \text { a }}$.

The spatial distribution of Sardine in Divisions VIIIc and IXa changed as compared with the 1980s. The availability of sardine has decreased in the northern area, but remains constant in the southern area. It is not at present clear whether the observed change in distribution is due to a migration driven by climatic effects, a migration driven by a reduction in stock size, or due to a local depletion of independent population units. Whichever case pertains, a reduction in fishing mortality is advised to prevent further decline of spawning stock biomass and promote recovery.

The southern mackerel component is of the order of $25 \%$ of the Northeast Atlantic mackerel. Egg surveys also indicate that SSB of this component has increased.

### 3.11.2 Hake - Southern stock (Divisions VIIIc and IXa)

State of stock/exploitation: The stock is outside safe biological limits. SSB is currently estimated to be just. below $\mathbf{B}_{\text {pa. }}$ SSB decreased sharply between 1982 and 1986 and has since then remained low, although there has been an increase in the most recent years. Fishing mortality has been variable, but has generally declined since 1987. Status quo F is silightly above $\mathrm{F}_{\mathrm{pa}}$. Mean recruitment in the 1990s has been well below the average of the previous period.

Management objectives: There are no explicit management objectives for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to reduce or maintain $F$ below $F_{F}$ and to increase or maintain spawning stock biomass above $\mathbf{B}_{\text {pa }}$

Precautionary Approach reference points (established in 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 20500 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 33600 t |
| $\mathbf{F}_{\text {lim }}$ is 0.45 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.27 |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ the lowest observed spawning stock biomass | $\mathbf{B}_{\mathrm{pa}} \sim \mathbf{B}_{\text {lim }} \times 1.64$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ the fishing mortality above which the stock <br> dynamics are unknown | $\mathbf{F}_{\mathrm{pa}} \sim: \mathbf{F}_{\text {lim }} \times 0.61$ |

Advice on management: ICES recommends that fishing mortality be reduced to below $F_{p a}$ corresponding to a catch of less than 8000 t in 2002 . This allows SSB to increase above $B_{p a}$ in the shortterm.

Comparison with previous assessment and advice: The trends in recruitment, SSB and fishing mortality are similar to the previous assessment. Fishing mortality is slightly higher and SSB is slightly lower. There is still a systematic bias to under-estimate terminal fishing mortality, and to over-estimate SSB. The rationale for advice is the same as last year (based on $\mathbf{F}_{\mathrm{pa}}$ ).

Relevant factors to be considered in management: The present assessment is considered to give an accurate
picture of the historic development of this stock. However, biomass has been overestimated and fishing mortality underestimated in recent years. It is therefore possible that this assessment gives a too optimistic impression of the state of the stock, and future assessments may well revise the stock size downward.

In order to protect juveniles, fishing is prohibited in some areas during part of the year.

Hake is taken in a mixed species trawl fishery, and the management of other stocks such as horse mackerel, megrim and anglerfish needs to be taken into account when considering the requirements of the hake stock.

## Catch forecast for 2002:

Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)=0.28$; Landings $(2001)=8.6 ; \operatorname{SSB}(2002)=35.7$.

| $F(2002)$ on wards | Basis | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0.17 | $0.6 \mathrm{~F}_{(98.00)}$ | 5.2 | 41.0 |
| 0.21 | $\mathrm{F}_{0.1}$ | 6.4 | 39.7 |
| 0.22 | $0.8 \mathrm{~F}_{(98-40)}$ | 6.8 | 39.3 |
| 0.27 | $\mathbf{F}_{\mathrm{pa}}$ | 8.0 | 38.0 |
|  |  | 8, |  |
|  | 14Ifs.4x | y |  |
|  |  | $4$ |  |

## Weights in ' 000 t .

Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term predictions not reliable. $\mathbf{F}_{\text {max }}$ is not well defined.

Elaboration and special comment: Spanish and Portuguese fleets exploit this stock in a mixed fishery using trawls, gillnets and long lines.

Fishing mortalities on the recruiting year classes are estimated to be very low as small fish (less than 27 cm ) have been underreported in the landings since 1989. Low Fs (less than assumed natural mortality) on the older ages are also estimated by this assessment since 1995, possibly due to a change in target species. The assessment becomes unstable when $F$ is very low - the stock dynamics are driven by the natural mortality, not by the fishing mortality - therefore, medium-term predictions are not reliable.

Analytical assessment using commercial CPUE and survey data. Information from surveys at age 0 is
included in this year's assessment. The stockrecruitment relationship is driven by the high values of earlier years, since the recent values are clustered and do not show a clear relationship (recruitment in 2000 the lowest of the series). Combined age-length keys are used prior to 1993.

Source of information: Report of the Working Group on the Assessment of Southem Shelf Demersal Stocks, September 2001 (ICES CM 2002/ACFM:05).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 2-5 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |

### 3.11.3

State of stocks/exploitation: The state of these stocks in relation to precautionary reference points is not known. SSB of both species has decreased over most of the assessment period, but an increase has been observed since 1995. Fishing mortality for both species has generally declined during the 1990s. For both species current $S S B$ is estimated to be close to average and current fishing mortality is below average.

Management objectives: There are no explicit management objectives for these stocks.

Precautionary Approach reference points set in 2000: The time series is short and reference points were not defined.

Advice on management: In order to prevent a decline in SSB, ICES recommends that $F$ should be
kept below $F_{\text {sq }}$ ( 0.21 and 0.20 , respectively) for both species. This corresponds to landings in 2002 of less than 1220 t for $L$. boscii and of less than 330 t for $L$. whiffiagonis.

Comparison with previous assessment and advice: The trends in SSB, F and R are similar to last year's assessment.

Relevant factors to be considered in management: The TAC covers both megrim species ( $L$. boscii and $L$. whiffiagonis) and has been set well above actual catches in recent years.

Both megrim species are caught together in fisheries, which also take a large number of other commercial species, including southern hake.

Catch forecast for 2002 :
L. boscii: Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)=\mathrm{F}_{s q}=0.21$; Landings $(2001)=1.27 ; \operatorname{SSB}(2002)=6.09$.

| $\mathrm{F}(2002)$ onwards | Basis | Landings <br> $(2002)$ | SSB <br> $(2003)$ |
| :---: | :---: | :---: | :---: |
| 0.17 | $0.8 \mathrm{~F}_{98-00}$ | 1.01 | 6.37 |
| 0.21 | $1.0 \mathrm{~F}_{98-00}$ | 1.22 | 6.13 |
| 0.26 | $1.2 \mathrm{~F}_{98-00}$ | 1.43 | 5.91 |

Weights in ' 000 t .
L. whiffiagonis: Basis: $\mathrm{F}(2001)=\mathrm{F}(98-00)$ scaled to $\mathrm{F} 00=0.20$; Landings $(2001)=0.31 ; \operatorname{SSB}(2002)=1.63$.

| $\mathrm{F}(2002)$ onwards | Basis | Landings <br> $(2002)$ | SSB (2003) |
| :---: | :---: | :---: | :---: |
| 0.16 | $0.8 \mathrm{~F}_{98-00}$ | 0.27 | 1.74 |
| 0.20 | $1 \mathrm{~F}_{98-00}$ | 0.33 | 1.67 |
| 0.24 | $1.2 \mathrm{~F}_{98.00}$ | 0.38 | 1.61 |

Weights in '000 t. There are no Precautionary Reference points, and hence no shading was applied.

Elaboration and special comment: Megrim species are generally taken as a by-catch in mixed fisheries by Portuguese and Spanish trawlers, and also in small quantities by the Portuguese artisanal fleet. L. boscii accounts for about $70-90 \%$ of combined megrim landings. $L$ boscii is distributed equally in Divisions VIIIc and LXa, and $L$. whiffiagonis is distributed in both Divisions, with its highest abundance in Division VIIIc.

Total landings data for these stocks are not available before 1986. However, some Spanish ports have longer landing series for both species, and the Spanish survey provides abundance indices since 1983. These data
sources indicate stable, but low, abundance up to 1986, increasing sharply to 1990, and decreasing again to the low level observed in the initial years. In Divisions VIIIc and IXa the peak spawning period of both megrim species is in March.

Age-based analytical assessment using commercial CPUE and survey data.

### 3.11.4

State of stocks/exploitation: The combined stocks ( $L$. piscatorius and $L$ budegassa) are outside safe biological limits. The biomass of both species combined is estimated to be around $33 \%$ of the $\mathbf{B}_{\text {MSY }}$ in 2001, and the fishing mortality has been above the estimated $\mathbf{F}_{\text {MSY }}$ since the beginning of the time series.

Management objectives: There are no explicit management objectives for these stocks.

Precautionary Approach reference points: The ASPIC model provides estimates of the biomass relative to $\mathbf{B}_{\text {MSY }}$, and of $\mathbf{F}$ relative to $\mathbf{F}_{\text {MSY }}$. The $\mathbf{B}_{\text {MSY }}$ and $\mathbf{F}_{\text {MSY }}$ points are used in the advice as a lower boundary for the biomass and an upper boundary for $F$.

Advice on management: ICES advises that $F$ should be reduced by $30 \%$, corresponding to landings in 2002 of $3500 t$ for both species combined. This will allow $F$ to be at or below $F_{\text {MSY }}$ with high probability, and for biomass to increase to $\mathbf{B}_{\text {MSY }}$ in the mediumterm (around 2005).

Comparison with previous assessment and advice: Trends in both F and B ratios are similar to those in last year's assessments. For the most recent years, however, the estimate of the F-ratio is higher and the B-ratio is lower than in the last year's assessment. This is consistent with the retrospective pattern. There are some changes to the model parameters and this has resulted in a more optimistic forecast.

Relevant factors to be considered in management: Given that these two species are not usually sorted in the landings and that the proportion of landings by species is based on samples taken from the various ports, an assessment with both species combined was carried out. Previous TACs have been well above the landings. A portion of the catch of $L$. piscatorius and $L$. budegassa is taken together with other species in mixed trawl fisheries.

The length-frequency distributions of $L$. piscatorius indicate that in recent years there is no evidence of strong recruiting year classes.

## Catch forecast for 2002:

Both species combined ( $L$ piscatorius and $L$ budegassa)
Basis: $\mathrm{F}(2001)=\mathrm{F}(2000) ; \mathrm{F} / \mathrm{F}_{\mathrm{MSY}}=1.1 ;$ Landings $(2001)=3.5 ; \mathrm{B} / \mathbf{B}_{\mathrm{MSY}}(2002)=0.44$.

| F/F/ $\mathrm{MSY}^{(2002)}$ | Basis | Landings(2002) | B/B $\mathrm{B}_{\text {MSY }}$ (2003) |
| :---: | :---: | :---: | :---: |
| 0.7 | $0.7 * \mathrm{~F}_{00}$ | 3.5 | 0.66 |
| \% |  |  |  |
|  |  |  |  |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Elaboration and special comment: Both species are caught in mixed fisheries by Portuguese and Spanish fleets. In the early 1970 s , commercial interest for these species increased and a directed artisanal fishery developed in Spain, originally targeting large fish.

A surplus production model incorporating covariates (ASPIC) was used as in previous assessments. The model provides estimates of stock biomass and fishing mortality relative to their respective MSY values.

ASPIC is used to provide guidance reference points, as well as a perspective of the evolution of total biomass and prediction of landings under different fishing mortalities.

Source of information: Report of the Working Group on the Assessment of Southern Shelf Demersal Stocks, September 2001 (ICES CM 2002/ACFM:05).

## 3．11．5 Mackerel in Divisions VIII and IXa（Southern component）

Evaluation of this component is given in Section 3．12．3，dealing with the combined mackerel assessment．

## 3．11．6 Southern horse mackerel（Trachurus trachurus）（Divisions VIIIc and IXa）

State of stock／exploitation：The stock is harvested outside safe biological limits，but the fishing mortality is only slightly above $\mathbf{F}_{\mathrm{pa}}$ ．The spawning stock is estimated to be above $\boldsymbol{B}_{\mathrm{pa}}$ ．

Management objectives：There are no explicit management objectives for this stock．

Precautionary Approach reference points（established in 1998）：

| ICES considers that： | ICES proposes that： |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 136000 t，the lowest observed biomass． | $\mathbf{B}_{\text {pa }}$ be set at 205000 t ．This affords a high probability of <br> maintaining $S S B$ above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of the assessment． |
| $\mathbf{F}_{\text {lim }}$ is 0.27, the fishing mortality rate above which <br> recruitment and stock dynamics are unknown． | $\mathbf{F}_{\text {pa }}$ be established at 0.17. This $F$ is considered to provide <br> approximately $95 \%$ probability of avoiding $F_{\text {lim }}$, <br> into account the uncertainty of assessments． |

Technical basis：

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\text {pa }}=\mathbf{B}_{\text {loss }} * 1.5$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\text {pa }}=\mathbf{F}_{\text {liu }} * 0.63$ |

Advice on management：Fishing mortality should be below 0．113，corresponding to landings of less than 34000 t in 2002．This will keep SSB above $\mathrm{B}_{\mathrm{pa}}$ in 2003. ICES recommends，that the TAC for this stock should only apply to Trachurus trachurus．

Comparison with previous assessment and advice： This year＇s assessment shows close agreement with last year＇s assessment．The spawning stock biomass estimated from the 1995 egg surveys is in good
agreement with the 1995 SSB estimated by VPA using CPUE－at－age series of two October surveys，the July survey，and of two commercial fleets．The SSB in 2000 is estimated to be lower than the forecast from last year＇s assessment．This may be due to poor recruitments in recent years．

Relevant factors to be considered in management：The TAC up to 1999 was 73000 t ，and 68000 t for 2000 and 2001．The TAC includes all Trachurus species．

Catch forecast for 2002：
Basis： $\mathrm{F}(2001)=\mathrm{F}(98-00)=\mathrm{F}_{\mathrm{sq}}=0.19 ;$ Landings $(2001)=52 ; \operatorname{SSB}(2001)=221$ ．

## Weights in＇ 000 t ．

Shaded scenarios are considered inconsistent with the precautionary approach．

Medium- and long-term projections: No medium or long-term projections were made.

Elaboration and special comment: Trawl, purse seine, and artisanal fisheries exploit this stock. The increase of $F$ in 1998 was due mainly to the higher catches obtained by the Spanish purse seiners and to a lesser extent by the Portuguese trawlers and purse seiners. The high Spanish purse seiner catches in 1997, 1998 and 1999 are a result of the decrease in abundance of species like sardine, which caused the fleet to switch target species to horse mackerel and other species.

Source of information: Report of the Working Group on the Assessment of Mackerel, Horse Mackerel, Sardine and Anchovy, September 2001 (ICES CM 2002/ACFM:06).

### 3.11.7.a Sardine in Divisions VIIc and IXa

State of stock/exploitation: No precautionary approach reference points have been proposed for this stock. Fishing mortality has decreased since 1998 and spawning stock biomass has remained at a low level. The perception of the state of the stock depends on the relative contributions to the stock from the northern and southern areas. These relative contributions are presently unknown. Abundance is reduced in the northem part while abondance has been stable in the south. Acoustic surveys indicate a strong 2000 year class, but its size is still uncertain since previous indications of strong recruitment for this stock have later been shown to be overly optimistic. Since the early 1990 s, there has been an overall decrease of the distribution area.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: ICES recommends that fishing mortality be reduced to below $\mathrm{F}=0.25$, corresponding to a catch of less than 95000 t in 2002 in order to prevent short-term decline in stock size.

Comparison with previous assessment and advice: Trends in this year assessment agree well with the previous one. SSBs in the most recent years have been adjusted downward because the strength of the 1998 year class was re-evaluated.

Relevant factors to be considered in management: At present the spawning stock biomass is considered to be close to its lowest historical level. The 1998 year class, which initially was estimated to be a strong year class, now appears to be below the geometric mean of the time series. Acoustic surveys indicated a strong 2000 year class, which mainly occurred off north Portugal.

Fishing mortality increased from 1995 to 1998, when its highest value since 1980 was reached. Fishing mortality decreased since 1998. Spain and Portugal undertook management measures to reduce fishing effort (i.e. closed periods, limitation of fishing days) and the overall catches (daily and/or annual allowable catches per boat and/or per fisherman organisation), which may have contributed to the reduction in the fishing mortality.

Catch forecast for 2002:
Basis: $F(2001)=F_{s 4}(2000)=0.28$; Landings $(2001)=99,582 ;$ SSB $(2001)=339$.

Shaded scenarios likely to cause decrease in SSB.

The catches are allocated to areas according to the proportion of catch-at-age by area in recent years (19982000). This forecast is based on the assumption of no change in the spatial distribution of the population and stable fishing mortality levels. However, changes in the spatial distribution are being observed.

Elaboration and special comment: Since the 1940s there have been periods of high and low sardine landings (Figure 3.11.7.a.1). Because of spatial changes in fish distribution and the shift of the exploitation pattern towards older ages in the southern area it is difficult to obtain a meaningful comparison between the stock size and the fishing mortality in the mid-1980s and the late 1990 s , and to provide accurate estimates of the state of the stock.

The current assessment model is shown to be robust (both in relation to goodness-of-fit and stock trajectory) to the addition of new input data, but uncertainties about accuracy of estimates, and therefore about absolute stock levels still remain. The fishing mortality decreased
from 1990 to 1995, then increased until 1998 when it reached its highest value since 1980 . There was a sharp decrease in 1999. Mean recruitment in the 1990s is estimated to be lower than the mean recruitment in the 1980s. The stock shows two periods of high productivity in the mid-1980s and mid-1990s. Periods of low productivity occurred at the beginning of the 1980 s , the beginning of the 1990 s , and at present.

The changes in stock abundance in different areas remain a matter of concern. The biological relationship between the different areas and the general stock definitions are still unclear. This may imply a vulnerability of the fishery at both a local and a global level. Therefore, close monitoring of this stock is still needed, as well as a better understanding of the stock structure and behaviour.

As absolute values of historic stock size cannot be calculated reliably and in view of uncertainty about the biology of the stock, ICES does not have a proper basis to
propose precautionary reference points for management purposes.

The analytical assessment used was based on catches in numbers and by age, acoustic survey results, and egg surveys in 1988, 1997, and 1999.

### 3.11.8 Anchovy

### 3.11.8.a Anchovy in Sub-area VIII (Bay of Biscay)

State of stock/exploitation: The stock is inside safe biological limits in 2001. SSB is above $\mathbf{B}_{\mathrm{pa}}$, and the fishing mortality has remained well below $\mathbf{F}_{\mathrm{pa}}$ in recent years.

Management objectives: There are no explicit management objectives for this stock. However, for any management objectives to meet precautionary criteria, their aim should be to keep SSB above $\mathbf{B}_{\mathrm{p}^{\mathrm{a}}}$ and reduce or maintain $F$ below $\mathbf{F}_{\mathrm{pa}}$.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{jim}}$ is 18000 t , the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}=36000 \mathrm{t}$. |
| There is no biological basis for defining $\boldsymbol{F}_{\text {lim. }}$ | $\mathbf{F}_{\mathrm{pa}}$ be established between $1.0-1.2$. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=18000 \mathrm{t}$ | $\mathbf{B}_{\mathrm{pa}}=$ SSB that can withstand two successive years of <br> poor recruitment. |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=\mathrm{F}$ for $50 \%$ spawning potential ratio, i.e., the $F$ at <br> which the $S S B / R$ is half of what it would have been in <br> the absence of fishing. |

Advice on management: ICES recommends that a preliminary TAC for 2002 is set to 33000 t . This is based on the conservative assumption that recruitment in 2001 and beyond is 8.5 billion (mean of the below mean year classes in the historical series), and that the fishing mortality is the average of that of recent years ( $\mathrm{F}=0.65$ ). This TAC should be revised in the middle of the year 2002, based on the results of the fishery and of acoustic and egg surveys in May-June.

Comparison with previous assessment and advice: The year class 2000 was in the previous assessment set to be of average strength. The estimate now available is almost five times that value. Also the survey indices have been revisited and this has resulted in an upward adjustment of SSB.

Relevant factors to be considered in management: Due to the short life span of the anchovy, the fishery
depends largely on the abundance of the incoming year class, the abundance of which cannot be estimated before the next spring as one-year-olds. Advice for the full year related to biomass reference points will have to be conservative, and maybe more restrictive than necessary. Therefore, ICES proposes that if the fishery is regulated with a TAC based on an analytical approach, a two-stage management regime should be implemented. In such a two-stage regime, a preliminary TAC should be set at the beginning of the year based on an analytic assessment in the autumn, and revised according to measurements of the stock by acoustic and Daily Egg Production Method (DEPM) surveys in MayJune. In order to be precautionary, the preliminary TAC set at the beginning of the year should aim at keeping the stock safely above $\boldsymbol{B}_{\mathrm{im}}$ even if the incoming year class is poor.

Catch forecast for 2002:
Basis: Landings (2001) $=33,000 \mathrm{t} ; \mathrm{F}(2001)=0.43 ; \mathrm{SSB}(2001)=95$.

| $\mathrm{F}(2002)$ | Basis | SSB (2002) | Catch (2002) |
| :---: | :---: | :---: | :---: |
| 0.13 | $0.2 \mathrm{~F}_{(95-2000)}$ | 63 | 8 |
| 0.26 | $0.4 \mathrm{~F}_{(95-2000)}$ | 60 | 15 |
| 0.39 | $0.6 \mathrm{~F}_{(95-2000)}$ | 57 | 22 |
| 0.52 | $0.8 \mathrm{~F}_{(95-2000)}$ | 54 | 28 |
| 0.65 | $\mathrm{~F}_{(95-2000)}$ | 51 | 33 |
| 0.78 | $1.2 \mathrm{~F}_{(95-2000)}$ | 49 | 38 |
| 0.91 | $1.4 \mathrm{~F}_{(95-2000)}$ | 46 | 42 |

Weights in '000 t.

Elaboration and special comments: The abundance of this short-lived species will vary considerably according to fluctuations in recruitment. The recruitment is likely to be strongly dependent on environmental factors. The low accuracy of the environmental indexes as recruitment predictors makes it impossible at present to estimate the population abundance one year in advance. ICES considers that a full operative model to evaluate alternative management regimes, including the one proposed by STECF, needs to be developed.

The stock is exploited by Spanish purse seiners, mostly in the first half of the year, and French trawlers mostly in the second half of the year. Most of the fish (around $85 \%$ ) have spawned at least once before being caught, since the French fishery takes place outside the spawning season and the Spanish fishery is outside the spawning area.

Analytical assessment (ICA) is based on catch-at-age data from French and Spanish fisheries and stock
biomass estimates from egg (1987-2001) and acoustic surveys (1989-2001).

### 3.11.8.b Anchovy in Division IXa

State of stock/exploitation: No precautionary approach reference points have been proposed for this stock and the state of the stock in relation to safe biological limits is unknown.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: ICES recommends that catches in 2002 be restricted to 4900 t (mean catches from the period 1988-1999 (excluding 1995 and 1998)). This level should be kept until the response of the stock to the fishery is known. ICES recommends that a management plan, including monitoring of the development of the stock and of the fishery with corresponding regulations should be developed and implemented.

Relevant factors to be considered in management It is recognised that the state of the resource can change quickly, and therefore in-year monitoring and management should be considered. At present, the scarcity of biological information for this stock hampers the provision of advice on more appropriate management measures.

Catch forecast for 2002: Not available.

Elaboration and special comments: In recent years there has been considerable progress in assembling data for assessing the stock.

There is a regular fishery for anchovy in Sub-division IXa South (Gulf of Cadiz). The fleets in the northern part of Division IXa occasionally target anchovy when its abundance is high, as occurred in 1995. Catch statistiscs are available from Portugal since 1943. Before 1988, Spanish data included catches from other areas. In 2000, catches decreased, probably caused by a large reduction in the fishing effort by the Barbate single-purpose purseseine fleet. Most of these vessels accepted a tie-up scheme in 2000 and 2001 because the EU-Morocco Fishery Agreement was not renewed.

The differences found between areas (specially between Sub-division IXa South and the remaining ones) in trends in historical catches, size composition, growth rate, and maturity-length relationships, support the suggestion that the populations inhabiting these areas may have different biological characteristics and dynamics. Thus, the anchovy population in IXa South appears to be well established and relatively independent from other populations along the Division, which seem to be abundant only when suitable environmental conditions occur. Catches in IXa South consist largely of 0.1 yearold fish with a negligible proportion of older fish which could be attributed to either high mortality or emigration.

At present, there is not sufficient information to estimate appropriate reference points.

Source of information: Report of the Working Group on the Assessment of Mackerel, Horse Mackerel, Sardine and Anchovy, September 2001 (ICES CM 2002/ACFM:06).

### 3.12 <br> Widely Distributed and Migratory Stocks

### 3.12.1 Overview

A number of stocks assessed by ICES are not confined to the individual areas considered in other sections of this report. They include species with stock units that are distributed over much wider areas such as hake and a number of deep-water species, and migratory species such as mackerel, horse mackerel and blue whiting.

The Northern Hake is fished throughout Sub-areas IV, VI, VII and VIII. The stock, which is estimated to be about $88,000 \mathrm{t}$ in 2000 , has been at a low level for a number of years and is considered to be outside safe biological limits. The landings, which are mainly taken by Spain and France, have decreased in recent years and the 1999 landings of $39,300 \mathrm{t}$ were the second lowest recorded for over twenty years. Recruitment has been very poor in 1997 and 1998 and the stock is not expected to increase unless there is a substantial reduction in fishing mortality.

The North East Atlantic mackerel stock which is considered to consist of three spawning components (North Sea. Western and Southern) is fished over a very wide area extending throughout Sub-areas II, IV, VI, VII and VIII. Considerable mixing of the components occurs at various times throughout the year. The fishery is conducted by a number of countries, but Norway, United Kingdom, Russia, Ireland and the Netherlands take the main catches. The total catch in 1999 was estimated to be over $609,000 \mathrm{t}$. The spawning stock has increased in recent years and
in 2000 was estimated to be over 3.9 million $t$. This high SSB is expected to be maintained in the future if fishing mortality is kept at or below $\mathbf{F}_{\mathrm{pa}}$ -

The Western horse mackerel fishery extends throughout Sub-areas IV, VI, VII and VIII. The stock is exploited by a number of countries, Netherlands and Ireland take the main catches. The catch in 1999 was estimated to be about $275,000 \mathrm{t}$, which was the lowest since 1990. The stock is inside safe biological limits. Following the outstanding 1982 year class, which for more than a decade contributed a significant part of the catches, recruitment of horse mackerel has been weak. SSB is bound to be low as this year class is fished out and the sustainable yield is unlikely to be higher than about 130000 t per year.

The Northern Blue Whiting stock is fished in Sub-areas II, V, VI and VII and by a number of countries, mainly by Norway, Russia, Iceland, Denmark, Faroe Islands, United Kingdom and Ireland. The 1999 catches were over 1.3 million $t$ and were the highest recorded from the fishery. Most of these catches were landed for industrial purposes. The spawning stock, that in 2000 was estimated to be 2.8 million t , has been boosted by the very good year classes in 1995 and 1996. However, it is expected that the stock will rapidly decline in the near future as recruitment seems to return to normal and will not be able to maintain the present high catches.

State of stock/exploitation: The stock is outside safe biological limits. Fishing mortality has been above $\mathbf{F}_{\mathrm{p}}$ for the entire period of the assessment, which is since 1978, and has even been above $\mathbf{F}_{\text {lim }}$ in most years since 1988. Current $F$ is just above $\mathbf{F}_{\text {lim. }}$. SSB has generally declined and has been below $\mathbf{B a}_{\mathrm{pa}}$ since 1987, and even
below $\mathbf{B}_{\text {lim }}$ for most years since 1990. Recruitment estimates for 1997-2000 are the lowest recorded.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 120000 t , the lowest observed biomass in the <br> 1998 assessment. | $\mathbf{B}_{\mathrm{pa}}$ be set at 165000 t Biomass above this affords a high <br> probability of maintaining SSB above $\mathbf{B}_{\text {Iim }}$ taking into <br> account the uncertainty in assessments. |
| $\mathbf{F}_{\text {lim }}$ is 0.28, the fishing mortality above which stock <br> dynamics are unknown. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.20 . This F is considered to have a high <br> probability of avoiding $\mathbf{F}_{\text {lim }}$ and a $50 \%$ probability of <br> maintaining $S S B$ above $\mathbf{B}_{\mathrm{pa}}$ in the next 10 years, taking <br> into account the uncertainty in assessments. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss. }}$ | $\mathbf{B}_{\mathrm{pa}} \sim \mathbf{B}_{\mathrm{lim}} \times 1.4$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}} \sim \mathbf{F}_{\text {lim }} \times 0.72$, implies a less than 10\% probability that <br> $\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$. |

Advice on management: In the light of the continued decrease in SSB and very poor recruitment since 1997, ICES recommends a recovery plan that will ensure a safe and rapid recovery of SSB to a level in excess of 165000 t . If a recovery plan is not implemented ICES recommends that fishing mortality on hake should be reduced to the lowest possible level in 2002.

Rebuilding plan: Rebuilding of the hake stock can be obtained by reducing the fishing mortality, or by a reduction in F and an improvement of the selection pattern.

An emergency plan for Northern Hake has been implemented since $1^{\text {st }}$ September 2001. This comprises a low TAC for 2001 and the use of mesh size of 100 mm for trawlers targeting Hake in the Bay of Biscay and for trawlers operating in two non-Nephrops areas (one in the Bay of Biscay, one in the Celtic Sea). ICES has not been able to quantify the likely impact of these changes in mesh size, but they will not be sufficient to reduce exploitation to the level needed to rebuild the hake stock and additional reduction in mortality is needed.

A fishing mortality of zero in 2002 is not expected to rebuild SSB to $\mathbf{B}_{\mathrm{pa}}$ by 2003, but fishing mortality less than 0.12 ( $\mathrm{F}_{98-00}$ reduced by $60 \%$ ) in 2002, 2003 and 2004 is expected to rebuild it by 2005 (see Table 3.12.2.3). This table also shows that with a smaller reduction in $\mathrm{F}(50 \%)$, it would require one year more to rebuild $S S B$ above $B_{\mathrm{pa}}$. Given the state of the stock, and the risk of impaired recruitment, the fastest possible rebuilding to $\mathbf{B}_{\mathrm{pa}}$ is strongly advised.

Setting the TAC at low level may reduce fishing mortality, but past experience has shown that it is very difficult to control fishing mortality by TACs alone. ICES therefore recommends that in addition to TAC constraints, restrictions in effort of fleets exploiting hake should be implemented. Large closed areas and seasons may contribute to stock recovery, but only if accompanied by major reductions in effort.

Since hake is a late maturing fish [ $23 \%$ age 3 are mature, $60 \%$ age $4,90 \%$ age 5 and $100 \%$ at age 6 and above], any improvement in the selection pattern preventing from catching younger fish (ages $0-2, \sim$ less than 30 cm ) will allow $S S B$ to increase in the medium term only. An improvement in the selection pattern alone is unlikely to be effective enough to rebuild SSB. At status quo $F$ and with no catch at age $0-2$ the SSB is expected to be $10 \%$ higher in 2006 than with the current selection pattern. SSB will be $30 \%$ higher in 2010, but still below $\mathbf{B}_{\mathrm{p}^{\mathrm{a}}}$.

However, improving the selection pattern would increase the probability that a reduction in $F$ will allow a rebuilding in SSB. Furthermore, this improvement is a prerequisite of any future sustainable exploitation of this stock.

Comparison with previous assessment and advice: The trends in F, SSB and R are similar to those estimated in previous assessment. However, there has been a revision of the database since 1995 (Danish landings and length distribution, revision of French landings for 1999, French tuning information available for 1998 and 1999, minor revision of catch at age for A

Coruna fleet since 1995），and there have also been changes in the tuning process（new fleets，taper and full year range）．This has led to an upward revision of $F$ （between 1986 and 1996）and downward revision of SSB prior to 1997．Recent F and SSB have been revised downward and upward respectively．The decline in SSB is estimated this year less sharp than last year． Recruitments in recent years are estimated higher in this year＇s assessment．However，they are still the lowest of the time series．

Relevant factors to be considered in management： SSB cannot be rebuilt above $B_{p a}$ in the short－term，even with an $F$ of 0 in 2002.

Information from the fishery indicates a decrease in the amount of small hake caught in recent years（ $64 \%$ of fish less than 30 cm in 1997 compared to around $30 \%$ in 1998－2000）．This might be explained by an improvement in the selection pattern，changes in fishing strategy，because the small fish became inaccessible to sampling，or simply a consequence of weak year classes in recent years．

Hake is caught in nearly all fisheries in Sub－areas VII and VIII．LPUEs series show different trends in
different areas and between different fleets．In recent years for some fleets there has been an increase in LPUE in Sub－area VII and a generally decreasing LPUE trend in Sub－area VIII．The assessment of the stock seems to be driven more by Divisions VIIIa，b indices than by those from Sub－area VII，although the Sub－area VII indices are included in the assessment．However， even though there are some conflicting signals in LPUE between areas in recent years，the matter of concern is the overall declining trend in the stock size since the beginning of the assessment period（1978）．This declining trend is evenly indicated when separate mean indices from Sub－areas VII and VIII are used in the assessment，even though the decrease is slightly lower when using indices from Sub－area VII．

Catch forecast for 2002：Forecasts with both a TAC constraint for 2001 and an $\mathbf{F}_{\text {sq }}$ for 2001 are presented below．In 2000 ，the minimum mesh size increased which may improve the exploitation pattern and the Spanish fishery was closed in November．This suggests that $F_{s q}$ may not provide the more accurate prediction of the catch in 2001．No restriction on fleets has been reported yet and if the TAC is overshot the forecasts using an $F_{s q}$ for 2001 would be the more realistic．

Medium－term projections：Medium－term results using both a TAC constraint for 2001 and using status quo $F$ in 2001 are presented．

Elaboration and special comment：Since the 1930s， hake has been the main species supporting trawl fleets on the Atlantic coasts of France and Spain．In 1999， Spain took $60 \%$ of the landings，France $20 \%$ ，UK about $8 \%$ and Ireland $5 \%$ ．Hake are caught throughout the year，the peak landings being made in the spring－ summer months．The three main gear types used by vessels fishing for hake as a target species are lines（ E \＆W，Spain），fixed－nets，and otter trawls（all countries）．By－catches of mainly juvenile hake are taken in the Nephrops fisheries in the Northem Bay of Biscay．These fisheries have a high proportion（ $80 \%$ ） of small hake（less than 30 cm ）in their catches，but
account for less than $20 \%$ in the total international catch of these small hakes.

Hake spawn from February through July along the shelf edge, the main areas extending from north of the Bay of Biscay to the south and west of Ireland. 0groups descend to the seabed (at depths in excess of 200 m ), moving to shallower water with a muddy seabed ( $75-120 \mathrm{~m}$ ) by September. There are two major nursery areas: in the Bay of Biscay and off southern Ireland. Three years old hake begin to move into the shallower regions of the Bay of Biscay and Celtic Sea, but as they approach maturity they disperse to offshore regions.

Hake movements are indicated by the seasonal distribution of catches. From the beginning of the year until March/April hake are present in the North of the Bay of Biscay. They appear on the shelf edge in the Celtic Sea in June and July. Between August and December the hake fishery is centred to the west and south-west of Ireland, with a decline in catch rates in shallower waters.

Length composition data by fishery unit are available annually for 1978-1989 and quarterly for 1990-2000. Prior to 1992, these were converted to age
compositions by numerical methods. For 1992-2000, age readings were used. Some discards data are used in the assessment. However more of the available discards data should be included.

In September 2001 a Spanish survey took place in the Porcupine bank (Division VIlb-k), providing an index of abundance of hake. This survey should be continued in order to provide information, independent on the fishery, on the abundance (mainly of old fish) on this area, which could be used in the assessment.

### 3.12.3

Mackerel
3.12.3.a Mackerel (combined Southern, Western and North Sea spawning components)

State of stock/exploitation: The combined stock is harvested outside safe biological limits. The spawning stock biomass in 2001 is estimated to be well above $\mathbf{B}_{\mathrm{pa}}$, and the fishing mortality in 2000 is just above $F_{p a}$. The North Sea component remains severely depleted.

Management objectives: The agreed record of negotiations between Norway, Faeroe Islands and EU in 1999, states:
"For 2000 and subsequent years, the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality in the range of 0.15-0.20 for appropriate age groups as defined by ICES, unless future scientific advice requires modification of the fishing mortality rate."
"Should the SSB fall below a reference point of 2300 000 tonnes ( $\boldsymbol{B}_{p a}$ ), the fishing mortality rate, referred to
under paragraph 1 , shall be adapted in the light of scientific estimates of the conditions prevailing. Such adaptation shall ensure a safe and rapid recovery of the SSB to a level in excess of 2300000 tonnes."
"The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES,"

Agreements for international waters have to be included here as well, but were not available at the meeting.

The rationale for ICES proposing $\mathrm{F}_{\mathrm{Pa}^{a}}=0.17$ is to have a high probability of avoiding exploiting the stock above $\mathrm{F}_{1 \mathrm{~lm}}$. In addition, projections indicate that $\mathrm{F}=0.17$ will optimise long-term yield and at the same time result in a low risk for the stock to decrease below $\mathbf{B}_{\text {pa }}$. If $F$ on average is kept below 0.17 , ICES regards the management plan to meet precautionary criteria.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| There is no biological basis for defining $\mathbf{B}_{\mathrm{lim}}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 2.3 million $t$ |
| $\mathbf{F}_{\text {lim }}$ is 0.26, the fishing mortality estimated to lead to <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.17. This F is considered to provide <br> approximately $95 \%$ probability of avoiding $\mathbf{F}_{\text {lim }}$, taking <br> into account the uncertainty in the assessments. |

Technical basis:

|  | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {loss }}$ in Western stock raised by $15 \%:=2.3$ million <br> $\mathbf{t}$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.26$ | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {lim }} \times 0.65 . \mathbf{F}_{0.1}=0.17$ |

Advice on management: ICES advises a fishing mortality in 2002 of no more than $F_{p a}$ (0.17), corresponding to landings in 2002 of less than 694000 t . Preliminary information from an egg survey in 2001 suggests that this projection is too optimistic. ICES advises that any agreed TAC should cover all areas where North-East Atlantic mackerel are fished.

The North Sea spawning component still needs the maximum possible protection.

- There should be no fishing for mackerel in Divisions IIIa and IVb,c at any time of the year.
- There should be no fishing for mackerel in Division IVa during the period 1 February-31 July.
- The 30 cm minimum landing size at present in force in Sub-area IV should be maintained.

Comparison with previous assessment and advice: The assessment method was unchanged from last year, and the results are well in accordance with last year's assessment.

Relevant factors to be considered in management: Egg surveys were carried out in the western and southern spawning areas during February-July 2001. Preliminary egg production estimates show a decline in both the Western and the Southern area. The results of the fecundity studies are not yet available and until these results are included in the assessment, it is difficult to be confident about the accuracy of the assessment. Tag recapture data indicate an increasing trend in total mortality since 1995-1996. Both the egg surveys and the tag recaptures indicate that the projection could be too optimistic.

Little is known about discards in the mackerel fishery; however, sampling for discards has improved. ICES recommends that observers should be placed on vessels in order to estimate discards in those fisheries where discarding of mackerel is perceived to be a problem.

The closure of the mackerel fishery in Divisions IVb,c and IILa throughout the whole year is designed to protect the North Sea component in this area and also the juvenile Western mackerel which are numerous, particularly in Division IVb,c during the second half of the year. This closure has unfortunately resulted in increased discards of mackerel in the non-directed fisheries (especially horse mackerel fisheries) in these areas as vessels at present are permitted to take only $10 \%$ of their catch as mackerel by-catch. No data on the actual size of mackerel by-catch are available, but the reported landings of mackerel in Divisions IIIa and IVb,c for 1997 might seriously under-estimate catches due to discarded by-catch.

Closure of Division IVa for fishing during the first half of the year was recommended for several years. This
was based on the perception that the western mackerel entered the North Sea in July/August, and stayed there until December before migrating back to their spawning areas. Updated observations taken in the late 1990s suggested that this retum migration actually started in mid- to late February. This was believed to result in large-scale misreporting from the Northern part of the North Sea (Division IVa) to Division Vla. It was recommended that the closure date for IVa be extended to the $1^{\text {st }}$ February. This was adopted for the 1999/2000 fishing season. There is some indication that this has achieved its objective. However, it should be noted that in the first quarter of 2000 , the timing of migration from the North Sea was much earlier than in previous years, probably starting in December 1999. Detailed information from the fishery are still not ready for November 2000-March 2001, but a first impression is that the mackerel might have left the North Sea a little later than last year. This indicates that the migration pattern of mackerel is not fixed and can show rapid and substantial changes.

Catch forecast for 2002:
Basis: $F(2001)=F(98-00$, unscaled $)=F_{s q}=0.1835$; Landings (2001) $=726 ; \operatorname{SSB}(2001)=4023$.

Weights in ' 000 t .
N: Northern area comprising the Western areas, North Sea, Skagerrak and Norwegian Sea (I, IIa, IIla, IVa, Vb, VI, VII, VIIIa, b,d); catches in the international zone in Ila are included.
S: Southern area (VIIIc, IXa).
Shaded scenarios considered inconsistent with the precautionary approach.

The catches are allocated to areas according to the proportion of catch-at-age by area in recent years (19982000). This forecast is based on the assumption of no change in the spatial distribution of the population and stable fishing mortality levels.

The mid-year prediction for 2001 is based on $\mathbf{F}_{\text {sq }}$. For the first time the TAC for 2001 covers also the international waters, but it is uncertain if this TAC will be fully effective.

Medium- and long-term projections: No medium- or long-term projections were carried out.

Elaboration and special comment: This year's assessment indicates that the stock is slightly lower than predicted in the previous years. According to this estimate, the stock is now well above $\mathbf{B}_{\text {pa }}$ and the largest in the time-series. The spawning stock is well above $\mathbf{B}_{\mathrm{pa}}$ and is harvested just above $\mathbf{F}_{\mathrm{pa}}$. The upward trend in the present stock estimate is uncertain, and the perception of a substantial increase in stock size depends on a limited number of observations of SSB. In
particular, there is little information to support the abundance estimates of the youngest year classes, and the predictions are sensitive to these. For the first time, small catches were reported from the Barents Sea.

Stock components: ICES currently uses the term "North East Atlantic Mackerel" to define the mackerel present in the area extending from ICES Division IXa in the south to Division IIa in the north, including mackerel in the North Sea and Division IIIa. The spawning areas of mackerel are widely spread, and only the area in the North Sea is sufficiently distinct to be clearly identified as a separate spawning component. Tagging experiments have demonstrated that after spawning, fish from Southern and Western areas migrate to feed in the Norwegian Sea and the North Sea during the second half of the year. In the North Sea they mix with the North Sea component. Since it is at present impossible to allocate catches to the stocks previously considered by ICES, they are at present, for practical reasons, considered as one stock: the North East Atlantic Mackerel Stock. Catches camot be allocated specifically to spawning area components on biological grounds, but by convention the catches from the Southern
and Western components are separated according to the area where they are taken.

In order to be able to keep track of the development of the spawning biomasses in the different spawning areas,
the North East Atlantic mackerel stock is divided into three area components termed the Western Spawning Component, the North Sea Spawning Component, and the Southern Spawning Component:

| North-East Atlantic Mackerel |  |  |  |
| :---: | :---: | :---: | :---: |
| Distributed and fished in ICES Sub-areas and Divisions IIa, IIIa, IV, Vb, VI, VII, VIII and IXa |  |  |  |
| Spawning compenent | Western | Southern | North Sea |
| Spawning Areas | VI, VII, VIIIa,b,d,e. | VIIIc, IXa. | IV, III. |

The Western Component is defined as mackerel spawning in the western area (ICES Divisions and SubAreas VI, VII, VIII a,b,d,e). This component comprises $71-86 \%$ of the entire North East Atlantic Stock. Similarly, the Southern Component is defined as mackerel spawning in the southern area (ICES Divisions VIIIc and IXa). Although the North Sea component has been at an extremely low level since the early 1970s, ACFM regards the North Sea Component as still existing. This component spawns in the North Sea and Skagerrak (ICES Sub-Area IV and Division IIIa). Current knowledge of the state of the spawning components is summarised below:

Western Component: The catches of this component were low in the 1960s, but increased to more than 800000 t in 1993. The main catches are taken in directed fisheries by purse seiners and mid-water trawlers. Large catches of the western component are taken in the northern North Sea and in the Norwegian Sea. The 1996 catch showed a large reduction of about 200000 t , compared with 1995, because of the reduced TACs. The 1999 catch decreased by nearly 60000 t compared to that of 1998 . The SSB of the Western Component declined in the 1970 s from above 3.0 million $t$ to 2.2 million $t$ in 1994, but was estimated to have increased to 2.7 million $t$ in 1999 and decreased to 2.6 million $t$ in 2000. A separate assessment for this stock component is made in order to maintain a longer time-series of stock-recruitment data.

North Sea Component: Very large catches were taken in the 1960 s in the purse seine fishery, reaching a maximum of about 1 million $t$ in 1967. The component subsequently collapsed and catches declined to less than 100000 t in the late 1970 s . Catches during the last five
years have been assumed to be about 10000 t . The size of the North Sea Component was last estimated at 68000 t by egg surveys in 1999. This component is considered to be severely depleted and outside safe biological limits. An exceptionally large number of juvenile mackerel (1996 year class) was observed throughout the North Sea and adjacent areas during 1997, but did not appear in the IBTS survey in 1998, and did not produce an increase in the spawning population in 1999. These fish are therefore likely to have been of Western origin.

Southern Component: Mackerel is a target species for the hand line fleet during the spawning season in Division VIIIc, during which about one third of the total catches are taken. It is taken as a by-catch in other fleets. The highest catches $(87 \%)$ from the Southern Component are taken in the first half of the year, mainly from Division VIIIc, and consist of adult fish. In the second half of the year catches consist of juveniles and are mainly taken in Division IXa. Catches from the Southern Component increased from about 20000 t in 1993 to 44000 t in 1999, and decreased to 36000 t in 2000 . Egg surveys indicate that the size of the Southern Component increased from 1995 to 1998 and may have been in the order of $25 \%$ of the total stock in 1998 , while it was considered to have been about $15 \%$ in previous years.

Combined Assessment: Analytic assessment is based on catch numbers at age for the period 1984-2000 and egg survey estimates of SSB from 1992, 1995 and 1998.

Source of information: Report of the Working Group on the Assessment of Mackerel, Horse Mackerel, Sardine and Anchovy, September 2001 (ICES CM 2002/ACFM:06).

${ }^{5}$ Estimations based on Mackerel Egg Surveys. ICES CM 2000/G:01 Page 5.
${ }^{6}$ Since 1990 assumed by the Working Group to be $10,000 \mathrm{t}$.

State of stock/exploitation: The stock status is undefined. The current fishing mortality is above $\mathbf{F}_{0.1}$. Spawning stock biomass has decreased compared with the mid-1980s and is estimated to continue to decline at all levels of fishing mortality. Fishing mortality on the youngest ages is increasing.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points: ICES withdraws the $B_{p a}$ reference point. The reference point $\mathbf{B}_{\mathrm{pa}}(=500000 \mathrm{t})$ was established in 1998 and was based on the egg survey estimate of the SSB that produced the exceptionally strong 1982 year class. This year class has dominated the stock development since then and recruitment has not been at a comparable level. The reference point needs to be revised in view of the recruitment experience over the last 20 years.

Advice on management: ICES advises that catches in 2002 be effectively limited to less than 98000 t , corresponding to $F=0.15$ which in 2000 was estimated to be $\mathrm{F}_{0.1}$. ICES also recommends that the TAC for this stock should apply to all areas in which Western horse mackerel are fished, i.e. Divisions Шa, IIa (western part), VI, Vb, IVa, VIIa-c, VIIe-k, and VIIIa,b,d,e. ICES also advises that in Divisions VIIe,f directed horse mackerel fisheries in which juveniles are abundant, and industrial fisheries in which horse mackerel is taken as a by-catch, should be prohibited.

Comparison with previous assessment and advice: The assessment was done with the same method as last year. The new assessment estimates much lower values of recruitment than the previous assessment. The SSB has been adjusted considerably downwards and the fishing mortality correspondingly upwards compared to last year's assessment. The assessment is unstable.

Relevant factors to be considered in management: The extraordinarily strong 1982 year class was nearly 20 times larger than the average of subsequent year classes
and 8 times larger than the second largest, the 1993 year class, in the documented history of the fishery 19822000. The 1982 year class reached its maximum biomass in 1987 and has decreased since then.

In the absence of outstanding year classes, sustainable yield is unlikely to be higher than about 130000 t , dependent on the exploitation pattern. It is therefore clear that catches will have to be reduced unless another outstanding year class is produced. It is not known how abundant the more recent year classes are, but the assessment indicates that they may be well below average since 1996.

Recently fisheries in Divisions VIIe,f have taken large catches of mainly juvenile horse mackerel from the western stock. There has been a clear change in the age-structure of the catches from older to younger fish since 1996. Therefore, ICES expresses concern about this high exploitation of juvenile fish at a time when the recruitment is at a low level.

If the current increase in targeted juvenile mortality continues, landings will have to be reduced at a faster rate than that for an adult fishery. ICES recommends that a management strategy similar to that for North Sea Herring, in which both adult and juvenile mortality are independently restricted, be explored for this stock.

If the fishing mortality in 2001 is the same as in 2000 the catch in 2001 will decrease below the 175000 t recorded for 2000 . Continued fishing at the level estimated for 2000 will result in a further reduction of catch in 2001. The decline in SSB is estimated to continue throughout 2002 and 2003.

The TAC has been overshot considerably since 1988, except for 2000 . However, the TAC has only been given for parts of the distribution and fishing areas (EU waters). ICES advises that if a TAC is set for this stock, it should apply to all areas where western horse mackerel are caught, i.e. Divisions IIa, IIIa (western part), IVa, Vb, VIa, VIIa-c, VIIe-k and VIIIa,b,d,e.

Catch forecast for 2002：
Basis： $\mathrm{F}(2001)=\mathrm{F}(2000)=\mathrm{F}_{\mathrm{sq}(4-10)}=0.23$ ；Landings $(2001)=155 ; \operatorname{SSB}(2001)=612$ ．

Weights in＇ 000 t ．
Shaded scenario considered inconsistent with the precautionary approach．

Elaboration and special comment：There have been changes in the distribution of this stock，which has resulted in additional fleets outside the TAC area exploiting the stock．In 2000，the catches in the North Sea were reduced drastically．

The recent history of this stock reflects the development of a single large year class within the period of 17 years for which data are available．The frequency of the occurrence of such large year classes cannot be evaluated on the basis of the short time－series．

As in previous years some countries with major catches did not carry out biological sampling programmes． Although this has improved since 1998，the lack of
biological data severely hampers the assessment．The maturity ogive is not well estimated，and there is uncertainty about natural mortality（ 0.15 ）．

The assessment carried out uses the results of the international horse mackerel egg surveys．An egg survey on this stock，carried out in 1998 estimated the spawning stock biomass to be 1.4 million $t$ ．A new egg survey was carried out in 2001．Preliminary results suggest a considerable reduction in egg production．

### 3.12.5 Blue whiting combined stock (Sub-areas I-IX, XII and XIV)

State of stock/exploitation: The stock is considered to be outside safe biological limits. In recent years the stock has rapidly declined. SSB is estimated to have been at $\mathbf{B}_{\mathrm{p}}$ in 2000 and will be close to $\mathbf{B}_{\text {lim }}$ in 2001 . Fishing mortality has increased from around the proposed $\mathbf{F}_{\mathrm{pa}}$ in 1997, to well above $\mathbf{F}_{\mathrm{pa}}$ in 1998 and 1999, and well above $\mathbf{F}_{\text {lim }}$ in 2000. Total landings in 2000 were 1.4 million $t$, far above the ICES recommended catch of 800000 t . Landings in 2000
mainly consisted of the strong 1996 and 1997 year classes. The strength of incoming year classes is unknown.

Management objectives: At present there are no agreed management objectives for this stock and there is no agreed TAC for the combined area. It has been suggested by NEAFC, based on previous ICES advice, that the fishery should be managed with a constant catch of 650000 t .

Precautionary Approach reference points (proposed in 2000):
The reference points are provisional as there is doubt about the present productivity of the stock.

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 1.5 mill t | $\mathbf{B}_{\mathrm{pa}}$ be set at 2.25 million $\mathbf{t}$ |
| $\mathbf{F}_{\text {lim }}$ is 0.51 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.32 |

Technical basis

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} \exp \left(1.645^{*} \sigma\right) \sigma=0.25$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}(0.51)$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {med }}(1998)$ |

Advice on management: ICES recommends that the fishery in 2002 for blue whiting in all areas be closed until a rebuilding plan has been implemented including provisions described below.

Rebuilding plan: A rebuilding plan should be established in which the fishing mortality is reduced to a low level until SSB has increased to above $\mathbf{B}_{\mathrm{pa}}$. An inherent part of this plan must ensure that the entire catch taken by the fisheries is controlled and regulated. At present $86 \%$ of the catches is not subject to TACs. The rebuilding plan must ensure that the TAC applies to all areas in which blue whiting are distributed. In addition, measures must be taken to eliminate catches of juvenile blue whiting that are taken as by-catch in the mixed industrial fisheries. A reduction in F in 2001 would accelerate the rebuilding process.

Relevant factors to be considered in management: The fishery is largely unregulated and the exploitation rate is not sustainable. The spawning stock biomass reached a peak in 1999 due to the strong year classes 1995, 1996 and 1997, and is expected to decline rapidly
at the present level of fishing mortality, to below $\mathbf{B}_{\text {lim }}$ in 2002.

Current exploitation rate and pattern mean that very few year classes support the fishery. The year classes dominating in the fishery are harvested heavily before they can reproduce or reach full growth potential. The estimate of year class strength for such young age groups is uncertain. There has been a shift towards dominance of the younger ages in the stock in recent years, in accordance with the increased fishing mortality.

Blue whiting is widely distributed in the eastern North Atlantic. Its distribution extends from the Strait of Gibraltar to the Barents Sea. It consists of several populations with genetic "leakage" between them, but it is treated as one stock as it so far has not been possible to define an unambiguous border between populations.

Comparison with previous assessment and advice: The present assessment is in accordance with the assessments made in 1999 and 2000.

Catch forecast for 2002:
Basis: $\mathrm{F}_{\{2001\}}=\mathrm{F}_{(2000)}=0.86 ;$ Landings ${ }_{(2001\}}=1.159 ; \mathrm{SSB}$ in $2001=1.514$.

Weights in ' 000 t , Mean F , ages 3-7.

Shaded scenarios considered inconsistent with the precautionary approach．SSB is not likely to rebuild to $\boldsymbol{B}_{\mathrm{pa}}$ in the short term，even with no fishery．

Medium－and long－term projections：Medium term projections were made using two assumptions on fishing mortality for 2001，one assumption sets F at status quo and the other uses a lower $F$ of 0.4 ．These projections suggest that the stock will reach $\mathbf{B}_{\mathrm{p}}$ with a high probability in 5－10 years at an F of 0.15 or lower from 2002 onwards．

Elaboration and special comment：Most of the catches are taken in the directed pelagic trawl fishery in the spawning and post－spawning areas（Divisions Vb ， VIa，b and VIIb，c），but juveniles are also caught in a mixed industrial fishery in Sub－area IV and Division IIIa and in the pelagic trawl fishery in the northern areas（Sub－area I and II，Divisions Va，XIVa，b）．These fisheries in the northern areas have taken $340000-$ 1390000 t per year in the last decade while catches in the southern areas（Sub－area VIII，IX，Divisions VIId，e and $\mathrm{g}-\mathrm{k}$ ）have been stable in the range of $25000-$ 34000 t ．The Portuguese and Spanish fleets do not target blue whiting in Division IXa，only a small pair trawl fleet takes blue whiting as a target species fishing in Spanish waters（Divisions VIIIc and IXa）．The catch taken by this fleet is only a very low percentage of the total catch．In Division IXa blue whiting is taken as by－ catch in mixed trawl fisheries．There are significant discards in this division．

Most countries that have substantial catches from this fishery sample the catches adequately．Sampling from the mixed industrial fishery in the North Sea is not satisfactory at present．

Estimates of spawning biomass by acoustic surveys are well above the level indicated by the assessment． Although the acoustic surveys may be indicative for the trends in biomass，the absolute values are considered not fully representative．

The analytical assessment is based on catch data， acoustic surveys and commercial CPUE data．

## ACFM REPORT 2001 PART 3 OF 3

These resources are assessed on a bi-annual basis and Coop. Res. Rep. 242 (2000) includes an overview of these resources and their status. The advice given in

2000 is clarified below in an answer to NEAFC and Norwegian requests for further information.

### 3.12.6.a Answer to Special Request on the Management of Deep-water Species

NEAFC requested ICES to consider the following with regards to deep-sea species:
a) Characterize and classify the most important deep-sea species (listed in Annex 2 in the request) according to their life history strategies and rank them by vulnerability to exploitation together with more well known deep-sea species, e.g., redfish and Greenland halibut;
b) Clarify advice statements for stocks where little biological information is available in order to generate consistency in advice (as outlined in Annex I pt 1-3 of the request);
c) Give established reference points used as basis for statements on stock status (as outlined in Annex I pt 5 in the request); and
d) Provide advice on how to improve datacollecting systems and advice on appropriate improvement for monitoring deep-sea resources (as outlined in Annex I pt 6 of the request).

## Norway requested ICES:

To evaluate the present assessment approach of treating different species of deep-water sea fish resources as one unit.

This is essentially the same request as a) above. Answers to the two requests are therefore combined in this section of the ICES advice on fishery management.

## Answer to point a) of the NEAFC request and to Norway

ICES considers that evaluation of stock status on each species should be done based on the population dynamics of that specific species and that all deep-water species should not be treated as having the same population dynamics. ICES has in its advice assessed the stocks individually based on available data. The ranking requested by NEAFC further enlightens the differences in population dynamics among deep-water species.

Use of life history parameter as a basis for management

As noted above management should be based on population dynamic information. However, for deepwater species such data are largely lacking and much of the scientific basis for management must therefore be taken from the general biology of the species. There is a well-developed theoretical framework on life history dynamics as a basis for scientific advice on exploitation.

ICES has used life history parameters to rank the species according to productivity which, according to the theoretical framework should be informative guides on vulnerability to exploitation:

- For a given fishing mortality, stocks of lower productivity will decrease faster than more productive stocks.
- Once depleted, the more productive species will be able to rebuild more quickly.

Vulnerability includes many factors in addition to species life history. Some factors are biological, e.g. aspects of species biology like shoaling, migrations, habitat preferences, whereas others reflect the fisheries, e.g., markets for the species and fleet capacity. Many deep-water species are widely distributed, and features of their life history may not be constant across their range or may change in response to exploitation. For these reasons life history parameters are useful, but not perfect guides to sustainable management. However, because the most and best information is available on life histories they are the primary guide at this time.

Below, deep-water species are ranked by their life history parameters, which are indicators of productivity. As noted above this means that those stocks ranked as more vulnerable will be those stocks for which detrimental impacts of fishing will be more difficult to reverse.

Ranking the deep-water species according to life history parameters

Annex IF of the NEAFC lists the following species:

| Common Name | Scientific Name |
| :--- | :--- |
| Blue ling | Molva dypterygia |
| Ling | Molva molva |
| Tusk | Brosme brosme |
| Roundnose grenadier | Coryphaenoides <br> rupestris |
| Black scabbardfish | Aphanopus carbo |
| Greater silver smelt | Argentina silus |
| Orange roughy | Hoplostethus atlanticus |
| Red sea bream | Pagellus <br> bogaraveo |
| Greater forkbeard | Phycis blennoides |
| Alfonsinos | Beryx spp. |

Available information on life bistory characteristics was compiled, and the deep-water species were ranked together with three reference species; redfish (Sebastes marinus and $S$. mentella) and Greenland halibut (Reinhardtius hippoglossoides). The three reference species have been exploited for an extensive period within the ICES area, and more data on their biology and population dynamics are available than for other deep-water species. The ranking was made on the basis of several biological parameters: longevity, growth, natural mortality, fecundity, and length or age at first maturity (Tables 3.12.6.a.2-6). Rank 1 is assigned to the species for which the sustainable catch level should be
the lowest fraction of the virgin biomass. Less vulnerable species were assigned higher ranks. Where the biological parameters were considered to be quite similar between two or more species the same rank was assigned. The available data did not allow ranking of all species (or species groups) according to all parameters. The species with no data are listed at the top of the tables and given no rank (as indicated by "?"). Some parameters may be highly correlated. For example, longevity, growth rate and natural mortality are most often derived from the same data, or they may rely upon the same, unverified, assumptions. It is then to be expected that these different parameters provide the same species ranking.

The estimated life history parameters used to rank the species are taken from the literature. Numbers given may have been estimated by different methodologies, have wide confidence intervals, or apply to local areas or environments. Where data are available from the ICES areas they were preferred. When no information was available information was extrapolated from other areas. Parameter estimates from the Mediterranean, where at least growth is clearly different, were not included in the analyses.

In order to summarise the detailed information, a simple rank average was produced and the species (or species groups) were ordered (Table 3.12.6.a.1). This analysis is of course crude. It should be emphasised that the underlying data are of variable quality and that new information is needed for several species in order to achieve a more reliable ranking. Nonetheless, the main pattern as indicated is believed to be robust.

Table 3.12.6.a. 1 Summary of ranking of the deep-water species and the reference species redfish and Greenland halibut. A low rank means high vulnerability. Cases where no rank could be assigned due to lack of information are indicated by "?". The overall rank in the rightmost column is an average of the available ranks in each row.

|  | Life history parameter |  |  | $\begin{array}{c}\text { Rank } \\ \text { average }\end{array}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Species | Longevity | $\begin{array}{c}\text { Growth } \\ \text { rate }\end{array}$ | $\begin{array}{c}\text { Natural } \\ \text { Mortality }\end{array}$ | Fecundity | \(\left.\begin{array}{c}Length <br>

and age at <br>
first <br>
ignored)\end{array}\right\}\)

## Longevity

Estimates of longevity are based upon maximum age observed from otolith readings (Table 3.12.6.a.2). For several species age is difficult to determine and age readings may not be validated. Although some validations have been attempted, satisfactory validations in the sense of Beamish and McFarlane (1983) are only available for few deep-water species. For orange roughy and roundnose grenadier, age validation has been carried out, but results apply only to juveniles (Gordon
and Swan, 1996; Mace et al., 1990). For orange roughy and Sebastes, radiometric dating of otolith cores has been carried out, and the results suggest longevity in accordance with otolith growth zone readings (Fenton et al., 1991; Francis 1995; Kastelle et al., 2000; Smith et al., 1995).

Orange roughy, roundnose grenadier, and the deepwater squalids have the longest life-spans. Most of the other species have intermediate longevity (15-30 yrs), but the Beryx species are relatively short-lived.

Table 3.12.6.a.2 Deep-water species ranked according to longevity.

| Rank | Species | Longevity (years) | Authors |
| :---: | :---: | :---: | :---: |
| 1 | Orange roughy | 125 | Annala and Sullivan, 1996; Tracey and Horn, 1999 |
| 2 | Roundnose grenadier | $>60$ | Allain and Lorance, 2000; Bergstad, 1990; Kelly et al., 1997 |
| 2 | Deep water squalid sharks Centroscymnus coelolepis Centrophorus squamosus | $60-70$ | Clarke, in press, and WD |
| 3 | Sebastes | 45-50 | Nedreaas, 1990 |
| 3 | Blue ling | -30 | Bergstad and Hareide 1996; Magnusson et al. 1997 |
| 3 | Greater silver smelt | -35 | Bergstad, 1993 |
| 4 | Greenland halibut | 15-20 | ICES Arctic Fisheries WG |
| 4 | Ling | -20 | Bergstad and Hareide 1996; Magnusson et al. 1997 |
| 4 | Tusk | $\sim 20$ (?) | Bergstad and Hareide 1997; Magnusson et al. 1997 |
| 4 | Black scabbardfish | $\begin{array}{\|l} \hline 8 \\ 12 \text { from whole otoliths } \\ \sim 25 \text { from sections } \\ \hline \end{array}$ | Morales-Nin et al., 1996 FAIR 1999; BASBLACK 2000 |
| 4 | Red (Blackspot) Seabream | 16 | Menezes et al., 2001 |
| 4 | Greater Forkbeard | 15 ? | FAIR 1999, Sub-t. 5.12, Doc. 55 |
| 5 | Beryx decadactylus | 13 | Krug et al., 1998 |
| 5 | Beryx Splendens | 11 | Krug et al., 1998 |

## Growth rate

The $k$ parameter of the von Bertalanffy growth equation is used here as an expression of growth rate and species with the lowest ranks have the lowest growth parameter (Table 3.12.6.a.3). This coefficient represents the rate at which the individuals of a species reach their asymptotic length, while $L_{\infty}$ is a measure of asymptotic size (Francis, 1996). However, these two parameters are highly correlated and strongly different. $L_{o,} k$ pairs may
fit properly the same set of length-at-age data, especially when the full age range of the population is not represented in the sample. This may for example be a great problem for black scabbardfish for which both juveniles and adults are lacking in samples from the west of the British Isles and off Portugal (only subadults (a "sub-adult" is a juvenile, but a rather large juvenile approaching maturity) are caught). Ripe specimens have only been found near Madeira and the Azores.

Table 3.12.6.a.3 Deep-water species ranked according to growth rate.

| Rank | Species |  | Growth rate, $k$ ( $\mathrm{y}^{-1}$ ) | Authors/comments |
| :---: | :---: | :---: | :---: | :---: |
| ? | Ling |  |  | Probably Rank 3 |
| ? | Blue ling |  |  | Probably Rank 3 |
| ? | Tusk |  |  | Probably Rank 2 |
| ? | Greater Fork beard |  |  |  |
| ? | Centroscymnus coelolepis Centrophorus squamosus |  |  |  |
| 1 | Orange roughy |  | 0.06-0.07 | Annala and Sullivan, 1996; Tracey and Hom, 1999 |
| 2 | Sebastes |  | 0.06-0.11 | Nedreaas, 1990 |
| 3 | Roundnose grenadier | $\begin{aligned} & 0 \\ & 0 \\ & 0 \\ & 8 \\ & 0 \\ & 8 \\ & 9 \end{aligned}$ | $\begin{aligned} & 0.105 \\ & 0.100 \\ & 0.128 \\ & 0.101 \\ & 0.06 \\ & 0.06 \end{aligned}$ | Bergstad, 1990 <br> Kelly et al., 1997 <br> Allain and Lorance, 2000 |
| 3 | Greenland halibut |  | 0.02-0.03 (probably underestimated) | Bowering and Nedreaas 2001 (growth curves linear) |
| 4 | Red (Blackspot) Seabream | $\begin{aligned} & 0 \\ & 9 \end{aligned}$ | $\begin{aligned} & 0.17 \\ & 0.102 \\ & \hline \end{aligned}$ | Menezes et al., 2001 |
| 4 | Beryx decadactylus | $\begin{aligned} & 0^{2} \\ & 0 \end{aligned}$ | $\begin{aligned} & 0.11 \\ & 0.165 \end{aligned}$ | Menezes et al., 2001 |
| 5 | Greater silver smelt | $\begin{aligned} & 8 \\ & 0 \\ & 9 \end{aligned}$ | $\begin{aligned} & 0.20 \\ & 0.17 \end{aligned}$ | Bergstad, 1993 |
| 5 $\therefore$ | Beryx splendens | $\begin{aligned} & 0 \\ & 0 \\ & \hline \end{aligned}$ | $\begin{aligned} & 0.134 \\ & 0.141 \end{aligned}$ | Menezes et al., 2001 |
| 6 | Black scabbard fish |  | 0.251 | Morales-Nin et al, 1996 |

Based on the growth data, orange roughy is again the species with the lowest rank. Black scabbardfish appears to be much faster growing. The estimated $k$ is based upon the age reading from Morales-Nin and SenaCarvalho (1996), however, the ages estimated from sectioned otoliths, e.g., as used by Connolly and Kelly (FAIR 1999), would provide a much lower $k$ parameter. The results from the recently finished BASBLACK project suggest that growth rate is rather high (see WD by Figueiredo et al. 2001).

## Natural mortality

Estimates of the natural mortality of deep-water species were derived either from catch curves of unexploited stocks (roundnose grenadier, tusk) or from crude estimates according to the maximum age observed in the populations (Annala and Sullivan, 1996; Anon. 2000 a). Such data were only available for a few species (Table 3.12.6.a.4).

Table 3.12.6.a.4 Deep-water species ranked according to natural mortality rate.

| Rank | Species | Natural mortality, M ( ${ }^{-1}$ ) | Authors/comments |
| :---: | :---: | :---: | :---: |
| ? | Blue ling |  |  |
| ? | Greater silver smelt |  |  |
| ? | Red (Blackspot) Seabream |  |  |
| ? | Greater forkbeard |  |  |
| ? | Centroscymnus coelolepis Centrophorus squamosus |  |  |
| ? | Alfonsino (Beryx spp.) |  |  |
| 1 | Orange roughy | 0.04-0.045 | Annala and Sullivan, 1996; Tracey and Horn, 1999 |
| 2 | Sebastes | 0.1 | ICES Arctic Fisheries WG |
| 2 | Roundnose grenadier | 0.1 | Lorance et al. in press |
| 2 | Tusk | 0.1-0.2 | Anon. 2000a |
| 3 | Greenland halibut | 0.15 | Value used by ICES WGs |
| 3 | Black scabbard fish | 0.17 | Martins et al., 1989 |
| 3 | Ling | 0.2-0.3 | Derived from Z estimates compiled by SGDEEP 2000. |

## Fecundity and reproductive processes

Deep-water species are adapted to an environment where disturbance may be weaker or more rare than in the more shallow water ecosystems. Life history theory predicts several features of their reproductive biology. Deep-water species may have developed a reduced fecundity balanced by a much higher survival of adult fish. For the long-lived species, the total egg production of an adult may be spread over a long period and this may be necessary to ensure sufficient recruitment. Reduction of the adult biomass by fishing may thus have a stronger negative effect on the deep-living fishes than for species living on the shelf. Data on fecundity are still limited (Table 3.12.6.a.5), as is exact information on reproductive strategies in general. There may also be geographical variations. E. g. the roundnose grenadier to the west of Britain appears to spawn at least 2 batches per year (Allain, 1998, 1999, in press) and the spawning period may be protracted. However, in the Skagerrak, the same species appears to have a single well-defined late autumn spawning period (Bergstad and Gordon, 1994).

The estimate of fecundity may have a very different meaning in terms of resilience to exploitation and/or capacity of recovery, depending on the early life history and dispersion processes of larvae. Early life history processes are generally poorly known for deep-water
species. There is probably a potential for compensation to exploitation, but the actual potential may be very limited. The fecundity of orange roughy may increase as the stock reduces (Koslow, et al., 1995), however this may not be the case for all stocks (Clark, et al., 2000). The scope for compensation would seem very limited for the deep-water squalids.

Within teleosts, there should be a major difference between species that have a short spawning period, such as the orange roughy, and species that spawn all year round or during most of the year (e.g. roundnose grenadier west of Britain, greater argentine in the Skagerrak). The survival rate of eggs, larvae and early juveniles would be expected to be different for species for which a short spawning period is finely tuned to some expectedly "optimal" survival conditions for the spawned eggs, and for species whose progeny is dispersed more widely in space and time. This leads to a "success of reproduction" parameter. This is very poorly known for deep-water species. However, for the orange roughy, the recruitment seems to be episodic (Clark, 1998; Clark, et al., 2000; Koslow, et al., 2000). It could be argued that the recraitment of species that spawn all year round should be less variable as it is more likely that a more constant proportion of the progeny encounters favourable conditions, while for the orange roughy the conditions are either good or bad for all of a given year class of one population.

Table 3.12.6.a.5 Deep-water species ranked according to fecundity.

| Rank | Species | Fecundity |  | Authors |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Total (N.. ${ }^{-1}$ ) | relative( $\mathrm{N} . \mathrm{kg}^{-1} \cdot \mathrm{y}^{-1}$ ) |  |
| ? | Black scabbard fish |  |  |  |
| ? | Greater forkbeard |  |  |  |
| ? | Alfonsino |  |  |  |
| 1 | Deep water squalid sharks Centroscymnus coelolepis | $\begin{gathered} 7-11(3) \\ 13 \end{gathered}$ | $1 \text { or } 2(5)$ | Girard and Du Buit 1999; Girard, 2000) Clarke, WD |
|  | Centrophorus squamosus | $\begin{gathered} 8-19(4) \\ 8 \end{gathered}$ | 1 or 2 (5) | Girard and Du Buit, 1999; Girard, 2000 Clarke, WD |
| 2 | Greater silver smelt | Few thousand |  |  |
| 3 | Greenland halibut | 20000-70000 |  | $\begin{aligned} & \hline \text { Gundersen } \\ & 1999 \end{aligned} \text { et } \begin{array}{ll} \text { al. } \end{array}$ |
| 3 | Roundnose grenadier (2) | $\begin{gathered} 23000 \\ (2500-70000) \end{gathered}$ | 25000 | Allain, 1998, 1999, in press |
| 4 | Red (Blackspot) Sea Bream | 290000-1125000 |  | Krug, 1998 |

| 5 | Ling | Millions |  |  |
| 5 | Blue ling | Millions |  |  |
| 6 | Tusk | Millions |  |  |

(1) Data for the North-east Atlantic; values from the southern hemisphere are lower due to the smaller size of the fish.
(2) per batch.
(3) Ovarian fecundity: number of simultaneous ovules in the ovaries.
(4) Uterine fecundity: number of simultaneous embryos in the uterus.
(5) Hypothetical mean number of pup/year/female estimated from the ovarian or uterine fecundity, and duration of the reproductive cycle derived from indirect method.

## Length and age at first maturity

Length at first maturity is known for many species (Table 3.12.6.a.6). Age at first maturity is less often determined, and the estimates frequently depend on
assumed rather than validated age data. It is difficult to rank the species according to these criteria. The parameter of interest is not the length or age per se, rather at what stage in their life they start to reproduce. A better basis for the ranking would have been age/length at first maturity as a proportion of an estimate of maximum age/length. A precise proportion could not be derived for all species, bat an approximate measure was used whenever possible as basis for the final ranking given in Table 3.12.6.a.6.

Data from Australia and New Zealand suggest that orange roughy matures at a very high age (25-30 yrs), but this is not really late in life for a species with a life span of 100 years or more. Others may spawn for the first time at an age corresponding to a half or a third of their maximum life-span. The lings and tusk grow to about half their maximum size before maturing, but others such as roundnose grenadier and greater silver smelt are comparatively big when spawning for the first time.

Table 3.12.6.a.6 Deep-water species ranked according to length and age at first maturity.

(1)Data for the Northeast Atlantic, fish in the southern hemisphere mature younger at a lower size (Horn et al., 1998; Tracey and Horn, 1999).

## Answer to point b) of the NEAFC request

Annex I of the NEAFC request reads as follows:

## Request for clarification of advice for deep-sea species

The following points are issues where review and clarification of advice on deep-sea species presented in the June 2000 ACFM report are requested:

1. Two statements are made that are generally applicable to deep-sea fisheries where there is little biological information:
"ICES recommends immediate reduction in these fisheries unless they can be shown to be sustainable"
and
"Consistent with a precautionary approach, fishing should not be allowed to expand faster than the acquisition of information necessary to provide a basis for sustainable exploitation."

Both statements appear on p. 186 of the ACFM June 2000 report, where a general recommendation is made for many stocks. The second statement is also repeated in respect of argentine, orange roughy, red seabream, greater forkbeard, and alfonsinos.

The statements are contradictory. The former states that catches should be reduced (but gives no indication by how much). The latter statement implies catches can be maintained at current levels. This ambiguity in the advice should be resolved.
2. Comparing different stocks, there does not seem to be consistency between the estimated level of stock depletion and the level of the proposed reductions. Specifically,

- Orange roughy is estimated as being outside safe biological limits and biomass is estimated as being about half $\mathrm{B}_{\text {msy }}$ in Sub-area VI. This is a similar situation to that estimated for black scabbardfish, tusk and roundnose grenadier, but whereas in those cases an effort reduction of 30 to $50 \%$ is advised, for the orange roughy the advice only implies that catches should not increase. The advice seems to be on a different level of risk acceptance than ICES has accepted for many other species.
- Roundnose grenadier is estimated to be depleted to $30 \%$ of unexploited stock size, and a $50 \%$ effort reduction is envisaged. In comparison, tusk is estimated to be more depleted (to $20 \%$ of unexploited stock size), yet the advice is to reduce effort by only $30 \%$.

3. For ling, total mortality in the stock is estimated to be 0.7 to 0.8 (implying an F of around 0.5 to 0.7 ) and advice is to reduce fishing effort by $30 \%$. This implies that acceptable fishing mortality levels are in the range about 0.4 to 0.5 . This is the same sort of range as proposed for more productive species on the continental shelf, and for which close monitoring of the stocks allows reduction of risk by taking appropriate remedial actions in the case of stock declines. Such options are not available in the case of deep-sea species. Additionally, the stock is reported to be "outside safe biological limits in some parts of its range" by ACFM. Given that, as advised on p. 265, "the species and stocks are $a$ priori not able to cope with high or even moderate exploitation rates", the implied levels of risk for this stock seem much higher than those normally considered acceptable.
4. ICES is asked to clarify, for black scabbardfish. to which zones the advice is intended to be applied.
5. For several stocks, reference is made that the stock is "outside safe biological limits". However, the precautionary reference points and the basis for their definition is not given in the ACFM report, although mention is made of these in the corresponding Study Group report. As for the other stocks, ICES is asked to state explicitly its precautionary reference points as the basis for defining safe biological limits, and to describe the risks incurred on violating such limits.
6. ACFM recommends that "a comprehensive data collection system is urgently required, and research on all stocks should be increased to provide the data necessary for assessment". It would be helpful if ACFM would review the existing and proposed data-collection systems and advise on extensions or modifications that may be required to make them appropriate for monitoring deep-sea resources. Specifically, STECF in 2000 has recommended minimum standards of data collection for many stocks, including deep-sea species; and NEAFC has had a log-book reporting scheme in existence for some years (see EU regulation 2807/83).

## Answer to the NEAFC request point b)

## Clarification of advice statements, Annex I, Pts. 1-4.

## Pt. 1 Apparent contradictory statements

The sentence "Consistent with a precautionary approach, fishing should not be allowed to expand faster than the acquisition of information necessary to provide a basis for sustainable exploitation" only applies to deep water fisheries that may develop on virgin stocks (stocks that have not previously been exploited) or on stocks where exploitation clearly has only been on a marginal or limited part of the entire population. New fisheries, expansion into unexploited areas, or significant changes in the fisheries (i.e. introduction of
new gears or fleets) should be permitted only when these fisheries expand very slowly, and are accompanied by programmes to collect data which allow evaluation of stock status. Species for which this type of advice is applicable is listed under Category $I$ in Table 3.12.6.a.7.

Most exploited deep-water species are at present considered to be harvested outside safe biological limits. ICES recommends immediate reduction in these fisheries unless they can be shown to be sustainable. When these fisheries have been reduced, consistent with a precautionary approach, fishing should not be allowed to expand faster than the acquisition of information necessary to provide a basis for sustainable exploitation. Species/stocks for which this type of advice applies is listed under Category 2 in Table 3.12.6.a.7.

Table 3.12.6.a. 7 Species/stock grouped according to which advice statement applies. Category 1 comprises stocks for which new fisheries may develop, but only if the state of the stock is closely monitored. Category 2 comprises stocks that are fully exploited or overexploited and for which immediate reduction in the fishery is recommended. * indicates that all known stocks of the species falls in that category. Mainly based on ICES Coop. Res. Rep. No. 242, including some new evaluations of expanding fisheries.

| Species/Stock | Category 1 <br> Developing new fisheries | Category 2 <br> Fully or overexploited | Comment |
| :---: | :---: | :---: | :---: |
| General recommendation | Advice 2000: <br> Fisheries on such species be permitted only when they expand very slowly, and are accompanied by programs to collect data which allow evaluation of stock status | Advice 2000: <br> Immediate reduction unless fisheries can be shown to be sustainable |  |
| Blue ling |  | All Populations <br> Advice 2000: <br> there should be no directed fisheries for this stock and measures should be implemented to reduce/minimise catches of this stock in mixed fisheries. |  |
| Ling |  | All Populations <br> Advice 2000: overall fishing effort should be reduced by $30 \%$. |  |
| Tusk | Hatton Bank fishery (Part of Sub-area VI and XII) | All areas except Hatton Bank <br> Advice 2000: overall fishing effort should be reduced by $30 \%$. | Mainly by-catch in ling fishery. |
| Roundnose grenadier | Stocks outside Sub-areas VI, VII, Vb | Sub-areas VI, VII and Vb combined <br> Advice 2000: <br> reduction in fishing effort by $50 \%$ for Sub-areas VI and VII and Division Vb combined. | Status of fishery and stock in the Skagerrak (IIIa) unclear but landings are high compared with size of area. |
| Black scabbardfish | Stock in Sub-area X | Stock in Sub-areas V, VI, VII, and XII Stock in Sub-area IX is probably Category 2. <br> Advice 2000: <br> Reduction in fishing effort by $50 \%$. | Stock structure remains unclear. |
| Greater silver smelt or argentine | All Populations |  | Applies primarily to areas where target fishery is expanding, e.g. V, VI, VII |
| Orange roughy | Stocks in all areas except VI | Sub-area VI <br> Advice (see pt 2 below): <br> a significant reduction of effort to around $50 \%$. | Stock structure and status unclear except in Sub-area VI |
| Red (=blackspot) seabream |  | All Populations |  |
| Greater forkbeard | All Populations |  | State of stocks unknown |
| Alfonsinos (Beryx spp.) | All Populations |  | State of stocks unknown |
| Deep-water squalid sharks | All Populations |  | State of stocks unknown |

Pt. 2 Inconsistencies in advice. Comparisons between stocks.

The analysis presented in the answer to the NEAFC request a) suggests that the three species mentioned in the NEAFC request, i.e. Orange roughy (average rank 1.6), Tusk (average rank 3.8) and Roundnose grenadier (average rank 2.4 ), differ in their vulnerability to fishing.

Orange roughy is vulnerable to fishing both because of its life history (see answer to request a)) and because it is an aggregating species. Catch per unit of effort data may be a poor indicator of impact of harvesting because the index may stay high despite sequential depletion of local aggregations. The vulnerability of orange roughy was not fully reflected in last year's advice. An assessment of the orange roughy in Sub-area VI is available, while the stock status in other Sub-areas cannot be assessed due to insufficient data. No new evaluation of the orange roughy in Sub-area VI is available this year, but on the basis of the 2000 assessment showing a very depleted stock, a significant reduction of effort to around $50 \%$ is proposed. The fishery in Sub-area VI is more intensive than in other Sub-areas. The reduction of effort proposed is similar to that proposed for the somewhat less vulnerable but heavily exploited roundnose grenadier.

The advice on tusk was not based on an estimate of the overall biomass to be below $20 \%$ of the virgin stock biomass. Tusk is estimated to below $\mathrm{U}_{\text {tim }}$ ( $20 \%$ of virgin biomass) in Division Vb only. Elsewhere CPUE has been declining, but data since 1996 are not available for some of the most important fisheries. There is not sufficient reliable data to evaluate stock status in these areas, but the fisheries have continued in the same manner and may even have expanded since 1996. ICES therefore judged that an overall significant reduction in effort is required and proposed a $30 \%$ reduction.

Compared with data available for tusk, data for roundnose grenadiers cover a much wider area (Division Vb and Sub-areas VI and VII). The assessment is therefore considered more reliable than that of tusk, but the grenadier is more vulnerable to fishing than the tusk. The biomass estimate for roundnose grenadier is close to $\mathrm{U}_{\text {lim. }}$. Compared with tusk, and despite the stronger confidence in the grenadier assessment, a stronger reduction in effort is advisable for grenadier, mainly because of the differences in vulnerability between the two species. This was the basis for the advice on a $50 \%$ reduction in effort.

## Pt. 3 Ling - Acceptable mortality level

Ling has a wide geographical and bathymetrical range also comprising shelf and coastal waters. Ling has life history characteristics and ecology that makes it less vulnerable to exploitation than the more long-lived deep-sea species such as orange roughy, Sebastes a.o. The available biological parameters suggest that exploitation limits might be comparable to, e.g., Northeast Arctic cod. Such stocks seem by experience to be able to sustain fishing mortalities around 0.4. This is the background for the 2000 advice" that the overall fishing effort be reduced by $30 \%$."

## Pt. 4 Black Scabbardfish - Zones to which the ICES advice applies

The data available cover the black scabbardfish in Subareas V, VI, VII and XII. However, there is also a fishery on black scabbardfish in Sub-area IX. ICES will include this component in the overall advice for management of the black scabbardfish until evidence that Sub-area IX supports a single stock separate from that in other areas becomes available. Therefore the advice for a reduction in fishing effort by $50 \%$ applies to the Sub-areas V, VI, VII, XII and IX.

A new fishery for black scabbardfish in Sub-area $X$ is developing. The catch rates obtained are very high compared with other longline fisheries for this species. This suggests that abundance in this Sub-area is much higher than in other sub-areas. There is insufficient data available for a proper analysis of the stock situation. It is proposed that the fishery is allowed to develop following the principle specified for a new deep-water fishery as discussed under the answer to point 1) above. The fishery in Sub-area $X$ is developing under close monitoring by observers collecting relevant data following this advice.

Answer to NEAFC request point c): Give established reference points used as basis for statements on stock status (as outlined in Annex 1 of the request pt 5).

The Precautionary Approach gives two strong justifications for advice on and management of deepwater species being more conservative than for the shelf stocks, which have been the historic focus of fisheries. Specifically, the Precautionary Approach requires that decisions be risk averse when there is risk of harm that is serious or difficult to reverse, and that management should be more cautious when uncertainty is greater. The discussion below addresses these justifications in the general case for deep-water species. Deep-water (and shelf species) show diverse life histories, so there may be occasional exceptions to each argument, and advice and management should always be based on the best information available.

First, any specific negative change in stock status will be more serious for deep-water species than for shelf stocks, and more difficult to reverse. As described in the answer to the NEAFC request pt 1 , see above, the life histories of deep-water species mean that they are less productive than shelf stocks. Being less productive, they can sustain only lower exploitation rates, and they can only increase more slowly in response to management actions intended to improve stock status.

Second, for several reasons uncertainty will be higher for deep-water stocks. Data are sparse for deep-water species in the ICES area, and even with expanded research and monitoring efforts, will remain less complete than data for shelf stocks for many years to come. Moreover, the types of information available for these species are rarely the time-series of agestructured catch and survey data, which form the basis for assessments of shelf stocks. Therefore advice and management will have to be based on indicators of stock status other than B and F, and the performance of these indicators as guides to advice and management is poorly known. Also, because of the differences in life histories between deep-water and shelf species, knowledge of perturbations of population status (reductions in abundance, changes in age composition, etc.) from which shelf species can recover cannot be transferred with confidence to deep-water species.

Reference points for deep-water species must be set in context of both of those factors. Because any harm will be more serious and more difficult to reverse for deepwater stocks than for shelf stocks, limit reference point of deep-water species must be set to ensure that stocks are in better condition than the stock status associated with limit reference points for shelf stocks. Because uncertainty is greater for deep-water stocks, precautionary reference points will have to be further from limit reference points than is the case for shelf stocks, to achieve the same degree of risk avoidance by management.

ICES used biological reference points for deep-water species for the first time in 1998 and suggested using the following limit and PA reference points:
$\mathrm{F}_{\text {lim }}=\mathrm{F}_{35 \% \mathrm{SPR}}$
$\mathrm{F}_{\mathrm{pa}}=\mathrm{M}$
$\mathrm{B}_{\text {lim }}=0.2 * \mathrm{~B}_{\text {max }}$ (maximum observed biomass, may be a smoothed (over time) estimate)
$\mathrm{B}_{\mathrm{pa}}=0.5^{*} \mathrm{~B}_{\mathrm{max}}$

For many stocks there is no absolute biomass estimate available and instead ICES uses indicators, e.g. a CPUE index from a research vessel survey (preferably) or from logbook data for commercial fishing. These indices are notated U so that $\mathrm{U}_{\mathrm{lim}}$ is an index for $\mathrm{B}_{\text {timb }}$,
etc. Using such indices posed for data poor situations the references points become:
$\mathrm{U}_{\text {tim }}=0.2 * \mathrm{U}_{\text {max }}$ (maximum observed biomass indicator, may be a smoothed (over time) index)
$\mathrm{U}_{\mathrm{pa}}=0.5^{*} \mathrm{U}_{\mathrm{max}}$
For most deep-water stocks the only information available on fishing mortality rates is from catchcurves (if an estimate of M is available) and, given that the assessment methods used (Production and modified DeLury models) generate estimates of current and virgin exploitable biomass, these biomass reference points were used for all stocks.

ICES advice on deep-water species in 2000 did not refer explicitly to reference points for the individual stocks. However, $\mathrm{U}_{\text {lim }}=0.2 * \mathrm{U}_{\text {max }}$ and $\mathrm{U}_{\mathrm{pa}}=0.5 * \mathrm{U}_{\text {max }}$, were adopted for all the deep-water species for which advice was provided, although further work is needed to determine if deep-sea species can recover readily from depletion to $20 \%$ of the unexploited condition. As knowledge accumulates on deep-water species and fisheries, ICES will continue to bring forward and refine reference points for these stocks. ICES will assess the status of the deep-water species again in 2002.

Answer to NEAFC Request point d). Provide advice on how to improve data-collecting systems and advice on appropriate improvement for monitoring deep-sea resources.

Assessments of deep-water species depend on retrospective time-series of catch and effort. Currently used time-series are referenced to ICES Sub-areas and Divisions or aggregates of these. Because of the patchy distribution of deep-water fish interpretation of such time-series depends on knowledge of the fishing grounds where these catches were taken. Therefore, detailed spatial information on catch and effort is important. Landings and effort data on more relevant reporting areas, such as rectangles would be of special importance for fisheries statistics for Sub-area XII.

ICES finds that the existing data could be improved by:

- Providing more detail on spatial information on where the fishing took place. Many deepsea species extend their occurrence over very wide areas, but with very uneven distribution within these areas. Information on a fine scale would be of great value to the assessments.
- Including the depth of the fishing ground in the logbook.
- Expanding the species list to include request for information on sharks and rays.

NEAFC issued in 1998 "Recommendation on a scheme of control and enforcement in respect of fishing vessels fishing in areas beyond the limits of national fisheries jurisdiction in the convention area ("The scheme"). This scheme was entered into force on 1 July 1999. The EU has implemented corresponding reporting practices for their own and non-EU vessels fishing within its $\mathrm{EE} Z$.

Articles 7 and 8 of the NEAFC scheme concerning logbooks and reporting of catch and effort are those most relevant to the ICES work on deep-sea resources. ICES has attempted to identify desired changes with the view to facilitate the improvement of basic information and data flow to the assessment process.

## Spatial Information

In accordance with Article 7b (and Annex IV), logbooks shall contain species-specific catch and effort information on the spatial scale of 'small statistical rectangle or fishing location'.

The fishery for deep-water species are under VMS satellite tracking, a system that provides very detailed information on the position of the vessel. Such detailed data will be subject to confidentiality considerations, but it may be an efficient solution to the statistics problem to link the logbook databases with the VMS databases with a time lack. From a stock assessment point of view such a time lag of between 3 and 6 months would be acceptable.

However, such detailed statistics have not consistently been available. Usually data only allow an aggregate catch and effort estimate on the scale of ICES Sub-area or Division, and this system of areas is not suitable for deep-sea fish stocks. It would therefore be of great value to the assessments if data on the requested finerscale data were made available. This would enable aggregation of catches by more natural sub-areas. It is therefore suggested that catch and effort data by statistical rectangle be provided to ICES.

ICES should cooperate with NEAFC and together explore the possibility of compiling a database from which time-series of data by statistical rectangles can be constructed.

## Depth on Fishing Ground

Logbooks used in deep-water fisheries do not include information on depth of fishing, although fishing operations may extend over wide depth ranges within short time-periods. The lack of provision for the recording of depth is a shortcoming in the scheme. Even within a statistical rectangle the depth may vary considerably, and it is known from several previous studies that target species and communities change markedly with depth. Inclusion of depth information, even coarse data such as an average depth of tows or
longline sets, would therefore facilitate more detailed data analysis.

If VMS data were linked to the logbook databases it would be possible to infer the fishing depth using fishing charts and an entry in the logbook would not be necessary.

## Species List

Attachment II related to Article 8 lists the species included in the scheme. For most species this list is adequate, but a problem is the lack of species-specific information for sharks and rays. Deep-sea sharks have life histories that make them particularly vulnerable to enhanced mortality rates, and life history patterns vary among species. ICES has obtained some speciesspecific landings and effort data through national sampling schemes, but the data sets are limited and do not cover a sufficient proportion of the catch. Provision of species-specific data on sharks and rays would constitute a considerable improvement.

Sharks and rays are notorious difficult to identify and therefore either an educational scheme among the fishermen or an observer programme is required for a breakdown to species.

## Discards

The recording of discards is optional (Annex IV). ICES has compiled discard information, mainly based on observers reports, but again the scale of such observations is limited both geographically and temporally. The assessments would benefit from a change of the scheme whereby the recording of discards (by species) becomes mandatory. Experience suggests that reliable discard data can only be obtained through an observer scheme.

### 3.13

Stocks in the Baltic

### 3.13.1 Overview

The main fisheries for cod in the Baltic use demersal trawls, high opening trawls (operating both pelagically and demersally), and gillnets. There has been an increase in gillnet fisheries in the 1990 s and the share of the total catch of cod taken by gillnets has in recent years been about $50 \%$. The Baltic herring is exploited mainly by pelagic trawls and demersal trawls and, during the spawning season, by trap-nets/pound-nets in coastal areas. The herring trawl fishery is largely a mixed herring and sprat fishery where share of herring varies significantly by sub-divisions and seasons. The main body of the sprat catch is taken by pelagic pair trawling and used for industrial purposes. There has been an increase in catches of sprat in the most recent years and 1997 catches were at a record high of 529000 t in the whole Baltic. The sprat catches have since decreased continuously to 389000 t in 2000. Baltic salmon is exploited by drift net, trap net and longline fisheries.

An overview of catches of fish in the Baltic until 1999 as officially reported to ICES, is given in Section 3.13.2.

For Baltic cod there is one management unit covering all Sub-divisions 22-32. ICES considers the stocks in Sub-divisions 22-24 and Sub-divisions 25-32 as separate stocks, however, and advice is provided on them separately.

ICES reiterates its advice that the cod stocks should be managed separately in order to better adapt the exploitation to the present development in the two stocks.

IBSFC has in September 1999 adopted a Long-Term Management Strategy for the Cod Stocks in the Baltic Sea

The IBSFC agreed to implement a long-term management plan for the two cod stocks, Eastern and Western stocks, as defined by ICES, which is consistent with a precautionary approach and designed to ensure a rational exploitation pattern and provide for stable and high yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of Spawning Stock Biomass (SSB) greater than 160000 tonnes for the Eastern stock and 9 000 tonnes for the Western stock
2. A long-term management plan shall be implemented, by which annual quotas shall be set
for the fishery on the Eastern stock, reflecting a fishing mortality rate of 0.6, and for the Western stock 1.0, both for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of 240000 tonnes for the Eastern stock and 23000 tonnes for the Western stock, the fishing montality rates referred to under paragraph 2 will be adapted in the light of scientific estimates of the conditions then prevailing, to ensure safe and rapid recovery of spawning stock biomasses to levels in excess of 240000 tonnes and 23000 tonnes, respectively, for the Eastern and Western stocks.
4. For allocation purposes, a combined TAC will be established; The Contracting Parties agree to further collaborate, inter alia, through bilateral agreements to ensure an efficient management of the cod stocks.
5. The exploitation pattern in the fisheries for cod and in particular, the selectivity shall be improved in the light of new scientific advice from ICES with the objective to enhance the spawning biomass of cod and reduce discards.
6. Additional technical measures including, inter alia, further limitation on effort, restrictions on fishing days, closing of areas and/or seasons, obligation to change fishing ground in case of high abundance of juveniles, special reporting requirements, and other appropriate control measures should be considered.
7. The IBSFC shall, as appropriate, adjust management measures and elements of the plan on the basis of any new advice provided by ICES.

A review of this arrangement shall take place no later than year 2003.

For cod, unusually strong year classes in 1976,1979 and 1980 formed the basis for an increase in the stock in the eastern Baltic and an expansion in the fisheries. Catch levels more than doubled and the fishery attracted vessels from other Baltic fisheries and from fleets normally operating outside the Baltic Sea. In almost all years landings have been far above the levels recommended by ICES. The decline in stock size and landings started around 1985 and continued up to 1992. Fleet capacity and fishing effort have now been reduced to some extent, but fishing mortality increased as the stocks declined. Improved recruitment in the early 1990s has resulted in spawning stock biomasses increasing above the 1992 minimum, and this increase has been seen especially in the western Baltic cod stock. After a slight increase in 1994-1995, the SSB of
the eastern Baltic cod stock has decreased again in 1996-1999 to a historically low level.

The success of cod reproduction is, among other things, dependent on certain minimum levels of salinity and oxygen concentration for the fertilisation and survival of the eggs and larvae. The unusually long period with low influx of North Sea water from the late 1970s to the early 1990s was in general a period of low recruitment. The influx in 1993 resulted in improved environmental conditions, which allowed the possibility of improved recruitment but did not secure it. Since 1993 there have not been major influxes. The effect of an intrusion of North Sea water into the Baltic Sea is usually sufficient to support better environmental conditions for two spawning seasons (about 1.5 years) at the most, because after that period the salinity and oxygen levels in the deep water layers decrease below the level at which cod eggs can survive.

The recent improvement in recruitment and the reversal of the downward trend in spawning stock biomass has been seen in both the Western (Subdivisions 22 and 24) in 1994-1997 and Eastern (Subdivisions 25-32) cod stocks in 1994-1995. However, fishing mortalities are still estimated to be high in the Western stock and increased from a lower level in the Eastern stock. In the Western stock the increase in spawning stock biomass in recent years was caused mainly by the 1994 year class, and it is expected that the spawning stock biomass will increase with the present exploitation pattern, due to the 1997 year class, which is estimated to be above average. The Eastern stock has been below the long-term average since 1986, and thus a recovery of the stock can hardly be expected with the present exploitation pattern and tendency for fishing mortality to increase. It is therefore considered that a precautionary approach, including reductions in fishing effort is needed if these stocks are to recover on a more permanent basis.

The landings of sprat for industrial purposes have increased markedly during the last decade. Herring and sprat are used mainly for human consumption when landed in the countries on the eastern Baltic coasts, but for production of fishmeal and oil in the countries on the west coast.

Herring in the Baltic is assessed as five stocks. This is to be regarded as a compromise between using the larger number of stocks/populations that have been identified for biological reasons and the practical constraints, e.g. in what units are catch figures available, and what are the possibilities for correctly allocating individual fish to particular stocks.

Sprat is assessed as one unit for the entire Baltic.

The exploitation rate of pelagic stocks in the Baltic has increased since the mid-1990s. Due to the low abundance of cod the natural mortality of Baltic herring and sprat is low at present. The Baltic sprat is considered to be harvested inside safe biological limits. A sharp decrease in mean weight at age of sprat has been observed since 1993. A continuous decreasing trend in mean weight at age has been observed in most herring stocks in the Baltic since the mid-1980s. This decline in mean weight at age partly explains the declining trend in biomass of the herring stock in Subdivisions $25-29,32$ (including Gulf of Riga). At the present the mean weight of herring remains at a very low level. Still, there have been some indications in the last few years that the decreasing trend of the mean weight is slowing down. Due to the decreasing SSB and increasing trend in fishing mortality the Central Baltic herring is assumed to be outside of biological limits.

It has, for several reasons, been difficult to estimate the absolute stock size for the pelagic stocks, although the development of stock size in relative terms is better described. Inconsistencies between years in the results from acoustic surveys and low precision in the estimates of species composition in the mixed fisheries have contributed to the variation in stock estimates given during the latest years. However, a fourfold increase in sprat catches between 1991 and 1997 has been observed and the development of this fishery, and consequently the rate of fishing mortality, should be closely monitored.

The multispecies interactions may periodically have astrong influence on the state of fish stocks in the Baltic, depending on the abundance of cod as the main predator in the Baltic Sea ecosystem. To take into account the multispecies effects, the data from multispecies assessment methods are used in the assessment of pelagic stocks. However, interactions with other potential top predators, such as salmon and seal that are potentially very important in the northern Baltic Sea, are not yet quantified and are therefore not directly included in the present ICES advice.

The spring-spawning of herring stock in Sub-divisions 22-24 and Division IIIa migrates after the spawning season into the Kattegat, Skagerrak and eastern parts of the North Sea, where it mixes with the North Sea autumn-spawning herring stock during the feeding period. Difficulties in allocating catches to the Baltic spring-spawning stock and to the considerably larger North Sea stock, uncertain catch statistics, and conflicting trends in survey indices have resulted in unreliable assessments for the spring-spawning stock of herring in Sub-divisions 22-24 and Division IIIa.

For Baltic salmon and sea trout see overview in Section 3.13.15.

## International Baltic Sea Fishery Commission (IBSFC)

### 3.13.2 Nominal catches in the Baltic Area

Officially reported catches in the Baltic until 1999 are given in Tables 3.13.2.1-5. These are the catches officially reported to ICES by national statistical offices for publication in the ICES Fishery Statistics.

In the assessments, the working groups try to estimate discards and slipped fish, landings which are not officially reported, and the composition of by-catches. These amounts are included in the estimates of total catch for each stock and are used in the assessments; thus, they appear in the tables and figures produced by working groups. These estimates vary considerably between different stocks and fisheries, being negligible in some cases and constituting important parts of the total removals from other stocks. Further, the catches used by the working groups are broken down into subdivisions, whereas the officially reported catches by
some countries are reported by the larger Divisions IIIb, c , and d. The trends in Tables 3.13.2.1-5 may not, therefore, correspond to those on which assessments have been based, and are presented for information only, without any comment from ACFM.

The 1990 catches listed under the Federal Republic of Germany and the German Democratic Republic refer to catches by vessels from the respective former territories during the whole of 1990 , before and after political union. Thus, catches taken by vessels registered in the former German Democratic Republic in the months after unification are included in the German Democratic Republic figures.

The catch data used in the assessments are given in other tables.

Table 3.13.2.1 Nominal fish catches in the Baltic from 1973-1999 (in 000 t). Anadromous species, except salmon, not included. (Data as officially reported to ICES.)

#### Abstract

Answer to request for information on herring stock components: ICES has compiled information on herring stock components in the central Baltic. This information is insufficient to justify a new assessment structure with several subunits and further documentation is required before such stock units could be reliably re-defined. Until this work is completed, ICES will present an assessment for the stock components combined in Sub-divisions 25 $29+32$ (incl. Gulf of Riga) and a separate assessment for the Gulf of Riga herring.

State of stock/exploitation: Although the exact stock size is uncertain, there is high confidence that the
spawning biomass has continued to decrease and is close to the historic low. The fishing mortality increased throughout the late 1990s and the stock is currently harvested outside safe biological limits. Current fishing mortality is above $\mathrm{F}_{\mathrm{pa}}$ and even above $\mathrm{F}_{\mathrm{tim}}$.

Management objectives: There are no explicit management objectives for this stock. However, for any management objective to meet the precautionary criteria, $F$ should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and spawning stock biomass should be maintained above $\mathbf{B}_{\mathrm{pa}}$ once an appropriate value is identified.

Precautionary Approach reference points (unchanged since 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ not defined | $\mathbf{B}_{\mathrm{pa}}$ not defined |
| $\mathbf{F}_{\text {lin }}$ is 0.33 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.17 |

Technical basis:

| $\mathbf{B}_{\text {lim }}$ not defined | $\mathbf{B}_{\mathrm{pa}}$ not defined |
| :--- | :--- |
| $\mathbf{F}_{\text {lim: }}: \mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\mathrm{med}}$ |

There is no biological basis at present for determining biomass reference points. Past proposed biomass reference points were based on lowest observed biomass. However, it is uncertain how relevant past spawning biomass sizes are as a guide to precautionary reference points for this stock in the present regime of low productivity and low weights at age.

Advice on management: ICES recommends that fishing mortality in 2002 should be reduced below the $\mathrm{F}_{\mathrm{pa}}=0.17$ to allow the SSB to increase. The TAC for herring in Sub-divisions 25-29, 32 should be set so that the catch of this stock in 2002 is less than 73000 t . To allow the SSB to rebuild to historic sizes associated with good recruitment, a rebuilding plan should be developed.

Rebuilding plan: Two examples of medium-term scenarios that could be implemented for rebuilding are discussed below.

Relevant factors to be considered in management: The TAC for herring has been kept far above the reported landings since 1989. Herring and sprat are mostly caught in mixed fisheries, but directed fisheries exist in some countries.

The implication of a substantially reduced harvest of the herring stock as advised should be considered when implementing the management plan for sprat fisheries.

The species composition in these mixed pelagic fisheries has changed profoundly during the 1990 s.

Sprat now constitutes about $60 \%$ of reported landings compared to less than $10 \%$ in earlier years. The mismatch of species proportions in quotas and in landings has created incentives for misreporting. by species. Such misreporting seriously affects rebuilding of the herring stock. The misreporting also affects the quality of the assessments of both sprat and herring. To ensure that mixed fisheries operate in compliance with quotas for both herring and sprat, measures must be taken to ensure that reporting is accurate. Reporting of catches by species must be based on appropriate sampling. The respective TACs must reflect species abundances in the sea.

Large variability in mean weight at age has been observed during the last decade. A general decrease in growth, caused by environmentally changed feeding conditions has been coupled with changes in relative abundance of stock components. Increased proportions of slow-growing herring, especially in Sub-divisions 25 and 26 have decreased the weight at age even further in these areas. Migrations of stock components with different growth rates between spawning areas and feeding areas contribute to the large seasonal and area variability in mean weights. Also any changes in the area distributions of reported landings contribute to the variability. These factors increase the uncertainty in the prognoses and make it more difficult for management to set TACS that meet the desired objectives.

Much of the estimated decline in SSB has been attributed to the overall decrease in mean weights at age, as the numbers of mature herring (spawning stock in numbers) have remained stable during 1982-1996
(Figure 3.13.4.1). The decrease in SSB since 1997 has, however, been associated with a marked decline in numbers.

Comparison with previous assessment and advice: The present assessment gives about $22 \%$ higher estimates of SSB and $32 \%$ lower fishing mortality than
last year's assessment. These changes are principally due to revised data for natural mortalities and coverage corrections of the acoustic survey data, together with a shorter age span for the assessment data. This latter point created the major effect on the assessment. The trends in spawning stock and fishing mortality have, however, not changed.

Catch forecast for 2002:
Basis: $F(2001)=F_{\text {sq }}=F(1998-2000)=0.47$; Landings $(2001)=191 ; \operatorname{SSB}(2001)=442$.

Weights in ' 000 t .
Shaded scenario considered inconsistent with the precautionary approach.

Medium- and Iong-term projections: Two mediumterm predictions are given in Figures 3.13.4.2 and 3.13 .4 .3 , both based on the assumption of a $15 \%$ reduction in F for year 2001 and using mean weights at age for 1998-2000. In Figure 3.13.4.2, F is reduced to $80 \%$ of the $\mathrm{F}_{\mathrm{pa}}$ level for the whole period 2002-2010, whereas in Figure 3.13.4.3, F is kept at $\mathrm{F}_{\mathrm{pa}}$. Fishing at $0.8 * \mathbf{F}_{\mathrm{pa}}$ would result in average annual catches from 75000 t to 135000 t between 2002 and 2010. SSB is projected to reach 750000 t (the previously proposed $\mathbf{B}_{\text {lim }}$ for the stock). Fishing at $\mathbf{F}_{\mathrm{pa}}$ would result in catches of about 130000 t , with $S S B$ remaining around 600000 t . The $\mathbf{B}_{\mathrm{pa}}$ formerly proposed is inserted in the figures for illustration purposes. Continuation of the present exploitation is expected to lead to a continued reduction of SSB.

Elaboration and special comment: The assessment is uncertain, due to the complexity of the stock structure and the uncertain split between herring and sprat in most pelagic fisheries in the area.

The following stock components were also considered separately: Sub-divisions 25-27, Sub-divisions 28 (Gulf of Riga excluded), $29 \& 32$, and Gulf of Riga (see below). IBSFC proposed to use Sub-divisions $29 \mathrm{~S}+32$, Open Sea herring in Sub-divisions 25-28, and Coastal herring in Sub-divisions 25 and 26. However, taking data availability into account those components for which assessment and advice were presented, were considered to be the best compromise.

For herring in Sub-divisions 25-27, SSB has steadily decreased since the mid-1980s. In the last three years the SSB has been at the lowest observed level (about 2 times lower than the average value in 1980-2000). Fishing mortality was high in the 1980s and has increased steadily thereafter. Recruitment has been at or
below the long-term average since the mid-1980s. Landings have declined from around 160000 t in the 1980 s to around 80000 t in the 1990 s , Table 3.13.4.1.

For the Gulf of Riga herring, SSB and recruitment have been high since 1990 with the exception of the 1996 year class. Fishing mortality was below $\mathbf{F}_{\mathrm{pa}}$ during the 1990s, except for 1996-1998. Landings have increased since 1992 and reached 39800 t in 1997 (see section below on Gulf of Riga herring).

For herring in Sub-divisions 28,29 and 32 (excl. Gulf of Riga herring), SSB has steadily decreased since the end of 1980 s and is at present at the lowest observed level. Recruitment in the 1990s has been close to or below the long-term average. Fishing mortality has increased considerably since the mid-1990s. Landings decreased from $140000-120000 \mathrm{t}$ during most of the 1980 s to a rather stable level in the 1990 s fluctuating around 90000 t , Table 3.13.4.2.

In order to illustrate the degree of consistency in the way that the separate assessments have been performed comparisons were made between the result from the whole area (Sub-divisions $25-29,32$ ) and the sum of the results from Sub-divisions 25-27, Sub-divisions 28 (Gulf of Riga excluded), 29 and 32, and Gulf of Riga (Figure 3.13.4.4). The agreement between the sum of the parts and the whole is generally good for total stock biomass, average weight in the stock, spawning stock biomass, yield/SSB and fishing mortality. However, differences are apparent in the numbers of recruits estimated in the earlier assessment years where the sum is smaller than the result from the whole area. The trends in stock development are similar for the two larger stock units where there is a declining trend; whilst the Gulf of Riga exhibits an increasing trend. Fishing mortalities in the earlier years of the assessment
are higher in the Gulf of Riga than for the whole area; whilst for the most recent years the fishing mortalities in Sub-divisions 28 (Gulf of Riga excluded), 29 and 32 are higher than for the whole area.

$\mathrm{F}(2001)=0.85 * \mathrm{~F}(2000), \mathrm{F}(2002-2010)=\mathrm{F}_{\mathrm{pa}}$.

Figure 3.1.3.4.4 Herring in SD $25-29+32$ (incl. Gulf of Riga). Comparisons between estimates from different assessments

### 3.13.4.a Herring in the Gulf of Riga

State of stock/exploitation: The stock component is at present considered to be within safe biological limits. SSB and recruitment have been high since 1990 , with the exception of the 1996 year class. Fishing mortality was below $\mathbf{F}_{\mathrm{pa}}$ during the 1990s, except for 1996-1998.

Management objectives: There are no explicit management objectives for this stock component. However, for any management objective to meet the precautionary criteria, F should be less than the $\mathrm{F}_{\mathrm{pa}}$ and spawning stock biomass should be maintained above the Bab $_{\text {pa }}$

Precautionary Approach reference points (proposed in 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 36500 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 50000 t |
| $\mathbf{F}_{\text {lim }}$ not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4 |

## Technical basis:

| $\mathbf{B}_{\mathrm{lim}:}: \mathbf{B}_{\mathrm{p} 2} / \exp (1.65 * 0.2)$ | $\mathbf{B}_{\mathrm{p} 3}:=\mathrm{MBAL}=50000 \mathrm{t}$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}:$ not defined | $\mathbf{F}_{\mathrm{pn}:}$ from medium-term projections |

Advice on management: At the current exploitation rate the stock component is forecasted to remain within safe biological limits. The expected landings in 2002 corresponding to this rate are 33200 t .

Comparison with previous assessment and advice: The present assessment gives $14 \%$ lower estimates of SSB than last years assessment and F is increased by $43 \%$.

## Catch forecast for 2001:

Basis: $F(2001)=F_{s q}=F(1998-20000)=0.33$; Landings $(2001)=33.5 ; S S B(2001)=123$.

Shaded scenarios considered inconsistent with the precautionary approach

Elaboration and special comment: Herring catches in the Gulf of Riga include both Gulf herring and open-sea herring, which enter the Gulf of Riga from April to June for spawning. The herring in the Gulf of Riga is fished by Estonia and Latvia. The landings, which were about 30000 t in the early 1970 s , decreased to $12000-$ 15000 t in the 1980 s . Since 1992 the catches have increased, reaching 39800 t in 1997 (the figure includes unallocated catches and some catches of Gulf herring outside the Gulf of Riga). The structure of the fishery has remained unchanged in recent decades: approximately $70 \%$ of the catches are taken by the trawl fishery and $30 \%$ by the trapnet fishery on the spawning grounds.

Analytical assessment is based on catch data and CPUE series. Gulf of Riga herring is used as a component of the herring in Sub-divisions 25-29 and 32, separated in the landings by means of otolith structure.

A stock-recruitment relation with stochastic variation is used for generating possible future recruitment figures. During the projection period ( 10 years) the spawning stock is projected to increase.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

### 3.13.5 Herring in Sub-division 30, Bothnian Sea

State of stock/exploitation: Although the exact stock status is uncertain, the stock is considered to be harvested outside safe biological limits. The spawning stock biomass has been high in the early 1990s, but has decreased since 1994 and is presently close to the $\mathbf{B}_{\mathrm{pa}}$. The fishing mortality has increased since 1993, being above $\mathbf{F}_{\mathrm{pa}}$ since 1997 and at $\mathbf{F}_{\text {lim }}$ in 2000. Landings have been at the high level of around 60000 t since 1994.

The 1997 and 1999 year classes have been well above the long-term average.

Management objectives: There are no explicit management objectives for this stock. However, for any management objective to meet the precautionary criteria, $F$ should be less than $\mathbf{F}_{\mathrm{pa}}$ and the spawning stock biomass should be maintained above $\boldsymbol{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (proposed in 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 145000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 200000 t |
| $\mathbf{F}_{\text {liri }}$ is 0.30 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.21 |

## Technical basis:

| $\mathbf{B}_{\text {lim: }}:$ spawning stock biomass, where probability of <br> lower recruitment increases | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{jim}}{ }^{*} \exp (1.645 * 0.2)$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}:}: \mathbf{F}_{\text {med }}$ |

Advice on management: ICES recommends to reduce the fishing mortality to no more than $F_{p a}$ corresponding to landings of less than 39500 t in 2002.

## Relevant factors to be considered in management:

 This stock is part of the IBSFC management unit 3. The exploitation of the stock has increased in the 1990 s, and according to medium-term projections (Figures 3.13.5.1-2) the present fishing mortality is notsustainable. A reduction in fishing mortality to below $\mathbf{F}_{\mathrm{pa}}$ has a high probability of keeping the spawning stock biomass above $\mathbf{B}_{\mathrm{pa}}$ in the longterm.

Comparison with previous assessment and advice: This years assessment gives about $25 \%$ higher estimates of spawning stock biomass than last years assessment and a corresponding decrease in fishing mortality.

Catch forecast for 2002:
Basis; $\mathrm{F}(2001)=\mathrm{F}_{\mathrm{sq}}=\mathrm{F}(1998-2000)=0.30 ;$ Landings $(2001)=60 ; \mathrm{SSB}(2001)=203$.

| $\mathrm{F}(2002)$ | Basis | SSB(2002) | Landings (2002) | SSB (2003) |
| :---: | :---: | :---: | :---: | :---: |
| 0.00 | No fishing | 201 | 0 | 251 |
| 0.21 | $\mathbf{F}_{\mathrm{pa}}=0.7 * \mathbf{F}_{\text {sq }}$ | 195 | 39 | 206 |
| \$ \% \% < |  | 193: | 4, | \% ${ }^{\text {\% }}$ |
|  |  |  |  |  |

Weights in '000 t.
Shaded scenario considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections were calculated for a 10 -year period based on Monte Carlo simulations.

Medium-term projections for 10 years, starting from the most recent estimate of the survivors, are presented for different fishing mortality levels in Figures 3.13.5.1-2.

The medium-term projection using the average fishing mortality from 1998-2000 ( $\mathrm{F}_{\mathrm{bar}}=0.30$ ) reveals a decreasing trend over a 10 -year period and there is a high probability of the spawning stock biomass being close to the $\mathbf{B}_{\text {lim }}$ of $145000 \mathbf{t}$.

Elaboration and special comment: About $90 \%$ of the total catch is taken by trawl fishery. Trapnet fishery is of minor importance. In the trawl fishery more effective and larger trawls have been introduced in the 1990s. Fishing effort is to a large extent market-driven.

Source of information: Report of the BaItic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

### 3.13.6 Herring in Sub-division 31, Bothnian Bay

State of stock/exploitation: The status of the stock is unknown, but the current assessment, although uncertain indicates that spawning stock biomass was high in the 1980s and has declined considerably since the mid-1990s to a very low level. The fishing mortality was high in the 1990s. Landings have been decreasing and they were at a record low in 2000 ( 3000 t ). The 1994, 1995 and 1999 year classes were above the longterm average, and preliminary information indicates that this also applies for the year class in 2000.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points: There are no Precautionary Reference points proposed for this stock.

Advice on management: ICES advises that exploitation rates should be decreased from their recent high levels.

Relevant factors to be considered in management: This stock is part of the IBSFC management unit 3. The exploitation of the stock has increased in the 1990s. Recruitment is influenced not only by the size of the spawning stock, but to a large extent by the environmental conditions. The herring TAC is set for IBSFC management unit 3 , which includes Subdivisions $29 \mathrm{~N}, 30$ and 31 . The management of this stock should take account of the recommendations of management actions in other parts of management unit 3.

Comparison with previous assessment and advice: This years assessment gives about $14 \%$ lower estimates of spawning stock biomass than last years assessment, together with a $40 \%$ higher fishing mortality. Previous estimates of the stock productivity have been overoptimistic.

Elaboration and special comment: The main body of the total catch is taken by trawl fishery. Total fishing effort in the trawl fishery is to a large extent marketdriven, and the fluctuation in total trawl catches and the length of fishing seasons depend upon the onset of winter and ice cover in the autumn. Normally the trawl fishing season starts in late April and stops for the spawning season in late May to July. Trawl fishery starts again in August/September. The ice cover usually appears in early November.

| 2001 |  |  | 6931 | 0.3600 |
| Average |  |  |  |  |

State of stock/exploitation: The stock is considered to be within safe biological limits. SSB has increased in recent years and attained its historical maximum of $1.6-1.7$ million tonnes in 1996-1997. Since then the SSB has decreased to 1 million $t$ in 2001, which remains well above the long-term average. In the most recent years the estimates of fishing mortality have almost doubled the values of the early 1990 s and have come close to $\mathbf{F}_{\mathrm{pa}}$. The 1998 year class is estimated to be very weak, whereas the 1999 year class is estimated to be strong. The 2000 year class is predicted to be below average.

Management objectives: In Resolution XIII, September 2000, the IBSFC agreed to implement a long-term management plan for sprat in the Baltic:
"The IBSFC agreed to implement a long-term management plan for the sprat stock which is consistent with a precautionary approach and designed to ensure a rational exploitation pattern and provide for stable and high yields. This plan shall consist of the following elements:

1. Every effort shall be made to maintain a level of spawning stock biomass (SSB) greater than 200000 t .
2. A long-term management plan, by which annual quotas shall be set for the fishery, reflecting a fishing mortality rate of 0.4 for relevant age groups as defined by ICES shall be implemented.
3. Should the SSB fall below a reference point of $275000 t$, the fishing mortality rate referred to under paragraph 2 will be adapted in the light of scientific estimates of the conditions then prevailing, to ensure safe and rapid recovery of the spawning stock biomass to levels in excess of 275000 t .
4. The IBSFC shall, as appropriate, adjust management measures and elements of the plan on the basis of any new advice provided by ICES.

A review of this arrangement shall take place not later than in the year 2003."

ICES considers that the agreed management plan is consistent with the precautionary approach, provided the reference points are used as upper bounds on $F$ and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lan }}$ is $200000 \mathbf{t}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 275000 t |
| $\mathbf{F}_{\text {lim }}$ is not yet defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.40 |

Technical basis:

| $\mathbf{B}_{\mathrm{lim}}:$ MBAL | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{lim}} * 1.38 ;$ some sources of uncertainty in assessment <br> taken into account |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:-$ | $\mathbf{F}_{\mathrm{pa}}: \sim$ average $\mathbf{F}_{\mathrm{med}}$ in recent years, allowing for variable <br> natural mortality |

Advice on management: ICES recommends that the fishing mortality should remain below $F_{p \text {, }}$ corresponding to catches less than 369000 t .

Relevant factors to be considered in management: Sprat and herring are taken mostly in mixed pelagic fisheries. Management of sprat fisheries should take account of the recommendation to greatly reduce fishing mortality and catches of herring in Subdivisions $25-29$ and 32.

The strong 1997 and 1999 year classes will constitute over $50 \%$ of catches in 2002 . The future of the fishery will depend greatly on the strength of future recruiting year classes. The fishing mortality this stock can
sustain is dependent on natural mortality, which is linked to the abundance of cod. Strong recruitment and low predation in recent years contributed to the high SSB in the mid-1990s. However, the SSB is predicted to decrease markedly in the medium-term under the present fishing intensity. If the cod stock is to recover a much lower exploitation rate on sprat is necessary.

Comparison with previous assessment and advice: This years assessment gives about $10 \%$ higher estimates of spawning stock biomass for recent years than last years assessment did, mostly as a result of applying updated estimates of predation mortality on sprat. The trend in stock development is similar in both assessments.

Catch forecast for 2002:

| 4 |  | 3\%1\% | Sis | S24 |  |

Weights in '000 t.
Shaded scenarios are considered to be inconsistent with the precautionary approach.

Medium- and long-term projections: The medians of spawning stock biomass under status quo fishing mortality tend to result in an equilibrium of about 770000 t SSB (Figure 3.13.7.1-2). Fisheries in 2004 and onwards will depend very heavily on the strengths of future recruitment.

Elaboration and special comment: The assessment is based on catch data and acoustic surveys. Better sampling of industrial fisheries has improved the quality of the data input to the assessment.

Natural mortality is expected to vary over time as abundance of predators varies. Hence annual estimates of $\mathbf{F}_{\text {med }}$ are expected to continue to be comparably variable, and multispecies interactions should be considered in setting precautionary reference points.

Landings increased from 1983, reaching a record high in 1997, and decreased thereafter. The increase in landings since 1992 is due to the development of an industrial pelagic fishery. The catches in this fishery consist mainly of sprat (about 65\%) and herring. With
the current advice to reduce $F$ on herring by more than $50 \%$, the proportion of herring in the industrial pelagic catches will either have to decrease, or the herring catch alone will limit this fishery.

Sprat is fished with pelagic trawls during the first half and in the last few months of the year. Most catches used for human consumption are taken in mixed fisheries for herring and sprat.

### 3.13.8

State of the stock/exploitation: The present fishing mortality is 1.11 , above the F of 1.0 agreed by IBSFC. SSB is estimated to be 29900 t in 2001, above the $\mathbf{B}_{\mathrm{rs}}$ ( 23000 t ). Recruitment has been below average since 1998.

Management objectives: IBSFC have adopted a longterm management strategy for cod in the Baltic (section 3.13.1). ICES considers that the agreed management plan is consistent with the precautionary approach, provided the reference points are used as upper bounds on F and lower bounds on SSB, and not as targets.

Reference points: There is doubt about whether these cod form a closed population, as there may be substantial exchange with adjacent cod stocks. Such exchange could inflate R/SSB reference points, which are very high for this stock, e.g. $\mathrm{F}_{\text {med }}=1.08$, and the high fishing mortality estimates may not accurately represent the exploitation rate for the unit stock. Further consideration of the magnitude and consequences of exchange is needed before establishing an appropriate $\mathbf{F}_{\text {lim }}$.

Precautionary Approach reference points (Unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is not yet defined | $\mathbf{B}_{\mathrm{pa}}$ be set at 23000 t |
| $\mathbf{F}_{\text {lim }}$ is not yet defined | $\mathbf{F}_{\mathrm{pa}^{\mathrm{a}}}$ is not yet defined |

Technical basis:

| - | Previous MBAL |
| :--- | :--- |
| - | - |

Advice on management: ICES recommends that the fishing mortality in 2002 should be reduced by at least $10 \%$ to below the $F$ of 1.0 agreed by IBSFC, corresponding to a catch below 36300 t .

Relevant factors to be considered in management: The catch forecast is sensitive to the estimated size of the 1998 and 1999 year classes which account for about $70 \%$ of the yield in 2002. Following year classes also appear to be below average, and catches are expected to decline further if fishing is kept at $\mathrm{F}_{\mathrm{pa}}$.

The fishery is largely based on recruiting year classes, and discarding is substantial. An increase in the minimum trawl mesh size, as agreed by IBSFC to be implemented by January 2002, may significantly reduce the amount of discards.

The stock has been rebuilt from the low SSBs of the early 1990s as a result of strong recruitment, especially from the 1994, 1996 and 1997 year classes. The patterns of recruitment to this stock over time and relative to spawning biomass suggest that there may be recruitment dispersal and/or migration between this stock and adjacent cod stocks in the Baltic and/or Kattegat.

Comparison with previous assessment and advice: The current assessment has revised the estimate of the SSB in 1999 downwards; mainly due to changes in the mean weight at age in the stock. This has not changed
the state of the stock with respect to safe biological limits, and the advice is consistent with last years.

Catch forecast for 2002:
Basis: $\mathrm{F}(2001)=\mathrm{F}_{\mathrm{sq}}=1.11$; Landings $(2001)=40500$; $\operatorname{SSB}(2002)=27,400$.

| F (2002) | Basis | $\begin{array}{\|c\|} \hline \text { Landings } \\ (2002) \end{array}$ | $\begin{gathered} \hline \text { SSB } \\ (2003) \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 61,700 |

| 1.00 | $0.9 * \mathbf{F}_{\mathrm{sq}}$ (IBSFC agreed) | 36,300 | 29,400 |
|  |  |  |  |

Weights in t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections were simulated over 10 years, using the IBSFC agreed F of 1.0 . The outcome shows less than $10 \%$ probability that the SSB will fall below the $\mathrm{B}_{\mathrm{pa}}$ of 23000 t . The long-term projection reference points are estimated as $\mathbf{F}_{0.1}=0.17$ and $\mathbf{F}_{\mathrm{max}}=0.28$. The input and results from the yield per recruit analysis estimates $S / R$ reference points at $\mathbf{F}_{\text {med }}=1.08, \quad \mathbf{F}_{\text {hig }}=1.74$ and $\mathrm{F}_{\text {low }}=0.43$.

Elaboration and special comment: As a result of the high fishing mortality, SSBs and yield are dependent on ages $2-4$. The contribution of ages 2 and 3 in the yield has for recent years been around $70 \%$ of the landings. The estimates of the size of the year classes attaining these ages in the forecast are uncertain, being based on partly recruited fish or solely on research survey information. For the period 1992-1994 landings are uncertain due to incomplete reporting; however, the data quality has improved significantly since then.

|  |  |  |  |  |

State of stock/exploitation: The stock is outside safe biological limits. Although the actual status of the stock cannot be estimated precisely the available information indicates that the SSB in 2001 is well below $\boldsymbol{B}_{\text {pa }}$. The fishing mortality is poorly estimated, but is well above $F_{\text {pa }}$. In the most recent years the stock has been below $\mathbf{B}_{\text {lim }}$ and the fishing mortality has been fluctuating around $\mathbf{F}_{\text {lim. }}$. Recruitment since the late 1980s has been below average.

Management objectives: IBSFC have adopted a longterm management strategy for cod in the Baltic (section 3.13.1). ICES considers that the agreed management plan is consistent with the precautionary approach, provided the reference points are used as upper bounds on $F$ and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 160000 t | $\mathbf{B}_{\text {pa }}$ be set at 240 000t |
| $\mathbf{F}_{\text {lim }}$ is 0.96 | $\mathbf{F}_{\text {pa }}$ be set at 0.6 |

Technical basis:

| $\mathbf{B}_{\text {lin: }}:$ SSB below which recruitment is impaired | $\mathbf{B}_{\text {pa }}:$ MBAL |
| :--- | :--- |
| $\mathbf{F}_{\text {lim: }}$ Fmed 98 | $\mathbf{F}_{\mathrm{pa}}: 5$ percentile of $\mathbf{F}_{\text {med }}$ |

Advice on management: ICES recommends that no fishery for cod be permitted in the eastern Baltic in 2002. Concerning TAC for 2001, see Section 3.13.16.

Rebuilding plan: A rebuilding plan should be developed as soon as possible, including criteria for reopening the fishery. The current area and seasonal closures are not considered to be sufficiently effective to achieve rapid and safe rebuilding. Large closed areas and seasons may contribute to stock recovery, but only if accompanied by major reductions in effort or catch. Increases in minimum mesh size in trawls to be introduced on the $1^{\text {st }}$ January 2002 may help improve the exploitation pattern and reduce discards.

Relevant factors to be considered in management: Cod in the Baltic have traditionally been taken in a directed fishery with very few cod occurring as by-catch in other fisheries. It should therefore be possible for managers to effectively reduce fishing mortality on cod without disrupting fisheries on other species.

There are no indications of substantial movements of fish from this stock to areas outside of Sub-divisions $25-32$, so management measures do not need to consider migration effects in relation to this stock. However, management measures should consider the possible displacement of effort onto the western Baltic cod stock where ICES advice is also for a reduction of $F$ in 2002.

Recruitment is influenced not only by the size of the spawning stock, but to a large extent by the environmental conditions (e.g., volume of water with high salinity and high oxygen content). Since the early 1980s fewer and smaller influxes of saline North Sea water were observed than in earlier years. This is reflected in the recruitment pattern, with most recent year classes below the long-term average. It is not possible to predict if and when the present regime of saltwater movements will change. Even though it is not possible to predict these environmental changes precisely, they need to be taken into account in both short-term management and medium-term recovery plans, to ensure that SSB does not become further depleted during the current period of low recruitment, and that rebuilding schedules are realistic. There have been no recent inFlows of saline water to the eastern Baltic. Environmental data for early 2001 indicate very poor conditions in the main spawning areas, so cod reproduction in the eastern Baltic in 2001 is unlikely to be successful.

Comparison with previous assessment and advice: Fishing mortality has consistently been under-estimated and stock size over-estimated in the previous assessments. In addition, weights at age in 1999 have been lower than previously assumed.

Catch forecast for 2002：
Basis： $\mathrm{F}(2001)=\mathrm{F}_{\mathrm{sq}}=\mathrm{F}(1998-2000)=1.12$ ；Landings $(2001)=79.6 ; \operatorname{SSB}(2002)=92.5$ ．

Weights in＇000t．
Shaded scenarios considered inconsistent with the precautionary approach．

Medium－and long－term projections：Medium－term projections are not reported because the point estimates and probabilities from the assessment were not considered reliable．

Elaboration and special comment：Analysis has indicated that age－reading problems have resulted in considerable uncertainty about the absolute level of SSB and F，but that annual trends are robust to these effects．

Misreporting caused severe problems in the quality of the data in the early 1990s and is still thought to occur．

The earlier surveys were not adequately coordinated． Recent work on standardizing surveys has implied that surveys today are coordinated and use similar gears．

Calibrations of the historical time series information to the new gear standards were impossible to finalise this year．This adds uncertainty to their use as tuning indices．

The landings increased from about $150000 t$ in the mid－1970s to around 360000 t in the early 1980 s ，but decreased thereafter．The fisheries developed during the 1970s with more fleets entering in the early 1980s，and the intensity of the fishery increased further with the introduction of a gillnet fishery at the end of the 1980s and the beginning of the 1990s．The size of the gill－net fleet has decreased in recent years，and the majority of catches are now taken by mobile gears．

State of stock/exploitation: The total landings of flounder were quite stable from the early 1970s until 1994, when reported landing increased markedly. Reported catches in 1995 and 1996 were well above the previous average, but have decreased thereafter.

Results from a tentative assessment of the stock in Subdivisions 24 and 25 suggest a relatively stable spawning stock of around 25000 t since the late 1970s (Table 3.13.10.2).

Comparison with previous assessment and advice: The tentative assessment is consistent with that of last year.

Elaboration and special comment: Flounder is taken as a by-catch in the cod trawl and gillnet as well as in coastal fisheries. There are also directed trawl fisheries for this species in Sub-divisions 24 and 25 . For 1994

1998 high total landings of flounder were recorded, likely due to misreporting of other fish species as flounder (Table 3.13.10.1).

The majority of the landings are caught in Subdivisions 24,25 and 26 . The amount of discarded flounder is not known, but it is assumed to be high because landings depend on market price and minimum marketable size.

For most of the flounder stocks the data available are insufficient to make an analytical assessment and catch forecasts. An assessment could be made only for the flounder stock in Sub-divisions 24-25.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

Total landings (tonnes) of Flounder in the Baltic by sub-division and country. (There are some gaps in the information, therefore "Total" is preliminary.

### 3.13 .11 <br> Plaice

State of stock/exploitation: The available data do not permit the current stock size and exploitation to be assessed.

Elaboration and special comment: Sub-divisions 22 and 24 are the most important areas for plaice fishery in the Baltic. The total landings of plaice (Table 3.13.11.1) were high in the 1970 s, but have decreased
since the 1980s to the lowest on record in 1993 (269 t). Since then the landings have increased to 2700 t , mainly due to increased landings from Sub-division 22.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

Plaice in Sub-divisions 22 to 32

Total landings (tones) of Plaice in the Baltic by sub-division and country. (There are some gaps in the information, therefore "Total" is preliminary.

${ }^{1}$ From October-December 1990 landings of Germany, Fed. Rep. are Included.
${ }^{2}$ For the years 1970-1981 and 1990 the catches of Sub-divisions 25-28 are included in Sub-division 24.
${ }^{3}$ For the years 1970-1981 and 1990 the Swedish catches of Sub-divisions 25-28 are included in Sub-division 24. ${ }^{4}$ Provisional.

State of stock/exploitation: The available data do not permit the current stock size and exploitation to be assessed.

Elaboration and special comment: The total landings of dab (Table 3.13.12.1) were stable at around 2000 t per year in the 1980 s and the early 1990s. The reported catches in 1994 and 1995 increased to 3000 t , but in 1996 they returned to the previous level. From 1997 onwards the landings decreased to under 1500 t , landings characteristic to the beginning of the 1970 s .

The temporary increase in landings reported for 1994 and 1995 is influenced by misreporting of other species as dab.

Most catches were taken from Sub-division 22, followed by Sub-division 24 with only up to $12 \%$ of the total landings.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

${ }^{1}$ From October-December 1990 landings of Germany, Fed. Rep. are included.
${ }^{2}$ For the years 1970-1981 and 1990 the catches of Sub-divisions 25-28 are included in Sub-division 24.
${ }^{3}$ For the years 1970-1981 and 1990 the Swedish catches of Sub-divisions 25-28 are included in Sub-division 24.
${ }^{4}$ Provisional.
${ }^{5}$ In 1995 Danish landings of Sub-divisions 25-28 are included.

State of stock/exploitation: The available data do not permit the current stock size and exploitation to be assessed.

Elaboration and special comment: The landings of turbot in the Baltic increased from less than a 100 t in the 1960 s and 1970 s to nearly 500 t in the early 1990 s , and again to above 1000 t in the mid-1990s. Catches declined after 1996, and are now about 500 t (Table 3.13.13.1).

The main turbot fishery takes place in Sub-divisions 22, $24,25,26$ and 28. Due to the high market demand a directed turbot gillnet fishery developed in the 1990s.

At present the IBSFC regulations of the turbot fishery are a temporary closure of fishing during the spawning
season, and a minimum landing size. There are also additional national regulations, for example, a minimum mesh size for some fisheries.

The landings are uncertain due to incomplete reporting, especially for the early years.

Although there are ongoing study programs in several countries focusing on the status of turbot stocks in the Baltic, the data available are insufficient to allow evaluation of the appropriateness of the present management measures in respect to the precautionary approach.

State of stock/exploitation: The available data do not permit the current stock size and exploitation to be assessed.

Elaboration and special comment: The landings of brill in the Baltic are low and are typically less than

50 t (Table 3.13.14.1) and are mainly taken in Subdivision 22.

Source of information: Report of the Baltic Fisheries Assessment Working Group, April 2001 (ICES CM 2001/ACFM:18).

Brill in Sub-divisions 22 to 32

million in 2000 . The wild smolt production, which may be about 0.5 million, constitutes about $15 \%$ of the total smolt production. Most of the stocks remain in the coastal area within about 150 km of the point of release, but a high proportion of those from Poland and some from southern. Sweden migrate further into offshore areas. Coastal populations are mainly taken in gillnets or trap nets. In the Gulf of Bothnia, they are caught as a by-catch in fisheries for whitefish. The stocks entering the offshore area are exploited by salmon drift netting and long lines. Sea trout are important for the recreational fishery in coastal areas and rivers. The catches of sea trout have been quite variable in recent years, but it seems likely that misreporting of salmon as sea trout in some years has influenced the statistics.

IBSFC has not established any management objectives
for sea trout.

The populations in the Gulf of Bothnia (Sweden and Finland), particularly those in Sub-division 31, are in a poor state. Several of these populations are overexploited to the extent that they now exist mainly as non-migratory brown trout populations. The state of the populations in the remainder of the Baltic Sea is variable, but in general better than in the Gulf of Bothnia.

Sea trout are affected by M74 to a much lesser degree than salmon are. Populations in some rivers in the Gulf of Finland and the southern part of Gulf of Bothnia and northernmost part of the Main Basin have exhibited a limited incidence of M74. The situation in the Main Basin is less well known.

River names with a siash (/ show main fivertributary. Fiver names with hyphen (न show names in diferent cotntres.
Figure 3.13.15.a. 1 Baltic salmon rivers divided into three categories (see above figure). Only lower parts of rivers with current salmon production or potential for production of wild salmon are shown. The presence of dams, which prevents access to areas, is indicated by lines across rivers. Notation: river name in bold = river with wild smolt production; river name underlined $=$ river with potential for establishment of wild salmon; normal font $=$ river with releases. no natural reproduction.

State of stocks/fishery: Parr densities in most rivers being monitored in the Gulf of Bothnia are improving and smolt production should exceed the $50 \%$ target for most monitored rivers by 2002 . Wild smolt production in the Main Basin is more uncertain due to poorer monitoring, but is thought to be as good or better than in rivers Flowing into the Gulf of Bothnia. The survival rate of smolt to adult has not been determined for these larger smolt year classes. Therefore the status of the wild stock as a whole, although unquestionable improved, remains uncertain. Catches of salmon are given in Tables 3.13.15.b. 1 and 3.13.15.b.2.

Salmon smolt production in the Gulf of Bothnia and Baltic Main Basin are shown below (in millions):

${ }^{1}$ Data on wild smolt production since the 1990 s is to a large extent based on annual surveys. Smolt production estimates based on counts only for rivers Tornionjoki and Simojoki ( $20-30 \%$ of total production). ${ }^{2}$ Preliminary data.

Wild stocks: There are wild salmon populations in 13 rivers discharging into the Gulf of Bothnia. In the early 1990 s, most populations in this area were depleted, producing $5-20 \%$ of their potential. The management measures taken, including the reduction in TAC and the national regulatory measures, coincided with the occurrence of a strong brood-year class in 1990 and increased parr densities in almost all of these rivers in 1996-2000. Improved parr densities are expected to give high smolt runs in 2001-2002 (3-4 year old smolts) and good spawning runs in 2002-2005 (Table 3.13.15.b.3). In a small number of rivers entering into the Gulf of Bothnia populations are improving only slowly, often from returning numbers so low that the stocks were at risk of extinction. The spawning run in 2000 , originating from the small year classes 1994

1995, was low and estimated egg deposition was about the same as in year 1999. The spawning runs of multi-sea-winter wild salmon are expected to be low also for the year 2001, mainly because the population in the sea consists at present mainly of 1995-1996 year classes which suffered high M74 mortality (Table 3.13.15.b.4). However, the spawning run of one sea-winter salmon is expected to increase in 2001.

In the Main Basin area the status of populations is somewhat better in terms of parr densities and number of spawners than in the Gulf of Bothnia. In general, smolt production in rivers in the area are higher in relation to production capacity than in the Gulf of Bothnia. However, the status of individual rivers is generally uncertain due to incomplete monitoring. Recent parr surveys in Latvian rivers suggest that these stocks are not affected by M74.

Reared stocks: Most of the salmon smolt recruitment originates from the releases. Tagging results suggest that survival of reared smolts has declined since the early 1990 s , and no indication of increase has been observed (Figure 3.13.15.b.1).

Management objectives: The IBSFC objective is to increase the natural production of wild Baltic salmon to at least $50 \%$ of the natural production capacity of each river by 2010 , while retaining the catch level as high as possible.

Advice on management: ICES advises that a continuation of the national and international measures in place in 1997-2000, with the TAC for 2002 of 410000 salmon, is consistent with the Salmon Action Plan.

ICES further advises that the exploitation in rivers should be closely monitored and kept sufficiently low to allow the number of spawning fish to increase. Some rivers have reached what is considered to be full production and many more rivers may achieve this status shortly. As rivers reach full production densitydependent interaction may become a concern and there may be implications for the best way to distribute harvest among rivers. For these reasons IBSFC should consider setting spawning stock targets for individual rivers, which are at or near full production.

Relevant factors to be considered in management: Many indices show that many populations are benefiting from current management measures, thereby increasing the probability of achieving the management objective. However, there is less or no improvement in parr densities in some rivers, particularly those with very low escapements at the beginning of the current management initiative. Therefore, the exploitation rate
must be kept very low on the Baltic salmon while the stocks are exploited in mixed fisheries. Otherwise the small stocks, which are recovering much more slowly, could suffer over-exploitation. From a biological perspective all wild stocks should be rebuilt as quickly as possible.

ICES is aware that current harvest advice would result in a certain amount of reared fish returning to their release site, and thus not being harvested with current management measures. If river-specific measures could be developed to harvest such surplus reared fish without by-catch of wild salmon, such harvesting could proceed, and be incremental to the TAC without causing a conservation concern. Some relevant experience on strategies for harvesting surplus reared salmon without increasing exploitation on wild stocks has been acquired in other jurisdictions, and could guide development of national programs to harvest surplus reared salmon. However, any such programs should be reviewed by ICES prior to implementation, to ensure that they provide protection to wild stocks.

TAC is an effective tool to safeguard salmon in the Main Basin to allow them to begin their spawning run. However, to restrict fishing mortality in coastal fisheries directed at homing wild salmon, complementary technical measures are essential. In the Gulf of Bothnia the date of opening coastal fisheries has been delayed to restrict the harvest of the early run when the proportion of multi-sea-winter wild salmon is the largest. As the spawning migration covers a short time period and is progressing quickly, a change in opening date would cause large differences in exploitation and have a corresponding effect on spawning stock size.

There is evidence from tagging that survival rate from smolt to adult may be declining. Such declines could offset the improvements in smolt production and justify caution in harvesting. Increasing catches, before the survival rate of these larger smolt runs is known, could jeopardise the progress achieved to date with the salmon recovery plan. In addition, the lowered relative abundance of the reared component in the standing stock leads to a higher exploitation of the wild component in the TAC management regime.

The factors influencing the development of M74 are poorly understood. The M74 mortality has varied over the years (Table 3.13.15.b.4) and sudden unpredictable changes in the incidence of the disease may occur. This is an additional justification for a cautious harvesting.

The salmon fishery in the Baltic Sea is based mainly on reared fish. In recent years reared fish should have constituted about $90 \%$ of the catch, based on the ratio of smolt production of reared and wild fish. Nevertheless, data on coastal tagging and sampling of
spawners indicate that the proportion of wild salmon in the catch is higher than previously considered, which implies a higher survivorship for wild smolts compared to reared.

Yield from salmon smolt releases has been decreasing since 1994. Lower catches have been explained by reduced TAC and strong regulations in coastal fisheries. Decreases are also considered to result from reduced survival of salmon in post-smolt phase. According to tagging data the return rate for year classes since 1996 is lower than average rates in the long term. Return rates fluctuate in the same tempo in Sweden and Finland, which indicates that long-term variation may be caused by temporary changes in the Baltic Sea ecosystem (Figure 3.13.15.b.1). A ca. 20\% survival rate has traditionally been assumed for reared salmon; however, it seems likely that the post-smolt survival is considerably below this value at present.

Management measures taken have decreased the offshore and coastal exploitation since the early 1990s. This has resulted in an increase in the proportion of reared fish returning to the rivers (Figure 3.13.15.b.2). Similarly there seems to be a trend of increasing catch in rivers with large compensatory releases. However, the differences in development in rivers is so pronounced that it is impossible to draw general conclusions regarding the size of the increase over the entire Main Basin and Gulf of Bothnia (Figure 3.13.15.b.3).

Some reviews assume that present management measures result in a large amount of non-exploited surplus of reared salmon in the rivers. The limited information available does not support the idea of a large non-exploited amount of salmon in the Main Basin. Instead in the Gulf of Bothnia there may be some non-harvested surplus of reared salmon, but there are considerable differences among rivers. Based on the limited data available, there seems to be a difference among Finnish and Swedish rivers. There is probably a latger number of non-exploited fish in Swedish rivers, because the coastal fishery outside rivers and river fisheries are less intense than in Finland. ICES recognises that present data on abundance of reared salmon spawners in rivers are based mainly on small scale mark-recapture estimates, made 3-5 years ago. ICES therefore recommends that larger studies should be carried out to estimate the exploitation and abundance of spawners in several rivers. These studies should be carried out before any management plan is implemented to utilise an assumed large number of non-exploited reared salmon in the rivers.

Non-reported catches and discards are estimated to be about $20 \%$ of the reported landings (in numbers), each being about the same magnitude. About $70 \%$ of discards are caused by seal damages. Catch losses have continued to increase and the most serious damage
occurs in the Sub-divisions 29-31. These losses are not included in the TAC, so as catch losses by seals continue to increase, the total number of salmon killed in the fishing gear will increase even with a status quo TAC, affecting achievement of rebuilding objectives. Moreover, it is pointed out that the effect of seals has consequences on fishery at different levels:

- the direct catch loss due to damaged or escaped fish;
- capital losses due to gear damages;
- indirect effects through changes of fishing strategy;
- effects of fishery through competition for the salmon resource.

## Forecast for 2001:

Wild stocks: From surveys of juvenile salmon in the rivers it was estimated that the wild smolt run in 2000 was 1.16 million. This was about $72 \%$ of the potential production as presently estimated. The number of spawners in 1996-1998 and densities of parr in 19971999 in Finnish and Swedish rivers suggest that the smolt production in these rivers will peak in 2001 and come down a little again in 2002 (Table 3.13.15.b.3).

Reared stocks: The production of reared smolts in 2000 was 5.86 million, and is expected to be 5.61 million in 2001.

Elaboration and special comment: In some rivers parr densities in recent years have been far above the range of historically reliable data. Although earlier studies have found no density dependency from parr to smolt or smolt to adult survivorship, that situation may not apply at the higher densities now observed. Until survivorship rates at current parr densities can be assessed, the forecasts of smolt production and adult returns in the next few years will be uncertain.

At present the assessment is based on a complex of stocks from rivers having wild salmon populations. There is an indication that the populations in the larger rivers have increased, while the status of populations in smaller, more vulnerable rivers is improving much more slowly (Table 3.13.15.b. 3 and Figure 3.13.15.b.4).

Because of the depleted state of many wild populations it is necessary to monitor the status of as many populations as possible. However, better analysis of the status of salmon populations will require an intensified long-term monitoring, which for practical reasons will have to concentrate on a few selected rivers (index rivers). A number of index rivers have been established as a part of the IBSFC Salmon Action Plan. According to the IBSFC the status of wild salmon populations in these rivers will be considered the basis for monitoring
the fulfilment of the Salmon Action Plan. It is only in the Gulf of Bothnia, however, where both smolt trapping and counting of spawners are planned to take place in the same river. ICES stresses that both elements must occur in index rivers in the Main Basin and the Gulf of Finland as well as in the Gulf of Bothnia. Otherwise it will be not be possible to evaluate reliably the future development of populations in these areas.

Estimates of wild smolt production are available for each region, but estimates in the Main Basin are based on limited surveys.

Because the management objective is to achieve $50 \%$ of the potential production level, the potential production level should be well defined. Ideally target production sizes should include consideration of both the production capacity of habitats and stock-recruitment curves. However, Baltic salmon populations have been depleted for more than 30 years and there is no empirical basis for estimating parameters of such models. Estimates of potential production in the Baltic Sea rivers are normally based on measurements of the reproductive area in combination with an estimated smolt production per unit area. These estimates may need to be revised when more data accumulate at higher production levels. In addition, the potential production estimates should be considered as average potential values, which suggest that even after rebuilding is completed they may be substantially exceeded in some years, and may also occasionally experience shortfalls.

ICES considers that the following guidelines are appropriate for use in the development of more reliable values of potential production:

1) An inventory of the size and quality of the parr rearing habitat areas for each river according to an agreed protocol. This should preferably be combined with electrofishing surveys stratified by quality of areas;
2) Measurement of the parr and smolt production in regional index rivers for a number of years. Because of the large variation it is necessary to measure for a number of years at high production levels before estimating the potential production in a river;
3) The values for the index river are transferred to other rivers in the region via measurement of the habitat area and the quality gradation of them.

The stock estimates are based on electrofishing surveys, smolt trapping, age-disaggregated catch and tagging data.

Figure 3.13.15.b. 3 Catch of reared salmon in four rivers where gear have operated with constant effort in years 1987-2000. The figures are given per 1000 smolts released.

Figure 3.13.15.b. 4 Estimated smolt production by river in \% of the average potential for wild salmon rivers in The Gulf of Bothnia including predictions for 2001-2002. The line showing $50 \%$ of the (uncertain), potential production is indicated.

State of stocks/fishery: ICES considers that the wild stocks are outside safe biological limits. Parr densities increased in most monitored rivers in 1999, but decreased again in 2000 (Table 3.13.15.c.1).

Salmon smolt production in the Gulf of Finland is shown below (in thousands):

${ }^{1}$ Data on wild smolt production assumed until 1994. 1995 figures based on surveys. ${ }^{2}$ Preliminary data. ${ }^{3}$ Data on wild production in Russia reported for 1995-2000: 11000 smolts annually. Not included in table.

Wild stocks: Based on earlier evidence there are wild salmon populations in 9 Estonian rivers in the Gulf of Finland. Surveys indicate that parr densities vary strongly in these rivers, and densities are much lower than in rivers of similar type at these latitudes in average (Table 3.13.15.c.1). Five of these populations have been supported by smolt releases in the last few years.

Minor natural reproduction occurs as a consequence of large long-term releases in one Finnish river in the area. Surveys also indicate that some natural reproduction occurs in one or two Russian rivers. Also these two populations are supported by long-term releases (Table 3.13.15.b.3). However, there are no national plans to attain self-sustainable populations in these rivers.

Reared stocks: Most of the salmon catch in the Gulf of Finland originates from smolt releases. Despite increases in releases, the catches have decreased considerably in the last few years, which indicate a lowered initial smolt survival of released salmon (Figure 3.13.15.c.1). Also tagging results give evidence for decreased survival of reared smolts (Figure 3.13.15.b.1).

Management objectives: The IBSFC objective is to increase the natural production of wild Baltic salmon to at least $50 \%$ of the natural production capacity of each river by 2010 , while retaining the catch as high as possible.

Advice on management: ICES recommends that, in light of the precarious state of wild stocks in the Gulf of Finland and the very low wild smolt production in 2000, fisheries should only be permitted at sites where there is virtually no chance of taking wild salmon along with reared salmon. It is particularly urgent that national conservation programmes to protect wild salmon be enforced around the Gulf of Finland.

Relevant factors to be considered in management: At present wild salmon populations occur in nine Estonian rivers and many of these populations are at risk of extinction. The potential smolt production is very small compared to all other wild salmon populations in the Baltic Sea. It is uncertain whether a much reduced TAC would affect the status of these stocks. The TAC has been reduced 4 times since 1996, but in 2000 it was still more then 3 times the catch, and not restrictive on harvests. Coastal fisheries at sites likely to be on migration paths of wild salmon from Estonian rivers present a particular threat to biological viability of these wild stocks. Coastal and river fisheries intercepting these populations should be prohibited. All possible means should be used to prevent all fishing in rivers and river mouths supporting these wild stocks. Additionally enhancement releases should be continued and expanded to avoid possible extinction of these stocks.

M74 caused high mortality among offspring of sea-run females in Finnish hatcheries in 1992-1997, but the M74-related mortality has lowered since 1998 . No estimates are available for the mortality in 2001 (Tabie 3.13.15.b.4). Hatchery experiments suggest that M74related mortality is low in Estonian salmon populations.

Tagged reared Latvian salmon recovered in the Gulf of Finland suggest that wild and reared Latvian salmon to some extent are also exploited in this area.

Forecast for 2001: A status quo projection for Subdivision 32 gives a catch prediction for 2001 and 2002 of 18000 and 26000 fish, respectively, to be compared to the catch in 2000 of 28000 fish. The TAC for 2001 of 70000 salmon is therefore not restrictive to the fishery.

Wild stocks: In Estonian rivers the wild production is less than in preceding years. Densities of $0+$ parr in 2000 decreased from 1999 in most of the rivers, and production of smolts is expected to remain low in the coming years. Using the most recent estimate of wild production of 3800 smolts, they represent less than $1 \%$ of the total smolt production (wild plus reared smolts). This is a much lower figure than in the Main Basin and the Gulf of Bothnia.

Reared stocks: The smolt production is expected to be about 800000 smolts in 2001.

Elaboration and special comment: Considering that at present released smolts are estimated to outnumber wild smolts by approximately $50: 1$ in this area, the current management measures may be insufficient to ensure preservation of these stocks. Under these circumstances it would be appropriate to adopt additional measures specifically intended to prevent the biological extinction of wild salmon in the Gulf of Finland.

Small reproduction areas and unpredictable variation in the size of year-classes is characteristic of Estonian wild salmon rivers. Electrofishing surveys since the 1970s indicate that there has been no spawning in some years. In spite of improvement in the water quality in the 1990s, the natural reproduction has not increased in these rivers.

Fishing effort in the Estonian coast increased significantly in the 1990s. This partly illegal fishery developed quickly because the coastal fish stocks, salmonids included, had been under-exploited and catches were relatively good. The decline of agriculture and other industries in the region that resulted in
decreased pollution of the streams should have had a positive effect on the salmon stocks. However, the decrease in the offshore fishery and improvement of water quality did not compensate for the effect of the increased coastal fishery, which exploits salmon and sea trout populations as by-catch.

The Finnish offshore and especially coastal fishery catch the major part of the total landings in the Gulf of Finland. However, the total effort has decreased in the last few years, because of the low catch per unit of effort combined with low price and particularly due to increased seal damages. Damage caused by seals is most severe at fishing sites furthest away from the coast, which has caused the trap net fishing to move closer to the shoreline.

There was no Russian commercial salmon fishery in the Gulf of Finland in year 2000, but the catch consisted of by-catch from other fisheries.

The assessment shows a very low initial survival for released smolts in the last four years compared to the early 1990 s.

The analytical assessment is based on catch at age estimated from tag recoveries and catch samples. Estimates of wild production are based on limited surveys and do not include all rivers. Lack of data on the productivity in the freshwater phase prevents calculation of the appropriate TAC strategy to meet any target based on smolt production.

Figure 3.13.15.c. 1 Salmon catches and smolt production in the Gulf of Finland in 1987-2000.

## 3．13．15．d Sea trout

## State of stocks／fishery：

Wild stocks：Currently approximately 400 rivers in the Baltic Sea support wild populations of sea trout．There are no estimates of the original number of sea trout populations or quantitative estimates of the total natural smolt production．Stocks in several rivers in the Main Basin are considered to be in good or satisfactory condition with nursery areas well utilised．However， populations in numerous small Danish brooks are assessed to be in poor condition．In the Gulf of Bothnia the status of most stocks particularly in Sub－division 31 is poor or unknown（Table 3．13．15．d．1）．Several of these populations are probably overexploited to the extent that they now mainly exist as non－migratory brown trout．

Reared stocks：Sea trout smolt production is shown below（in thousands）：

| \＃－a\％m | 8u\＃⿺辶 |  | SH1H⿰⿱丶⿸⿴巳一丶月土） | 7isal |
| :---: | :---: | :---: | :---: | :---: |
|  | Mat\＃ | \＃ilinim | Husime |  |
| \％． | disink |  |  |  |
| 1987 | 994 | 1081 | 358 | 2433 |
| 1988 | 1312 | 1083 | 226 | 2621 |
| 1989 | 1537 | 906 | 198 | 2641 |
| 1990 | 1237 | 1035 | 237 | 2509 |
| 1991 | 665 | 1186 | 259 | 2110 |
| 1992 | 1023 | 1247 | 314 | 2584 |
| 1993 | 1576 | 1171 | 251 | 2998 |
| 1994 | 1485 | 985 | 285 | 2755 |
| 1995 | 1967 | 1243 | 378 | 3588 |
| 1996 | 1509 | 1416 | 139 | 3064 |
| 1997 | 2726 | 970 | 220 | 3916 |
| 1998 | 2545 | 943 | 378 | 3866 |
| 1999 | 2506 | 971 | 355 | 3832 |
| 2000 | 1825 | 987 | 353 | 3164 |

Hatchery production in the Main Basin has increased in recent years，while the smolt production in the Gulf of Bothnia has been rather stable．

Forecast for 2001：Not available．

Elaboration and special comment：The production of sea trout in the Baltic Sea is dominated by reared production to a similar extent as production of salmon is．

Sea trout stocks in the Baltic Sea exhibit two types of migration pattern．Most of the stocks migrate in the coastal area within about 150 km of the point of release，but particularly those from Poland and some
from southern Sweden migrate further into offshore areas．The fish that migrate only short distances are mainly exploited in coastal and river fisheries，and they are also affected by the coastal salmon tisheries．Fish that migrate offshore are to a large extent taken as a by－ catch in the offshore salmon fishery．The stocks remaining in coastal waters are only exploited in local fisheries and may therefore be managed on a national or local basis，but the stocks migrating into offshore areas would benefit from international management measures．It is not known to what extent stocks in southern Sweden migrate to offshore areas．The management of many of these populations would benefit from knowledge of their migration pattern．

The exploitation pattern is rather variable in different areas．In the Gulf of Bothnia and Gulf of Finland sea trout are to a large extent caught in gill nets for whitefish，and to a minor extent in a recreational net fishery or in trap nets．National management agencies around the Gulf of Bothnia and Gulf of Finland should consider changes in local fishery regulations as well as implementation of restoration programs to improve the status of these sea trout populations，which are in a poor state．

${ }^{1}$ Additional sea trout catches are included in the salmon statistics for Denmark until 1982 (tabie 3.1.2).
${ }^{2}$ Finnish catches include about $70 \%$ non-commercial catches in 1979-1995,50 \% in 1996-1997.
${ }^{3}$ Rainbow trout included.
${ }^{4}$ Sea trout are also caught in the Western Baltic in Sub-divisions 22 and 23 by Denmark, Germany and Sweden.
${ }^{5}$ Preliminary data.
${ }^{6}$ Catches reported by licensed fishermen and from 1985 also catches in trapnets used by nonlicensed fishermen.
${ }^{7}$ Finnish catches include about $85 \%$ non-commercial catches in 1993.
${ }^{8}$ JCES Sub-div. 22 and 24.

+ Catch less than 1 tonne.
"Catches in 1979-1997 included sea and coastal catches, since 1998 costal (C) and sea (S) catches are registered separately na=Data not available

IBSFC has requested ICES to:
"Update the advised [cod] TAC for 2001, taking into account the most recent survey and catch information."

Because of new information about the state of the stock, ICES advises that there be no fishing for eastern Baltic cod in 2002 (see Section 3.13.9) and that fishing cease on the eastern stock as soon as possible, i.e. for the remainder of 2001.

IBSFC established a cod TAC for 2001 of 105000 t . The assessment of both the western and the eastern stocks in 2001 are lower than was estimated in 2000. A 2001 TAC set at a particular fishing mortality is therefore lower than was estimated in 2000. The 2001
assessment presents a further year of data and is therefore more precise than the 2001 forecast presented last year. Also, because the assessment is subject to noise it cannot be expected that the assessment in 2001 will be exactly identical to the assessment presented in 2000.

Because the splitting of TAC between the two cod stocks is not specified, no precise estimate of a 2001 catch corresponding to particular fishing mortalities can be given. As an illustration, the advice for the western stock was for a reduction in F of $20 \%$, while the advice for the eastern stock was for a reduction in F to $0.3^{*} \mathrm{~F}_{\text {sq }}$ The predicted catch for 2001 for this option was in the advice provided last year 87600 t , while the assessment now available indicates a catch from the two stocks combined for this option of 67500 t .

### 3.13.17 Cod catches in pelagic fisheries

ICES used the Intemational Baltic Sea Sampling Program database (IBSSP II) to assess cod by-catches in the pelagic fisheries and to evaluate the consequences of lowering the present $10 \%$ by-catch rule of cod in the herring and sprat fisheries (IBSFC fishing rule 8.3).

The distributions of samples by Sub-division and share of trips with observed by-catch of cod are presented in Figure 3.13.17.1. In general, the cod by-catches in sampled pelagic fisheries were generally low (near zero), but the highest share of trips with by-catch was in Sub-divisions 24-26.

Tables 3.13.17.1-2 present the total amount of cod bycatch and discards in the pelagic fishery raised from the combined herring and sprat landings by
year/quarter/Sub-division/country strata for the years 1998-2000. The highest by-catch of cod in the pelagic fishery was in the first and second quarter of the three years. Discards occurred in all quarters of 2000 , with more than $85 \%$ (by weight) in the third quarter, but only in the first quarter of 1999, and none were recorded in 1998.

The total share of cod by-catch in the combined total landings of sprat and herring fisheries was within the range of $1.3 \%$ to $2.0 \%$ in the years $1998-2000$. Whilst it is not possible to evaluate how much of the cod bycatch is recorded in official catch statistics, a lowering of the present $10 \%$ by-catch fishing rule will not significantly improve the state of the cod stock.

Table 3.13.17.1 The total cod by-catch and discard in pelagic fisheries by Sub-division and year (t).

Figure 3.13.17.1 The share of journeys with occurring cod by-catch in pelagic fisheries by Sub-division and (the numbers in brackets indicate the number of journeys).

ICES investigated the effect on biological reference points of changes in the maturity ogives of Baltic herring and sprat. For each of the two stocks three maturity ogive options were used to estimate biological reference points. The results of the calculations are presented in Tables 3.13.18.1 and 3.13.18.2.

The estimates for $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{F}_{\text {lim }}$ for herring remain unchanged from those reported last year; whilst the
estimate of $\mathbf{F}_{\mathrm{pa}}$ for sprat remains unchanged from that reported last year.

No new maturity ogives were used for the assessments of the herring and sprat stocks in the Baltic, but mean maturity ogives covering the years 1997-2000 were calculated (Tables 3.13.18.3 and 3.13.18.4).

Table 3.13.18.1 The impact of different maturity at age on the estimated reference points foro herring in Subdivisions $25-29+32$.

### 3.13.19 <br> Answer to special request from MBSFC on the selection properties of trawls with double netting

## IBSFC has requested ICES to:

"evaluate the selection properties for Baltic cod trawls using double-nettings made of twine exceeding ca. 4 mm in diameter."

Cod-end selectivity is affected by many factors. A key determinant is the mesh size in the cod-end, but also netting twine diameter and properties such as twine stiffness affect cod-end selectivity (e.g. Polet \& Redant, 1994, and Ferro \& O'Neill, 1994). A systematic examination of the magnitude of these effects was carried out within the EU-project VARSEL (Study of factors affecting the variability of cod-end selectivity) (Anon., 1997; Lowry, 1995; Lowry \& Robertson, 1994, 1996). Identifying individual contributions to selectivity from each factor proved difficult as the results were affected by a combination of other factors (e.g. catch size, variable operational conditions during the experiments, etc.). In 1999-2001 a joint German-Polish experiment has been conducted in which the effect of twine size and number of twines on cod-end selectivity was investigated for cod in the Baltic. Three singletwine cod-ends with netting with twine diameters ranging from 4 to 8 mm and two double-twine cod-ends with netting of 4 and 6 mm were tested. The trials were carried out on the same research vessel, under similar operational conditions, at the same time of the year, same fishing ground and with identical trawls. Any differences observed, therefore, are likely to be caused predominantly by changed twine diameters/netting twine configuration. The results are summarised in the table below:

L50 for cod as a function of nominal twine size and numbers of twine.

|  | Twine |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  | Single <br> 4 mm | Single <br> 6 mm | Single <br> 8 mm | Double <br> 4 mm | Double <br> 6 mm |
| L50 of <br> cod <br> $(\mathrm{cm})$ | 37.7 | 31.7 | 26.8 | 33.0 | 24.9 |

There is a clear negative correlation between nominal twine diameter and cod-end selectivity for Baltic cod. An increase in twine diameter by one millimeter is expected to result in a reduction of L50 with single twine of 2.7 cm , and with double twine of ca 4 cm .

Although the results originate from a research trawler and therefore cannot directly be transferred to commercial ships, the results indicate that increasing the number of twines is one of the most effective ways to reduce the selection of Baltic cod at a given legal mesh size.

At present there are no suitable means to measure twine diameter at sea, particularly if the twine consists of a hollow-core braid. Dahm (1983) suggested a photographic and Ferro (1989) an electronic measuring method. Both gave reproducible results in intercalibration tests, but only under laboratory conditions. Ferro's measuring principle has recently been taken up in the development of a precise twine diameter measuring instrument, but designed for laboratory use only.

Polet, H. and Redant F., 1994: Selectivity experiments in the Belgian Norway lobster (Nephrops norvegicus) fishery.

The amounts of cod not retained and landed by the fishermen were estimated based on data collected under the EU Study Programme (98/024): International Baltic Sea Sampling program (IBSSP II), and two previous projects having the same objectives. Observers on board commercial fishing vessels collect data and all relevant biological information and details concerning the catch. Discard data are only available from 1996 onwards. At present, almost 10000 hauls/set have been sampled for the period from the $3^{\text {rid }}$ quarter in 1995 to the end of 2000 . The sampling is ongoing and includes all countries around the Baltic Sea, except Lithuania.

The discard results obtained by sampling are aggregated by year, country, Sub-division, quarter and metier (fishery). For each stratum, the age distribution in numbers of the discard was compiled.

The discard by age group was raised by the ratio:
Total commercial landings of cod by stratum/total landings in samples by stratum.

National landing statistics were available dis-aggregated into landings for a number of metiers, defined with respect to discard patterns and covering all fisheries where significant discards are present. The metiers were defined independently in each country. After raising to the total national level, the data were aggregated to the fleets comparable to the assessment input; namely, trawl and gillnet.

The extrapolations of missing strata are made taking into account the following priorities:

1. Same quarter, another country.
2. Same country, same quarter, adjacent Sub-division.
3. Another country, same quarter, adjacent Subdivision.

Before discard data can be integrated into the stock assessments, more than 5 consecutive years are needed for the time series. In order to investigate the extrapolation of the time series backwards in time, the discard percentages for each stratum were listed for each year of discard data (Table 3.13.20.1). No obvious pattern of variability was observed, although a more comprehensive analysis is necessary to determine what pattems, if any, are present in the data.

Because of the short time series available, the discard estimates were neither integrated into the stock assessment of the western nor the eastern stock of cod. An additional problem is that due to annual variability, extrapolation of discards back in time requires a more complete overview of the discard pattern.

## Western Cod Stock (Sub-divisions 22-24)

The total discards in numbers by metier and year is given in Table 3.13.20.2. The overall mean discards per year in numbers is 48000 for gillnet and 18 million for trawl. Most years have around 15 million in total except 1996 and 1998, which have more discards. This is consistent with the two high recruitments of age group 1 cod in 1995 and 1998.

Table 3.13.20.3 gives the discard and the landings by age group. Age group 1 is the most dominating age group in the discard in all years except 1999 - a year when the strong 1997 year class dominated discards as age group 2 .

## Eastern Cod Stock (Sub-divisions 25-32)

The total discard in numbers and years is given in Table 3.13.20.4. The overall mean discard in numbers is 6.5 millions per year in gillnet and 12 million for trawl.

Table 3.13.20.5 gives the discard and the landings by age group. Age groups 1,2 and 3 are all very abundant in the discards. Age group 3 and older are mostly discarded from the gillnet fishery.

Table 3.13.20.1 Discard percentage (of total catch) by age group in the period 1996-2000.

### 3.14.1 Overview of Nephrops Stocks

## Functional Units and Management Areas

Functional Units are defined by groupings of statistical rectangles according to the present knowledge on the distribution of Nephrops stocks. Management Areas are defined using as far as possible, existing ICES Sub-area and Division boundaries. ICES provides catch advice by Functional units. However, under the existing quota system, a TAC is often set for an area that is larger than the management area that is considered appropriate. Therefore the present TAC areas do not allow management of the stocks in individual Functional Units taking differences in exploitation into account. While for some management areas it may be advised to reduce exploitation, it may be possible to increase catches in others management areas within the same TAC area. If the sum of the recommended catches for the separate areas is taken as the basis for setting the TAC for the whole area, this could lead to an undesirable and an unsustainable increase in exploitation for some management areas within the TAC area.

The problenn is particularly relevant in Sub-areas IV and VII. ICES reiterates its advice given in previous years that management of Nephrops stocks should be at the Management Area level as defined in Figures 3.14.1.13.14.1.3 and Table 3.14.1.1 As an alternative, specific management tools could be developed aimed to control fishing effort on a much smaller geographical scale than is the case in the existing system.

In an attempt to partly resolve this problem (at least with respect to Sub-area VII), ICES suggests that a separate Nephrops TAC for Division VIla be considered, as is common practice already for several finfish stocks (such as cod, whiting, plaice and sole).

## Recommended and Agreed TACs

ICES notes that the agreed TACs are nearly always above those recommended by ICES.

## Assessment Methods Employed

The assessment of the stocks was based on a variety of methods:

- Analysis of long-term trends in fishery data (landings, effort, CPUE, LPUE, etc.);
- Length-based assessments (LCA) (for a very small number of stocks only - see below);
- Age-based analytical assessments (VPA);
- Y/R analyses based on the output of the VPA; and
- Fishery independent surveys (mostly underwater TV surveys).

For those stocks that show severe signs of overexploitation, short-term catch predictions were made, based on the outcome of a VPA.

Examination of trends in fishery data remains an important element of Nephrops assessments, especially for stocks with few biological or sampling data. For most stocks, the available information now extends over many years.

Previously, Length Cohort Analysis (LCA) has been widely used as an assessment tool for Nephrops stocks. This method is no longer applied in cases where the steady-state assumptions inherent in the LCA method are not met or where an age-based assessment is possible. A weakness of LCA is that it gives no information on recruitment overfishing. Where this occurs, the LCA method can give severely misleading conclusions about stock status with respect to growth overfishing.

Age-based VPA for Nephrops, on the other hand, suffers from:

- uncertainties in the slicing of length into 'age" distributions (despite the application of an improved slicing technique, which now gives 'real' instead of 'nominal' age groups);
- the year-to-year variations in emergence of Nephrops (which may result in unrealistic estimates of stock biomass, particularly for the females); and
- in a number of cases, the lack of discard data (which results in levelling off the estimates of the recruits and in a false impression of stability in recruitment).

Fishery independent surveys have become an increasingly useful tool in the assessment of Nephrops stocks. Firstly, as a means to obtain fishery independent estimates of stock size and biomass and secondly, as a means to validate the trends in total stock biomass shown by the analytical assessments. For some stocks, where landing statistics were believed to be unreliable, or where sampling levels were inadequate for a 'traditional' analytical approach, they have even become the only means for assessing the state of exploitation of the stock and for making predictions on its fisheries potential.

## Male vs. Female Exploitation

Female Nephrops are less available for exploitation than males. Females are mainly caught in the summer months, but when berried (usually between early autumn and spring of the next year) they stay in the burrows and cannot be caught by trawls. In most stocks, this is reflected by much lower fishing mortality rates and much more optimistic Y/R predictions for females than for males. However, in summer fisheries, fishing mortality
can be as high on females as on males. Stocks exploited in fisheries where the dominating part of the effort is exerted in summer are more vulnerable to spawning stock depletion, and there is a greater risk that such stocks will become depleted and outside safe biological limits.

Males are the most vulnerable component of the stock (while at the same time accounting for the majority of the landings). Therefore, overall evaluation of exploitation of the stocks, and hence the management advice, is largely based on considerations of the male stock.

The difference in exploitation pattern between males and females, and uncertainty about the reliability of the nominal VPA estimates of female stock biomass and recruitment (the trends in these however, are believed to be reliable), are the main reasons why stock biomass and recruitment are given for males and females separately, and not for the sexes combined.

## Advice for 2002 and 2003

ICES provides advice in this report for 2002 and 2003.

For many stocks there was no basis this year to revise the advice given previously (1999). However, there are concerns about the state of some stocks, and additional management recommendations are made where appropriate.

For most Nephrops stocks occurring north of the Bay of Biscay, there is little or no change in the assessed state of the stocks, and hence the advice on management options largely remained unchanged. Where relevant and necessary, the corresponding TAC proposals were adjusted, to match recent trends in the fishery and/or stock.

In Skagerrak and Kattegat (IIIa) there is a mis-match between the current minimum landing size ( 40 mm carapace length) and the selectivity of the diamond mesh codends used, resulting in large quantities of Nephrops being discarded. The introduction of more selective trawls should be encouraged, to reduce discards.

For the Norwegian Deep (IVa) and Off Horn Reef ( $\mathrm{IVb}, \mathrm{c}$ ) stocks, there is evidence of a rapidly expanding fishery, with increasing landings and, particularly in the Off Horn Reef stock, increasing LPUEs.

For nearly all southern stocks (Bay of Biscay FUs $23+24$; and Iberian Peninsula, FUs $25,26+27,28+29$, 30 and 31) however, there are serious reasons for concern. There is evidence of declining trends in LPUE/CPUE and/or biomass and recruitment, and ICES proposes that drastic management action should be taken. In view of the alarming state of these stocks, advice is given for the year 2002 only, and ICES recommends that these stocks be reassessed in 2002.

### 3.14.2.a Nephrops in Division IIa (Management Area E)

There are two Functional Units in this Management Area: a) Skagerrak (FU 3) and b) Kattegat (FU 4).

State of stock/exploitation: The stocks in this Management Area appear to be exploited at sustainable levels.
$a+b)$ Skagerrak and Kattegat combined: Age-based assessment for FUs 3 and 4 combined, suggests that male and female stock biomass are generally increasing. Female recruitment seems to have been stable, while male recruitment seems to have increased in the most recent years. There is some doubt about the reliability of the VPA estimates of recruitment. Strong male recruitment however, is evident from discard monitoring data, which show a considerable increase in the male discards ( $<40$ mm CL ), particularly in $2000 . \mathrm{F}_{\mathrm{bar}}$ for males has recently increased, but is still below long-term average. Y/R analysis based on outputs of VPA shows that current $F$ is close to $F_{\text {max }}$ for males, and well below $\mathrm{F}_{\text {max }}$ for females.

Management objectives: There are no management objectives set for this fishery.

Advice on management: ICES expects that biomass will remain stable or slightly increase in these stocks, and that yield will increase in the next coming years, following the very high numbers of undersized (male) Nephrops ( $<40 \mathrm{~mm} \mathrm{CL}$ ) in the catches, particularly in 2000. ICES recommends that the total landings from Division IIIa be maintained at the 2000 level. This corresponds to a TAC for both 2002 and 2003 of not more than 4700 t.

Relevant factors to be considered in management: The mismatch between minimum landing size ( 40 mm CL in Division IIIa) and the selectivity of the 70 mm diamond mesh cod-ends results in large quantities of Nephrops being discarded. Square meshed 70 mm cod-
ends have successfully been introduced in Sweden, and their use should be encouraged to reduce discards.

ICES also notes that the use of two different minimum landing sizes for Nephrops in Divisions IIIa and IV is likely to cause an enforcement and policing problem in countries where Nephrops from the two areas are being landed.

Since most of the trawl fisheries for Nephrops in Division IIIa are mixed fisheries, increased effort in this fishery will affect by-catch levels of other commercial species caught unless the species and size selectivity properties of the Nephrops trawls is improved.

Comparison with previous assessment and advice: Previous age-based assessments on these FUs (carried out in 1999) were not considered to be sufficiently reliable for management purposes. Proposed TAC of 4700 t represents a net increase of 900 t over the current TAC. This is justified by strong recruitment in the most recent years (as shown by the discard data), and the close relationship between recruitment levels and LPUEs 4 years later.

Elaboration and special comments: The majority of landings are made by Denmark and Sweden, with Norway contributing small landings from the Skagerrak. During the last 10 years, landings from the Skagerrak varied between 1900 and 3250 t , while landings from the Kattegat varied between 900 and 1800 t (with the lowest landings recorded in 19921995).

LPUE and mean size data are available for both FUs. Length compositions are available from 1991 onwards.

Figure 3.14.2.a. 1 Skagerrak and Kattegat (FUs 3-4): Output VPA: Trends in Catches, Fbar, Stock Biomass and Recruitment

### 3.14.2.b Nephrops in Division IVa, rectangles 44-48 E6-E7+44 E8 (Management Area

 F)There are two Functional Units in this Management Area: a) Moray Firth (FU 9) and b) Noup (FU 10).

## State of stock/exploitation:

All stocks in this Management Area appear to be exploited at sustainable levels.
a) Moray Firth: Age based assessment shows that stock biomass and recruitment in both males and females have been generally stable in the 1990s, although at a lower level than in the mid- and late 1980s. Annual LPUEs show large fluctuations (without obvious trend), but were generally higher in the early and mid-1980s than in the 1990s. Abundance trends from the TV camera surveys (1993-2000) are in broad agreement with the VPA, showing slight increase in stock biomass in the most recent years. $\mathrm{F}_{\mathrm{bar}}$ fluctuates for both males and females, without obvious long-term trend. Y/R analysis based on outputs of VPA shows that current $F$ is close to $F_{\text {max }}$ for males, and well below $\mathbf{F}_{\text {max }}$ for females.
b) Noup: Increasing trends in LPUE, and landings per area and effort per area indices, suggest that current levels of fishing effort are acceptable for this stock.

Management objectives: There are no management objectives set for this fishery.

Advice on management: For the Moray Firth stock, there is no reason to take restrictive action, and ICES recommends to set the TAC for this FU corresponding to the current landings, i.e. at $\mathbf{1 5 0 0} \mathbf{t}$. The Noup stock also is not giving cause for concern, so that the 1999 suggestion of 400 t continues to apply. Landings from statistical rectangles outside these FUs but within the Management Area are comparable to those observed in the early 1990 s, and the previous allowance made for these rectangles ( 100 t ) should be applied again. Taken together, the TAC advice for Management Area $F$ amounts to 2000 t for both 2002 and 2003.

Relevant factors to be considered in management: In the North Sea TAC area (which comprises eight Nephrops stocks, with quite different states of exploitation), the present aggregated management approach runs the risk of unbalanced effort distribution. Adoption of management initiatives to ensure that effort can be appropriately controlled in smaller areas within the overall TAC area is recommended.

Comparison with previous assessment and advice: The proposed Management Area TAC of 2000 t represents a net increase of 150 t over the current advice. This is justified in view of the less pessimistic assessment for the Moray Firth stock, which makes up almost three-quarters of the landings from this Management Area.

Elaboration and special comments: Only UK vessels fish for Nephrops in this Management Area. Nephrops directed trawlers account for $75-85 \%$ and $50-75 \%$ of the total landings from the Moray Firth and the Noup respectively. The use of 70 mm multi-rig trawls has declined in both fisheries following the UK national ban, but effort using multi-rig trawls with larger mesh sizes has increased in the most recent years. Moray Firth landings fell to about 1000 t in 1998 and 1999 , but have increased again by almost $50 \%$ in 2000 . Landings from the Noup have fluctuated along the same overall pattern as effort, and have remained generally stable since 1995.

LPUE, landings/area and effort/area data are available for both FUs, but mean size data are available for the Moray Firth only. TV camera surveys were carried out in Moray Firth in 1993-2000 (except 1995) and were compared with the VPA estimates of biomass and recruitment. Length composition data is available for the Moray Firth since 1981.

### 3.14.2.c <br> Nephrops in Division IVa, West of $2^{\circ} \mathbf{E}$, excluding Management Area $\mathbf{F}$ (Management Area G)

There is only one Functional Unit in this Management Area: Fladen Ground (FU 7).

State of stock/exploitation: The state of exploitation of the stock shows spatial variation, with the most heavily fished parts considered to be exploited at sustainable levels.

Fladen Ground: The relatively high LPUEs, the evidence from the TV surveys, the low values of the fishing pressure indices (compared to other stocks), and the results of the length-based assessment all suggest that this FU remains in a healthy state. Parts of this stock are exploited at considerably lower levels than others. Annualised LPUEs and mean sizes in landings are generally stable. TV camera surveys (1992-2000, except 1996) suggest that total stock biomass exceeds 100000 t .

Management objectives: There are no management objectives set for this fishery.

Advice on management: ICES recommends a status quo TAC for Management Area $F$ of $9000 \mathbf{t}$ for both 2002 and 2003.

Relevant factors to be considered in management: There is concern over the quality of the landings data.

The risks of an overall North Sca TAC leading to unbalanced effort distribution over the North Sea Nephrops FUs, or of a rapid quota uptake in the Fladen leading to difficulties in the rest of the North Sea remains. Therefore, the adoption of management initiatives to ensure that effort can be properly controlled at a FU level is recommended.

The 9000 t proposed represents $7.5 \%$ of the estimated stock biomass. This harvest ratio is at the lower end of the harvest ratios observed in other stocks.

Comparison with previous assessment and advice: All analyses confirm the earlier statements on the state of exploitation of this stock. Therefore, ICES sees no reason to change its previous advice.

Elaboration and special comments: Most landings from this Management Area are reported by UK-Scotland (over $90 \%$ of the total international landings), together with much smaller quantities by Belgium, Denmark, Norway and UK-England. The Fladen Ground is exempt from the UK legislation banning 70 mm mesh multi-rig trawls, but the proportion of effort by multi-rig Nephrops vessels has strongly declined in the early 1990s. The overall trend in landings from the Fladen Ground is upward, with the highest figures recorded in 1995, 1997 and 1999. Throughout the 1990 s, reported landings repeatedly exceeded the recommended TAC. Effort shows a longterm increase in the Scottish fleet, but has declined in the Danish fleet (owing to a shift in effort to other grounds)

LPUEs, mean sizes, and landings/area and effort/area indices are available for this stock. Stock abundance and biomass estimates from TV surveys are available for 1992-2000, and are considered to be reliable. Length composition data are available since the beginning of the 1990 s , but the data sets for the earlier years are not sufficiently extensive for assessment purposes.

Figure 3.14.2.c. 1 Fladen (FU 7) : Long-term trends in landings, effort, CPUEs/LPUEs and mean sizes of Nephrops in catches and landings.

### 3.14.2.d Nephrops in Division IVa, East of $2^{\circ} \mathbf{E}+$ rectangles 43 F5-F7 (Management Area S)

There is only one Functional Unit in this Management Area: Norwegian Deep (FU 32).

State of stock/exploitation: Despite recent increases in landings, abundance seems to have been stable since 1994. The stock does not appear to be fully exploited, and there may be scope for further cautious increases in landings and in effort.

Management objectives: There are no management objectives set for this fishery.

Advice on management: Pending further information on the state of exploitation of this stock, ICES advises that effort be allowed to increase only slowly from the present level, corresponding to an increase in catches of about $10 \%$ to 1200 t .

Relevant factors to be considered in management: The Danish LPUE figures for this FU seem to have levelled off in the most recent years, but this trend is valid only for the areas that are presently exploited, and which constitute only part of the stock. Sediment maps for this Management Area indicate that there are possibilities to let the fishery expand into new grounds, which have scarcely been fished to date.

Comparison with previous assessment and advice: Results of 2001 data analyses confirm the overall picture of a stock that is not fully exploited.

Elaboration and special comments: The majority of the landings from this FU are made by Denmark and Norway. During the last five years, landings have fluctuated between 750 t and 1150 t , with the highest figures recorded in 1999 (approx. 1130 t) and 2000 (approx. 1050 t - provisional). The LPUEs of Danish vessels has increased from $50-75 \mathrm{~kg} /$ day in the early 1990 s to over $200 \mathrm{~kg} /$ day in the late 1990 s . Mean sizes in both research vessel catches and commercial landings are high compared to neighbouring areas (Skagerrak and Kattegat).

LPUE and mean size data are available since 1989 and 1997 respectively. Length-frequency data for this fishery were insufficient to allow analytical assessments.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

### 3.14.2.e Nephrops in Divisions IVb,c, West of $1^{\circ} \mathbf{E}$ (Management Area I)

There are two Functional Units in this Management Area: a) Farn Deeps (FU 6) and b) Firth of Forth (FU 8).

State of stocl/exploitation: All stocks in this Management Area appear to be exploited at sustainable levels.
a) Farn Deeps: LPUEs fluctuating around a generally upward trend up to 1993, stable from then onwards. CPUEs decreased in the late 1980s, but generally are stable since then. Age-based assessment shows that both male and female stock biomass are fairly stable. Recruitment in both males and females are variable, with above-average values in the most recent years. $F_{\text {bar }}$ for both males and females fluctuating without obvious trend, but values for the most recent years are below the long-term average. Y/R analysis based on outputs of VPA shows that current $F$ is slightly above $\mathbf{F}_{\text {max }}$ for males, but well below $\mathbf{F}_{\text {max }}$ for females.
b) Firth of Forth: LPUEs fluctuating without obvious long-term trend, but with generally higher values in the early 1970s, the mid-1980s and the late 1990s. Age-based assessment suggests that stock biomass is stable in both males and females. Overall, recruitment seems to have increased since the early 1990s. Results of TV surveys broadly confirm the trends in the VPA estimates of stock biomass. $\mathrm{F}_{\mathrm{bar}}$ for both males and females fluctuating without obvious trend. $Y / R$ analysis based on outputs of VPA shows that current $F$ is above $F_{\text {max }}$ for males, but well below $\mathbf{F}_{\text {max }}$ for females.

Management objectives: There are no management objectives set for this fishery.

Advice on management: The basis for the advice is unchanged and therefore ICES reiterates its previous advice and recommends a Management Area TAC of 4170 t for both 2002 and 2003.

Relevant factors to be considered in management: Since 1993, landings from this Management Area have exceeded the TAC recommended by ICES. Up to the early 1990s, effort has increased much faster in the Farn Deeps than in the Firth of Forth. While effort has recently decreased in both FUs, there is still the potential for an imbalance in the exploitation rates. With the current large North Sea TAC area (which comprises eight Nephrops FUs), there is no mechanism for controlling effort locally. Management should therefore be carried out at the FU level recommended by ICES.

Comparison with previous assessment and advice: Results of this year's analytical assessments generally confirm those of the assessments carried out in 1997 and 1999.

Elaboration and special comments: Landings from this Management Area are almost solely by UK-England (FU 6) and UK-Scotland (FU 8) Nephrops directed vessels. Farn Deeps effort increased by about four times since the early 1970s to a peak in 1994. Landings have fluctuated considerably (between 1460 and 3700 t) in the last 10 years, also reaching a peak in 1994. Since 1994, both effort and landings have decreased again. Firth of Forth effort and landings have generally increased since the late 1960s. Effort decreased in the most recent years, while landings seem to have stabilised around 2000 t . Landings increased in 1997-99, without a corresponding increase in effort.

LPUE and mean size data, and landings/area and effort/area indices are available for both units. CPUE data available for the Farn Deeps since 1985. Length composition data available since 1985 for the Farn Deeps and since 1981 for the Firth of Forth. TV surveys carried out in both FUs (1996-2000 for the Farn Deeps, and 1993-2000, except 1995 and 1997 for the Firth of Forth).

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

Figure 3.14.2.e. 1 Farn Deeps (FU 6): Output VPA: Trends in Catches, Fbar, Stock Biomass and Recruitment.

Figure 3.14.2.e. 2 Firth of Forth (FU 8): Output VPA: Trends in Catches, Fbar, Stock Biomass and Recruitment.

There are two Functional Units in this Management Area: a) Botney Gut - Silver Pit (FU 5) and b) Off Horn Reef (FU 33).

State of stock/exploitation: The Botney Gut - Silver Pit stock appears to be exploited at sustainable levels, and the Off Horn Reef stock is not fully exploited.
a) Botney Gut - Silver Pit: Annual LPUEs show considerable variation and values for different vessel and gear types show different trends. Agebased assessment suggests that stock biomass is fairly stable in both males and females, albeit with a slight downward trend in male biomass in most recent years. Estimates of recruitment are stable, but are considered questionable (owing to the lack of discard length frequency data). $\mathrm{F}_{\text {bar }}$ has recently increased, particularly in males. Y/R analysis based on outputs of VPA shows that current $F$ is close to $\mathbf{F}_{\text {max }}$ for males, and below $\mathbf{F}_{\text {max }}$ for females.
b) Off Horn Reef: Upward trends in landings and LPUE indicate that the stock is not fully exploited, and might yield some further increases in landings.

Management objectives: There are no management objectives set for this fishery.

Advice on management: The stocks in FU 5 and 33 appear to be able to sustain catches of the order of recent years and therefore ICES advises an overall Management Area TAC of $2100 \mathbf{t}$ for both 2002 and 2003.

Relevant factors to be considered in management: In the North Sea TAC area, the present aggregated management approach runs the risk of unbalanced effort distribution between this and the other Nephrops Management Areas. Adoption of management at the level of the Management Areas is recommended.

Comparison with previous assessment and advice: Results of this year's assessments generally confirm the conclusions that could be drawn from the 1997 and 1999 assessments.

Elaboration and special comments: Belgium (mostly FU5), Denmark (mostly FU 33), the Netherlands (mostly FU 5) and the UK (mostly FU 5) are involved in these fisheries. International landings from FU 5 have generally increased, from less than 200 t per year in the mid-1960s to 1050-1200 t in the late 1990s. Belgian Nephrops directed effort has considerably decreased, particularly in the early 1990 s , owing to the decommissioning of mostly older and less profitable vessels. A Nephrops directed fishery, using light beam trawls, has developed in the Netherlands in recent years. An almost exclusively Danish Nephrops directed fishery is expanding in FU 33, resulting in an almost tenfold increase of the landings, from about 75 t in 1991 and 1992, to 720 t in 1999.

LPUE and mean size data are available for FU 5, LPUE data only for FU 33. Length-frequency data on landings are available for FU 5 and for the Belgian fleet only. There is no discard sampling in these fisheries, and this makes the VPA estimates of recruitment questionable.

### 3.14.2.g Nephrops in Divisions VIId,e (Management Area K)

Advice on management: There are no reported landings of Nephrops from this area. It is suggested that a zero TAC be set to prevent mis-reporting.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ ACFM:16).

### 3.14.2.h Nephrops in Division VIa (Management Area C)

There are three Functional Units in this Management Area: a) North Minch (FU 11), b) South Minch (FU 12) and c) Clyde (FU 13).

## State of stock/exploitation:

All stocks in this Management Area appear to be exploited at sustainable levels.
a) North Minch: Annual LPUEs have fluctuated without trend, despite a twofold increase in effort over the past 25 years. VPA estimates of stock biomass and recruitment fluctuating, but there is no evidence of long-term trends. Relatively stable biomass levels are also evident from the results of the TV camera surveys. $F_{b a r}$ of both males and females fluctuating, without long-term trend. Y/R analysis based on outputs of VPA shows that current $F$ is close to $F_{\max }$ for males, and below $F_{\max }$ for females.
b) South Minch: Annual LPUEs fluctuating without trend. Male stock biomass has been stable till 1994, but has slightly declined since then. Female stock biomass has generally increased till the mid1990s, then stabilised. Recruitment shows little variation, but currently is slightly below the longterm average, particularly in males. TV camera surveys suggest that abundance is fluctuating but stable. $F_{\text {bar }}$ of both males and females fluctuating without trend. Y/R analysis based on outputs of VPA indicates that current $F$ is at $F_{\text {max }}$ for males, and below $F_{\text {max }}$ for females.
c) Clyde: LPUEs were at a low level in the early 1990s, but markedly increased since then. Overall, annual LPUEs have been fluctuating along a slightly upward long-term trend. Age-based assessment suggests stable stock biomass for males, and increasing biomass for females. Recruitment in the last eight years has been above the long-term average. TV camera surveys suggest continued increase in abundance from 1995 to 1998, lower abundance levels in 1999, and higher levels again in $2000 . \mathrm{F}_{\text {bar }}$ shows a feeble upward trend for males, except for the last three years, and is fairly stable for females. Y/R analysis shows that current $F$ is well above $F_{\text {max }}$ for males, and below $\mathbf{F}_{\text {max }}$ for females.

Management objectives: There are no management objectives set for this fishery.

Advice on management: There is no basis to revise the advice given previously, and therefore ICES reiterates its advice of a Management Area TAC of 11300 t for both 2002 and 2003 .

Relevant factors to be considered in management: Catch composition data indicate that the creel fisheries in these FUs are taking higher proportions of berried females than the trawl fisheries. This could result in higher losses to the female spawning stock than in other FUs, where berried females are less accessible to exploitation.

In 1999, attention was drawn to the shift in effort between the FUs in this Management Area and the change in balance in the landings which this entailed. Since then, the landings from the Clyde have declined, returning the balance to that observed during the early 1990s.

Comparison with previous assessment and advice: The results of the analytical assessments confirm the conclusions that could be drawn from the 1997 and 1999 assessments.

Elaboration and special comments: Only UK vessels are involved in these fisheries. In FUs 11 and 12, Nephrops directed trawlers and creelers account for 75 $85 \%$ and $10-15 \%$ of the landings respectively. In FU 13 , over $95 \%$ of the landings are taken by Nephrops directed trawlers. The use of 70 mm mesh size multirig gear has been eliminated following the UK national ban. Landings and effort in all three FUs have increased since the 1960s. In the North Minch and South Minch, landings have declined in recent years, corresponding to a decrease in Nephrops directed effort. Landings from the Clyde were very high in the mid-1980s, lower in the early 1990s, and higher again in the late 1990s.

LPUEs and mean size data, and landings/area and effort/area indices are available for all FUs. Lengthfrequency data are available since 1981.

### 3.14.2.i $\quad$ Nephrops in Divisions Vb (EU zone) and VIb (Management Area D)

Advice on management: There are no reported landings of Nephrops from this area. It is suggested that a zero TAC be set to prevent mis-reporting.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

### 3.14.2.j $\quad$ Nephrops in Division VIIa, north of $53^{\circ} \mathrm{N}$ (Management Area J)

There are two Functional Units in this Management Area: a) Irish Sea East (FU 14) and b) Irish Sea West (FU 15).

State of the stock/exploitation: The stocks in this Management Area appear to be exploited at sustainable levels.
a) Irish Sea East: Annual LPUEs fluctuating, but generally lower in the 1990 s than in the late 1970 s and early 1980s. Landings fairly stable since the mid-1980s. Length-based Y/R analysis suggests that current $F$ is at or above $F_{\max }$ for males (depending on procedure used to estimate length composition of the discards), and at or below $\boldsymbol{F}_{\text {max }}$ for females. No age-based assessment carried out.
b) Irish Sea West: CPUEs and LPUEs have recovered from the low values in the early 1990s. Age-based assessment indicates an increase in male biomass, and relative stability in female biomass and in both male and female recruitment. $F_{\text {bar }}$ of males is currently stable and lower than 10 years ago. $F_{b a r}$ of females fluctuating without obvious trend, but higher than in most other Nephrops stocks. Y/R analysis based on outputs of VPA shows that current $F$ is slightly above $F_{\text {max }}$ for males, and at $\mathbf{F}_{\text {max }}$ for females.

Management objectives: There are no management objectives set for this fishery.

Advice on management: There is no basis to revise the advice given previously, and therefore ICES recommends that the landings from this Management Area in 2002 and 2003 be kept at a level corresponding to the average for $1995-1999$, i.e. at 9550 t .

ICES also notes that this Management Area is within a much larger TAC area (Sub-area VII), and that a single TAC set for the whole Sub-area will not
result in balanced exploitation. In an attempt to resolve this problem, ICES suggests a separate Nephrops TAC for Division VHa, as is done for several finfish stocks (such as cod, whiting, plaice and sole).

Relevant factors to be considered in management: Although exploited throughout the year, increased effort generally occurs during the summer months, when females are available for capture after hatching their eggs. This results in higher annual fishing mortality.rates on females than in most other northern FUs. The high F values on both sexes in the Irish Sea West suggest that the situation should be very carefully monitored.

Comparison with previous assessment and advice: The results of this year's assessments broadly confirm the conclusions that could be drawn from the 1997 and 1999 assessments. The proposed Management Area TAC of 9550 t represents a net increase of 150 t over the current advice, which is entirely due to an update of the reference period used to calculate the 5 years' average of the landings (viz. 1995-1999 as opposed to 1987-1991. This formed the basis for the advice given previously).

Elaboration and special comments: Most of the landings from this Management Area are taken by the UK and Ireland. Irish Sea East landings and effort increased to a peak in the late 1970s and early 1980s, and have now stabilised at about $60 \%$ of that level. In the Irish Sea West, both landings and effort have been reasonably stable over the past 12 years.

LPUE and mean size data are available for both units, CPUE data for the Irish Sea West only. Length composition data are collected on a regular basis for both FUs. The lack of discard samples from the Irish Sea East in the most recent years prevented the use of an age-based assessment for this stock.

### 3.14.2.k Nephrops in Divisions VLlb,c,j,k (Management Area L)

There are four Functional Units in this Management Area: a) Porcupine Bank (FU 16), b) Aran Grounds (FU 17), c) Ireland NW coast (FU 18) and d) Ireland SW and SE coast (FU 19).

State of stock/exploitation: All stocks in this Management Area are considered to be exploited at sustainable levels.
a) Porcupine Bank: Annual LPUEs of the Spanish Nephrops fleet steeply declined in the mid- and late 1980 s , but relatively stable since then. LPUEs of the French and Irish fleets have been fluctuating, but show little evidence of a decrease. Mean sizes in landings generally stable, No length- or age-based assessments carried out.
b) Aran Grounds: There are only LPUE and limited effort data on this stock. Landings and effort varied considerably over the past 6 years, following the same pattern, with low values in 1996 and peak values in 1998. No age-based assessment carried out.
c+d) Ireland coastal stocks: There are only LPUE and limited effort data on these stocks. Landings are strongly fluctuating (with a marked dip in 1994) along an overall downward trend. LPUE data show a dip in 1999 and 2000, but the data series is too short to draw definite conclusions, Data are insufficient to allow for length- or age-based assessments.

Management objectives: There are no management objectives set for this fishery.

Advice on management: ICES recommends that the landings be kept at a level corresponding to the average for 1995-1999, i.e an overall Management Area TAC of 4440 t for both 2002 and 2003.

Relevant factors to be considered in management: It should be noted that this Management Area includes four FUs and that a TAC set for the entire area will not necessarily result in a balance of exploitation between
the units. At present, this Management Area is within a much larger TAC area (Sub-area VII), where the problem referred to is even greater.

Comparison with previous assessment and advice: The proposed Management Area TAC represents a net increase of 440 t over the current advice, which is entirely due to an update of the reference period used to calculate the 5 years' average of the landings (viz. 1995-1999 as opposed to 1987-1991, which formed the basis for the advice given previously).

Elaboration and special comments: Landings from the Porcupine Bank are mainly by France, Ireland, Spain and the UK. Landings from the other FUs are mostly by Ireland. Spanish landings from FU 16 continued to decrease over the past 5 years, while French and Irish landings remained relatively stable. Total landings from the Porcupine Bank peaked in the early 1980s, but have decreased since. Landings from FU 17 have generally increased, while those from FU 19 decreased. Total international landings from the Management Area as a whole have increased between the mid-1980s and the late 1990s, exceeding the recommended TAC in almost all years since 1994.

CPUE, LPUE and mean size data are available for most FUs, but the extent of the data series is often limited.

Landings from 'Other rectangles' (i.e. rectangles that are not part of a FU) from this Management Area are sometimes considerable, and may even exceed those taken from the FUs. It does not seem logical that analytical assessments are being performed on FUs, which yield scarcely 100 t of Nephrops landings per year (or even less), while areas that yield several hundreds of tonnes remain unassessed. Therefore, ICES suggests that the available data on the distribution of these deep-water stocks be critically reviewed, and - if deemed necessary - that a revision of the FUs within this Management Area be considered.

Figure 3.14.2.k.2 Aran Grounds (FU 17): Long-term trends in landings, effort, LPUEs and mean sizes of Nephrops in catches and landings.
3.14.2.1 Nephrops in Divisions VIIf,g,h, excluding rectangles 31 E1 and 32 E1-E2 + VIIa, south of $53^{\circ} \mathrm{N}$ (Management Area M)

There are three Functional Units in this Management Area: FUs 20, 21 and 22, together called Celtic Sea.

State of stock/exploitation: The stock in this Management Area appears to be exploited at sustainable levels.
a) Celtic Sea (FUs 20, 21 and 22 combined): Annual LPUEs of French Nephrops trawlers fell in 198991, slightly increased till 1995, then decreased again. Mean sizes in catches and landings show an overall increasing trend. Age-based assessment (on males only) shows relative stability in stock biomass $_{t}$ and temporary decline in recruitment in 1997-1998. Estimates of recruitment should be considered cautiously, owing to the lack of a regular discard sampling programme. $\mathrm{F}_{\mathrm{bar}}$ for males is fluctuating, with the values for the most recent years at the lower end of the range. Y/R analysis (males only) based on outputs of VPA suggests that current $F$ is close to $\mathbf{F}_{\text {max }}$.

Management objectives: There are no management objectives set for this fishery.

Advice on management: There is no basis to revise the advice given previously, and therefore ICES recommends a TAC for Management Area $M$ of 3800 t for both 2002 and 2003.

Relevant factors to be considered in management: It is expected that the mesh size increase that was implemented in the beginning of 2000 , will have a long-term beneficial effect on the exploitation pattern of this stock. Comparison of the length-frequencies of the landings for 1998, 1999 and 2000, shows a net decrease in the proportion of smaller Nephrops in the 2000 landings.

Comparison with previous assessment and advice: Results of this year's assessment (using an improved
method for the calculation of the discard removals) give a less pessimistic appreciation of the state of exploitation, with much more stable values for (male) stock biomass, and a less dramatic decline in recruitment. Females were not assessed, for reasons of their overall scarcity in the landings. This makes the estimates of their removals too dependent on the estimates of the discards, for which regular sampling data are not available.

Elaboration and special comments: Landings from this stock are reported by France, Ireland and the UK. Until 1993, the French landings represented at least $80 \%$ of the total, since then their share has dropped to $55-65 \%$. There has been a considerable increase in Irish landings, from 650-750 t in early 1990s to over 1500 t in the late 1990 s. International landings reached a peak in 1995, and have generally decreased since, except in 2000, when they increased again to approx. 4250 t .

LPUE, mean size data and length compositions of the French landings are available for this stock. Discard data available for some years only.

A serious delay in the processing of the French fishery statistics prevented inclusion of the effort data for the years 1999 in the XSA tuning. For 2000, an estimate of overall effort was derived from logbook data. However, this estimate was not corrected for target species of the effort. Establishment of an Irish sampling programme, and more frequent discard samplings of the French fleet would greatly improve the quality of the lengthfrequency data, the more so since (a) the minimum landing sizes applied by the two fleets are different ( 25 mm CL in Ireland vs. 35 mm CL in France), and (b) discarding by the French fleet is substantial (owing to the large commercial minimum landing size).

### 3.14.2.m Nephrops in Divisions VIIIa, b (Management Area N)

There are two Functional Units in this Management Area: a) Bay of Biscay North (FU 23) and b) Bay of Biscay South (FU 24), together called Bay of Biscay.

State of stock/exploitation: The stock in this Management Area is showing signs of severe overexploitation.
a+b) Bay of Biscay North and South combined: Annual LPUEs fluctuating, with the values for 1995-1998 (the most recent data available) at the upper end of the range. Gear efficiency in the area has increased in the most recent years (following the use of twin-trawls and rock hoppers, which made trawling possible in areas that were previously inaccessible), and this may have helped maintaining the LPUEs at relatively high levels. Age-based assessment suggests that biomass for males are seriously declining. $F_{b a r}$ on males has fluctuated along a general upward trend. Female biomass seems also to be declining and $F_{\text {bar }}$ has fluctuated without evidence of a long-term trend, but these results were considered less reliable than for males. Y/R analysis based on outputs of VPA shows that current $F$ is well above $F_{\text {max }}$ for both males and females.

The assessment is accepted to be indicative of stock trends and shows a declining trend since the early 1990s. This is attributed to the exploitation rate being too high.

Management objectives: There are no management objectives set for this fishery.

Advice on management: In order to halt the decline of the stock ICES advises a $40 \%$ reduction in the exploitation rate. This correspends to a catch of 2000 t for 2002.

Relevant factors to be considered in management: The mesh size increase that was implemented in the year 2000, did not improve size selectivity, owing to the use of much more rigid twines, which actually reduce the size selective properties of the meshes.

Comparison with previous assessment and advice: The results of this year's assessment confirm the assessments performed in 1999 and indicate that the Bay of Biscay Nephrops stock is showing serious signs of depletion.

Elaboration and special comment: Nearly all landings from FUs 23 and 24 are taken by French trawlers. Landings have been generally high, though fluctuating (typically between 4500 and 7000 t), until the early 1990 s, but have decreased to a much lower level since then. Number of fishing days has decreased since 1994, owing to changes in fishing practices and decommissioning of vessels.

LPUE, mean sizes and length compositions of the landings are available for the two FUs combined. Discard data available for some years only.

As for the Celtic Sea, there was a serious delay in the processing of French fishery statistics for this area. The lack of effort data for the years 1999 and 2000 prevented the use of the XSA in the age-based assessment. Instead, a simple user-defined VPA was performed. The VPA estimates of recruitment should be treated cautiously, owing to the lack of adequate discard data for most years in the time series.

### 3.14.2.n Nephrops in Division VIIIc (Management Area O)

There are two Functional Units in this Management Area: a) North Galicia (FU 25) and b) Cantabrian Sea (FU 31 ).

State of stock/exploitation: All stocks in this Management Area are seriously over-exploited.
a) North Galicia: Annual LPUEs fluctuating along a marked downward trend. Age-based assessment (carried out for the first time on this FU) gives evidence of sharp declines in stock biomass and recruitment for both males and females. $F_{\text {bar }}$ values for males and females fluctuating, without obvious long-term trend. F values for females are considerably lower than for males. Y/R analysis based on outputs of VPA shows that current $F$ is well above $\mathbf{F}_{\text {max }}$ for males, but below $\mathbf{F}_{\text {max }}$ for females. Bottom trawl survey indices of abundance confirm overall picture of declining stock.
b) Cantabrian Sea: LPUEs strongly fluctuating, with high values in 1988-90 and 1997-98, and much lower values in the other years. LPUEs in 1999 and

2000 are the lowest on record. Mean sizes of both males and females sharply increasing. Bottom trawl survey indices of abundance suggest decline in stock. Insufficient data to perform length- or age-based assessments.

Management objectives: There are no management objectives set for this fishery.

Advice on management: ICES advises that fishing mortality on these stocks should be reduced to zero. If the by-catch of Nephrops in fisheries targeting other species makes this impossible, ICES recommends that suitable technical measures (closed areas, closed seasons, etc.) be investigated for implementation at the earliest possible opportunity in order to rebuild the stocks.

Catch options: Catch options for FU 25 (North Galicia), males and females combined. $\mathrm{F}_{2001}=\mathrm{F}_{1998-2009}$ scaled to $F_{2000}$. Recruitment $=G M$ for the years 19961999. Last column gives \% change in $\mathrm{TSB}_{2003}$ vs. $\mathrm{TSB}_{2001}$.

| 2000 |  |  |  | 2002 |  |  | 2003 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| F factor | Ref F | TSB | Landings | F factor | TSB | Landings | TSB |  |
|  |  | 311 | 81 | 0.0 | 247 | 0 | 279 | 4 |
|  |  |  |  | 0.2 | 247 | 12 | 266 | -1 |
| 2001 |  |  |  | 0.4 | 247 | 22 | 255 | -5 |
| F factor | Ref F | TSB | Landings | 0.5 | 247 | 27 | 249 | -7 |
| 1 |  | 269 | 65 | 0.6 | 247 | 31 | 244 | -9 |
|  |  |  |  | 0.8 | 247 | 40 | 234 | -13 |
|  |  |  |  | 1.0 | 247 | 48 | 224 | -17 |
|  |  |  |  | 1.2 | 247 | 45 | 216 | -20 |

Relevant factors to be considered in management: The mixed nature of the demersal fisheries in this Management Area has meant that historically the management measures for the target fish species have defined the levels of exploitation of Nephrops. This has prevented directed management of the Nephrops stocks in the area. However, to prevent further declines of the Nephrops stocks in Division VIIIc, fishing pressure on Nephrops must be substantially reduced. It is worth noticing that the agreed Nephrops TAC for VIIIc (1000 t until 1999, and 800 t for 2000) has never been restrictive.

Comparison with previous assessment and advice: Previous assessments of the North Galicia stock were length-based and gave an over-optimistic impression of the state of the stock. As pointed out in Section 3.14.1 Overview on Nephrops Stocks, LCA gives no
information on recruitment overfishing and this can lead to severely misleading conclusions about stock status.

Elaboration and special comments: All catches from these FUs are taken by Spain. Landings and effort in both FUs have declined, and are now record low.

LPUE and mean size data are available for both FUs. Length-frequency data available for FU 25 since 1986. Discarding in these fisheries is marginal. Abundance indices are available for both FUs, derived from bottom trawl surveys to estimate hake recruitment and to collect information on the relative abundance of demersal species in general.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

Figure 3.14.2.n. 1 North Galicia (FU 25): Output VPA: Trends in Catches, Fbar, Stock Biomass and Recruitment.

### 3.14.2.0 Nephrops in Divisions VIIId, e (Management Area P)

Advice on management: There are no reported landings of Nephrops from this area, so it is suggested that a zero TAC be set to prevent misreporting.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM: 16).

### 3.14.2.p Nephrops in Division IXa (Management Area Q)

There are five Functional Units in this Management Area: a) West Galicia (FU 26), b) North Portugal (FU 27), c) Southwest Portugal (FU 28), d) South Portugal (FU 29) and e) Gulf of Cadiz (FU 30).

## State of stocks/exploitation:

All stocks in this Management Area are seriously overexploited.
a+b) West Galicia and North Portugal: LPUEs for FU 26 relatively high and declining for two ports, or low and fluctuating without trend for two other ports. Mean sizes of both males and females increasing in most recent years. Age-based assessment for the two FUs combined (performed for the first time) gives evidence of sharply declining stock biomass and recruitment in both males and females. $F_{\text {bar }}$ for males strongly fluctuating, and currently at the lower end of the range. $\mathbf{F}_{\text {bar }}$ for females low and generally stable. Y/R analysis based on outputs of VPA shows that current $F$ is far above $\mathbf{F}_{\text {max }}$ for males, and at $F_{\text {max }}$ for females. Bottom trawl survey indices of abundance contirm picture of declining stock.
c+d) SW and S Portugal: Annualised CPUEs sharply declined in 1989-96, relatively stable since then. Mean sizes of both males and females in landings and in trawl survey catches increasing. Age-based assessment indicates that stock biomass and recruitment of both males and females have sharply declined in the early 1990 s, remaining at a very low level since 1994-95. F bar for males was $^{\text {b }}$ highest in the early 1990s, then decreased till 1997, but increased again in the most recent years. $\mathbf{F}_{\text {bar }}$ for females fluctuating, without evidence of a long-term trend.

Both length- and age-based Y/R analysis show that current $F$ is at $F_{\text {max }}$ for males, and slightly below $\mathbf{F}_{\text {max }}$ for females. The results of crustacean directed trawl surveys, usually carried out in JuneAugust, support perception of a declining stock.
e) Gulf of Cadiz: There is very limited data only for this FU, Landings have generally decreased since the beginning of the 1990s and are currently less than half of the peak figures in the mid-1980s. Insufficient data to allow length- or age-based assessments.

Management objectives: There are no management objectives set for this fishery.

Advice on management: For FUs 26+27, ICES advises a zero TAC in order to stop the further decline of stock biomass and to allow the stock to rebuild. This however, may not be possible, because of the mixed nature of the fishery. Therefore, ICES recommends that suitable technical measures (closed areas, closed seasons, etc.) be investigated for implementation at the earliest possible opportunity in order to rebuild the stocks.

For FUs $28+29$, ICES advises a reduction in $F$ of $40 \%$ in order to halt the deterioration of the stock and to facilitate rebuilding of stock biomass. This would correspond to a TAC of 120 t for the year 2002.

For FU 30, ICES recommends that effort be constrained to a level corresponding to the lowest landings in the most recent years, i.e. 50 t .

Taken together, this gives an overall Management Area TAC of $170 \boldsymbol{t}$ for the year 2002.

## Catch options:

1. Catch option for FUs $26+27$ (West Galicia and North Portugal), males and females combined. $\mathrm{F}_{2001}=$ $\mathrm{F}_{1998-2000}$ scaled to $\mathrm{F}_{2000}$. Recruitment $=$ GM for the years 1997-99. Last column gives \% change in TSB vs. $\mathrm{TSB}_{2001}$.

| 2000 |  |  |  | 2002 |  |  | 2003 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| F factor | Ref F | TSB | Landings | $F$ factor | TSB | Landings | TSB |  |
|  |  | 965 | 155 | 0.0 | 552 | 0 | 652 | 4 |
|  |  |  |  | 0.2 | 552 | 31 | 625 | 0 |
| 2001 |  |  |  | 0.4 | 552 | 58 | 600 | -4 |
| F factor | Ref F | TSB | Landings | 0.5 | 552 | 72 | 587 | -6 |
| 1 |  | 625 | 151 | 0.6 | 552 | 85 | 576 | -8 |
|  |  |  |  | 0.8 | 552 | 109 | 555 | -11 |
|  |  |  |  | 1.0 | 552 | 132 | 534 | -15 |
|  |  |  |  | 1.1 | 552 | 143 | 525 | -16 |

2. Catch option for FUs $28+29$ ( $S W$ and $S$ Portugal), males and females combined. $F_{2001}=F_{1998-2000}$ scaled to $\mathrm{F}_{2000}$. Recruitment $=\mathrm{GM}$ for the years 1993-2000. Last column gives $\%$ change in TSB vs. $\mathrm{TSB}_{2001}$.

| 2000 |  |  |  | 2002 |  |  | 2003 | \% change |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| F factor | Ref F | TSB | Landings | F factor | TSB | Landings | TSE |  |
|  |  | 897 | 201 | 0.0 | 851 | 0 | 1059 | 21 |
|  |  |  |  | 0.2 | 851 | 44 | 1009 | 15 |
| 2001 |  |  |  | 0.4 | 851 | 84 | 961 | 10 |
| F factor | Ref F | TSB | Landings | 0.5 | 851 | 103 | 939 | 7 |
| 1 |  | 874 | 198 | 0.6 | 851 | 122 | 917 | 5 |
| . |  |  |  | 0.8 | 851 | 157 | 876 | 0 |
|  |  |  |  | 1.0 | 851 | 189 | 839 | -4 |
|  |  |  |  | 1.1 | 851 | 205 | 820 | -6 |

Relevant factors to be considered in management: ICES notes that the advice given in 1997 and 1999 was not followed, despite the strong signs that the further depletion of the stocks in this area can only be stopped by severe reductions in fishing mortality.

Comparison with previous assessment and advice: Previous assessments of the West Galicia and North Portugal stocks (FUs $26+27$ ) were length-based, and gave an over-optimistic impression of the state of exploitation of these stocks. As pointed out in the 1999 Report of the Working Group on Nephrops Stocks (ICES, 1999), LCA gives no information on recruitment over-fishing, and this can give rise to severely misleading conclusions about stock status. The results of the SW and S Portugal (FUs $28+29$ ) agebased assessment confirm the overall picture of a severely declining stock.

Elaboration and special comments: The fishery in FUs 26,27 and 30 is mainly conducted by Spain, and that in FUs 28 and 29 by Portugal, on deep-water grounds ( $200-750 \mathrm{~m}$ ). The Portuguese fleet comprises two components: demersal fish trawlers and crustacean trawlers. Landings from all FUs within this Management Area have declined significantly in recent years. Effort in FUs 26 and 27 in general is declining. In FUs 28 and 29, effort fell in the late 1980s, and has since remained at that level.

CPUEs and/or LPUEs, effort data and mean size data are available for most FUs, except FU 30 (Gulf of Cadiz). Length-composition data are available for FUs $26+27$ combined and for FUs $28+29$ combined. Discarding is marginal in these fisheries. Research trawl survey data are available for FU 26 and for FUs $28+29$.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

### 3.14.2.q Nephrops in Division IXb and Sub-area $X$ (Management Area $R$ )

Advice on management: There are no reported landings of Nephrops from this area, so it is suggested that a zero TAC be set to prevent misreporting.

Source of information: Report of the Working Group on Nephrops Stocks, April 2001 (ICES CM 2001/ACFM:16).

EC has requested information on:

1) The stock identity of bass (Dicentrarchus labrax) in Community waters and, if necessary, adjacent waters in the Northeast Atlantic (not the Mediterranean);
2) The historical and current state of these stocks of bass;
3) Current problems in the exploitation of bass and advice on possibilities for overcoming these problems.

The answer given below is preliminary and in particular does not provide assessments of stock status. ICES will continue in 2001 to compile a database of assessmentrelated data and to carry out preliminary assessments, where possible, and will report on further progress in answering EC in June 2002.

Sea bass is not on the continuous ICES assessment programme and, therefore, work to provide the Commission with the needed data and information was split into several phases. The first task, which was completed during the first half of 2001, was to assemble an overview of the information on sea bass available in European fisheries laboratories.

ICES has prepared a description of the European fisheries in which sea bass are taken. This overview is found in the report of the Study Group on Sea Bass (CM 2001/ACFM:25) available through the ICES Secretariat. The species is an important seasonal component of inshore commercial and recreational fisheries, extending from the southern North Sea and Irish Sea southwards to the Iberian Peninsula. A directed mid-water trawl fishery takes spawning bass in VIIe, VIIf,g and VIIIa,b in the first quarter of the year.

The Study Group report also includes an inventory of the available data and information pertinent for the assessment of sea bass stocks, with an indication of their quality, but there has not been sufficient time to compile these data. Information on stock identity of sea bass has been compiled, from which the results of tagging studies and the seasonal distribution of the fisheries taking bass suggest, provisionally, four management/assessment units: a stock which moves between the English Channel and the southem North Sea; a stock which migrates along the west coast of Britain and into Cornish waters; a stock which remains largely within Irish waters; and a stock which moves between Biscay and the western English Channel. The
level of interchange between these stocks may inhibit genetic differentiation, but the seasonal fisheries taking each of the stocks are quite discrete. Nothing is known about the stock structure of bass around the coasts of Spain or Portugal.

It has not yet been possible to carry out an evaluation of the status of sea bass stocks in European waters, though it appears that there may be sufficient biological data for ICES divisions VIIa,d,e,f,g and $h$ over the period 19852000 to assess stock status. Catch data probably do not reflect the trends and level of exploitation given the character of the fisheries taking bass, in particular the large artisanal and recreational components. It is known, however, that directed effort on the spawning populations in VIIe,f,g has increased since the late 1980s. In this period, the appearance of several good year classes is associated with a northwards extension of the population range of bass, most noticeable in the North Sea.

A summary of existing conservation measures aimed at protecting bass fisheries is presented. These have been implemented at a national level in order to achieve the following management objectives:

1. To protect juvenile bass from heavy exploitation in nursery areas, where they remain for up to 5 years and may be particularly vulnerable. The UK introduced a minimum landing size ( 36 cm ) and a ban on mesh sizes of $70-89 \mathrm{~mm}$ in enmeshing nets (both later adopted in EC regulations), plus a ban on fishing for bass in 37 nursery areas in England and Wales. This has been shown to reduce growth overfishing (increase $Y / R$ ) and boost recruitment to the spawning stock.
2. To preserve markets, France has implemented a weekly landing limit of 5 t per vessel (since 1996), which was adopted by the UK in 2000 . This is the only quantitative control on the offshore fishery for spawning bass. This fishery is easily identified, and could be controlled by effort restrictions, if necessary.
3. To identify and protect recreational fisheries for bass, daily catch limits for non-commercial fishermen (Ireland and Spain, proposed in the UK), and a ban on commercial exploitation of bass (Ireland), have been introduced. These fisheries have a high economic value in several countries, but can also operate to the detriment of artisanal commercial fisheries by supplying low cost fish (illegally) to the market.

The EC in 1998 requested ICES to advise on the management of European cel:
"There is an increasing concern about the situation for the European eel stock and its future development. ICES is therefore requested, to provide information about the status of eel stock(s) and on any possible management actions, and to identify gaps in knowledge about eel in order to secure a sustainable development of the eel fisheries within the European Union."

Introduction: The European eel (Anguilla anguilla (L.)) is found and exploited in fresh, brackish and coastal waters in almost all of Europe, in northern Africa and in Mediterrancan Asia (Figure 3.16.1). Reproduction takes place in the open Atlantic Ocean, presumably in the Sargasso Sea. Larvae drift to the continent, transform into glass eel and migrate into continental waters, where the growing phase is known as yellow eel (Figure 3.16.2). Maturation starts after 220 years (males) or 5-50 years (females) depending on the climate and latitude. This stage, known as silver eel, migrates back to the Ocean. Spawning has never been observed in the wild and artificial reproduction is not yet successful: Genetic evidence suggests there is only one, genetically almost uniform, spawning stock.

Fisheries for eel are found throughout the distribution area. The target of the fisheries varies from glass eel (south-western Europe, north-western Africa), through yellow eel (throughout the distribution area) to silver eel (predominantly northern Europe). Fisheries are generally organised on a very small scale and apply a wide range of gears, including trawls, traps, fykenets, hooks, spears etc.

Aquaculture is exclusively based on wild caught glass eel. It takes place in several European countries, but is fully outnumbered by Asian aquaculture of European eel. European aquaculture production is less than the yield of fisheries, but increasing. The rising demand for glass eel has raised the price to extreme levels ( $300 € / \mathrm{kg}$ in Europe, $3000 € / \mathrm{kg}$ in Asia).

Glass eel catch is used for direct consumption (20 \%), for aquaculture ( $10 \%$ in Europe, $60 \%$ in Asia) and for re-stocking in (northern) outdoor waters ( $10 \%$ ). Natural immigration is estimated to be about $10 \%$ of the total glass eel recruitment.

### 3.16.1 State of stock and advice

State of stock exploitation: All information indicates that the stock is at a historic minimum. The current fishery is not sustainable. Fishing mortality is high both on juvenile (glass eel) and older eel (yellow and silver eel) in many water systems. Recruitment has declined since 1980 and recent information indicates that the
decline continues and recruitment reached a new historic minimum in 2001.

Management objective: There is no stock-wide objective for this stock. Some countries have formulated national policies that include both biological and economic considerations, but in most countries no management objective has been set.

Advice on management: ICES recommends that an international rebuilding plan is developed for the whole stock. Such a rebuilding plan should include measures to reduce exploitation of all life stages and restore habitats. Until such a plan is agreed upon and implemented, ICES recommends that exploitation be reduced to the lowest possible level.

Relevant factors to be considered in management: Actions that would lead to a recovery of the stock are urgently required. Conservation of the spawning stock can only be achieved by internationally co-ordinated management actions in continental waters. Management of eel fisheries is only possible at a water basin level, often spanning multiple jurisdictions. Uncoordinated management actions in isolated areas are not likely to lead to a recovery of the stock. Because of the length of the life cycle, it will take $5-20$ years before positive effects of management actions can be expected.

### 3.16.2 Possible measures to rebuild the stock

In order to rebuild the oceanic spawning stock, measures should aim for increased escapement of spawners from continental waters. This might be achieved through a reduction of exploitation, restocking of recruits, or restoration of habitats.
3.16.2.1 Protecting the stock by limiting exploitation

Measures to limit exploitation by fisheries will generally be site/area and circumstance specific and will have to consider exploitation in all life stages.

## Prohibition of fishing

Prohibition of fishing can be life-stage specitic or area specific. In addition to restrictions on existing fisheries, it is prudent to prohibit introduction of new fisheries and locally to prohibit fishing for currently unexploited life stages.

## Total allowable catches/quotas

With the diverse nature of eel fisheries, it is difficult to envisage how one TAC on a shared stock would be allocated and subsequently managed/enforced in the
scattered inland fisheries over the vast distribution area. TAC approaches are therefore probably not appropriate.

## Gear controls

Regulations on number, size, mesh-size, usage, and location of gear are already implemented in several eel fisheries. These measures should be strengthened, or introduced where they do not exist.

## Landing size limits

Minimum landing size restrictions reduce excessive exploitation of yellow and silver eel. Limits on maximum landing size would promote escapement of larger (female) spawners, but could also result in increases in fishing effort, which might deplete the stock of smaller sizes.

## Closed seasons

The timing of closed seasons must be related to local characteristics of eel and fisheries, and has primarily to consider closure during periods of vulnerability. Only banning of fishing over relatively long time periods (months) would be fully effective, e.g. if extending well into the periods of local glass eel immigration or silver eel emigration runs.

## Closed areas

Closed areas could be used to designate 'reserve' or 'refuge' areas where no exploitation would be permitted. These could also be locally effective in preventing extension of fisheries into new areas or for protection of vulnerable glass eel or silver eel runs.

## Licensing of fishermen

Licensing specific to eel fishermen and their gear offers opportunities for controlling and monitoring fishing effort and, ultimately, fishing mortality.

### 3.16.2.2 Enhancing the stock by re-stocking of recruits

Whether re-stocking contributes to spawner escapement is questionable. Restocking might, however, contribute to the fisheries and might be considered a compensatory measure for the decline in the catches. Re-stockings from nearby estuaries (in contrast to transports from southern to northem Europe) minimises the risks of transfer of diseases and parasites.

### 3.16.2.3 Protecting and recovering the stock by

 habitat restorationThe loss of habitat has strongly affected the capacity to produce eel. Destruction of habitat, loss of upstream accessibility, hazardous escapement through turbines
and deteriorated water quality all have a negative impact, almost throughout the distribution area. Migration barriers can be overcome with eel ladders and by-passes.

### 3.16.2.4 Elaboration and Special comments

Current scientific knowledge is inadequate to derive management targets specific for eel. Estimates of the total spawning stock and total recruitment for the eel in all of its distribution area are not available and are very unlikely to be feasible at all. Consequently, stock-wide management targets will have to be translated into derived targets for local management units. The number of water bodies for which adequate information is available to warrant local management on the basis of fully documented assessments is extremely limited. In the absence of such data, it might be feasible to derive proximate criteria. Length-frequency data are easily obtained and might offer simple reference points related to the average size of emigrating spawners. This approach has not yet been pursued in Europe. Provisional targets might have to be chosen on a rather arbitrary basis.

Eels are exploited in all life stages present in continental waters. Total yield has declined to about half since the mid-1960s. Other anthropogenic factors (habitat loss, contamination, and transfer of diseases) have had additional negative effects on the stock. Several hypotheses on the causes of the decline have been raised (including climate change), but no conclusive evidence is available.

Current monitoring is based on national programmes only. Several of the long-lasting time-series have come under pressure, because of decreased turnover of local eel fisheries and the impossibility of addressing the stock decline at the local level. However, in light of the poor state of the stock and the high anthropogenic impacts, it is of utmost importance that existing timeseries of monitoring recruitment, effort, and yield should be continued and preferably be supplemented.

Improvement of the advice depends crucially on agreement to, and implementation of, an international management process with appropriate feedback to scientific advisory bodies. Current national research scheduling for eel does not adequately react to intemational management needs. The formation of an institution directing and requesting particular monitoring and research on eel in both individual countries and on a coordinated basis is recommended.

Individual countries should develop or strengthen the legislative framework to enable management measures to be implemented.

Figure 3.16.1 Distribution area of the eel.

Figure 3.16.2
Life cycle of the eel. The names of the major life stages have been indicated. Spawning and eggs have never been observed in the wild and are therefore only tentatively included.

Figure 3.16.3 Time-series of glass eel monitoring in Europe. Each series has been scaled to the 1979-1994 average. The heavy line indicates the geometric mean of the series from Loire (F), Ems (D), Göta Älv ( S ) and Den Oever (NL), which are the longest and most consistent time series.

Figure 3.16.4 Landing statistics of the eel in the past 50 years, as reported by FAO database, with minor corrections. The catches in the first part of the time-series are under-represented as some countries did not report their catches until the mid- or late-1950s and one country not until 1974.

Figure 3.16.5 Trends in aquaculture production of the European eel.

### 4.1 Catches of North Atkantic Salmon

### 4.1.1 Nominal catches of salmon

Nominal catches of salmon reported by country in the North Atlantic (including ranched salmon in Iceland) for 1960-2000 are given in Table 4.1.1.1. Reported catches (in t), in four North Atlantic regions are illustrated in Figure 4.1.1.1, and those for NASCO Commission Areas, 1994-1998 are shown below.

| Area | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| NEAC | 3283 | 2754 | 2076 | 2229 | 2075 | 2643 |
| NAC | 260 | 292 | 229 | 157 | 152 | 150 |
| WGC | 85 | 92 | 59 | 11 | 19 | 21 |
| Total | 3628 | 3138 | 2364 | 2397 | 2246 | 2814 |

The catch data for 2000 (Table 4.1.1.1) are provisional, but the total nominal catch of 2814 t is amongst the lowest on record. Catches in most countries remain below the averages of the most recent 5 - and 10 -years period. Some of the reduction in catches in recent years may be accounted for by management plans, which have reduced fishing effort in several countries.

Where data were available, the nominal catch (in t) of wild fish in 2000 was partitioned according to whether the catch was taken by coastal, estuarine or riverine fisheries. These are shown below for the NEAC and NAC Commission Areas. The proportions accounted for by each fishery varied considerably between countries. In total, however, coastal fisheries accounted for $53 \%$ of catches in North East Atlantic countries compared to $9 \%$ in North America, whereas in-river fisheries took $41 \%$ of catches in North East Atlantic countries compared to $77 \%$ in North America. The breakdown by country is shown in Table 4.1.1.2.

| Area | Coast Weight | $\%$ | Estuary Weight | \% | River Weight |  | Total Weight |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| NEAC | 1407 | 53 | 161 | 6 | 1086 |  | 2654 |
| NAC | 13 | 9 | 22 | 14 | 117 |  | 152 |

### 4.1.2 Catch and release

Catch and release data for the 1990 s have been provided by 6 countries. In 1999, the proportion of the total rod catch that was released ranged from $100 \%$ in USA to $10 \%$ in Iceland. In 2000 , there was no fishing allowed in USA. Catch and release rates for other countries were $74 \% 53 \%, 42 \%$ and $34 \%$ for Russia, Canada, UK (England \& Wales) and UK (Scotland), respectively. In most of these countries, rates in 2000 are among the highest in each time series and indicate an increasing trend in recent years

### 4.1.3 Unreported catches of salmon

The total estimate of unreported catch within the NASCO Commission Areas in 2000 was 1269 t (Table 4.1.1.1), or $31 \%$ of the total of reported and unreported catch. The estimate for 2000 is an increase of $23 \%$ compared with 1999 (1 032 t ) and an increase of $21 \%$ compared to the 1995-1999 mean of 1051 t . After 1994 there are no data available on salmon catches in international waters. Limited surveillance flights, which were the basis of past estimates of catches in international waters, have not reported any salmon fishing where these have occurred in recent years. Estimates (in tonnes) of unreported catches for the Commission Areas are given below:

| Area | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| NEAC | 1157 | 942 | 947 | 732 | 1108 | 887 | 1135 |
| NAC | 107 | 98 | 156 | 90 | 91 | 133 | 124 |
| WGC | $<12$ | $<20$ | $<20$ | 5 | 11 | 12 | 10 |
| International waters | $25-100$ | n/a | n/a | n/a | n/a | n/a | n/a |

Where available, data are presented by country for 2000 (Table 4.1.1.3). The individual inputs to the total North Atlantic catch range from $0 \%$ to $16 \%$. While this broadly indicates the level of non-reporting by each country relative to the total catch in the North Atlantic, it should be noted that the method of estimation varies both within and among countries. The non-reporting rates range from $0 \%$ to $67 \%$ of the total national catch in each country.

### 4.1.4 Production of farmed and ranched salmon

The production of farmed Atlantic salmon in the North Atlantic area in 2000 was 658735 t. This was the
highest production recorded so far (Figure 4.1.1.2) and represented a $3 \%$ increase compared to 1999 (636 783 t) and a $30 \%$ increase on the 1995-1999 average (504 809 t). Partial data on the worldwide production of farmed Atlantic salmon were available for 2000 (704 134 t). This figure excludes a significant production in Chile. However, worldwide production of farmed Atlantic salmon in 2000 was over 200 times the reported nominal catch of Atlantic salmon in the North Atantic in the same year. This availability of farmed salmon has probably contributed to the decline in commercial fishing effort in many countries.

The total production of ranched Atlantic salmon in the North Atlantic was 11 t in $2000,22 \mathrm{t}$ less than in 1999
and the lowest value since 1984. Production in Iceland declined dramatically because no smolts were released for ocean ranching in 1999, thus only 2SW fish were harvested in 2000 . Production of ranched fish was less than $5 \%$ in each of the other three countries reporting (Ireland, UK(N. Ireland) and Norway).

### 4.2 Use of Case Studies to Illustrate Options for Taking Account of Risk in the Provision of Catch Advice

## Salmon advice in the standard ICES framework for fisheries advice

ICES considered this question, together with the supplementary request that "ICES provide information that will assist with the implementation and evaluation by NASCO and its Contracting parties of the decision structure (Annex 4 of document $\mathrm{CNL}(00) 18$, provisionally adopted by the Council).

Management of Atlantic salmon in the North American and Greenland Commission areas is based on a fixed escapement strategy. The fixed escapement is biologically-based, as the product of a research-derived estimate of the maximum productivity achievable for a unit of spawning habitat, i.e. 2.4 eggs $\mathrm{m}^{-2}$ in most of North America except Quebec where egg depositions are derived from specific SR relationships. These egg depositions are subsequently referenced to survey derived estimates of the amount of suitable habitat potentially available to salmon. All potential returning salmon in excess of the fixed escapement are considered to be available for harvest.

Since 1998, ICES has provided advice to clients within a framework of limit and precautionary reference points set by technical experts, and farget reference points set by managers, and has used a probabilistic framework suitable for risk-based management. This fixed escapement for North American salmon has some properties of both limit and target reference points, as the terms are used by ICES. The resemblance to a limit reference point is due to expected recruitment declining below the fixed escapement. Declining recruitment is a conservation concern, and hence, spawning escapement to North America below the fixed escapement is an undesirable event to be avoided with high probability. The similarity to a target reference point arises because the fixed escapement is also the escapement thought to produce maximum productivity for North American salmon, and hence is a desirable state that managers have agreed they wish to achieve with high probability.

The dual nature of the fixed escapement presents some special challenges when providing scientific advice in a risk management framework. According to current thinking and conclusions of diverse technical discussions, limit reference points should be avoided with high probability, and uncertainty should be considered fully in advice on proximity to limits. To
achieve this, in its management advice ICES has used precautionary reference points which are more precautionary than the limit reference points (ex, higher spawning biomasses, lower exploitation rates), to account for some sources of uncertainty. Then ICES generally advises harvest options which have a $95 \%$ probability of being in compliance with the limit reference points, and at least a $50 \%$ probability of complying with the precautionary reference point, given the assessment's estimate of current stock status. The combination of the precautionary reference points and strong risk aversion with regard to limit reference points ensures management based on the scientific advice has a very low risk of allowing the occurrence of conservation threats to the stock.

Applying this approach when using the salmon fixed escapement as a limit reference point means that advice would be framed to deliver escapements higher than the fixed escapement. A precautionary escapement would be set higher than the actual fixed escapement, and advised harvests would ensure escapements would have a high probability of being at or above the precautionary reference escapement. Thus the expected escapement if the advice were implemented would be higher than the biological fixed escapement to account for the magnitude of uncertainty in both the true best escapement and the true state of the resource. This directly contradicts the intention that all potential retuming salmon in excess of the fixed escapement are considered to be available for harvest, and delivers escapements exceeding those at which the stock is maximally productive due to density dependent effects in freshwater.

If the fixed escapement is used as target reference point, advice should try to continually deliver escapements as near the target as possible; on average being risk neutral with regard to the target. This meets the objective of allowing all potential returning salmon in excess of the fixed escapement to be available for harvest, but half the time escapements below the target will be expected. When uncertainty is large, there is risk of advising harvests which result in escapements well below the biological fixed escapement in some years.

To successfully advise on and manage salmon in a riskbased framework, ICES and NASCO must work together to resolve several issues. The current functional contradiction of the fixed escapement being partly a limit and partly a target must be resolved. Technical experts must clarify a) the degree to which falling below the fixed escapement constitutes a serious conservation problem, b) the major sources of uncertainty, and c) to the extent possible, their magnitudes. The uncertainties may include, for example, uncertainties in harvests and in the forecasts, and intrinsic inter-annual variance in the true best escapement. They must also specify how the various sources of uncertainty are addressed in the assessment and the advice. Managers must specify what their risk tolerances are, both with regard to reduction in
productivity below the highest possible, and the danger of harm to the stocks that is serious or difficult to reverse. Once the uncertainties, risk tolerances, conservation-related reference points and management target reference points are known the determination of the annual quota is a direct step. The quota is the harvest which gives a $50 \%$ probability of the escapement being at the target reference point, as long as the probability of forecast escapement falling below the precautionary reference point is within the risk tolerance of the managers. However if at that harvest the risk of escapement being below the precautionary reference point exceeds the manager's risk tolerance of harm to the stock, the quota must be reduced until the risk profile produces a tolerable probability of escapement being above the precautionary reference point. High uncertainty makes the risk profile very flat (see e.g. Figure 4.2.1.3), so managing risk within the tolerances means harvests will often have to be lower than the difference between the estimate of current returns and the management target, even when the target escapement already may be substantially higher than the precautionary conservation reference point. Similarly, in a risk framework, target and precautionary reference points that are very close together will also require lower quotas than the difference between estimated returns and the target escapement, even when uncertainty is fairly low.

The current management approach used for the West Greenland fishery may not meet the ICES standards for risk management in a precautionary framework. The advised catch options correspond to a $50 \%$ probability of achieving the fixed escapement. If the fixed escapement is only a management target based on achieving maximum productivity, risk is not being managed relative to conservation-based limit and precautionary reference points. If the fixed escapement is a conservation reference point, a risk neutral rather than risk averse approach is being followed, and there is a $50 \%$ chance of an undesirable event occurring.

Because many salmon fisheries exploit mixed stocks, the true situation can be even more complex. The conceptual conservation objective becomes ensuring that the fixed escapements are met for all stock components simultaneously. There are more sources of uncertainty in the assessments, and risks are higher because harvests of individual stock components cannot. be matched to the status of the components relative to their individual targets and limits. Moreover the stock at highest risk relative to its precautionary reference point determines the tolerable harvest or exploitation rate for all the stocks harvested together, even if risk to the other stock components is very low.

In order to formulate the current salmon catch advice, ICES will continue to use the fixed escapement strategy in the same way as used in recent years by ICES and NASCO. Throughout the following text, the advice consistently refers to the "management target" in NASCO terminology as "fixed escapements" to avoid
judging whether these escapements in ICES terminology are conservation limits or management targets.

### 4.2.1 Case studies for calculating risk for the provision of catch advice.

ICES considered case studies to illustrate two approaches for taking account of risk in the provision of catch advice. Both are partial steps towards moving salmon management advice into a more complete risk management framework. The first considers incorporating the uncertainties in a risk analysis to provide a probability profile of meeting the fixed escapement. The second approach addresses the possible role of management targets, in managing the risk of not meeting the fixed escapement.

The case studies below consider a) a mixed stock fishery example for two levels of abundance and b) a single stock example for a homewater fishery.

## a) Mixed stock fishery - West Greenland fishery

The deterministic calculation of catch options for the West Greenland fishery uses the point estimates of the input parameters. When the input parameters have uncertainty (for example the PFA value), the value at the risk neutral ( $50 \%$ ) probability level is used. The procedure is described in Appendix 2 and summarized for two stock levels (low and moderate, Figure 4.2.1.1). For the low abundance period, the catch option at the point estimates and for a $40 \%$ allocation of surplus to West Greenland was 19 t . For the period of moderate abundance, the deterministic catch option was 561 t .

The deterministic calculation does not provide any analysis of the risk of not achieving the fixed escapement in North America at the calculated catch level. The data inputs are uncertain and a risk analysis for the objective of achieving the fixed escapement must incorporate these uncertainties appropriately. The uncertainties included in these case studies are:

- Fixed escapement uncertainty for six stock areas
- Uncertainty in the forecast PFA value
- Uncertainty in the biological characteristics of the salmon in the fishery

Management error (for example, not catching the exact quota) has not been incorporated but it could be included if an estimate was made from historic data.

## Fixed escapement uncertainty

The 2SW spawner requirement for North America used by ICES is the sum of point estimates of individual river or fishing area spawner requirements. It has been shown that the sum of individual river or area requirements provides a probability level of less than $50 \%$ of
simultaneously meeting the fixed escapement in individual rivers or areas (ICES 1996/Assess:11). This excludes the uncertainty in the individual river fixed escapements which have not been quantified for the majority of rivers of North America (except for Quebec rivers). The sum of the $2 S W$ spawner requirements for North America is 152548 fish and adjusted for natural mortality to the point prior to the fishery (spawner reserve) is 170286 fish. To ensure that there is a $50 \%$
probability of spawner escapement at least $100 \%$ of fixed escapements for six stock areas simultaneously, 169000 2SW are required to return to North America equivalent to 1886502 SW fish released from the fishery (Figure 4.2.1.2). The uncertainty increases as the number of stock areas defined by managers increases. Additionally, the analysis assumes that the stock areas are all producing at the same rate relative to their fixed escapements.

Probability of achieving fixed escapements simultaneously in six stock areas

| Probability Level | In North America | Prior to fishery (adjusted by M for $\mathbf{1 1}$ months) |
| :--- | :---: | :---: |
| Point estimate | 152548 | 170286 |
| $50 \%$ | 169000 | 188650 |
| $75 \%$ | 173000 | 193100 |
| $90 \%$ | 177000 | 197600 |

## PFA Forecast Uncertainty

Forecasts of abundance in the year to come are dependent upon stochastic functional relationships. Generally, the forecasts have large uncertainty. The PFA forecasts for the low abundance and moderate
abundance periods are shown in Figure 4.2.1.3. The PFA forecast value at a $50 \%$ level for the moderate abundance period was 437000 fish compared to 183000 fish in the low abundance period.

|  |  | Forecast values |
| :--- | :--- | :--- |
| Probability level | Moderate abundance | Low abundance |
| $10 \%$ | 236782 | 120000 |
| $30 \%$ | 342213 | 155000 |
| $50 \%$ | 436770 | 183000 |
| $70 \%$ | 553223 | 215000 |
| $90 \%$ | 801849 | 280000 |

## Biological characteristics of the fish

Biological characteristics of the fish in the fishery of the coming year are also unknown. These are estimated based on characteristics of previous years taking account of any temporal trends in characteristics if they occur. In the deterministic approach, the point estimates (such as the average weight of previous years, the average fecundity of females in recent years) are used. In the risk analysis, the uncertainty in 4 characteristics is considered: proportion North American origin 1SW salmon, mean weight of 1 SW salmon of North America, the mean weight of 1 SW salmon of European origin, and the age correction factor for older age groups in the fishery. The variability in the number of 1 SW salmon at a given catch option is illustrated in Figure 4.2.1.4. For a catch of 50 tons, the expected catch of 1 SW salmon of North American origin can vary between 11700 fish and 15450 fish ( $10^{\text {th }}$ to $90^{\text {th }}$ percentiles).

## Completing the Risk Analysis

Incorporating all these uncertainties results in a measure of the reliability of the stock assessment for making management decisions. The reliability of the assessment has profound consequences on the catch options. In the theoretical example shown in Figure 4.2.1.5, two assessments provide the same point estimate ( $50 \%$ probability value) but the precisions are very different. Under a risk-prone management approach, the allowed
catch would be greater for the imprecise assessment: at a $70 \%$ risk level, the advised catch under the precise assessment would be 500 t but the uncertain assessment would provide for a catch of 800 t . The risk-averse management approach would advise for lower catch options for the imprecise assessment: at a $20 \%$ risk level, the precise assessment would provide a catch option of about 400 t but for the imprecise assessment, no catch is advised.

The risk analysis probability profiles for the two years of contrasting stock abundance are shown in Figure 4.2.1.6. In the moderate abundance year, a catch option of about 1250 t produces a $50 \%$ probability level of achieving the fixed escapement. This contrasts with the low abundance year when a catch option of just over 100 tons provides a $50 \%$ probability of meeting the fixed escapement. To adopt a more risk-averse approach, managers must select a lower probability (or lower risk) of stocks failing to meeting their fixed escapements. At a $65 \%$ probability level, there would not be any available harvest in the low abundance scenario and a quota of about 900 t in the higher abundance scenario.

The risk analysis described above has not incorporated management uncertainty. When management is imperfect, as is generally the case, the effect on the risk analysis is to increase the uncertainty in the probability of complying with any conservation reference points.

The analysis has also excluded any differences in status among the stock areas. In the case where stock status differs, the probability of meeting a fixed escapement for a given year will be overestimated because the spawning escapement to the areas will be different from those assumed in the model, for stochastic reasons, if nothing else. That is, if the fixed escapement is exactly being met on average for all stocks that year, escapements to approximately half of them will be below their respective stock specific fixed escapements and half above. An evaluation of performance of previous years' fisheries would provide valuable insight into the appropriateness of the data inputs and the assumptions of the risk analysis.

## b) Single River Example - Miramichi River

The Miramichi River, at a maximum axial length of 250 km and draining an area of about $14000 \mathrm{~km}^{2}$, has the largest Atlantic salmon run of eastern North America. There are two major branches: the Northwest Branch covers about $3900 \mathrm{~km}^{2}$ and the Southwest Branch about $7700 \mathrm{~km}^{2}$ of drainage area. The two branches drain into a common estuary and subsequently drain into the Gulf of St. Lawrence at latitude $47^{\circ} \mathrm{N}$. Separate branch assessments were introduced in 1992 to account for the differences in exploitation between the Northwest and Southwest branches. Native Peoples fisheries were historically conducted almost exclusively in the Northwest Miramichi (exploitation also occurs in the estuarial waters of the Miramichi River, downstream of the confluence of the two branches) and recreational fisheries exploitation also differs between the Northwest and Southwest branches.

Temporal stock distinctiveness has also been highlighted as an important component of the Atlantic salmon resource of the Miramichi. Early runs and late runs have different composition in terms of small and large salmon proportions and sex ratios. The early rums in both branches are also exploited more heavily than the late runs.

Atlantic salmon are presently exploited in Native Peoples and recreational fisheries. No large salmon ( $>=$ 63 cm fork length) can be retained in the recreational fishery (mandatory catch and release) and Native Peoples fisheries for small and large salmon are under gear, season and quota controls.

The spawning goal for the Miramichi River and each branch separately is based on an egg requirement of 2.4 eggs $/ \mathrm{m}^{2}$ of spawning and rearing habitat area. The objective is to obtain all the egg depositions from large salmon although compliance relative to the achievement of the fixed escapement is determined relative to egg depositions from both small and large salmon.

## Forecast of returns in 2001

The association between small salmon (almost exclusively 1 SW salmon) and large salmon returns the
subsequent year was examined over the time series, 1985 to 2000 (Figure 4.2.1.7). The ratio of small salmon to large salmon for this time period varied between 1.4 and 7.1 with the most recent year ratio (1999 small, 2000 large salmon) at 1.41 . The median ratio model for the recent five-year period ( 1995 to 1999) would predict returns of large salmon (including previous spawners) of 16400 fish (ranging between 14700 and 25200 ).

## Risk analysis of the fishery

The probability of meeting fixed escapements in 2001 was estimated from the predicted return of large salmon in 2001 based on the small:large salmon ratio of 1996 to 2000 and assuming that small salmon returns in 2001 would be similar to the previous five-year average. The model to assess the risk relative to the fixed escapement if fisheries were to occur in year 2001 can account for seasonal differences in harvest levels, catch-and-release mortality, and biological characteristics of the adults (Figure 4.2.1.8).

Risk is quantified in terms of the probability of meeting the fixed escapement and the egg loss resulting from the fisheries harvests as a percentage of total eggs in the returns of adult salmon to the river. Figure 4.2.1.9 shows the probability profiles for different combinations of losses of large and small salmon due to fisheries. For example, if losses of large salmon were 1000 fish and losses of small salmon were 10000 fish, egg loss as a percentage of total eggs in the returns would be slightly less than $10 \%$ and the probability of meeting the fixed escapement would be $35 \%$. For the Miramichi River overall, there is a $54 \%$ probability of meeting the fixed escapement in year 2001, in the absence of fisheries.

### 4.2.2 Case studies for use of management targets as a means of minimizing risk

NASCO (1998) proposed that "stocks be maintained above conservation limits [here called "fixed escapement" - pending resolution of the relationships among target, precautionary, and limit reference points and fixed escapement called both management target and conservation limit by NASCO] by means of management targets". The purpose of the management target would be to satisfy the management objective of ensuring a high probability that the fixed escapement will be exceeded. As discussed above, this usage differs from ICES' use of management targets. Within the ICES usage, management targets for biological characterstics of stocks are traits (escapements, stock sizes, etc) needed to deliver the social and economic objectives managers and users may have. (As described above, these targets must be high enough to avoid conservation problems with very high likelihood as well.) As NASCO uses "management targets" in the Draft Descision Structure it adopted, these "targets" appear to correspond most closely to precautionary reference points, including considerations of setting reference points higher than the biologically based limit reference points to reflect uncertainties, and managing
risk tolerances relative to the precautionary reference points.

Within the case study examples provided in the draft decision structure adopted by NASCO, the use of "management targets" at some value proportionally higher than the fixed escapement was used. The challenge is to assess whether a "management target" [precautionary reference point] can be defined which would provide a high probability of avoiding the conservation-related limit reference point [possibly the fixed escapement]. The derivation of a "management target" sensu NASCO can be based upon an assessment of the same uncertainties as shown previously, namely uncertainty in fixed escapements for six stock areas, uncertainty in the forecast PFA value, and uncertainty in the biological characteristics of the salmon in the fishery.

The use of a "management target" assumes that managers may choose to harvest all the surplus relative to the "management target", and its associated risk tolerance, and the risks are therefore assessed on the assumption that this will be done. The analysis provided in Section 4.2.1 illustrates how a "management target" could be set with a risk tolerance of 0.5 (i.e. risk neutral with regard to the "target") which would increase the probability of achieving the fixed escapement (i.e. complying with the limit reference point) by a fixed amount. For the higher abundance year, to achieve a probability of meeting the fixed escapement of $60 \%$ a "management target" of $128 \%$ of the fixed escapement would be required and this target would result in a harvest reduced by 250 t (from 1250 t at $50 \%$ to 1000 t at $60 \%$ ) (Figure 4.2.1.6). For the low abundance year, a probability of achieving the fixed escapement of $60 \%$ would result from a "management target" set at $116 \%$ of the fixed escapement, and would result in a harvest reduced by 100 t . The problem with this approach is that a "management target" defined as a fixed proportion above the fixed escapement, will not reduce risk by the same amount in different years, with difference in abundances and uncertainties. Although an average value could be employed, it could result in significant over-exploitation (or foregone harvest) in different years.

## Summary and relative merits of the approaches

Our analysis shows that there is no single "management target" as a percentage of the fixed escapement which will provide the same level of protecton against failing to meet the fixed escapement over variations in abundance and assessment uncertainty. ICES therefore favours the approach of providing an annual risk analysis which considers the variations in abundance, and in the uncertainty of the assessment. When risk tolerances are specfied, the quota level consistent with the risk analysis and acceptable risk can be read directly off the risk analysis probability profile plot (such as in Figure 4.2.1.6). ICES recognizes that managers may consider that risk tolerances might differ for different
fisheries and risk management of mixed stock fisheries is especially complex. ICES also stresses that within the precautionary approach, risk tolerances should be set in advance of the risk analysis, to ensure conservation is not compromised to deliver harvest opportunities.

### 4.2.3 Review of draft decision structure (NASCO CNL(00)18)

ICES tabled the Report of the Standing Committee on the Precautionary Approach (CNL(00) 18 Application of a Precautionary Approach to Management of Salmon Fisheries) for discussion and comment.

ICES considered that the draft decision structure provided a very useful first step in developing mechanisms for guiding managers towards appropriate actions for fisheries, compatible with the underlying goal that conservation requirements (both abundance and diversity) of contributing stocks are achieved. ICES endorsed the emphasis given in the draft decision structure to systematically monitoring the effect of management measures and taking results into account in future management decisions. It was also felt that the various elements of the decision structure, if widely applied to fisheries and stocks, would provide a useful audit trail, showing the data available for stocks and the basis of the management decisions taken for the fisheries where those stocks are represented. This would also provide clear indications of data deficiencies and highlight where lack of data was impeding sound management.

The presentation would be improved by adopting a flow diagram type of approach, similar to that provided in ICES report (ICES CM 2000/ACFM:13). This should make the review and evaluation of measures taken more explicit (by means of feedback loops) and should indicate where risk should be considered.

The step in the single stock framework that refers to stocks threatened by external factors is unclear, as it is not obvious what happens if the stock is threatened but is not yet below the conservation limit (for example recently introduced disease into a still productive stock). It may be better to incorporate this into the general assessment of status, such that if status is threatened by external factors, the reasons could be identified and appropriate pre-agreed management actions taken.

ICES noted the clear distinction between action under conditions of unsatisfactory stock status (i.e. identify reasons and implement corrective action) and actions under conditions of surplus (implement pre-agreed management actions to harvest the surplus). However, ICES felt it was likely that many stocks with an exploitable surplus are also subject to impacts that may cause them to fall below surplus at some future time, if measures to mitigate impacts (for example, habitat rehabilitation) are not implemented. Therefore, it was
insufficient to recommend implementation of measures only when status had become fully unsatisfactory.

ICES noted that in the pre-agreed decision structure, the decision should take account of all sources of uncertainty, with management targets being suggested where appropriate, however the draft decision framework did not fully address the incorporation of risk into the decision process. In this respect, the use of further case studies specifically to illustrate this would be valuable (see Section 4.2.1).

It was noted that no pre-agreed management actions were specified, though it is accepted that a generic structure may not be able to cover all specific cases. Moreover, the decision structure repeatedly refers to "pre-agreed management actions" with no indication of the source of such agreements. ICES notes that the process for gaining pre-agreement on specific actions to be taken under specific conditions is rarely simple and agreement on a decision structure without unambiguous specification of the "pre-agreed management actions" and their triggers is only a small step towards improved conservation.

In summary, ICES recommends some modifitcations and reference to similar salmon management structures being developed by contracting parties for use in homewater fisheries.

### 4.3 Differences in the occurrence of escaped farmed salmon in fisheries and stocks in different areas

In 2000, about 627000 t of farmed salmon were produced in the Atlantic area, with Norway and Scotland accounting for the majority of production (see Section 4.1.4). In comparison, the total nominal landings of salmon in commercial fisheries in the north Atantic in 2000 were about 2800 t .

Farmed salmon are abundant in large numbers in Norwegian coastal commercial salmon fisheries. The proportion is known to be lower in fjord and freshwater catches, but increases in spawning populations. Tagging experiments have shown that farmed salmon from Norway are caught in the Faroes fisheries, and it has been shown that the incidence of escaped farmed salmon in this fishery can be high. Estimates from the commercial fishery at West Greenland in 1991 and 1992 showed that the incidence of farmed fish was less than $1.5 \%$. Results from monitoring salmon fisheries and stocks in Scotland, Ireland and Northern Ireland have suggested a much lower proportion of farmed salmon. Fish farm escapees also occur in rivers in Canada and USA, particularly in areas with high density of farms.

Analyses carried out in Norway have shown that the occurence of farmed salmon is highest in rivers close to areas with high density of fish farms. In Ireland there have been 13 reported incidents between 1986 and 2000
involving 189000 adults and 120000 smolts escaping primarily from sites in the West, but also from sites in the North West, South West and North. There is a significant relationship between the number of escapees in the declared catches and the reported salmon farm escapes although these numbers are very low.

Wild salmon leave their home rivers as smolts in the spring and move quickly into oceanic areas. In the north east Atlantic areas, results from smolt tagging experiments and post-smolt surveys have strongly indicated that ocean currents are the vectors that force the fish northwards. Hatchery-reared salmon released as smolts in freshwater are thought to have a similar migratory pattern as wild salmon. Hatchery smolts released on the coast tend to return to the same area from where they were released, but apparently enter any river in that area to spawn.

In Norway, it has been observed that when released tagged hatchery-reared salmon post-smolts were kept in saltwater and sequentially over one year, there was annual variation in both survival and homing precision, with poor survival of the groups released in late summer and autumn, and poor homing precision of fish released in winter. Large salmon escaping early in the summer, a few months before spawning, tended to move northwards with the current, and when they were ready to spawn, they entered freshwater in that area. They did not appear to have a homing instinct .

Based on the current knowledge from the literature, the results from the tagging experiments, direction and speed of ocean currents, and from available information of the apparent low proportion of fish farm escapees in Ireland and Scoland relative to the production of farmed salmon, it is hypothetised that fish farm escapees from Faroes, Ireland and Scotland are transported with the currents, and fish that become sexually mature when they are relatively close to the coast enter Norwegian and Russian fisheries and salmon rivers. Under the same hypothesis some fish farm escapees from Ireland may enter fisheries and salmon rivers in N. Ireland and Scotland, some Irish and Scottish fish farm escapees may even turn up in Denmark and Sweden, and some Norwegian fish farm escapees may enter fisheries and rivers in Sweden, Denmark and Russia. It may be that a continuous supply of fish farm escapees in the coastal current leads to a high proportion in Norwegian coastal salmon fisheries, although their survival are still low.

### 4.4 Recent Research Developments

### 4.4.1 Infectious salmon anaemia: implications for wild salmon management

Information was presented to ICES about infectious salmon anaemia (ISA) in North America. Aggressive control measures taken in Canada resulted in only one site reporting the disease to date from the spring 2000 smolt class. No ISA was detected in wild and escapedfarmed fish entering the Magaguadavic River, where
positive tests for both groups were obtained for the first time in 1999. Positive tests for ISA were recorded for the first time in 2000 from the Margaree River Nova Scotia, the Morell River in Prince Edward Island, and the Saint John River New Brunswick, however, the initial results are problematic because they could not be confirmed. The first confirmed case of ISA from the East Coast USA salmon farming industry was announced on 16 March 2001. The US industry is now implementing measures similar to those used in Norway, Scotland and Canada to manage the problem. Genomics research found that European ISA isolates (Scotland and Norway) were $98-100 \%$ similar, whereas the Canadian isolate was only about $84-88 \%$ similar to the European group. The strains may have diverged from each other about 1900, which corresponds to a period of transfers of salmonids from North America to Europe (Rainbow trout) and from Europe to North America (sea run brown trout). Both species are asymptomatic hosts of the virus. It is not known where the virus originated. Independent testing of a widely used vaccine confirmed a significantly increased survival rate for fish that had been vaccinated.

### 4.4.2 Causes of fish farm escapes

The causes of escapes of farmed salmon from sea cages in British Columbia and East Coast North America were reviewed. In British Columbia, the reported number of escaped-farmed fish has stabilized at about $1 \%$ of the annual total salmon production. On average, there were 5.2 escape incidents per year in 1996 - 2000 . Escapes resulted from net failures ( $42 \%$ of the total; caused by predator attacks ( 6 of 11 net failures) and other factors), mechanical problems with cage systems or boats (4\%), handling errors ( $39 \%$ ), and boat collisions with cages (15\%).

The reporting of escapes in East Coast North America has been imperfect. Six incidents could be documented between December 1999 and December 2000. The smallest escape of salmon was 3000 , and the largest > 100000 . One event released 25000 rainbow trout. Three of these six releases were storm related, one involved a boat collision, one was due to vandalism, and the cause for one is uncertain. Escapes in these areas resulted predominantly from human error and storms. Severe storms predictably occur in autumn and winter. By contrast, it is difficult to predict when human error will occur. Thus the entry of farmed-salmon to fisheries and stocks will retain a large degree of unpredictability. Different salmon farming regions are also characterized by different climates and operating conditions. Releases of farmed fish to the wild, and their occurrence in fisheries and rivers, will vary in both magnitude and frequency among these regions depending upon the severity of the conditions.

Causes of post-smolt mortality in the marine phase

Possibility of by-catch of post-smolts in pelagic
fisheries
Between $10-20$ June 2000, special fishing experiments for post-smolts carried out in the Norwegian Sea yielded 268 post-smolts and 6 salmon in 14 tows during three consecutive days west and southwest of the Voeringplateau ( $68^{\circ} 30^{\prime} \mathrm{N}-63^{\circ} \mathrm{N}$ and $1^{\circ} \mathrm{W}-5^{\circ} \mathrm{E}$ ). Most of these fish were taken in three tows (170, 60 , and 34 respectively). The CPUE at this particular cruise was 9 post-smolts per trawl hour, which is one of the highest recorded since 1990. Microtagged and Carlintagged fish occurred for the first time in the same hauls. In Norway no microtagging was carried out in 2000, indicating a south European origin of these fish, which supports the hypothesis that south Norwegian fish and European fish are mixed on the feeding areas in the Norwegian Sea also at the post-smolt stage. These large catch numbers are of concern with respect to the potential impact of the mackerel fishery in the Norwegian Sea in June - August. There is overlap between the mackerel fishing areas and the anticipated northward migration routes for the post-smolts of south and central Europe and southern Norway (ICES CM 2000/ACFM:13). The surface trawl method used by the Norwegian Research vessels resembles the commercial fishing method which also operates with a flotation on the trawl wings. However, the commercially used trawls are considerably deeper and longer, they are towed at higher speed, i.e. $-5-6$ knots vs. 3-3.5 for the research ships, and the tows also last longer. The commercial trawlers thereby sweep much larger areas, and hence are likely to catch more post-smolts. So far it has not been possible to obtain detailed information on the methods used by the commercial ships, but the Norwegian Coastguards report a fleet of $25-30$ Russian and East European trawlers operating annually in the mackerel fishery in international area. Due to the assumed surface-near location of the post-smolts during migration and on their oceanic feeding grounds. ICES previously recommended that ICES/NASCO should look into the possibility for encouraging these commercial trawlers to lower the head rope of their gear to minimum 5 m below the sea surface (ICES CM 1999/ACFM:14). ICES recommends that the by-catch issue be further investigated to assess the possible impact on post-smolt survival.

## Salmon lice observations in selected Norwegian fjords and the Norwegian Sea

The status of salmon lice (Lepheoptheirus salmonis Krøyer) on seaward migrating post-smolts has been monitored by surface trawling in two southwest Norwegian fjords since 1998. The two southern fjords (Sognefjord and the Nordfjord) had been selected because they are different both hydrographically and in densities of fish farms, with the northern-most of these two fjords (Nordfjord) containing the largest number of
net-pens. Sampling in more northerly fjords was also carried out as these represent areas with low (Altafjord) or no fish farms at all and large numbers of wild postsmolts.

Overall infestation rates have varied greatly between the years, especially in the Sognefjord, where the mean number of lice per fish has been over 30 the two last years. These particular outmigrating cohorts may therefore have been subjected to infestation rates surpassing even conservative estimates of lethal limits. In the Nordfjord the average number of lice per fish was relatively high in 1998-1999, while it was zero in the samples of 2000 . This may be due to a combination of earlier entry of the post-smolts into the sea, and a thick layer of fresh water extending to the outlet of this fjord which may have protected the fish from infestation, thus underlining the possible importance of hydrography for survival at the time of smolt passage through the fjords.

Post-smolt samples from more northern fjords were infested with, on average, only 0.4 salmon lice per fish. None of the samples analysed from the Norwegian Sea, carried more than 10 chalimus or older stages of lice per fish. This may indicate that fish with high infestation rates either die, or lag behind the main cohorts of sea migrating post-smolts. At present there are insufficient data available to enable correlation of the influence of the observed lice infestation rates on subsequent return rates of 1 SW or MSW salmon to the particular fjords. However, the high observed infestation rates are a matter of concem, which should be investigated in more detail.

### 4.4.4 Marine growth checks as evidence for sub-catchment population structuring

The occurrence of summer checks on the scales of salmon returning to Scottish home waters in the years 1997-1999 was shown to be significandy greater than levels derived from the previous 35 -year period. There was no evidence that the incidence of checks varied between sexes. There was also no association between the presence of checks with either size at return or marine survival indices. The majority of checks tended to occur within a relatively narrow band within the third quarter of the marine zone. The proportion of salmon whose scales exhibited summer checks was highly variable both among years and sea age categories, but, in general, salmon showed a higher incidence of growth checks in their first year at sea than during their second year.

The incidence of summer checks was also strongly related to the subsequent run-timing (the calendar month when fish returned to freshwater) of the adult fish. The cause of the summer checks is unknown and the direct effects difficult to detect. Their relatively high incidence in recent years, however, may allow speculation on the mechanisms responsible for the observed patterns of association between groups of
salmon in the ocean. Patterns of variation are relatively consistent among years suggesting that either different "run-timing groups" of salmon are differentially predisposed to the causal event or, salmon are not randomly mixed in the ocean and different groups follow, to some extent, different migration routes.

These observations may assist our understanding of recent trends in matine survival. The structured variation in the incidence of summer checks between "run-timing groups" reported here provides an association through which differential trends in marine survival may occur as it demonstrates that these groups may encounter similar conditions in a patchy marine environment.

### 4.4.5 Estimates of $\mathbf{M}$ at sea for Atlantic salmon

In the run-reconstruction models of the pre-fishery abundance (PFA) for the North American and Nor theast Atlantic stock complexes, it is assumed that the natural mortality rate is $1 \%$ per month after the first year at sea. The assumed rate is from an analysis of weight and age data from the River Bush (U.K.). This rate of natural mortality is used to calculate the number of fish immediately after the first winter, prior to the high seas fisheries, and between the high seas fisheries and returns to homewaters. When high seas fisheries remove a large proportion of the stock several months before the animals are destined to return to the rivers, the estimate of the PFA is less sensitive to the assumed natural mortality rate than when fisheries are of low intensity. In the time series of catches and returns used to estimate the PFA, there have been reductions in the level of sea fisheries such that presumably a smaller proportion of the estimated PFA consists of actual observed/harvested animals than was the case a decade ago. The concern is that the perception of reduced / declining abundance is in part an artifact of the model assumption about natural mortality during the second year at sea in terms of its assumed level and assumed constant rate over time. Two methods for estimating mortality at sea were examined, the inverse-weight method and the maturity schedule method.

## Method 1 - Inverse Weight Method

This is based on the assumption that M decreases with increased size because marine natural mortality is assumed to be primarily the result of predation. Following on that approach, the inverse weight hypothesis is used to estimate natural survival during the second year at sea based on catches, size-at-age, and return rates to the river. Based on this the natural mortality rate between Greenland and home waters (approx. 12 months) is between $3 \%$ and $12 \%$, i.e. about $1 \%$ per month. M has been modelled for juvenile and adult fish as a power function of weight and using empirical observations of 113 species/stocks, derived parameter estimates for $M$ relative to weight. Based on these parameter values and using estimates of weight at
age for a known stock (in this case the River Bush salmon), the monthly mortality rate of Atlantic salmon in the second year of ocean life is about $3 \%$ per month.

## Method 2 - Maturity Schedule Method

It is possible to estimate the sea survival rates of 1 SW and 2 SW salmon during the first and second years at sea by modeling the dynamics in the ocean using a simple life history model. Assuming that survival rates at age for males and females are similar, the model provides equations relating the survival rates and maturation profiles for 1 SW and 2 SW salmon.

The model was applied to data from three rivers:

1. Saint John River hatchery returns of age-1 smolts stocked at Mactaquac
2. LaHave River at Morgans Falls, wild smolts
3. Rivière de la Trinité (Québec) wild smolts

Sex ratios for the wild smotts were derived from sampling. Sex ratio for the age-1 smolts from Mactaquac were obtained from one year's sampling and assumed constant for the years analysed.

The model results support the widely held view that the major source of mortality in the ocean occurs during the first year. They also provide evidence against the constant mortality rate assamptions used in the runreconstruction model and for at least one wild stock of eastern Canada, monthly instantaneous mortality rates of $5 \%$ (ranging between $2 \%$ and $15 \%$ ) would seem more appropriate.

Although there appears to be increasing evidence of M being greater than $1 \%$ per month in the second year at sea and that M varies annually, the Working Group cautioned that only three rivers were evaluated and the data series on only one was longer than ten years. For this reason the revised values from preceding analysis have not been used in the forecast model for 2002. While an analysis of more rivers would be required to assess the among stock variability in the estimated survival rates and the representative level for the North American stock complex, it will be necessary to incorporate revised values for the forecast model in future as they become available. The Working Group recommended that further evaluation of the maturity schedule method be undertaken particularly as it relates to the sensitivities of the survival estimates to the sex ratio values of the smolts and the assumption of equal survival of male and female salmon.

### 4.4.6 Potential impact of climate change on juvenile salmon

Climate change has been identified as an important source of aquatic disturbance on a global scale and may alter species composition and dominance in aquatic ecosystems. Cold water ecosystems are particularly at
risk and predictions from the climate change models for North America include: increase in mean surface air temperatures, increase in winter air temperatures, increased frequency and duration of summer hot spells, increased water temperatures in the range of $2-5^{\circ} \mathrm{C}$ with maximum changes occurring in spring and fall, advanced timing of snowmelt and spring runoff.

ICES reviewed an analysis of the hydrological conditions and river temperatures in the Miramichi River over a 50 year time period and the associated variability in juvenile salmon size-at-age during 1971 to 1999. The results of the analyses suggest that growth of juveniles in the Miramichi River is likely to be adversely affected by climate change, particularly during the spring months. Increases in air and water temperatures are expected to contribute to reduced size-at-age of juveniles with the potential effect of altering survival, age at smoltification, and ultimately sea survival.

### 4.4.7 Compilation of Tag Releases and Finclip Data by ICES Member Countries in 2000

Data on releases of tagged, fin-clipped, and marked salmon in 2000 were provided by ICES and are compiled as a separate report. A summary of Atlantic salmon marked in 2000 is given in Table 4.4.7.1. About 3.36 million salmon were marked in 2000, a decrease from the 4.43 million fish marked in 1999. The decrease was due largely to the reduced number of adipose fin clips. Primary marks are summarized in three classes: microtag (i.e., coded wire tag), external tag/mark, and adipose clips (without other external marks or fin clips. Secondary marks (primarily adipose clips on fish with coded wire tags) are also presented in the Annex. The adipose clip was the most used primary mark (2.35 million), with microtags ( 0.65 million) the next most used primary mark. Most marks were applied to hatchery-origin juveniles ( 3.30 million), while 45115 wild juveniles and 16150 adults were marked.

5

## ATLANTIC SALMON IN THE NORTH-EAST ATLANTIC COMMISSION AREA

5.1 Events of the 2000 Fisheries and Status of Stocks

### 5.1.1 Fishing in the Faroese area 1999/2000 commercial fishery

In the period 1991-1998 inclusive the Faroese salmon quota was bought out. However, the Faroese Government continued sampling inside the 200 mile EEZ during most years (ICES CM 2000/ACFM:13). No buyout was arranged for 1999 and 2000. No fishing took place in 1999 and the commercial fishery resumed in 2000. In the 1999/2000 season approximately 8 t were caught by M/S "Túgvusteinur" during 2
commercial fishing trips between late January and early April 2000 (ICES CM 2000/ACFM:13).

Description of the 2000/2001 commercial fishery : No fishery for salmon was undertaken by Farcese fishermen during the 2000/2001 fishing season and, consequently, no biological information was available for this season.

### 5.1.2 Homewater fisheries in the NEAC area

In the NEAC area there has been a general reduction in catches since the 1980s. This reflects a decline in fishing effort, both as a consequence of management measures and the reduced value of commercially caught salmon, as well as a reduction in the size of stocks.

Gear and effort: While there have been no changes in the types of commercial fishing gear used, the number of licensed gear units has, in most cases, continued to fall. Most fisheries for which data are available record a reduction of over $40 \%$ in gear units operated over the last 10 years. There are no such consistent trends for the rod fishing effort in NEAC countries over this period. Further initiatives to reduce fishing effort were introduced in several countries.

Catches: The overall nominal catch in the NEAC area in 2000 (2643 t) was substantially higher than that in 1999 (2075t). Catches in some northern European countries were particularly high and well above the recent five and ten-year averages; catches in most other NEAC countries were close to or below the long-term averages.

CPUE: CPUE data for the net and rod fisheries show differences between countries but no large scale geographic patterns emerge. ICES noted that reduction in the number of fisheries operating can benefit those fisheries still in operation and that the lack of consistent trends in CPUE may reflect the imprecise nature of these indices.

Composition of catches: No common trends were noted in the sea age composition of the 2000 catches in the NEAC areas. Differences in the age composition between countries in Northerm and Southern Europe noted in 1999 were less apparent in 2000.

In general, the incidence of farmed salmon in NEAC homewater fisheries remained at low levels ( $<2 \%$ ) and similar to recent years, despite the continued increase in the salmon farming industry. The proportion of farmed salmon ( $20 \%$ ) in the nominal catch for Norway did not increase, but this was a result of the significantly increased catch of wild fish. The number of farmed fish in the Norwegian catch was the highest recorded in the time series.

Origin of catch: From 1996 to 1999 a total of 409762 smolts, mainly hatchery reared were tagged and released
in Norway. A total of 3811 adult recoveries were reported from Norway and 19 from other countries ( $0.5 \%$ of the total number of salmon recovered). This is consistent with previous observations that very few Norwegian salmon are intercepted in other countries.

Exploitation rates: Exploitation rates showed no trends relative to long-term averages for 1SW stock components in the NEAC area, although significant downward trends were detected for the 2 SW component of some fisheries. There appeared to be no uniform pattern across NEAC countries.

### 5.1.3 Status of stocks in the NEAC area

There are over 1500 rivers supporting salmon in the NEAC area, but for most of these there is no information on the status of stocks. In this Section, stock status is described for around 40 monitored rivers of which many are of small size and contribute a proportionately small quantity of the salmon production in the NEAC area. In summary, the monitored rivers analysed in this section would suggest that the status of salmon stocks in the NEAC area is, in general poor (Figure 5.1.3.1). This broadly agrees with the results of the PFA-lagged spawner analysis which is based on national catch statistics and presented in Section 4.3.

Attainment of conservation requirements: Analysis of attainment of conservation limits (CL) in 2000 showed that the proportion of rivers with an egg deposition above their CL was higher than in 1999 but less than in 1998. However, a majority of rivers showed a decline in their level of attainment in 2000 compared to the previous year and in most cases the decline was substantial ( $30-80 \%$ ). This indicates that the recovery of salmon stocks observed in 1998, from a period of low attainment (1994-1997), has not appeared to continue. Although some areas were not represented in the data (e.g. Norway), the Working Group had no reason to assume that the indices were not representative of stocks in general and noted the analysis broadly corresponded to the results of the PFA analysis in Section 4.4.6.

Adult returns to rivers: Measures of adult returns back to the rivers showed that of the rivers examined in 2000, more than half showed increased counts. Both southern and northern rivers showed a significant decline over the last 10 years, whereas no clear trend was detected for the last 5 -year period.

Marine survival indices: For most rivers where information is available, marine survival indices were below both the previous 5 -and 10 -year means. Route regression analysis showed a significant downward trend in marine survival for 1 SW fish for the last 5 -and 10 -year period, while no trend was detected for $2 S W$ fish. A similar analysis showed a downward trend in marine survival for 1 SW and 2 SW hatchery fish over the last 10 years but no decline over the past 5 year period. These results are consistent with the information
on adult salmon counts and suggest that returns are strongly influenced by factors in the marine environment.

### 5.2 Evaluation of the Effects on Stocks and Homewater Fisheries of Significant Management Measures introduced since 1991

### 5.2.1 Evaluation of the effects of management measures introduced in Faroes since 1991

Between 1991 and 1998 the Faroese fishermen agreed to suspend commercial fishing for the salmon quota set by NASCO, in exchange for compensation payments. The number of fish spared as a result of this period of suspension is the catch that would have been taken if the fishery had operated, minus the catch in the research fishery which operated in most years. No buyout was arranged for 1999 or 2000 . Although no fishing took place in 1999, a single vessel carried out commercial fishing in 2000, catching approximately 8 t . As for last year, analysis was based on the assumption that full quota would have been taken, had full scale commercial fishing taken place. Thus, the maximum catch that would have been taken in 1999/2000 would have been 300 t (see below). For the $1999 / 2000$ analysis therefore the fish spared totalled 292 t ( $300 \mathrm{t}-8 \mathrm{t}$ ).

| Year | Quota (t) | Estimated increased returns to home waters in Europe |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 1SW | \% | MSW | \% |
| 1992 | 550 | 2842 | 0 | 70809 | 6 |
| 1993 | 550 | 11429 | 1 | 106307 | 10 |
| 1994 | 550 | 21078 | 1 | 134159 | 11 |
| 1995 | 550 | 12949 | 1 | 138533 | 13 |
| 1996 | 470 | 10573 | 1 | 122196 | 12 |
| 1997 | 425 | 9578 | 0 | 105368 | 14 |
| 1998 | 380 | 19699 | 1 | 103169 | 13 |
| 1999 | 330 | 17261 | 1 | 99130 | 12 |
| 2000 | 300 | 15332 | 1 | 87726 | 10 |

The calculated additional retums represent between $6 \%$ and $14 \%$ of MSW fish and up to $1 \%$ of 1 SW fish returning to homewaters between 1992 and 2000. However, about $65 \%$ of MSW salmon caught in the Faroes fishery would return to Scandinavian countries, Finland and Russia. If this were the case, they might have represented from $10 \%$ to $19 \%$ of MSW returns and up to $2 \%$ of $1 S W$ returns to northern European homewaters in those years. These returns were estimated from PFA analysis, (Section 4.3). If stocks and fisheries had remained stable, total catches would have been expected to increase by approximately the same proportions in respective areas. However, examination of trends in catches in NEAC countries suggests that any expected increase may have been masked by other factors such as changes in marine survival and/or management measures in homewaters.

Evaluation of the effects of management measures introduced in homewaters since 1991 ICES noted significant reductions in the number of gear units deployed in most countries in the NEAC area. Additional measures have been taken in some countries.

In Ireland new management and conservation legistation was brought into force in 1997 which was aimed at reducing effort and exploitation in the fishery and to facilitate enforcement. In order to show whether there has been a change in the catch subsequent to the introduction of measures in 1997, the data were analysed using a Non-Parametric Random Ratio (NPR) test (ICES CM 2000/ACFM:13). The results of this test indicate that drift net catches in the most recent 4 years were significantly lower than the preceding 7 years ( $p$ $<0.01$ ) in all regions. Similarly, draft net catches (excluding the North Western Region where the Moy River draft net was suspended in 1994) were also significantly lower in the most recent 4 years ( $p<0.01$ ) in all regions. A similar analysis showed that the exploitation rates in the period from 1997 to 2000 were also significantly reduced compared to the previous 10 year period ( $p<0.01$ ). It is concluded therefore that the measures introduced in 1997 contributed to a reduction in both the overall catch and the exploitation rate on Irish stocks.

In UK (England and Wales), the North East coast fishery is the largest net fishery and has taken $68 \%$, on average, of the national declared net catch over the period 1970-1992. A phase out of this fishery was introduced in 1993 and the number of licences issued has subsequently fallen by $50 \%$, from 142 in 1992 to 71 in 2000. The exploitation rate in 1992 was estimated to be in the region of $50 \%$. Assuming the remaining fishermen are representative and that there have been no major changes in the fishery, the average exploitation rate (1996-2000) would have fallen to around $32 \%$ (i.e. a $36 \%$ reduction). This is in close agreement with the reduction in the average drift net catch (1996-2000), which has fallen by $32 \%$ compared with the 5 years (1988-92) prior to the start of the phase out. A number of other smaller coastal mixed stock fisheries have also been phased out since 1991.

National measures introduced in UK (England and Wales) in 1999 to protect spring salmon are estimated to have saved around 3700 salmon from capure by net fisheries in 2000 before 1 June (based on the catch and the average proportion of fish taken in this period in the 5 years prior to the measures being introduced) and 1400 by rod fisheries (based on a similar proportion, but adjusted for catch and release).

ICES noted that a large number of other measures had been introduced. For example, in UK (England and Wales) the total number of licences issued has been reduced by $46 \%$ since 1991 , but the introduction of additional controls (e.g. increased close periods) has reduced the total allowable fishing effort by $60 \%$. In UK (Scotland), a voluntary cessation of net effort for the
first six weeks of the fishing season was agreed by the majority of fishermen and was introduced in 2000. In the rod fishery, there has been an increase in the practice of catch and release since 1994 as previously reported. These recent initiatives, and the continuing decline in overall net effort, are likely to reduce the impact on NEAC stocks. ICES expected these changes to reduce homewater exploitation rates.

### 5.3 Expected Abundance of Salmon in the North East Atlantic

NEAC - PFA model: No changes were made to the structure of the model used in 1999 to estimate prefishery abundance of salmon in the NEAC area. However, data inputs were reviewed and updated and for several countries the data sets were split into two or more regions to allow more precise input parameter values to be provided. No new information was provided to modify the way that stocks are grouped. The pre-fishery abundance estimates are therefore divided into Northern Europe (all Nordic countries plus Russia and Iceland) and Southern Europe (Ireland, UK and France) groups.

Trends in PFA for NEAC stocks: The PFA of maturing and non-maturing $15 W$ salmon and the numbers of 1SW and MSW spawners for the whole NEAC area and the Northern and Southem European groups are shown in Figures 5.3.1 to 5.3.6.

Figure 5.3.3 shows that recruitment of maturing :1SW salmon (potential grilse) in Northern Europe was generally high (around one million) in the 1970s and 1980 s , although the numbers have fluctuated quite widely, but there was a steady decline in these stocks from the mid 1980s to the mid 1990s. In the past four years there has been an upturn in the recruitment, with stocks in 2000 returning to the levels observed in the early 1990 s. The number of 1 SW spawners was low in the 1970s, increased through the 1980s but declined again in the 1990s (Figure 5.3.4). However, escapement in 2000 appears to have been good.

Numbers of non-maturing 1SW recruits (potential MSW returns) for Northern Europe are also estimated to have fluctuated around one million between 1970 and 1985, but subsequently fell to about half this level in the late 1990s; there has been a slight upturn in the past three years. The numbers of MSW spawners, however, show no trend over the time series although numbers appear to have been good in 2000 (Figure 5.3.3). It therefore, appears that the decline in recruitment has been balanced by the reductions in exploitation both in homewater fisheries and at Faroes. These trends in recruitment for the Northerm European stocks are broadly consistent with the limited data available on the marine survival of monitored stocks in Norway and Iceland.

In the Southern European stock complex (Figure 5.3.5), the numbers of maturing 1 SW recruits are estimated to have fallen substantially since the 1970 s. Recruitment was at its lowest during the 1990s and there was a further drop in the estimated recruitment in 1999 with value in 1999 and 2000 being the lowest in the time series. This pattern is consistent with the data obtained from a number of monitored stocks. Survival of wild smolts to return as $15 W$ fish fell to very low levels on the four monitored rivers in the Southern European area. This suggests that the marked reduction in 1SW returns in 1999 is likely to have been due in large part to a widespread decline in marine survival. Reductions have also been observed in freshwater production and marine survival could be affected by factors operating in freshwater.

The PFA estimates suggest that the number of nonmaturing 1SW recruits in Southern Europe has declined fairly steadily over the past 30 years (Figure 5.3.5); these stocks have also reached their lowest levels in the time series in 1999 and 2000. This is broadly consistent with the general pattern of decline in marine survival of $2 S W$ retums in most monitored stocks in the area. In more recent years, reductions in exploitation do not appear to have kept pace with the stock declines and the spawning escapement has thus also fallen over the period (Figure 5.3.6).

Forecasting PFA for NEAC stocks: In order to use the PFA estimates to provide quantitative catch advice, a forecast will be required of PFA recruits in the year of the fisheries. This means that it will be necessary to forecast the PFA two years forward from the latest estimate. The model used to forecast PFA for North American stocks is based upon both environmental (thermal habitat in the North-West Atlantic) and biological (lagged spawners) parameters. ICES has considered similar approaches for the NEAC area, but there is as yet insufficient information to develop such a model and no new data were supplied in 2001. There is still limited information on the factors affecting the distribution and survival of salmon during the marine phase of the life-cycle. ICES considers that inclusion of environmental parameters in a model must be based upon justifiable hypotheses concerning the impacts on freshwater and/or marine survival.

Evaluation of effects of farmed salmon on the catch advice: NASCO has asked ICES to evaluate the potential biases in the catch advice resulting from the inclusion of farmed escapees in the assessment models. The NEAC PFA model has previously only taken account of the presence of farm escapees in the Faroese catches and has not taken any account of farm escapees in other areas. The incidence of farmed fish in catches at West Greenland and in most homewater fisheries has been estimated to be less than $1.5 \%$. These fish will therefore have a minimal effect on the PFA and National Conservation Limit assessments.

However, substantial numbers of farm escapees occur in coastal, fjord and river fisheries in Norway. These fish have previously been included in the run-reconstruction model and therefore contributed to the back-calculated estimate of recruitment (PFA). The farm escapees have also been incorporated into the estimates of the numbers of spawners and thus contribute to the estimated eggdeposition. However, farm fish probably don't spawn as successfully as wild fish and their offspring may not be as viable as wild offspring; their contribution to the egg deposition was therefore reduced by a weighting factor in the model.

ICES therefore, modified the assessment models to take account of potential effect of farmed fish on the assessment. Over the past 10 years the average proportions of farmed fish in catches of 1SW and MSW salmon have been $8 \%$ and $14 \%$ respectively. Removing these fish from the PFA assessment results in the estimated recruitment of 1 SW and MSW salmon being reduced by an average of $10 \%$ and $18 \%$ over this period. The average proportion of farmed fish on the spawning grounds has been $11 \%$ and $15 \%$ for 1 SW and MSW salmon respectively. Taking account of these fish in the assessment, and assuming an arbitrary weighting factor (W) of 0.5 , the effective spawning numbers (and hence egg deposition) for 1 SW and MSW salmon were reduced by $2 \%$ and $4 \%$ respectively. The conservation limit estimated by the national lagged-egg deposition model in this scenario was also reduced by about $4 \%$. There is considerable uncertainty about the spawning success of farmed escapees and this evaluation took no account of the possibility of farmed fish having an adverse effect on the spawning success of wild fish.

For the 2001 assessment, the Norwegian input data for the PFA model have been split into three regions. However, it was not possible to provide data on farm escapees for these regions and this potential error will need to be taken into account when considering the catch advice.

### 5.4 Development of Age-Specific Conservation limits

Conservation limits have been set for all salmon rivers in France and UK (England \& Wales) although some of these are still provisional; progress has also been reported in developing conservation limits in other NEAC countries. In order to provide preliminary conservation limits for other countries, ICES has previously developed a lagged egg deposition model. This approach generates pseudo-stock-recruitment relationships, i.e. plots of lagged eggs (stock) against 1SW adults in the sea (recruits) for national stocks. ICES used a new, more objective method to determine the point where recruitment begins to decline (i.e the conservation limit) on these plots and these values have been summed for the appropriate stock groups. These conservation limits have then increased to take account of the natural mortality between recruitment and the time of retum in order to provide Spawning Escapement

Reserves (SERs) for maturing and non-maturing 1SW salmon from the Northern and Southern Europe. The SERs are shown as horizontal lines in Figures 5.3.3 and 5.3.5 The SERs are not shown on the total NEAC data (Figure 5.3.1) because evaluation of stocks against conservation limits is thought to be inappropriate at that level.

### 5.5 Catch Options or Alternative Management Advice

ICES has been asked to provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits in the NEAC area, ICES reiterated its concems about harvesting salmon in mixed stock fisheries, particularly for fisheries exploiting individual river stocks and sub-river populations that are at unsatisfactorily low levels. Annual adjustments in quotas or effort regulations based on changes in the mean status of the stocks is unlikely to provide adequate protection to the individual river stocks that are most heavily exploited by the fishery or are in the weakest condition.

ICES also emphasises that the national stock conservation limits discussed above are not appropriate for the management of homewater fisheries, particularly where these exploit separate river stocks. This is because of the relative imprecision of the national conservation limits and because this approach will not take account of differences in the status of different river stocks or sub-river populations. Nevertheless, ICES agreed that the combined conservation limits for the main stock groups (national stocks) exploited by the distant water fisheries could be used to provide general management advice for these fisheries.

In view of the uncertainties expressed about the most appropriate stock groupings and the preliminary nature of the conservation limit estimates, ICES is unable to provide quantitative catch options at this stage. In the absence of a predictive estimate of PFA and more reliable estimates of conservation limits, it is unlikely that quantitative catch advice will be developed in the near future. However, ICES feels that the following qualitative catch advice is appropriate based upon the PFA data and estimated SERs shown in Figures 5.3.3 and 5.3.5.

The Southern European stock complex is believed to include the main European stocks that have contributed fish to the West Greenland fishery; evidence from tagging studies suggests that the Nordic countries contribute relatively few fish to this fishery. It is therefore, appropriate that the European input to the advice on the West Greenland fishery should be based principally on the status of non-maturing 1SW from the Southern area.

Provision of catch advice for the Faroes fishery is more complex. Recent tagging studies at Faroes (1991/1992 - 1994/1995), suggest that the main country contributing to the MSW salmon to the fishery is Norway, with significant contributions also from Scotland and Russia. The 1SW salmon caught in the fishery come mainly from the Southern European countries. This therefore, means that the catch advice for both Northern and Southern European stocks must be taken into account when considering management actions for the Faroes fishery.

For all fisheries, ICES considers that management of single stock fisheries should be based upon local assessments of the status of stocks. Conservation would be best achieved by fisheries in estuaries and rivers targeting stocks which have been shown to be above biologically-based escapement requirements.
[NB In the evaluation of the status of stocks, PFA or recruitment values should be assessed against the spawner escapement reserve values while the spawner numbers should be compared with the conservation limits.]

Northern European 1SW stocks: The spawning escapement of 1SW salmon from the Northern European stock complex has been within but close to safe biological limits in recent years, although there is evidence of an upturn in the past few years. It should be noted that the inclusion of farmed fish in the Norwegian data will. result in the exploitable surplus being overestimated. ICES considers that overall exploitation of the stock complex at the current rate is acceptable, although the status of individual stocks varies considerably. Since very few of these salmon have been caught outside homewater fisheries in Europe, even when fisheries were operating in the Norwegian Sea, management of maturing 1SW salmon should be based upon local assessments of the status of river or sub-river stocks.

Northern European MSW stocks: The PFA of nonmaturing 1SW salmon from Northern Europe has been declining since the mid 1980 s and the exploitable surplus has fallen from around 1 million recruits in the 1970s to about half this level in recent years. ICES considers the Northern European MSW stock complex to be within safe biological limits, although it is recognised that the status of individual stocks will vary considerably. In addition, the inclusion of farmed fish in the Norwegian data will result in the exploitable surplus being overestimated. ICES therefore, considers that great caution should be exercised in the management of these stocks particularly in mixed stock fisheries and exploitation should not be permitted to increase.

Southern European 1SW stocks: The spawning escapement for the whole stock complex has fallen below the conservation limit throughout the past 10
years. Moreover, recruitment of maturing 1SW salmon in the Southem European stock complex has been below any previously observed value throughout this period. In both 1999 and 2000 recruitment before exploitation was below the spawning escapement reserve. ICES considers that reductions in exploitation rates are required for as many stocks as possible and that mixed stock fisheries present particular threats to conservation.

Southern European MSW stocks: The PFA of nonmaturing 1SW salmon from Southem Europe has been declining steadily since the 1970 s and the spawning escapement for the whole stock complex has been close to or outside safe biological limits throughout much of this period. The upper $95 \%$ confidence limit for PFA of spawners has been below the spawner escapement reserve for the past four years. Qualitative projection of these estimates suggests that the PFA is likely to remain below this reserve in 2001. ICES considers that further reductions in exploitation rates are urgently required for as many stocks as possible and that mixed stock fisheries present particular threats to conservation.

### 5.6 Data deficiencies and research needs in the NEAC Area

More research into the biology of salmon in the marine phase is required. This includes the need to monitor trends in marine mortality for a wider range of stocks than at present, and identify causes for mortality. It should also include the examination of relationships between postsmolt growth and marine mortality. The use of data storage tags will significantly improve the information on the marine life history of salmon.

Research on post-smolts in the early marine phase should be continued and expanded. This should include studies of interactions with parasites and assessments of the impact of sea lice on post-smolts.

A Study Group is required to quantitatively assess the level of bycatches of post-smolts in pelagic fisheries. It is recommended that such a group should comprise both those with information relating to postsmolt distribution and those who can provide information on the activity and distribution of pelagic fisheries.

A coordinated programme of tagging and release of farmed salmon should be undertaken to improve knowledge on the marine survival and migratory behaviour of these fish

If the commercial fishery at Faroes recommences, it is recommended that biological samples from the salmon caught should be collected. Historical samples from this fishery which have not yet been worked up should continue to be analysed.
6.1 Events of the 2000 fisheries and status of stocks

### 6.1.1 Fisheries in the NAC area

Gear and effort: Salmon are managed collaboratively by the Department of Fisheries and Oceans in 23 Salmon Fishing Areas (SFA) and by the province of Québec in 11 fishing zones (Q1 to Q11) (Figure 6.1.1.1). Three user groups exploited salmon in 2000: Native peoples, residents fishing for food in Labrador, and recreational fishers. Effectively in 2000, there were no commercial fisheries for Atlantic salmon in easterm Canada. Restrictions on commercial fisheries introduced in Canada in 1992 and subsequently in 1998 remained in force. These included the closure of commercial fisheries in Newfoundland and Labrador and most of Québec. In addition, the commercial fisheries in zone Q9 were closed and licenses bought back in 2000 . Commercial quotas normally fished by Native peoples in Ungava Bay (Zone Q11) remained closed. In the recreational fishery, large portions of New Brunswick and Nova Scotia were closed to salmon fishing and hook-and-release regulations for small salmon were extended to some rivers in Québec and Newfoundland. The retention of large salmon was permitted only in selected rivers of Québec and rivers of northern Labrador (SFA 1 and 2). Following river-specific in season reviews, retention of large salmon was prohibited on seven rivers in Québec. In USA there is no commercial fishery for salmon and angling (catch-and-release only) for sea-run salmon in 1999 was permitted only in the State of Maine. Commercial and recreational fishing using gillnets continued in SaintPierre et Miquelon (France) in 1999 and effort was similar to the average of the previous four years.

Catch: The provisional landings for Canada in 2000 were 150 t , similar to the 1999 harvest of 152 t (Table 4.1.1.1; Figure 6.1.1.2). The landings of small salmon in numbers ( 50108 ) and large salmon ( 11458 ) were similar to those in 1999. Recreational fisheries exploited the greatest number of small salmon in each province, accounting for $79 \%$ of the total small salmon harvests in eastern Canada. Food fisheries including the Native peoples and the Labrador resident fishery took the bighest share of large salmon ( $60 \%$ by number). There was no commercial fishery in eastern Canada in 2000. Unreported catch for the NAC area was estimated at 124 t down $7 \%$ from 1999.

In 2000, about 49700 salmon (20 700 large and 29000 small) were caught and released. This was similar to the number released in 1999. Most of the fish released were in New Brunswick (44\%), followed by Newfoundland
(43\%), Québec (9\%), Nova Scotia (3\%), and Prince Edward Island ( $<1 \%$ ). Expressed as a proportion of the fish caught, that is, the sum of the retained and released fish, the highest percentage ( $84 \%$ ) was released in Nova Scotia, followed by New Brunswick (57\%), Newfoundland ( $56 \%$ ), Prince Edward Island ( $49 \%$ ), and Québec (31\%).

In December of 1999, the State of Maine instituted a regulation closing all Maine rivers to Atlantic salmon fishing until further notice.

In Saint-Pierre et Miquelon (France) the harvest was 2.3 t , the same as in 1998 and 1999 and split equally among professional and recreational fishers.

Composition and origin of catch: No external tagged fish of USA origin were reported from Canadian fisheries in 2000. In Canada, returns to the majority of rivers in Quebec, Newfoundland and Labrador are comprised exclusively of wild salmon. Hatchery-origin fish were most abundant in returns to rivers in the outer Bay of Fundy and along the Atlantic coast of Nova Scotia. Aquaculture escapees in 2000 were sampled in one New Brumswick River (Magaguadavic, SFA 23), one international boundary river (St. Croix) and two coast of Maine rivers.

Exploitation rates: Exploitation rates in the recreational fishery of Newfoundland for rivers with retention of small salmon ranged between $6 \%$ and $28 \%$ in 2000 . Exploitation rates in two Labrador rivers were $2 \%$ to $9 \%$. In the recreational fishery of Québec, exploitation rates were $18 \%$ for small salmon and $10 \%$ for large salmon.

### 6.1.2 Status of stocks in the NAC area

Returns, recruits and spawners: Estimated (midpoint) $1 S W$ and $2 S W$ returns, spawners, and spawner requirements are shown for five of six regions in North America in Figures 6.1.2.1 and 6.1.2.2. Labrador returns and thus total North American returns have been unavailable since 1998. Returns of 2SW fish in 2000 were similar to or lower than the values in 1999 and remain among the lowest of the series in most areas except Newfoundland. 1SW returns increased slightly over those of 1999 but declined in Newfoundland and USA. The rank of the estimated returns in 2000 within the 1971-2000 time series and the estimated total spawning escapement of $2 S W$ salmon in each region expressed as a percentage of the spawning requirement for each region (except Labrador) follows. The closer the rank of 2000 returns is to 1 , the better the relative performance of the stock.

|  | Rank of 2000 returns in 1971-2000 time series <br> (1=highest) |  | Mid-point estimate of 2SW <br> spawners as proportion of <br> escapement requirement |
| :--- | :---: | :---: | :---: |
| Region | 1 SW | 2 SW | $(\%)$ |
| Newfoundland | 12 | 2 | 224 |
| Québec | 13 | 28 | 67 |
| Gulf (Mainland) | 22 | 27 | 65 |
| Scotia-Fundy | 24 | 30 | 14 |
| USA | 19 | 30 | 2 |

No estimate for Labrador is provided because there were no data available to carry out the analysis.

In all regions except Newfoundland the returns of 2 SW fish are near the bottom of the 30 -year time series. However, Newfoundland comprises only a small proportion of total salmon production. Returns of 1 SW salmon were at the midpoint of the time series in Newfoundland and Québec and below the mid-point an in the lower third to quarter for the other areas.

The North American run-reconstruction model was used to update the estimates of pre-fishery abundance of nonmaturing and maturing 1SW salmon from 1971-2000. The projected numbers of potential $2 S W$ spawners that could have returned to North America in the absence of fisheries can be computed from estimates of the prefishery abundance taking into consideration the 11 months of natural mortality at $1 \%$ per month. These values, termed "potential $2 S W$ recruits", along with total North American 2SW returns and spawners (19711999) and requirements are shown in Figure 6.1.2.3, and indicate that the overall North American spawner requirement could not have been met since 1992 even in the absence of all fisheries.

The changes made to the calculations that determine pre-fishery abundance of non-maturing 1 SW salmon for 1997 were continued for the determination of prefishery abundance in 1999 and 2000. They included the addition of a new parameter to define the fraction of the Lake Melville catches that are immature and, in the absence of a commercial fishery in Labrador, the development of a raising factor to estimate 2 SW returns to Labrador from a series of Labrador recruit estimates and pre-fishery abundance data from 1971-1996. A raising factor was also developed to include Labrador returns in the maturing component of pre-fishery abundance by dividing pre-fishery abundance without Labrador into pre-fishery abundance with Labrador based on the time series of Labrador recruit estimates and pre-fishery abundance data from 1971-1997.

In 2000, a revised method for estimating retums and spawners to Newfoundland was presented. The $90 \%$ confidence interval ranges of unweighted exploitation rates in the recreational fishery and ratios of small:large salmon were generated from the assessment rivers with
retention angling fisheries for the years 1995 to 1998. The large rivers were excluded from the analysis since they were treated separately. Population estimates from rivers with counting facilities were taken from the assessment information and their angling catches were excluded. Returns to rivers of the Bay St. George area (SFA 13) were treated separately. The dramatic changes to estimates of 1SW and 2SW salmon in 1995 and 1996 were due to the use of weighted versus unweighted averages for the large rivers where exploitation rates are lower than in smaller rivers. In 2000, the large rivers were treated separately and the river-specific exploitation rates or assessments were used.

The estimate of pre-fishery abundance of 94,118 nonmaturing 1SW salmon for 1999 is just $2 \%$ higher than in 1998 and the second lowest on record (Figure 6.1.2.4). The recent three years year are shown with hollow symbols to denote the use of a raising factor for Labrador. The results indicate a slight levelling off of the general decline from 807000 fish in 1975. For maturing 1SW salmon, the estimate for 2000 of 404724 fish was a $5 \%$ increase from 1999 but $5 \%$ less than in 1998 and the fourth lowest in the 30 -year time series. The total Northwest Atlantic population of 1 SW recruits (maturing and non-maturing) originating in North America in the Northwest Atlantic has varied but generally trended downwards since the 1970s, and the abundance recorded 1993-2000 was the lowest in the time series (Figure 6.1.2.5). During 1993 to 2000, the total population was varying at around one-half million fish, $45 \%$ of the average abundance 1972 to 1990. The decline has been common to both maturing and nonmaturing portions of the cohort but non-maturing 1 SW salmon have declined further.

The estimated 2 SW returns ( 533 ) to USA rivers in 2000 represent less than $2 \%$ of the spawner requirements for all rivers. This was $54 \%$ below the 1999 estimate and the lowest in the time series.

Egg depositions: Egg depositions in 2000 exceeded or equalled the river specific conservation requirements in 37 of the 67 assessed rivers ( $55 \%$ ) and were less than $50 \%$ of conservation requirements in 15 other rivers (Figure 6.1.2.6). Large deficiencies in egg depositions were noted in the Bay of Fundy and Atlantic coast of Nova Scotia where nine of the 12 rivers assessed had
egg depositions which were less than $50 \%$ of conservation requirements. Proportionally fewer rivers in Gulf ( $7 \%$ ) and Québec ( $0 \%$ ) had egg depositions less than $50 \%$ of conservation. Only $66 \%$ of the Gulf rivers and $72 \%$ of the Quebec rivers had egg depositions which equalled or exceeded conservation. In Newfoundland, $64 \%$ of the rivers assessed met or exceeded the conservation egg requirements and almost all the others ( $23 \%$ ) had egg depositions which were less than $50 \%$ of requirement. The deficits occurred in the southwest rivers of Newfoundland (SFA 13) and in Labrador.

Smolt production: It is not possible to estimate how many smolts in total leave the rivers of Atlantic Canada for any given year. However, juvenile abundance indices were considered as surrogates of smolt production from eastern Canada. To allow for the combined analysis of smolt counts and juvenile abundance surveys from all the rivers, the individual river surveys were divided by the average within river abundance for the period 1995 to 1998.

The index of smolts from North America was obtained by weighting the annual river indices by the relative proportion of the conservation egg requirements of the SFA or Zone to the total conservation egg requirements of the zones under consideration. An altemative weighting incorporated the relative contribution to the 2 SW spawner requirements of the six main areas within North America. This allows indices of smolt production from all areas of North America to be used but attributes weights to the area indices according to the expected contribution to 2 SW abundance. The number of rivers with available data has increased from two in 1971 to 25 or more rivers since 1995. The proportion of the indexed areas represented by the index rivers has increased from $11 \%$ in 1971 to more than $25 \%$ since 1993.

The relative index weighted by the area-index proportions suggests relative smolt production at two levels, the first in the 1970s with smolt production being less than $1 / 3$ of the production in the 1990 s, through the 1980s smolt production was highly variable, but increased steadily to the levels observed in the 1990 s .

The relative index for $2 S W$ recruitment (excludes the Newfoundland areas which do not produce 2SW salmon or weights all areas according to the 2 SW spawner requirements by area) suggests an overall similar trend. The index corresponds to the documented status of many other rivers. Smolt production from Newfoundland rivers has approximately doubled over the 1971 to 2000 time period. The Gulf smolt index is at its highest in the 1990s. The Québec smolt index has declined between 1983 and 2000. The relative index for Scotia-Fundy has essentially remained unchanged.

Marine Survival: Survival rates to 1 SW and 2 SW fish have been variable in recent years. In 1998-2000 there has generally been an increase in survival rates from the low values observed throughout eastern Canada in 1997. Return rates to most rivers of Newfoundland generally recovered in 1998-2000 above conservation limits although survival rates generally remain low. Considering that the historical survival rates (prior to 1992) represent survival to the river after commercial fisheries, for the rest of eastern Canada the recent survival rates and in particular the low rates in 1997 are dismal. Despite major reductions in marine exploitation, marine survival rates are still low and sea survival of the salmon populations has not increased as expected.

For USA, induced freshwater habitat constraints are substantial in some areas and productive capacity has been reduced. Causes include physical, chemical and biological induced constraints. Documented losses include hydropower development, acidification, and siltation. Suspected losses include interactions caused by the introduction of competitive or predator species, chemicals that disrupt endocrine development and localised effects associated with aquaculture. Mitigation of these losses has, for the most part, been insufficient. Stock rebuilding programmes have generally been unsuccessful, USA salmon stocks exhibit the same downward trend that has been shown for many Canadian salmon stocks, especially those located in the Bay of Fundy and along the Atlantic coast of Nova Scotia.

## 6.2 Effects on US and Canadian stocks and fisheries of the quota management and closure after 1991 in Canadian commercial salmon fisheries, with special emphasis on the Newfoundland stocks

ICES previously considered the impact of the closure of the Newfoundland commercial fishery in 1992 on the Newfoundland stocks. Within Newfoundland, the commercial fishery closure has resulted in increased escapements of both small and large salmon to many rivers, higher catches of large salmon (which were subsequently released) in the recreational fishery, and increased spawning escapements of both size groups. These increased spawning escapements have not, however, always resulted in increased smolt production. Some areas of Newfoundland, particularly the south coast, did not see increases in escapement as was expected from the closure of the commercial fishery. The expected benefits to the spawning escapements were not realised. However, in the absence of the fishery closures and other management measures the spawning escapement would have been even lower at current low marine survival.

## Age-specific stock conservation requirements

There are no changes recommended in the $2 S W$ spawner requirements from those presented in 2000. Spawner requirements for 2 SW salmon for Canada now total 123,349 and for the USA, 29199 for a combined total of 152548 .

### 6.4 Catch options or alternative management advice with an assessment of risks

It is possible to provide catch advice for the North American Commission area for two years. The first is a revised estimate for 2001 for 2 SW maturing fish based on revised estimates of the 2000 pre-fishery abundance and accounting for fish which were already removed from the cohort by fisheries in Greenland and Labrador in 2000. The second is an estimate for 2002 based on the pre-fishery abundance forecast for 2001. A consequence of these annual revisions is that the catch options for $2 S W$ equivalents in North America may change compared to the options developed the year before.

### 6.4.1 Catch option for 2001 fisheries on 2SW maturing salmon

A revised forecast of the pre-fishery abundance for 2000 is provided in Table 6.4.1.1. This value of 225708 is higher than the value forecast last year at this time of 179 897. A pre-fishery abundance of 225708 in 2000 can be expressed as $2 S W$ equivalents by considering natural mortality of $1 \%$ per month for 10 months resulting in 204229 2SW salmon equivalents. There have already been harvests of this cohort as 1 SW nonmaturing salmon in 2000 for both the Labrador (421) and Greenland (5041) fisheries (Tables 6.4.1.2 and 6.4.1.3) for a total of 54622 SW salmon equivalents already harvested, when the mortality factor is considered.

Table 6.4.1.1 uses the probability density projections for the revised pre-fishery abundance estimate of 225708 (at $50 \%$ probability) and subtracts the spawning reserve (170 286) and the harvests in Greenland and Labrador of 1 SW non-maturing fish in 2000 , and converts the remainder to 2 SW salmon equivalents. Catch options values $=\left[\mathrm{PFA}_{i}\right.$ - spawning reserve - harvest in Greenland and Labrador in 2000 of 1 SW non-maturing fish] $* \exp [-(0.01 * 10$ months $)]$ where $\mathrm{PFA}_{\mathrm{i}}=$ values from $25-75 \%$ and spawning reserve $=170286$.

Results indicate that there are harvest possibilities at forecasted levels which would be considered riskneutral or risk-averse, that is, at probability levels of $50 \%$ and below. It should be clear from the above that the numbers provided for catch options refer to the composite North American fisheries. As the biological objective is to have all rivers reaching their conservation
requirements, it is obvious that river-by-river management is necessary. On individual rivers, where spawning escapement requirements are being achieved, river catches corresponding to surplus escapement can proceed.

Regional assessments in some areas of eastern North America provide a more detailed consideration of expectations for 2001 , taking into consideration the contribution of all sea ages of salmon to the spawning population and relationships between 1SW and 2SW retruns of the smolt cohort. Data for 20 rivers in Québec, six rivers of the Gulf, and three rivers of the Scotia-Fundy geographic area for the period 1991-1992 to 1999-2000, during which most commercial salmon fisheries were closed, indicate that there are no expectations for significant increases in large salmon in 2001. The evidence for each of the three geographic areas suggests that the PFA forecast of approximately 225000 non-maturing fish in Greenland in 2000, i.e., triple the PFA value for the previous year and double the average PFA values of the previous 5 years, is highly unlikely.

Additionally, by area, expectations for 2001 are. By area, these are:

Labrador: salmon returns in the year 2001 will be from a higher number of spawners than in recent years but the lack of long-term monitoring facilities makes it difficult to describe stock status or provide current expectations.

Newfoundland: number of spawners has been relatively high in recent years, however, smolt output from most monitored rivers has declined in each of the past three years. In the absence of any improvement in marine survival rates, returns of small salmon in 2001 could be lower.

Québec: Returns of large salmon are expected to be adequate for the attainment of conservation requirements in 43 of the 44 salmon rivers in northern part of Québec; one river will remain closed. On the 74 salmon rivers in southern part of Québec, nine rivers remained closed to fishing and returns of large salmon are expected to be insufficient for attainment of conservation requirement on 34 rivers. Consequently, only the retention of small salmon will be permitted on those rivers.

Gulf: In SFA 15, returns in 2001 should approximate conservation requirements as they have in the last 5 years. Current levels of harvest have not been limiting the attainment of stock conservation. In SFA 16, neither large salmon nor eggs from small and large fish are expected to meet the conservation requirements in most rivers. In SFA 18, expectations are mixed with over half the rivers expected to meet conservation.

Scotia-Fundy: In SFAs 19-23, salmon returns (both large and smali) in 2000 are not expected, with few
exceptions, to be sufficient to meet conservation requirements, including those receiving hatchery stocking.

USA: Salmon returns (both large and small) in 2000 are not expected to be sufficient to meet conservation requirements in any river, including those receiving hatchery stocking.

### 6.4.2 Catch option for 2002 fisheries on 2SW maturing salmon

Most catches (93\%) in North America now take place in rivers or in estuaries. The commercial fisheries are now closed and the remaining coastal food fisheries in Labrador are mainly located close to river mouths and likely harvest few salmon from other than local rivers. Fisheries are principally managed on a river-by-river basis and in areas where retention of large salmon is allowed, it is closely controlled.

Catch options which could be derived from the prefishery abundance forecast for 2001 (295678 at the $50 \%$ probability level) would apply principally to North American fisheries in 2002 and hence the level of fisheries in 2001 need to be accounted for before providing these catch options. Assuming probability values between 25 and $75 \%$, accounting for mortality and the spawning requirement and considering an allocation of $60 \%$ of the surplus to North America, would yield catch options in $2 S W$ salmon equivalents of 77000 to 138000 fish. The numbers provided for catch options refer to the composite North American fisheries. As the biological objective is to have all rivers reaching their conservation requirements, river-by-river management will be necessary. On individual rivers, where spawning requirements are being achieved, there are no biological reasons to restrict the harvest.

### 6.4.3 Data deficiencies, monitoring needs and research requirements

Some progress was made on research needs identified last year. The Working Group reiterates many of last year's recommendations and suggests some further ones.

Estimates of total returns to Labrador no longer exist. There is a critical need to develop alternate methods to derive estimates of salmon returns and develop habitatbased spawner requirements in Labrador, and to monitor salmon returns in the Ungava regions of Québec.

There is a need to investigate changes in the biological characteristics (mean weight, sex ratio, sea-age composition) of returns to rivers, spawning stocks of Canadian and US rivers, and the harvest in food fisheries in Labrador. These data and new information on measures of habitat and stock recruitment are necessary to re-evaluate existing estimates of spawner requirements in Canada and USA and for use in the run reconstruction model.

There is a requirement for additional smolt-to-adult survival rates for wild salmon. As well, sea survival rates of wild salmon from rivers stocked with hatchery smolts should be examined to determine if hatchery return rates can be used as an index of sea survival of wild salmon elsewhere.

Further basic research is needed on the spatial and temporal distribution of salmon and their predators at sea to assist in explaining variability in survival rates.

Return estimates for the few rivers (Annapolis, Cornwallis and Gaspareau) in SFA 22 that do contribute to distant fisheries should be developed and, when these are available, the SFA 22 spawning requirements for these rivers ( 476 fish) be included in the total.

A consistent approach to estimating retums is needed, to incorporate broodstock, if offspring from such broodstock are stocked back into the management area from which their parents originated.

Accounting for escaped-farmed salmon from North America indicates a high but undocumented mortality. Scale analysis of salmon captured at West Greenland indicated an infrequent appearance of escaped-farmed salmon. In order to substantiate this conclusion farmedsalmon need to be included in background genetic analysis and the data re-examined for the presence of escaped-farmed salmon of North American origin.

### 7.1 Events in the 2000 fisheries and status of stocks

### 7.1.1 Fishery in the WGC area

Catch: In 1999, the West Greenland Commission of NASCO agreed on a multi-year approach for conservation of the salmon stocks occurring in Greenland, and therefore for 1999 and 2000 the catch at West Greenland in each of the years should be restricted to that amount used for subsistence in Greenland, which in the past has been estimated at 20 t . The Greenland authorities subsequently set the TAC for 2000 at 20 t . The fishery began on August 14 and was closed August 18 as the reported catch rapidly approached the allowed amount. The nominal catch totalled 20.5 t . In 2000, a private company was given permission to purchase salmon from the fishermen for distribution in Greentand. Most of the landings were sold through this arrangement, and only very few salmon were landed to the open markets. Despite the very short season and a considerably increased efficiency of the control system a relatively large part of the total fishery is still considered to remain unreported. The unreported catch in 2000 is estimated to be approximately 10 t .

Gear and effort: No new information was available on fishing gear and effort. However, only 45 licensed fishermen (out of 179 issued licences) reported having fished in 2000 . In total, 46 licensed and non-licensed fishermen (food fishermen) reported catches.

Origin of catches: North American salmon stocks have been found to be distinct from European stocks using mitochondrial and nuclear DNA (microsatellites), and analytical methods are provided to distinguish continent of origin with $100 \%$ accuracy. Based on this method samples obtained from catches in NAFO Division 1D (250 samples) and NAFO Division 1F ( 240 samples) could be classified to continent of origin. Applying the results of the above analysis to the reported catch indicated that 12.6 t ( 5100 salmon ) of North American origin and 7.6 t (2700 salmon) of European origin were landed in West Greenland in 2000.

The numbers of North American salmon landed annually at West Greenland were greatly reduced during the period 1996-1999, but remained unchanged from 1999 to 2000. The number of landed salmon of European origin was similarly reduced from 1995 to 1999, but increased again in 2000 due to a high proportion of European salmon in the southem division.

Biological characteristics of the catch: Biological samples (scales, length, weight) were collected from the salmon landed in NAFO Divisions 1D and 1F (250 and 241 samples, respectively).

Analysis of the samples showed no significant changes in the very high proportion of one-sea-winter fish of North American and European origins during recent years. In 2000, the two components comprised $97.4 \%$ and $100.0 \%$, respectively, of the catch samples, and they were among the highest proportions of a 14 -year data set. No two-sea-winter maiden fish were observed in the samples, but in the North American component $2.6 \%$ were previous spawners.

The downward trend in mean length of both North American and European 1SW fish since 1969 changed in 1996, as mean lengths increased. Mean lengths for both components showed an increasing trend during 1996-1999, whereas in 2000 the mean lengths decreased again and were among the lowest observed in the time series. Mean weights of both components decreased correspondingly from 1999 to 2000 . The low values for both mean lengths and mean weights observed in 2000 could be related to the relatively early fishing season, in which period the weight increase is known to be 2-3 \% per week.

Percentage river ages among fish sampled at West Greentand in 2000 were:

| River age | 1 | 2 | 3 | 4 | 5 | $6+$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| N American | 3.2 | 26.6 | 38.6 | 23.4 | 7.6 | 0.0 |
| European | 36.4 | 46.7 | 13.1 | 2.9 | 0.7 | 0.0 |

The proportion of river age 2 salmon of North American origin was in 1999 and 2000 somewhat lower than in 1998, which was close to the overall mean value of $34.8 \%$. The proportion of river age 1 salmon of European origin reached the highest values on record in the three most recent years $(28.6,27.7$ and $36.5 \%$, respectively). A high proportion of this group is reflecting a high contribution from the more southern European stocks.

### 7.1.2 Status of stocks in the WGC area

Salmon caught in the West Greenland fishery are nonmaturing 1 SW salmon or older, nearly all of which would return to homewaters in Europe or North America as MSW fish if they survived. In most years non-maturing 1 SW salmon make up more than $90 \%$ of the catch there are also 2 SW salmon and repeat spawners. The most abundant European stocks in West Greenland are thought to originate from the UK and Ireland although low numbers may originate from northern European rivers. For North American MSW salmon, the most abundant stocks in West Greenland are thought to originate in the southern area of the range.

Stocks originating in the Northeast Atlantic: Runreconstruction estimates of pre-fishery abundance of
non-maturing 1 SW salmon from southern areas (Figure 5.3 .5 b ) have been volatile over the period 1971-1999, but in steady decline over the past 14 years. In 1996-1999, it was estimated that even in the absence of all fisheries, the numbers of non-maturing recruits from the southern area were below the proposed spawning equivalent reserve. Non-maturing $1 S W$ salmon from northem stocks (Figure 5.3.3b) have declined since 1985, particularly in 1986-1987. The recovery of the stocks that was suggested in 1998 did not seem to continue in 1999 and 2000.

In most cases, adult salmon counts in index rivers within the NEAC area increased from 1997 to 2000 . However, over the last ten years, adult returns have been declining or showed no trend. Analysis of attainment of conservation limits (CL) indicated variable status of salmon stocks in different rivers of the NEAC area. Although homewater management measures have gone some way to reducing homewater exploitation rates, some rivers have never or seldom reached their CL over the last 10 years, whereas others have been consistently above their CL. Many rivers that have reached their CL in most years show a decreasing trend in escapement, however, and no tendency to recover was observed for rivers with low escapement values.

Stocks originating in North America: The runreconstruction estimate of pre-fishery abundance of non-maturing 1SW salmon for 1999 was 94118 fish, $2 \%$ higher than that of 1998 , this estimate being the second lowest in the 30-year time series (Figure 6.1.2.4).

Total returns of 2SW fish to Labrador and thus Canada could not be estimated since 1998. However, with the exception of insular Newfoundland where $2 S W$ salmon are only a small proportion of the total salmon production, returns to the important Gulf, Québec and Scotia-Fundy production areas were either the lowest or second lowest of the 30-year time series, 1971-2000 (Figure 6.1.2.3). The estimated 2 SW returns and spawners to USA rivers were in $200066 \%$ and $73 \%$ below the previous 5 -and 10 -year averages, respectively. Returns to most USA rivers are hatcherydependent. Spawning escapements remained low compared to conservation requirements.

Egg depositions exceeded or equalled the specific conservation requirements in only 23 of the 54 rivers (43 \%) that were assessed in Canada and were less than $50 \%$ of requirements in 18 other rivers (33\%). Large deficiencies in egg depositions were noted in the Bay of Fundy and Atlantic coast of Nova Scotia where 10 of the 11 rivers assessed had egg depositions that were less than $50 \%$ of requirements (Figure 6.1.2.6).

North American salmon stocks remain low relative to the 1970 s . The steady decline over the last twelve years is alarming (Figure 6.1.2.4). The 1 SW non-maturing
component continues to be depressed with river returns and total production amongst the lowest recorded. In addition, returns in 2000 of maturing 1 SW salmon (grilse) to North American rivers were very low. This being the case, improvement in 2 SW salmon returns and spawners is unlikely in 2001.

Thus, despite some improvements in 2 SW returns to some rivers in European and North American areas, the overall status of stocks contributing to the West Greenland fishery is low compared to earlier.

### 7.1.3 Changes in the continent of origin of salmon captured at West Greenland including changes in migration patterns

The Working Group noted the considerable increase in proportion of North American origin salmon in the fishery at West Greenland in recent years. The proportion of North American origin salmon has changed dramatically over the period of observation, 1969-1999, from below $40 \%$ to a record high level of $90 \%$ in 1999. The proportion of North American origin salmon declined in 2000 fishery samples; however, this may have been due to the early opening and short duration of the fishery. Thus, the catch samples while being descriptive of the fishery may not be a good representation of the salmon population at Greenland. The biological explanation(s) for these changes in North American and European salmon will continue to elude us due to incomplete knowledge of migration of the various components contributing to the West Greenland fishery and more importantly the relative contributions of various stock groupings. Previous tagging studies including tagging at West Greenland had shown that the southern European stock group contributed more heavily to Greenland than did the northern group. Within North America, it has been shown that stocks in the Gulf of St. Lawrence contributed more heavily than others to Greenland. The DNA analysis in 2000 showed that annual variations in proportional contributions do occur. Exploratory work into more detailed discrimination of origin of salmon captured at West Greenland will lead to a greater understanding of the mixed stock fishery.

To learn more about the reasons behind the increasing North American proportion in Greenland a new variable was created by summing the pre-fishery abundances of North American and European non-maturing Allantic salmon. Examination of the trends in North American proportion at Greenland and in the total pre-fishery abundance of North American plus southern European salmon indicates that the latter is actually declining ( $\mathrm{r}=-$ $0.69, \mathrm{P}<0.0001$ ) at the same time that the North American proportion at Greenland is increasing ( $\mathrm{r}=0.87$, $\mathrm{P}<0.0001$ ) (Figure 7.1.3.1). This can only occur if the proportion of southern European salmon migrating to Greenland is declining or if the proportion of North American salmon migrating to Greenland is increasing ( $\mathrm{r}=-0.52, \mathrm{P}<0.004$ ). However, given current trends the former is more likely the case.

Effects on European and North
American stocks of the West Greenland management measures since 1993

There have been three significant changes in the management regime at West Greenland since 1993. First, NASCO adopted a new quota allocation model to derive TACs based upon ICES assessment of the PFA of non-maturing 1SW North American salmon and the spawner requirements for these stocks. This resulted in a substantial reduction in the TAC in 1993 from that of 1992, and further reductions in subsequent years. The second change in management was the suspension of fishing in 1993 and 1994 for compensation payments. The third change in management was a multi-year agreement in 1999 restricting the allowable catches to 20 tons, solely for local consumption in Greenland.

The estimated numbers of salmon returning to home waters in the absence of a fishery, 1993-1994, or had the fishery in 1995-1999, not taken place are:

|  | Quota | Grnl <br> Year | Catch <br> T | EU <br> TAC | NA <br> Fish |
| :--- | ---: | ---: | ---: | ---: | ---: |
| 1993 | 89 | 89 | 0 | 12402 | 15052 |
| 1994 | 137 | 137 | 0 | 19091 | 23171 |
| 1995 | 77 | 77 | 83 | 8459 | 20177 |
| 1996 | 174 | 0 | 92 | 7239 | 20262 |
| 1997 | 57 | 0 | 58 | 3702 | 15598 |
| 1998 | 20 | 0 | 11 | 729 | 2740 |
| 1999 | 20 | 0 | 19 | 549 | 4847 |
| 2000 | 20 | 0 | 21 | 1844 | 4263 |

Estimation of TACs for 1993 and 1994 was based on the NASCO model, biological parameters (mean weights, proportions of NA fish, and age correction factors etc.) were assumed to be the mean of the 1992 and 1995 values. For the remaining years, estimates of fish that would have returned to home waters had there not been a fishery were based on same year biological characteristics and a natural mortality between Greenland and home waters of 0.10 . The mean number of potential returns per ton caught at Greenland is 208 and 106 North American and European salmon, respectively.

In the years 1972-1992, exploitation rates in Greenland of the North American component of the salmon stock averaged about $30 \%$ but varied between 10 and $45 \%$. The management measures in force in 1995-1997 resulted in an average exploitation rate of $13 \%$, while the arrangements since 1998 reduced the exploitation rate to about $5 \%$.

ICES notes that these calculations assume that natural mortality of salmon at sea has remained unchanged. As highlighted in several places in this document, marine survival has declined markedly, particularly for salmon of North American origin. Methods are being explored for including a downward trend in survivorship in this and various other calculations.

Age-specific stock conservation limits for all stocks occurring in the WGC area

Sampling of the fishery at West Greenland since 1985 has shown that both European and North American stocks harvested there are primarily (greater than $90 \%$ ) $1 S W$ non-maturing salmon that would mature as either 2 or 3 SW salmon, if surviving to spawn. Usually less than $1 \%$ of the harvest are salmon which have previously spawned and a few percent are 2 SW salmon which would mature as $3 S W$ or older salmon, if surviving to spawn. For example, in 1999, 96.8 of the sampled catch of North American origin and $100 \%$ of the sampled catch of European origin were 1SW salmon. For this reason, conservation limits defined previously for North American stocks have been limited to this cohort (2SW salmon on their return to homewaters) that may have been at Greenland as ISW non-maturing fish. The total requirement is 152548 fish, with 123349 and 29199 prescribed for Canadian and USA rivers, respectively; the reserve spawner requirement (includes 10 months of mortality at $1 \%$ ) is 170286 fish.

In 2000, revised estimates of provisional conservation limits for MSW salmon in Europe were presented based on the methods developed in 1999. The conservation limits were split into 1 SW and MSW components on the basis of the average age composition of catches in the past ten years. The stocks have also been partitioned into northern and southern groups, and tagging information and biological sampling indicates that the majority of the European salmon caught at West Greenland originate from the southern group. The provisional conservation limit for southern European MSW stocks is approximately 595000 fish. There is still considerable uncertainty in the conservation limits for European stocks. The above value has been increased from 530000 in the 2000 report. To date, the conservation limits for MSW salmon in Europe have not been incorporated into the modeling of catch options for West Greenland.

### 7.4 Catch options or alternative management advice with an assessment of risks

### 7.4.1 Overview of provision of catch advice

Concerns of the implications of applying TACs to mixed stock fisheries are relevant to the formulation of catch advice. In principle, adjustments in catches in mixed-stock fisheries provided by means of an annually adjusted TAC would reduce mean mortality on the contributing populations. However, there is no assurance that reductions in exploitation will affect those stocks that are not meeting conservation requirements, and benefits that might result for individual stocks would be difficult to demonstrate.

The procedures to develop catch advice, an evaluation of the models, and vulnerabilities in the existing procedures were presented in the 1997 and 1999 assessments. The processes remain unchanged in 2000 although some of the input data were modified to reflect new information (Section 7.5). Models based on thermal habitat in the northwest Atlantic and spawning stock indices are used to forecast pre-fishery abundance and provide catch advice for the West Greenland fishery. While the approach has been consistent since 1993, the models themselves have varied slightly over the years. The changes have been made to these models in attempts to improve the prediction and add more biological reality. In particular, the models since 1996 have used a spawning stock surrogate variable (lagged spawners) in an attempt to describe the variations in parental stock size of the non-maturing 1 SW component (PFA).

North American run-reconstruction model: The model is used to estimate pre-fishery abundance of 1SW non-maturing and maturing 2SW fish adjusted by natural mortality to the time prior to the West Greenland fishery. Region-specific estimates of 2 SW returns are shown in Figure 6.1.2.2. Estimates of 2SW returns prior to 1998 in Labrador are derived from estimated 2SW catches in the fishery using a range of assumptions regarding exploitation rates and origin of the catch. With the closure of the Labrador fishery, returns for Labrador were unknown in 1998 to 2000 and values for Labrador: were estimated from a raising factor developed by dividing pre-fishery abundance without Labrador into pre-fishery abundance with Labrador based on the time series of Labrador recruit estimates and pre-fishery abundance data from 1971-1996.

Update of thermal habitat: A thermal habitat index has been updated to include data from year 2000 and January and February 2001 year data. Two periods of decline in the index are evident ( 1980 to 1984 and 1988 to 1995) (Table 7.4.1.1 and Figure 7.4.1.1). The habitat index for February increased slighty (3\%) in 2001 from 1634 to 1685 . Both values are close to the long-term mean of 1653 .

Update of lagged spawners: The lagged spawner variable used in the model is an estimate of the 2SW parental stock of the PFA. Previous analyses indicated that the sum of lagged spawner components from Labrador, Newfoundland, Québec, and Scotia-Fundy and excluding Gulf and U.S. was the strongest explanatory variable for the model. Inclusion of the Gulf spawning component reduced the explanatory power of the variable. The estimation procedure remained unchanged in 2000 . Spawning escapement estimates for Labrador are not available for the years 1998-2000. The previously formulated lagged spawner variable will therefore not be available beyond 2002.

### 7.4.2 Forecast model for pre-fishery abundance of North American 2SW salmon

The model used to forecast pre-fishery abundance for 2001 was revised (Section 7.5) and results presented in Section 7.4.3 are based on this revised model. The basis for the revised model is the same two predictor variables as were used from 1999 to 2000: thermal habitat for February (term H2) and lagged spawners (sum of lagged spawners from Labrador, Newfoundland, Scotia-Fundy and Quebec, term SLNQ). The 2001 forecast of pre-fishery abundance was based on an alternative modelling approach that takes into consideration that habitat acts on PFA through survival rather than on absolute abundance. The reasons for adopting this model are given in Section 7.5.

There was a significant linear relationship between the PFA values and predicted values ( $\log$ transformed model; $\mathrm{r}^{2}=0.88$ ). The model continues to be influenced primarily by the spawning stock level in the predictive relationship for pre-fishery abundance. The habitat index accounted for about $10 \%$ of the total variance and SLNQ accounted for about $80 \%$. The predicted values fit the observed data quite well except in the late 1980s and 1990s when abundance was low (Figure 7.4.2.1).

The forecasted estimate simulated by the PFA model of pre-fishery abundance for 2001 using the February thermal habitat and lagged spawner model is about 295700 at the $50 \%$ probability level (Table 7.4.1.1). The lagged spawner variable (SLNQ) improved in the year 2001 primarily because of increases in Labrador since the mid-1990s and this is contributing substantially to the predicted increase in pre-fishery abundance.

Due to the time lag between forecasted and estimated pre-fishery abundance, the model predicts abundance two years in advance. Consequently, any developing trend in high positive or negative residuals indicating a poor fit to recent data will be hard to detect until after the fishery.

Using this model to estimate the 2000 pre-fishery abundance yields a value of 225700 , which is about $25 \%$ higher than the previously reported value of 179900 . Note that the previously reported value was based on the additive model without errors in the lagged spawners (Section 4.5). The inclusion of errors in the lagged spawners has been shown to increase the median value and to widen the distribution of the forecast. The relationship between the available 2SW to 1SW data from several rivers in Eastern Canada previously shown, indicated that the 2000 forecast of pre-fishery abundances, i.e., returns of 2 SW salmon to North America in 2001, is unlikely to be achieved. Consequently, there is considerable uncertainty regarding the projected reversal of the declining trend in pre-fishery abundance forecasted by the model.

### 7.4.3

The spawning requirement for all North American rivers is currently set at 1525482 SW -fish which is the equivalent of 170286 pre-fishery recruits (spawning reserve) prior to natural mortality between Greenland and home waters. The procedure for estimating the quota for West Greenland is summarised in Appendix 2.

Quota computation for the 2001 fishery requires an estimate of pre-fishery abundance, stock composition by continent [PropNA], mean weights of North American and European 1SW salmon [WT1SWNA and WT1SWE, respectively], and a correction factor for the expected sea-age composition of the total landings [ACF]. Exponentially smoothed values utilising data collected during the 1995-1999 fisheries are summarised below.

| Parameter | Value |
| :--- | :--- |
| PropNA | 0.779 |
| WT1SWNA | 2.954 |
| WT1SWE | 2.990 |
| ACF | 1.049 |

Greenland quota options are presented for the $25 \%$ and $75 \%$ cumulative probability levels of PFA (Table 7.4.3.1): Between the $25 \%$ and $75 \%$ probability level and at the $\mathrm{f}_{\mathrm{NA}}$ (proportion of the harvest allocated to Greenland) of 0.4 quota options range from 28 to 467 t with a median value of 200 t .

Growth of salmon through the fishing season can significantly affect the total number of fish harvested under a fixed quota. A sensitivity analysis was conducted to evaluate the effect of salmon growth in August and September on the total number of fish harvested under a theoretical 200 t quota (Figure 7.4.3.1). This analysis shows that the number of fish harvested under a fixed quota decines significantly as the median date of the fishery is delayed through August and September.

### 7.4.4 Risk assessment of catch options

The provision of catch advice in a risk framework involves the incorporation of the uncertainty in all the factors used to develop the catch options. The method is described in more detail in Section 4.2. Annual variations in uncertainty result in differing assessments and differing levels of precision. The risk analysis plots are calculated for consideration of the 2001 fishery in West Greenland.

The pre-fishery abundance of salmon in 2001 is predicted to be moderate relative to historic levels (Table 7.4.1.1). The risk analysis results suggest a moderate risk that the returns of 2 SW salmon to North America in 2002 will be below the conservation
requirement, even in the absence of any fisheries on this age group in Greenland in 2001 (Figure 7.4.4.1).

The risk analysis performed considers the most optimistic scenario of equal production rates in all six stock areas of North America. The reality is that the stock status differs greatly within North America and that the expected returns of salmon to the USA and Scotia Fundy areas will be severely below their respective conservation requirements. In the USA, the escapement for the entire area has never been above 3000 spawners since 1992 , no better than $10 \%$ of the requirement. Similarly, the Scotia-Fundy area lagged spawners have been less than 10000 fish over the last ten years. If all stocks were at their spawner requirements, the U.S.A. stocks would be expected to produce almost $20 \%$ of the $2 S W$ production from North America while the Scotia-Fundy stock is expected to produce just over $16 \%$ of the total. Under the current levels of spawning escapement, recruitment to USA rivers is not expected to be more than $2 \%$ of the total PFA, and Scotia-Fundy no better than $10 \%$ of the present PFA (Figure 7.4.4.2). The majority of the nonmaturing 1 SW salmon in the Northwest Atlantic in 2001 are expected to retum principally to the other areas, Quebec, Gulf, Labrador and Newfoundland. With this consideration, the risk analysis applies more appropriately to these four areas while the probability of the Scotia-Fundy area meeting its conservation requirement is very near zero and is zero for the USA stocks.

There is little information available to coniurm the possibility of an improvement in pre-fishery abundance in 2000 and 2001 as forecasted through modelling. Two sea winter adult returns in 2001 will provide initial indications regarding the overall abundance of nonmaturing 1SW salmon in 2000 . Associations between 1 SW returns in year $i$ and $2 S W$ returns in year $i+1$ observed in several rivers in eastern Canada suggest that abundance of 2 SW salmon in 2001 in eastem Canada will be similar to or less than recent years. Smolt production in 1999 and 2000 in monitored rivers of eastem Canada were similar to or below the average of the last five years. The adoption of risk neutral quota options on the basis of predicted sharp increases in prefishery abundance in 2000 and 2001 provides the potential for significant overexploitation if increases in pre-fishery abundance are not realized. Extreme caution is urged regarding harvest decisions for 2001, and adoption of conservative harvest levels is warranted until projected increases can be confirmed. The increasing advantage associated with each additional spawner in under-seeded river systems makes a strong case for a conservative management strategy.

The North American stock complex of non-maturing salmon remains in tenuous condition. fncreased spawning escapements to rivers of some areas of eastern North America resulted in improved abundance of the juvenile life stages, and perhaps now at adult life stages. Despite the closure of Canadian and West Greenland
commercial fisheries, sea survival of adults returning to rivers has not improved and in some areas has declined further. The abundance of maturing 1 SW salmon has also declined in many areas of eastern North America. Until sea survivals improve, the abundance of nonmaturing 1SW salmon in the Northwest Atlantic is not expected to improve above the levels of the last five years.

### 7.5 Changes to the model used to provide catch advice

The models used to predict pre-fishery abundance of the North American non-maturing stock complex and subsequent quota levels for West Greenland were revised based on exploratory work conducted by the Working Group and reported in the 1999 and 2000 reports. For the past several years, models used to predict the PFA were additive and hypothesized a linear effect of SLNQ and habitat on salmon abundance. An alternative approach, adopted in the 2001 assessment takes into consideration that habitat acts on PFA by mediating survival rather than on absolute abundance. The basis for these multiplicative models is the same two predictor variables ( H 2 and SLNQ ) used in previous assessments. In addition, the uncertainty in the lagged spawner and PFA variables were incorporated in the model simulations. The distribution of the multiplicative models is skewed to the origin and long tailed towards large values. The predicted abundance is always greater than 0 , contrary to what is given by the additive model. There is a greater cumulative probability for lower PFA levels (Figure 7.5.1) with the multiplicative model but the distribution suggests that there is insufficient information in the data to fix an upper bound on the PFA. Adoption of the multiplicative model resolves issues related to the biological logic of the model and the prediction of unreasonable PFA values, less than 0 , generated by the additive model in previous assessments. The primary changes in performance of the multiplicative model adopted for 2001 relate to changes in pre-fishery abundance forecasts and characterization of uncertainty about these forecasts.

### 7.6 Catch advice

Although a large proportion of the examined North American stocks meet conservation targets (Figure 6.1.2.6) many are failing to meet targets or are only barely doing so. Despite complete closures of mixed and single stock fisheries the very small surplus over spawning requirements and the uncertainty in the estimates make a strong case for even more conservative management measures.

ICES considers this stock complex to be outside safe biological limits and recommends that there should be no exploitation of the 2000 smolt cohort as non-
maturing ISW fish in North America or at Greenland in 2001, and also recommends that the cohort should not be exploited as mature 2 SW fish in North America in 2002. Exceptions are in-river harvests from stocks, which can be shown to be above biologically-based spawning escapement requirements. Further, exploitation rate on this cohort should be minimised in the North American Commission and in the West Greenland Commission Areas by controlling by-catch in other fisheries. It should also be noted that the assessment of stocks in Southern Europe which are alse exploited at West Greenland has shown that these stocks are also below their conservation limits and this further supports the advice for no fishery at West Greenland.

Data deficiencies, monitoring needs and research requirements in the WGC area

1. Continued efforts should be made to improve the estimates of the annual catches of salmon taken for local consumption in Greenland.
2. The mean weights, sea and freshwater ages and contiment of origin are essential parameters to provide catch advice for the West Greenland fishery. As these parameters are known to vary over time, the Working Group recommends that the sampling programme be continued and closely coordinated with fishery harvest plan to ie executed annually in West Greenland.
3. The catch options for the West Greenland fishery are based almost entirely upon data taken from North American stocks (with the current exclusion of Labrador, see Section 7.6). In view of the evidence of a long-term decline in the European stock components contributing to this fishery (southern European non-maturing ISW recruits) the Working Group emphasised the need for information from these stocks to be incorporated into the assessments as soon as possible.
4. Alternative models should be explored (for example different predictive variables, model formulations, univariate time series, non-parametric change-of-state analyses) to provide some index of plausibility of the quantitative forecasts.
5. Further basic research is needed on the spatial/temporal distribution and migration patterns of salmon and their predators at sea to assist in explaining variability in survival rates.
6. Samples should be obtained for DNA analysis from rivers in North America and Europe.

The status of the six stock areas should be incorporated into the analysis of risk of catch options.

#### Abstract

APPENDIX 1

CNL (00) 60 REQUEST FOR SCIENTIFIC ADVICE FROM NASCO TO ICES (JULY 2000)

1 with respect to Atlantic salmon in the North Atlantic area:
1.1 provide an overview of salmon catches and landings, including unreported catches by country and catch and release, and worldwide production of farmed and ranched salmon in 2000,
1.2 report on significant developments which might assist NASCO with the management of salmon stocks,
1.3 use case studies to illustrate options for taking account of risk in the provision of catch advice and comment on the relative merits of each option,
1.4 assess the possible reasons for the differences in the occurrence of escaped farmed fish in fisheries and stocks in different areas,
1.5 advise on the potential biases in the catch advice model resulting from the inclusion of fish farm escapes in the assessment models,
1.6 provide a compilation of tag releases by country in 2000.

2 with respect to Atlantic salmon in the North-East Atlantic Commission area:
2.1 describe the events of the 2000 fisheries and the status of the stocks, :
2.2 update the evaluation of the effects on stocks and homewater fisheries of significant management measures introduced since 1991,
2.3 further develop the age-specific stock conservation limits where possible based upon individual river stocks,
2.4 provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits,
2.5 update the information on by-catch of salmon post-smolts in pelagic fisheries, identify relevant data deficiencies, monitoring needs and research requirements.

3 with respect to Atlantic salmon in the North American Commission area
3.1 describe the events of the 2000 fisheries and the status of the stocks,
3.2 update the evaluation of the effects on US and Canadian stocks and fisheries of management measures implemented after 1991 in the Canadian commercial salmon fisheries,
3.3 update age-specific stock conservation limits based on new information as available,
3.4 provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits,
3.5 identify relevant data deficiencies, monitoring needs and research requirements.
4.1 describe the events of the 2000 fisheries and the status of the stocks,
4.2 update the evaluation of the effects on European and North American stocks of the Greentandic quota management measures and compensation arrangements since 1993,
4.3 provide a detailed explanation and critical examination of any changes to the model used to provide catch advice and of the impacts of any changes to the model on the calculated quota,
4.4 provide catch options or alternative management advice with an assessment of risks relative to the objective of exceeding stock conservation limits,
4.5 evaluate potential causes for the changes in the Continent of origin of saimon captured in the West Greenland fishery including potential changes in marine migration patterns,
4.6 identify relevant data deficiencies, monitoring needs and research requirements.

## NOTES:

1 With regard to question 1.3. ICES is requested to provide information that will assist with the implementation of and the evaluation by NASCO and its Contracting Parties of the decision structure (Annex 4 of document CNL(00)18) provisionally adopted by the Council.

2 In response to questions 2.I, 3.I and 4.I ICES is asked to provide details of catch, gear, effort, composition and origin of the catch and rates of exploitation. For homewater fisheries the information provided should indicate the location of the catch in the following categories: in-river, estuarine and coastal. Any new information on non-catch fishing mortality of the salmon gear used and on by-catch of other species in salmon gear and of salmon in any new fisheries for other species is also requested.

3 In response to question 4.1, ICES is requested to provide a brief summary of the status of the North American and North-East Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to questions 2.1 and 3.1 .

4 With regard to question 4.3 "change to the model " would include the development of any new model.

## APPENDIX 2

## Computation of Catch Advice for West Greenland

The North American Spawning Reserve (SpT) for 2 SW salmon of 152548 fish remains the same as in 2000.

This number must be divided by the survival rate for the fish from the time of the West Greenland fishery to their return of the fish to home waters ( 11 months) to give the Spawning Target Reserve ( SpR ). Thus:

Eq. 1. $\quad \mathrm{SpR}=\mathrm{SpT}^{*}(\exp (11 * \mathrm{M}) \quad($ where $\mathrm{M}=0.01)$
The Maximum Allowable Harvest (MAH) may be defined as the number of non-maturing $15 W$ fish that are available for harvest. This number is calculated by subtracting the Spawning Target Reserve from the pre-fishery abundance (PFA).

Eq. 2. $\quad \mathrm{MAH}=\mathrm{PFA}-\mathrm{SpR}$
To provide catch advice for West Greenland it is then necessary to decide on the proportion of the MAH to be allocated to Greenland ( $\mathrm{f}_{\mathrm{NA}}$ ). The allowable harvest of North American non-maturing 1 SW salmon at West Greenland NA1SW) may then be defined as

Eq. 3. $\mathrm{NA} 1 \mathrm{SW}=\mathrm{f}_{\mathrm{NA}} * \mathrm{MAH}$
The estimated number of European salmon that will be caught at West Greenland (E1SW) will depend upon the harvest of North American fish and the proportion of the fish in the West Greenland fishery that originate from North America [PropNA] ${ }^{1}$. Thus:

Eq. 4. $\quad \mathrm{E} 1 \mathrm{SW}=(\mathrm{NA} 1 \mathrm{SW} /$ PropNA $)-$ NA1SW
To convert the numbers of North American and European 1 SW salmon into total catch at West Greenland in metric t , it is necessary to incorporate the mean weights (kg) of salmon for North America [WT1SWNA] ${ }^{1}$ and Europe [WT1SWE] ${ }^{1}$ and age correction factor for multi-sea winter salmon at Greenland based on the total weight of salmon caught divided by the weight of 1 SW salmon $[\mathrm{ACF}]^{1}$. The quota (in t) at Greenland is then estimated as

Eq. 5. Quota $=($ NA1SW * WT1SWNA + E1SW $* W T 1 S W E) * A C F / 1000$
${ }^{1}$ Sampling data from the 1995-1999 fishery at West Greenland were used to update the forecast values by exponential smoothing of the proportion of North American salmon in the catch (PropNA), weights by continent [WT1SWNA, WT1SWE] and the age correction factor [ACF].
Table 4.1.1.1 Nominal catch of Salmon by country (in tonnes round fresh weight), 1960-2000. (2000 figures include provisional data).

Table 7.4.3.1 Quota options ( t ) for 2001 at West Greenland based on H 2 -SLNQ multiplicative forecasts of prefishery abundance. Proportion at West Greenland refers to the fraction of harvestable surplus allocated to the West Greenland fishery. The probability level refers to the pre-fishery abundance levels derived from the probabiltiy density function.

[^58]:    - No tishery occurred. sub-divisions $22 \cdot 32$ are normally less than one tonnes. From 1995 data includes

    Catches from the recreational fishery are included as follows: Finland from 1980, Sweden from 1988, Denmark from: 1998.
    Other countries have no, or very low recreatlonal catches.
    Danish, Finnish, German, Polish and Swedish catches are converted from gutted to round fresh weight w by multiplying by 1.1. Estonian, Latvian, Lithuanlan and Russian catches before 1981 are summarized as USSR catches.
    Estonian, Latvian, Lithuarian and Russlan catches are reported as hole fresf weight.

    Sea trout are included in the sea catches in the order of $3 \%$ for Denmark (before 1983), $3 \%$ for Estonia, Germany, Latvia, Lithuania, Russia, and coout $5 \%$ for Poland (bofore 1997).

    Estontar sea catches th Ste-division 32 in 1986 - 1991 include a small quantity of coastal catches.
    Estimated non-reported coastal catches in Sub-division 25 has from 1993 been included in the Swedish statistics.
    Danish coast catches are nen-profosional trolling catches.

    1) In 1993 Eishermen from the Face is land cought 16 tornes, which cre induded in tota Danish orthos.
[^59]:    Data from the recreational fishery are included in Swedish and Finnish data. Recreational fishery are included in Danish data from 1998. Other countries have no, or very low recreational catches.
    In 1996 sea trout are included in the Pollish catches in the order of $5 \%$.

    1) Russian coastal catches have in earlier reports been recorded as sea catches.
[^60]:    1.) River Lule älv missing before 1992 and River Indalsälven in year 2000.

    All estimates known to be based on material from less than 20 females in italics.
    2.) The estimates in the rivers Simojoki and Tornionjoki/Torne älv are if possible given as the percentage of females affected of M74 and secondly, percentage of yolk-sac-fry mortality.

[^61]:    ${ }^{1}$ Preliminary. Table revised because of additional data.
    ${ }^{2}$ For comparison with TAC.

[^62]:    ${ }^{1}$ mean of the catch proportions (\%) from 1987-1998. in brackets the stock component.
