#### Abstract

In 1989, the Northeast Fisheries Science Center implemented a domestic observer program in which fisheries information is collected at-sea by trained observers placed aboard commercial fishing vessels. The major purpose of the program is to obtain real-time data on the quantities and biological characteristics of discards in the Georges Bank, Gulf of Maine, and Mid-Atlantic fisheries. Catches (both kept and discard weights) are recorded on a tow basis, and size frequency measurements are made, by species, on both the kept and discarded components of the catch. Vessel performance and hydrographic data are also recorded for each tow (i.e., tow depth, tow time, tow speed, tow direction, gear configuration, wind speed, wave height, etc). Annually, about 2800 sea-days are allotted to the observer program.

The data collected have been used for a variety of purposes including: (1) estimating non-fish (marine mammal, sea turtle and sea bird) by-catch; (2) estimating species-specific discard levels for use in assessment analyses; and (3) evaluating impacts of management measures - such as time/area closures and trip limits - on fleet behavior and performance. As an example of this latter use of the observer program, we report the results of an experimental fishery (in which observers were required) for Atlantic cod (Gadus morhua) during January-June 1994 in a closed area on Georges Bank established iv protect haddock (Melanogrammus aeglefinus). The experimental fishery was authorized as a research initiative designed to assess whether a fishery for cod (and other mixed groundfish) could be prosecuted without having significant bycatches of haddock.

## INTRODUCTION

Since 1970, a seasonal areal closure of the northeast corner of Georges Bank has been implemented annually to protect spawning concentrations of haddock (Melanogrammus aeglefinus) '. This spawning area closure (originally designated as Area B but subsequently referred to as Area II) was first enacted by the International Commission for the Northwest Atlantic Fisheries (ICNAF) in March and April 1970 (Fig. 1a). The closure prohibited 'fishing with gear capable of catching demersal species' (ICNAF, 1969) and was designed to reduce haddock catches and supplement existing catch limitations by spreading catches throughout the year (Halliday, 1988). Fishermen's support for such closures has traditionally been very strong; in fact, the enactment of the haddock spawning closure in 1970 by ICNAF has been attributed to the insistence of USA fishermen (Halliday, 1988)

Both the USA and Canada retained the use of the ICNAF haddock spawning area fishery closures after extension of fishery jurisdictions in 1977, with minor adjustments in gear restrictions and closure duration (Clark et al., 1982). After 1971, the duration of the Area II closure was expanded by both countries to include the months of March through May. In October 1984, the delimitation of the USA-Canada maritime boundary resulted in a subdivision of Area II between the USA and Canada. Nonetheless, the Area II closure has since been independently maintained by both countries with little change. Since 1985, Canada has continued to close its sector of Area II to fishing during March-May. Similar closures were enacted in USA Area II waters in 1985 and 1986. In 1987, the USA - under provisions of the Northeast Multispecies Fishery Management Plan (Groundfish FMP) - expanded the duration of the Area II closure to include the February-May period. This four-month closure period was maintained annually through 1993 in the USA portion of Area II.

Effective 1 January 1994, a revised USA management program was implemented for groundfish (i.e., Amendment 5 to the Groundfish FMP). As one part of a suite of conservation measures to 'eliminate the overfished condition of the principal groundfish stocks' (NEFMC, 1993), the Area II seasonal area closure was extended spatially and temporally. Closed Area II was enlarged by 20 minutes longitude to the west and 15 minutes latitude to the south (Fig. 1b) and the closure implemented for six months, 1 January to 30 June. The rationale for this time/area enlargement was to provide additional protection to the concentrations of haddock in the area, viz.

> In the case of the expansion of Area II, significant landings of haddock are reported from the area around the current [pre-1994] boundary line and when the area is opened. There are reports of illegal fishing just over the boundary during the closure. Haddock that are aggregated to spawn in this area are extremely susceptible to being targeted, particularly around the margins of the area and upon the termination of the closure. Based on historical landings, nearly one quarrer of the total landings of haddock are caught within the area included in the proposed expansionduring the closure, and about one third of haddock landings are caught within the expanded area during January through June. Based on an analysis of the fishing effort in the area and displacing that effort to other areas in the region with the next-highest catch rates in the 1988-90 period, the haddock that would have been saved amounts to $21 \%$ of the total landings of haddock while the landings of other groundfish would have increased by 1 percent. Without calculating for displaced effort, the haddock savings would have amounted to 33 percent and other groundfish species to about one percent of the total landings (Ham et al., 1991).' (NEFMC, 1993).

[^0]The 1994 regulations prohibited any fishing in Area II during the closure period, except for vessels using pot gear to tish for lobsters and for vessels using dredges to catch sea scallops. Retention of any haddock caught incidentally by scallop dredge vessels was not permitted.

Concurrent with the enactment of the expanded Area II closure in 1994, an Experimental Fishery program was established. This fishery was authorized as a research exemption under the Groundfish FMP, and allowed a restricted number of trawl vessels to tish in the newly-expanded, L-shaped portion of Area II during the closure period provided that scientific observers were carried aboard the vessel's. The purpose of the Experimental Fishery was to monitor the catch and bycatch of cod and haddock in the expanded area during the January through June closure period. Additional objectives were to: (1) assess whether a limited trawl fishery for cod (and other mixed groundfish) could be prosecuted in the expanded area without incurring significant bycatches of haddock; and (2) determine when concentrations of spawning and post-spawning haddock were no longer resident in the area.

In this paper, we summarize and evaluate the performance of the 1994 Experimental Fishery using tow-by-tow data collected by the scientific observers placed aboard each vessel in the experiment. Information is provided on total catches, total fishing effor, species composition, discarding practices, size frequency composition of the landings and discards, and spatial and temporal trends in catch, effort and CPUE. Attention is focused on haddock and the 12 other finfish species covered under the Groundfish FMP ${ }^{2}$ - although data are provided on all of the species caught in the Experimental Fishery. Comparisons are made between catches taken inside and outside of Area II, by species and month. We also report the results of two sea sampling trips made on Georges Bank in July 1994 after Area II was re-opened for fishing.

## METHODS

## Design and Conduct of the Experimental Fishery

The operational plan for the Experimental Fishery data required the deployment of scientific observers aboard commercial vessels authorized to fish in the expanded portion of Closed Area II.! A limited number of trawl vessels were solicited to voluntarily participate in the experiment. Vessel and observer schedules were coordinated to ensure that all scientific data collection needs would be met.

Industry participation was initiated with inquiries to vessel owners and captains who had landed trips from the $L$-shaped area during the preceding winter/spring season. Prospective participants were briefed on the purpose, design, and administrative requirements of the experiment. All vessels licensed to fish in the groundfish fishery, however, received written notification in December 1993 that an experimental fishery would be conducted and that participating vessels would be required to take approved observers and submit logbooks. The number of participants was limited to that required to keep pace with the scheduled $2-4$ experimental fishèry trips per month.

[^1]Once a vessel was selected to participate in the Experimental Fishery, an 'Experimental Fishing Certificate for the Expanded Portion of Closed Area II' was issued and arrangements made to provide observer coverage. The Certificate was hand-delivered to the vessel captain, at which time the objectives and procedures of the experimental fishery program were discussed. Any questions or concerns on the part of the saptain or crew were addressed. While fishing in the experimental area, each participating captain agreed to the following conditions:

1. The vessel could fish anywhere within the expanded closed area, but not within the inner triangle portion comprising the former Closed Area II. Within the L-shaped expanded area, the captain was free to decide where and when to fish. No restrictions were placed on the number of tows or how fishing operations should be conducted. However, each captain was informed that broad coverage of the expanded area would be beneticial in providing a synoptic basis for analyzing the experimental fishery data.
2. Vessels could fish only with regulated mesh (i.e., $51 / 2$ in [13.97 cm$]$ during January-March; 6 in ( 15.24 cm ] from April 1994 onwards).
3. Catches of 'regulated multispecies' (cod, American plaice, pollock, redfish, winter flounder, witch flounder, and yellowtail flounder) of legal size could be landed, but no haddock could be retained.
4. The vessel had to be accompanied by a National Marine Fisheries Service (NMFS) approved observer.
5. Vessels were under no obligation to remain in the experimental area for the entire trip.
6. An Experimental Fishery Certificate was issued and valid for a single trip. If a vessel wished to make a subsequent trip in the Experimental Fishery Program, a new Certificate had to be issued.

As word of the Experimental Fishery spread through the industry, vessel owners and captains contacted NMFS requesting details on the experiment and expressing interest in participation. In the few cases where the number of interested vessels exceeded the available observer coverage, vessels were selected randomly.

All scientific observers were provided by the Northeast Fisheries Science Center (NEFSC) Fisheries Observer Program. Observers were instructed to observe as many hauls as possible and, for each haul, record data on fishing location, fishing effort, catches, discards, gear characteristics, hydrographic information, and other information as specified in the NEFSC Foreign and Domestic Observer Manual. Additionally, the observers were requested to obtain length frequency samples from haddock and other Groundfish FMP species.

Cooperation at-sea was generally excellent between the vessel operators and the scientific observers. In addition to providing all required data, many captains and crew members provided additional anecdotal information on vessel operations and the status and management of the groundfish fishery.

## Data Processing and Analysis

Copies of the tow-by-tow logs completed by the scientific observers on each trip in the Experimental Fishery were forwarded to the NEFSC Woods Hole Laboratory for review and analysis. Data analyses included: (1) individual tow summaries of fishing effort and catches, by species and disposition (retained or discarded); (2) trip summaries of the tow-by-tow locations where fishing occurred [both inside and outside of Area II]; (3) month/area summaries of catches, effort, and CPUE; and (4) size frequency summaries, by species and area fished, of landings and discard samples. Spatial and temporal patterns in fishing effort, catches, and CPUE were evaluated by month. CPUE was defined as catch (i.e., total, species, kept, discarded) per hour fished, expressed as pounds per hour (lb/hr). No adjustments were made for possible differences in fishing power among vessels. Discard rates were calculated by species and species groups (e.g., groundfish FMP species) and calculated as the percentage of the total catch weight (by species/species group) discarded.

Tows were assigned to Area II if all, or any part, of the tow was made inside of Area II. Tows made outside of Area II were collectively analyzed as a single group, although these hauls were made over a very wide geographical area. Comparisons of catches, species composition, and CPUE from tows made inside and outside of Area II were conducted to provide initial insight on the impacts of the Area II closure in protecting haddock and other groundfish FMP species. More refined GIS-type analyses; however, are required to delineate finer-scale spatial patterns - both within Area II and between Area II and externally adjacent (or more distant) areas.

## RESULTS

## Experiment-Wide

During the January - June 1994 Experimental Fishery, 14 trips were made by 12 different vessels (Table 1). Participating vessels were from the Massachusetts ports of Boston (1), Gloucester (6) and New Bedford (2), and the Maine ports of Portland (2) and Rockland (1). The vessels were absent from port for a total of 137 days, fishing 1,882 hours ( 78.4 days, gear on bottom) and accomplishing 522 tows. Average trip duration was 9.8 days [range: 9-13 days], average fishing time per trip was 134 hours [range: $62-186 \mathrm{hrs}$ ], average number of tows per trip was 37 [range: 20-58], and average tow duration was 3.6 hours [range: 2.1-4.8 hrs].

All trips but one (i.e., trip 10) fished both inside and outside of Area II (Table 1; Fig 2). Total catches, discards, fishing effort, number of tows, and haddock catch per unit effort (CPUE) for the entire experiment are summarized by area (inside vs outside Area II) in Tables 2-4; individual trip data are presented in Tables $5-7$. Of the 522 tows made during the experiment, 445 tows ( $85 \%$ ) were observed by the scientific observers (Table 2). Sixty nine percent (305) of the observed tows occurred in Area II and 140 tows were observed outside of Area II. Observed tows accounted for $90 \%$ of the total hauls in Area II and $76 \%$ of the tows made outside Area II. Retained catches were recorded by the scientific observers from all hauls (observed and unobserved), but discards could only be tallied in observed hauls. Fishing captains do not normally maintain records of discards. Therefore, discard estimates are not available from unobserved tows. Accordingly, all of the results subsequently presented are based solely on observed hauls.

Experiment-wide catches totaled 609,741 pounds (lb) [276.6 metric tons (mt)] of which $422,241 \mathrm{lb}$ ( 191.5 mt ) were Groundfish FMP species $(69 \%)$ and $69,032 \mathrm{lb}(31.3 \mathrm{mt})$ was hadcock (Table 2). Haddock accounted for $11.3 \%$ of the total catches and $16.3 \%$ of the Groundfish Fitp catch. Although total observed fishing effort in Area II - in terms of both number of tows and hours fished was twice as great as outside of Area II, total Area II catches were 3.5 X higher ( 474,491 vs 135.250 lb ), Groundtish F.MP catiohes 3.8 X higher ( 333,366 vs $88,875 \mathrm{lb}$ ), and haddock catches 7.5 X higher ( 60.934 vs 8.098 lb ) than outside of Area II (Table 3). While Groundfish FMP species accounted for about the same percentage of the total catches in both areas ( $70 \%$ in Area II, $66 \%$ outside of Area II), haddock accounted for $18.3 \%$ of the Groundfish FMP catches in Area II compared to $9.1 \%$ of the FMP catches outside the closed area (Table 2). For the entire January-June period, haddock CPUE in Area II was 3 X higher than outside Area II ( 53.1 vs $17.4 \mathrm{lb} / \mathrm{hr}$ : Table 4).

Nearly all ( $96 \%$ ) of the haddock caught were discarded (Table 2). Within Area II, this was due to the experimental fishery requirement that any haddock caught could not be retained (although haddock were inadvertently kept on three tows inside the closed area due to a misunderstanding that haddock could be retained if a tow was not completely within Area II). Outside of Area II, retention of haddock was legally restricted to $500 \mathrm{lb}(227 \mathrm{~kg})$ per trip.

Discards of all species combined amounted to $206,867 \mathrm{lb}$ ( 93.8 mt ), of which the groundfish FMP species constituted $37 \%$ ( $75,845 \mathrm{lb} ; 34.4 \mathrm{mt}$ ) (Table 2). Haddock discards ( $66,052 \mathrm{lb} ; 30.0 \mathrm{mt}$ ) accounted for $32 \%$ of the total discards and $87 \%$ of the discards of FMP groundfish. Other species heavily discarded included skates ( $98,036 \mathrm{lb} ; 44.5 \mathrm{mt}$ ), and spiny dogfish ( $19,422 \mathrm{lb} ; 8.8 \mathrm{mt}$ ) (Table 3). Together with haddock, these species accounted for $89 \%$ of the total biomass of fish discarded.

In route to the fishing grounds, vessel captains were asked to identify the species targeted for fishing. Cod was designated as the target species sought in nine trips, 'mixed groundfish' in four trips, and pollock in one trip (Table 5). Trip catches were consistent with these designations (rables 5-7). Cod accounted for $34 \%$ of the total catches during the experiment and $50 \%$ of the total catch of groundfish FMP species (Table 5). Captains generally fished according to the 'style' of their port, i.e., Gloucester vessels tished for a mix of groundfish, New Bedford vessels fished for cod and flounders, and Maine vessels fished for cod, pollock and American plaice.

Nearly 50 different species were caught during the Experimental Fishery (Appendix Table 1). Relative contributions (percent by weight) of individual species to the total experiment-wide catch of $609,741 \mathrm{lb}$ were as follows: cod ( $34 \%$ ), skates ( $19 \%$ ), pollock ( $12 \%$ ), haddock ( $11 \%$ ), monkfish ( $5 \%$ ), American plaice (3\%), yellowtail flounder (3\%), spiny dogfish (3\%), white hake ( $2 \%$ ), other fish ${ }^{3}(1 \%)$, cusk ( $1 \%$ ), witch flounder ( $1 \%$ ), American lobster ( $1 \%$ ), winter flounder ( $1 \%$ ), ocean pout ( $1 \%$ ), wolffish $(<1 \%)$, redfish ( $<1 \%$ ), silver hake ( $<1 \%$ ), red hake $(<1 \%)$, other invertebrates ${ }^{4}(<1 \%)$, and windowpane flounder ( $<1 \%$ ) (see Table 3). Additionally, two white-sided dolphins, Lagenorhynchus acutus, were incidentally captured during one of the trips and returned to the sea. No other marine mammals, sea turtles or sea birds were caught during the experiment.

[^2]
## Area II

Within Area II, catches from the 304 observed tows ( $1,1+8$ fishing hours) totai $24,474,491 \mathrm{lb}$ $(215.2 \mathrm{mt})$, of which $302,634 \mathrm{lb}(137.3 \mathrm{mt})$ were retained ( $64 \%$ ) and $171,857 \mathrm{lb}(78.0 \mathrm{mt})$ were discarded (Tables 8-10). Fishing activity occurred in all six months but was not even!y distributed in time or space. Experimental fishing effort was lowest in January ( 15 observed tows; 72 hrs fished), intermediate during February and May ( 32 and 37 tows; 76 and 110 hrs tished), and highest in March, April, and June (61-97 tows/month; 230-92 hrs fished/month) (Table 8). The majority of tows were made in the top northwest corner of the expanded closed area (Fig. 3). During March through June, fishing was concentrated along the north-south boundary line separating the expanded closed area from the former Closed Area II, and also along the USA-Canadian boundary line (i.e., the Hague Line). In the first few months of the experiment, vessels moved throughout the expanded area to locate target species; in the latter three months, some vessels towed in locations where it was felt haddock could be avoided.

Groundfish FMP catches $(333,366 \mathrm{lb} ; 151.2 \mathrm{mt})$ comprised $70.3 \%$ of the total catch in Area II, and accounted for $88.3 \%(267,120 \mathrm{lb} ; 121.2 \mathrm{mt})$ of all retained catches (Tables 8 and 9 ). Cod was the most frequently caught species ( $161,997 \mathrm{lb} ; 73.5 \mathrm{mt}$ ) accounting for $34 \%$ of the Area II total catch and $49 \%$ of the catch of Groundfish FMP species. Haddock catches in Area II totaled $60,934 \mathrm{lb}(26.7 \mathrm{mt})$, $12.8 \%$ of the aggregate Area II total and $18.3 \%$ of the areal Groundfish FMP catch. All but $2 \%$ of the haddock caught were subsequently discarded (Table 11).

Prior to April, haddock catches in Area II were minor (Jan-Mar total: 1,968 lb) accounting for less than $3 \%$ of the closed area catches per month and less than $4 \%$ of the monthly catches of FMP Groundfish (Table 8). The average catch per tow of haddock during January through March was only 18.2 lb (Jan: 12.0 lb ; Feb: 0.3 lb ; Mar: 29.2 lb ); in these months, haddock CPUE averaged just $5.2 \mathrm{lb} / \mathrm{hr}$ (Jan: $2.5 \mathrm{lb} / \mathrm{hr}$; Feb: $0.1 \mathrm{lb} / \mathrm{hr}$; Mar: $7.7 \mathrm{lb} / \mathrm{hr}$ ) (Fig. 4). The largest catch of haddock taken in any one tow during these three months was 407 lb (Table 5). Apart from this tow and another tow in which 102 lb of haddock were caught, none of the remaining 106 observed tows during January-March in the closed area caught more than 78 lb of haddock (Fig. 5).

Beginning in April and continuing through May, haddock CPUE markedly increased in every trip made in Area II, rising from $50 \mathrm{lb} /$ tow ( $10.5 \mathrm{lb} / \mathrm{hr}$ ) in trip 8 to $669 \mathrm{lb} /$ tow ( $186 \mathrm{lb} / \mathrm{hr}$ ) in trip 12 (Table 6). Average haddock catch per tow in April was $130 \mathrm{lb} /$ tow ( $30 \mathrm{lb} / \mathrm{hr}$ ) and $577 \mathrm{lb} / \mathrm{tow}$ ( $194 \mathrm{lb} / \mathrm{hr}$ ) in May (Table 8; Fig. 4). During these two months, catches of haddock exceeded 100 lb in 51 (38\%) of the 134 observed tows and exceeded 500 lb in 17 tows. Tows with the highest haddock catches occurred in the northwest corner of the closed area (near the 50 fathom contour) and along/near the boundary of former Closed Area II (Fig. 5). The largest catch of haddock taken in a single tow during April and May was $4,600 \mathrm{lb}$ - more than twice the total haddock caught in Area II during the first three months of the Experimental Fishery.

In June, haddock CPUE declined to $105 \mathrm{lb} / \mathrm{hr}$ ( $396.7 \mathrm{lb} /$ tow) - lower than in May but substantially higher than any other month (Fig. 4). The last trip in the Experimental Fishery made in June (i.e., trip 14) also fished on 1 July, the first day that all of Area II was re-opened. On this date, three observed tows were made in the inner triangle of former Closed Area II. Two large hauls of haddock were taken ( $9,000 \mathrm{lb}$ and $3,500 \mathrm{lb}$ ) indicating that high concentrations of haddock still existed in the re-opened area.

Over the entire January-June period, $87(28 \%)$ of the 305 observed tows in Area II eaught no haddock, and in 114 other tows ( $37 \%$ ) haddock catches were 50 lb or less (Table 12). Overall, $93 \%$ of the Area II hauls ( 284 tows) caught less than $500 \mathrm{lb}(227 \mathrm{~kg}$ ) of haddock.

Spatial distributions of haddock catches in individual hauls are presented, by month, in Figure 5. Similar distributions of catch per tow are presented for cod, flounders (yellowtail, winter, American plaice, and witch), white hake, and monkfish in Figures $6-12$. Spatially, these relative density distributions are consistent with those observed in recent NEFSC spring research vessel bottom trawl surveys.

Atter cod (which accounted for $34 \%$ of the Area II catch), the most frequently caught species were skates $(20 \%)$, haddock ( $13 \%$ ), pollock ( $12 \%$ ), yellowtail flounder ( $4 \%$ ), monkfish ( $4 \%$ ), American plaice ( $4 \%$ ), and spiny dogfish (3\%) (Table 8). However, the relative contributions of these species to the overall retained catch was quite different as $90 \%$ of the skates ( $84,159 \mathrm{lb} ; 38.2 \mathrm{mt}$ ) and all of the dogfish ( $13,672 \mathrm{lb} ; 6.2 \mathrm{mt}$ ) were discarded (Tables 10 and 11). As a result, cod accounted for $53 \%$ of the retained catches, pollock for $18 \%$, yellowtail flounder and monkfish for $6 \%$ each, and American plaice for $5 \%$ (Table 9). The Groundfish FMP species accounted for $88 \%$ of the retained catches in Area II.

Fish were discarded for three main reasons. Haddock caught in Area II could not retained under the provisions governing the Experimental Fishery. Spiny dogfish; ocean pout, skates, other fish; and other invertebrates were heavily discarded ( $\mathbf{~} 90 \%$ discard rates: Table 11 ) due to the limited market value of these species to the vessels in the experiment. For the remaining species, discards generally reflected the culling of undersized fish - due to market considerations or existing legal minimum size restrictions.

## Outside Area II

Catches, landings, and discards taken outside of Area II during the Experimental Fishery are summarized by species in Tables 13-15, respectively. Catches by trip are presented in Table 7. A total of 140 tows were observed comprising 466.2 hrs of fishing effort. Expectedly, the temporal distribution of fishing activity outside of Area II differed from that in Area II as the vessels in the Experimental Fishery differentially allocated their fishing activities between the two areas. Fishing effurt outside of Area II was lowest in April (5 tows; 19 hrs fished) (Table 13) - when fishing effort in Area II was highest (Table 8). Highest fishing effort outside of Area II occurred in March (53 tows; 167 hr ) and May ( 36 tows; 126 hrs); during these two months, effort in Area II was similar indicating that vessels divided their fishing activities nearly equally among the two areas.

Catches in observed tows made outside of Area II totaled $135,250 \mathrm{lb}(61.3 \mathrm{mt})$ of which $66 \%(88,875 \mathrm{lb} ; 40.3 \mathrm{mt})$ were Groundfish FMP species and $6 \%$ was haddock ( $8,098 \mathrm{lb} ; 3.7 \mathrm{mt}$ ) (Tables 8 and 13). More than $75 \%(6,189 \mathrm{lb} ; 2.8 \mathrm{mt}$ ) of the haddock caught were discarded (Table 15). As in Area II, cod was the predominant species caught ( $45,272 \mathrm{lb} ; 20.5 \mathrm{mt}$ ), accounting for $35 \%$ of the total catch and $53 \%$ of the Groundfish FMP species catch.

Haddock catches outside of Area II did not exceed 500 lb per trip in the first 11 trips in the experiment (i.e., the trips made between January and mid-May: Table 7). In these trips, haddock catches accounted for about $2 \%$ (range: $0-9.6 \%$ ) of the trip catches taken outside Area II, and for about $2.4 \%$ (range: $0-10.2 \%$ ) of the Groundfish FMP species caught outside Area II (Table 7).

On a monthly basis, haddock catches accounted for less than $4 \%$ of the total catches outside of Area II during January through May (Table 13). Apart from April when haddock CPUE.jseemingly increased [to $16.5 \mathrm{lb} / \mathrm{hr}$ - although this is based on only 5 observed tows), monthly catch rates of haddock prior to June were extremely low (i.e., less than $6.9 \mathrm{lb} / \mathrm{hr}$; less than $24 \mathrm{lb} / \mathrm{tow}$ ) (Table 13)! In June, haddock catches and haddock catch rates outside of Area II sharply increased (Table 13; Fig. 4); more haddock were caught in June ( $5,759 \mathrm{lb}$ ) that in the first five months combined ( $2,339 \mathrm{lb}$ ). This increase was due to two large hauls of haddock in June ( $3,500 \mathrm{lb}$ and $1,000 \mathrm{lb}$ ) made just outside of the Area II boundary.

Of the 140 observed tows made outside of Area II during the experiment, $44 \%$ ( 61 tows) contained no haddock, and in 56 other tows ( $40 \%$ ) haddock catches were 50 lb or less (Table 12). In only two tows did haddock catches outside of Area II exceed 500 lb (i.e., the June tows mentioned above).

The species composition of the catches made outside Area II was similar to that in Area II. Cod accounted for $35 \%$ the total catches followed by skates ( $15 \%$ ), pollock ( $13 \%$ ), monkfish $(9 \%$ ), haddock ( $6 \%$ ), spiny dogfish (4\%), white hake ( $4 \%$ ), and American plaice ( $3 \%$ ) (Table 13). Of the retained catches, cod accounted for $47 \%$, pollock for $17 \%$, monkfish for $12 \%$, and white hake for $5 \%$ (Table 14). Since discarding practices outside of Area II were nearly identical to those inside Area II, species discard percentages were also similar (Tables 11 and 16).

## July 1994 Sea Sampling Trips to Georges Bank

On 1 July, the entirety of Area II (both the expanded area and the inner triangle) was re-opened for fishing. To assess post-opening catch rates of haddock and other Groundfish FMP species, observers were placed on two vessels that intended to fish in the Area II region. Both trips sailed in mid-July and were absent from port for 10-11 days (Table 1). However, one of the trips (i.e, trip i5) fished completely outside of the Area II region targeting cod and flounders, while the second trip (i.e., trip 16) fished completely inside Area II targeting yellowtail (Figure 13).

Within Area II, 37 of 48 tows ( $77 \%$ ) were observed (Table 17); haddock catches in these hauls amounted to only 22 lb , and comprised less than $1 \%$ of the total catch ( $24,792 \mathrm{lb} ; 11.2 \mathrm{mt}$ ). Haddock catches were negligible primarily because the vessel used a trawl designed for catching flatfish. As intended, yellowtail flounder was the principal species caught during the trip, accounting for $45 \%$ ( $11,331 \mathrm{lb} ; 5.1 \mathrm{mt}$ ) of the total catch and $77 \%(10,192 \mathrm{lb} ; 4.6 \mathrm{mt})$ of the retained catches (Table 18). Most of the yellowtail catches were taken in the inner triangular section of Area II (Figure 14). Large quantities of skates were also caught ( $10,178 \mathrm{lb} ; 4.6 \mathrm{mt}$ ), but $90 \%$ of these catches ( $9,258 \mathrm{lb}, 4.2 \mathrm{mt}$ ) were discarded.

In the July trip that fished outside of Area II, 36 of 40 tows ( $90 \%$ ) were observed (Table 17). Groundfish FMP species accounted for $66 \%(12,410 \mathrm{lb} ; 5.6 \mathrm{mt}$ ) of the total catches ( $18,877 \mathrm{lb} ; 8.6 \mathrm{mt}$ ), with cod and American plaice each accounting for $20 \%$ of the total (Table 18). Haddock catches totaled $798 \mathrm{lb}, 4 \%$ of the aggregate catch and $6 \%$ of the FMP species caught. Approximately $25 \%$ of the total trip catch was discarded, consisting mostly of spiny dogfish and skates.

## Size Composition of the Experimental Fishery Catches

During the January-June Experimental Fishery, 9,430 length frequency measurements were made from 13 species. Samples were taken inside and outside of Area II from both the retained catches and the discards. Most of the sampling ( 9,408 fish) focused on nine of the Groundfish FMP species and on monkfish (Table 19); sampling of three additional species was insignificant (halibut: 15 fish; American lobster: 5 individuals; shad, 2 fish).

Sampling of haddock was the top priority. A total of 4,801 haddock were measured, constituting $51 \%$ of all the sampled fish. Within Area II, length frequencies were taken from 3,968 haddock ( 3,884 discards; 84 kept ); outside of Area II, 833 haddock were measured ( 564 discards; 269 kept ) (Fig. 15). The size range of haddock discarded in both areas was similar (Table 19), but large haddock ( $>60 \mathrm{~cm}$ ) comprised a greater proportion of the discards in Area II than outside of Area II. Since, in both areas, nearly all of the haddock caught had to be discarded (i.e., culling was not much affected by the minimum legal size of 19 inches [ 48 cm ]), the larger size composition of the Area II discards indicates that older, mature haddock were proportionally more dominant inside of Area II than outside.

For cod, the principal species caught in both areas, size frequency distributions inside and outside of Area II were virtually identical (Table 19; Fig. 16). Discarded fish ranged from 37 to 49 cm (14.6-19.3 in) and averaged about $42 \mathrm{~cm}(16.5 \mathrm{in})$; retained cod ranged between 47 and 117 cm ( $18.5-46.1 \mathrm{in}$ ) and averaged about $70 \mathrm{~cm}(27.6 \mathrm{in})$. The lack of overlap in sizes between discarded and retained fish reflects culling in accord with the legal minimum size for cod of $48 \mathrm{~cm}(19 \mathrm{in})$.

Size frequency plots for the other eight species sampled (yellowtail flounder, pollock, winter flounder, witch flounder, American plaice, windowpane flounder, white hake, and monkfish) are presented in Figures 17-23. In general, size compositions were similar inside and outside of Area II, with culling consistent with prevailing minimum size regulations (in the cases where these exist) Is marketing demands. Of course, the presence of the scientific observers aboard the Experimental Fishery vessels may have subliminally affected culling practices - particularly for species regulated by minimum size restrictions.

## Impact of the Closed Area II on Haddock and Other Groundfish FMP Species

Enlargement of Closed Area II in 1994 was enacted to protect haddock from being fished during the spawning season when they become concentrated. The closure period was expanded in time to include January to ensure that haddock beginning to aggregate in the area would be provided the fullest protection.

One obvious approach to evaluate the added protection afforded to haddock (and other Groundfish FMP species) by the expanded Area II closure is to examine the Experimental Fishery catch rates inside and outside of Area II. Higher catch rates generally reflect higher densities of fish. Hence, to the extent that catch rates in Area II are higher than those outside, the absence of a fishery in Area II will generate considerable 'savings' of fish beyond those that would have occurred under the pre-1994 closure design.

Overall catch rates (lbs/hr fished) in the Experimental Fishery during the January-June period are presented, by area and species, in Table 4. CPUE values (retained and discard catches combined) in Area II were higher than outside Area II for: (1) all species combined ( 414 vs $378 \mathrm{lb} / \mathrm{hr}$ ); (2) total Groundfish FMP species ( 290 vs $262 \mathrm{lb} / \mathrm{hr}$ ); and (3) for seven of the 13 Groundfish FMP species (hadduck, cod, pollock, yellowtail flounder, winter flounder, American plaice and ocean pout). For the remaining FMP species, CPUE values in the two areas were identical for windowpane flounder and red hake, and only marginally different for witch flounder, white hake, and silver hake. Only redfish CPUE was substantially higher outside of Area II than inside.

Haddock CPUE in Area II was threefold higher than outside Area II ( 53 vs $17 \mathrm{lb} / \mathrm{hr}$ ), cod CPUE was $39 \%$ higher and pollock CPUE was $31 \%$ higher. The catch rate of yellowtail flounder was nearly 3 X greater inside Area II than outside ( $15 \mathrm{vs} 6 \mathrm{lb} / \mathrm{hr}$ ), while the Area II catch rate for American plaice was twice as high as that outside ( $15 \mathrm{vs} 8 \mathrm{lb} / \mathrm{hr}$ ) (Table 4 and Fig. 24).

During January-March, haddock catch rates both inside and outside of Area II were very low ( $<8 \mathrm{lb} / \mathrm{hr}$ ) (Tables 8 and 13; Fig. 4). In April and May, haddock CPUE within Area II was substantially higher than outside the area (April: 30 vs $17 \mathrm{lb} /$ tow; May: 194 vs $7 \mathrm{lb} /$ tow). In June, catch rates of haddock in both areas exceeded $100 \mathrm{lb} / \mathrm{hr}$. As previously mentioned, the high catch rate of haddock in June outside of Area II was due to two large haddock catches made just outside the Area II boundary line.

Within Area II, catch rates of cod and all other Groundfish FMP species (excluding haddock) peaked in April, and were higher than those for haddock in each month but May and June (Fig. 4). Outside Area II, the catch rate of cod peaked in March and cod CPUE was higher than haddock in all months but June.

For other species taken in the Experimental Fishery, catch rates in Area II were generally the same or higher than those outside of Area II - except for monkfish ( $15 \mathrm{vs} 26 \mathrm{lb} / \mathrm{hr}$ ) and wulffish ( 0.4 vs 3.3 lb/tow) (Table 4).

In toto, the generally higher catches rates in Area II compared to those outside of Area II suggest that fish densities were higher inside the closed area than outside. Prohibiting a commercial fishery in the expanded area in 1994 therefore prevented high concentrations of fish from being exploited.

## DISCUSSION

The purpose of the experimental fishery was to monitor the catch and bycatch of cod and haddock in the expanded portion of Closed Area II during January through June 1994. Commercial fishermen indicated that it was possible to prosecute a fishery for mixed groundfish in the newly-expanded portion of the closed area - without catching significant quantities of haddock.

During January through March 1994, haddock catches in the expanded closed area were low ( $1,968 \mathrm{lb}$ in total) accounting for less than $2 \%$ of total Area II catches. During this same time period, $60,478 \mathrm{lb}$ of other FMP Groundfish species were taken in the closed area. Clearly, fishing in these months had little negative impact on haddock.

However, during April through June, haddock comprised $16 \%$ of the total catches in Area II and $22 \%$ of the catch of FMP Groundfish species. In May and June when haddock catches and haddock CPUE were the highest in Area II, haddock comprised $34 \%$ of the total catches and $46 \%$ of the Groundfish FMP species caught. Obviously, had an open fishery for mixed groundfish been conducted in the expanded area during April-June, total haddock catches would have been extremely high.

Traditionally, the period of peak haddock spawning on the northeastern part of Georges Bank is during March and April (Overholtz, 1987). However, the timing and duration of spawning can vary from year to year due to influence of temperature. In 1994, high concentrations of haddock (i.e., $>400 \mathrm{lbs} / \mathrm{tow}$ ) were not detected in the Experimental Fishery until mid-March suggesting that haddock spawning occurred later in 1994 than the traditional pattern. Catches of haddock in tows made in Area II in late June were among the highest observed in the experiment indicating that haddock were still aggregated in early summer.

After 1 July when Area II was re-opened for fishing, large catches of haddock from Area II were reported by commercial fishermen. Observations made from two sea sampling trips conducted in mid-July, however, did not substantiate the existence of large concentrations of haddock - although haddock may have already dispersed by this time. Also, the fishing gear used in the July sea sampling trip to Area II was not optimal for catching haddock.

Since haddock caught in Area II could not be retained, several of the vessels in the Experimental Fishery moved to different fishing locations after haddock were caught. These movements were likely intended to avoid subsequent catches of haddock and reduce culling time. The large catches of haddock taken during the last few trips in the Experimental Fishery prompted some of the vessel captains to suggest that the closure period should be extended further into the summer.

Haddock and cod accounted for $13 \%$ and $34 \%$, respectively, of the total catches taken in Area II. As a group, catches of the 13 Groundfish FMP Species in Area II accounted for $70 \%$ of the overall areal total. Area II catches were thus dominated by species regulated under the Northeast Multispecies Fishery Management Plan. Haddock, cod and yellowtail flounder on Georges Bank are all presently at record-low abundance levels; the haddock and yellowtail stocks have 'collapsed' and an imminent danger exists that the Georges Bank cod stock will soon collapse (NEFSC, 1994). Given that these three species comprised a major fraction of the monthly catches made in Area II during the January-June 1994 Experimental Fishery, maintaining the enlarged Area II seasonal closure in 1995 (and thereafter) is prudent as one component of the suite of conservation measures aimed at eliminating the overfished conditions of these stocks.

## ACKNOWLEDGEMENTS

The authors wish to thank John Kenney of the National Marine Fisheries Service, Northeast Regional Office (NERO), Fisheries Engineering Group, for coordinating vessel logistics and vessel selections. We also thank Peter Colosi, NERO, for his assistance in issuing Exemption Certificates and in providing regulatory guidance. We extend our gratitude and thanks to the scientific observers who collected all of the Experimental Fishery data. Lastly, we are grateful to the captains and vessel owners who participated in the experiment.

## HADDOCK

AREA II

OUTSIDE AREA II

Figure 15. Size frequency distributions of haddock samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted line represents the minimum legal size for haddock of 48 cm .

## COD

AREA II

OUTSIDE AREA II

Figure 16. Size frequency distributions of cod samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted line represents the minimum legal size for cod of 48 cm .

## YELLOWTAIL FLOUNDER

AREA II

OUTSIDE AREA II

Sampled only 2 discarded fish

Figure 17. Size frequency distributions of yellowtail flounder samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted line represents the minimum legal size for vellowtail flounder of 33 cm .

Figure 18. Size frequency distributions of pollock and winter flounder samples (kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted lines represent the minimum legal size for pollock of 48 cm and for winter flounder of 30 cm .

## WITCH FLOUNDER

AREA II

OUTSIDE AREA //

Sampled only 1 discarded fish

Figure 19. Size frequency distributions of witch flounder samples (discards an : $k$ ept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted line represents the minimum legal size for witch flounder of 36 cm

## WINDOWPANE FLOUNDER

Figure 20. Size frequency distributions of windowpane flounder samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II.

AREA //

OUTSIDE AREA II

Figure 21. Size frequency distributions of American plaice samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II. The dotted line represents the minimum legal size for American plaice of 36 cm

## WHITE HAKE

AREA II

Sampled only 2 discarded fish

OUTSIDE AREA I/

Figure 22. Size frequency distributions of white hake samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II.

## MONKFISH

Figure 23. Size frequency distributions of monkfish samples (discards and kept) in the 1994 Experimental Fishery (January-June). Data are from observed tows and are provided separately for samples taken inside and outside of Area II.

Figure 24. Catch per unit of effort (lbs/hr fished) of retained catches and discands for 11 different species taken in the 1994 Experimental Fishery (January-June). Data are from observed tows and are presently separately for Area II and outside of Area II.

Appendix Table 1. Scientific names of species caught in the 1994 Experimental Fishery.

| Haddock | Melanogrammus aeglefinus |
| :---: | :---: |
| Cod | Gadus morhua |
| Pollock | Pollachius virens |
| Yelloutail Flounder | Pleuronecres ferrugineus |
| Winter Flounder | Pseudopleuronectes americanus |
| Witch Flounder | Glyptocephalus cynoglossus |
| Windoupane Flounder | Scopthalmus aquosus |
| American Plaice | Hippoglossoides platessoides |
| Redfish | Sebastes fasciatus |
| White Hake | Urophycis tenuis |
| Red Hake | Urophycis chuss |
| Silver Hake | Merluccius bilinearis |
| Ocean Pout | Macrozoarces americanus |
| Cusk | Brosme brosme |
| Wolffish | Anarhichas lupus |
| Monkfish | Lophius americanus |
| Skates | Raja spp. |
| Spiny Dogfish | Squalus acanthias |
| Other Fish |  |
| Herring | Clupea harengus |
| Mackerel | Scomber scombrus |
| Shad | Alosa sapidissima |
| Alewife | Alosa pseudoharengus |
| Menhaden | Brevoortia tyrannus |
| Butterfish | Peprilus triacanthus |
| Scup | Stenotomus chrysops |
| Bluefish | Pomatomus saltatrix |
| Sculpins | Myoxcephalus spp. |
| Sea Raven | Hemitripterus americanus |
| Fourspot Flounder | Paralichthys oblongus |
| Summer Flounder | Paralichthys dentatus |
| Halibut | Hippoglossus hippoglossus |
| Lumpfish | Cyclopterus lumpus |
| Cunner | Tautogolabus adspersus |
| Tilefish | Lopholatilus chamaeleonticeps |
| Wrymouth | Cryptacanthodes maculatus |
| Buckler Dory (John Dory) | Zenopsis conchifera |
| Lamprey | Petromyzon marinus |
| Marlin-spike | Nezumia bairdi |
| Conger Eel | Conger oceanicus |
| Torpedo Ray | Torpedo nobiliana |
| Shark | Carcharhinus spp. |
| American Lobster | Homarus americanus |
| Other Invertebrates |  |
| Long-finned Squid | Loligo pealei |
| Short-finned Squid | Illex illecebrosus |
| Sea Scallop | Placopecten magellanicus |
| Surfclam | Spisula solidissima |
| Rock Crab | Cancer irroratus |
| Jonah Crab | Cancer borealis |
| Red Crab | Geryon quinquedens |
| Octopus | Ocropus bairdii |

[^0]:    I Scientific names for all species mentioned in the remainder of this paper are given in Appendix Table 1.

[^1]:    ${ }^{2}$ The 13 finfish species covered under the Groundfish FMP are: haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white bake, red hake, silver bake, and ocean pout.

[^2]:    ${ }^{3}$ Other fish were comprised of 20 different species (see Appendix Table 1).
    4 Other invertebrates were comprised of eight different species (see Appendix Table 1).

[^3]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver bake, and ocean pout.
    ${ }^{2}$ Other fish were comprised of 23 different species (Appendix Table 1 ).
    ${ }^{3}$ Other invertebrates were comprised of eight different species (Appendix Table 1).

[^4]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.
    : Other fish were comprised of 23 different species (Appendix Table 1).
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

    - Total catches (retained and discards)/total fishing effort.

[^5]:    ' Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.
    ${ }^{2}$ Six tows on this trip were made on 1 July.

[^6]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.
    2 Other fish were comprised of 23 different species (Appendix Table 1).
    3 Oihor invertohratoc wore romnrised of eipht different snecies (Annendix Table 1).

[^7]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail tlounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.
    2 Other fish were comprised of 23 different species (Appendix Table 1).
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

[^8]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

[^9]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white bake, red hake, silver hake, and ocean pout.

[^10]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1).
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

[^11]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1)..
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

    - Total $=$ total discards during January-June/total catches during January-June.

[^12]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1).
    ${ }^{3}$ Other invertebrates were comprised of eight different species (Appendix Table 1).

[^13]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1).
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

[^14]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1).
    3 Other invertebrates were comprised of eight different species (Appendix Table 1).

[^15]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.
    : Other fish were comprised of 23 different species (Appendix Table 1).
    ${ }^{3}$ Other invertebrates were comprised of eight different species (Appendix Table 1).

    - Total $=$ total discards during January-June/total catches during January-June.

[^16]:    1 From observed tows.
    2 Northeast Multispecies Groundfish FMP Species (13): haddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

[^17]:    1 Thirteen species in Northeast Multispecies Fishery Management Plan (FMP): baddock, cod, pollock, yellowtail flounder, winter flounder, witch flounder, windowpane flounder, American plaice, redfish, white hake, red hake, silver hake, and ocean pout.

    2 Other fish were comprised of 23 different species (Appendix Table 1).
    ${ }^{3}$. Other invertebrates were comprised of eight different species (Appendix Table 1).
