## PELAGIC FISH CCHMITTEE

1982
by
A. Maucorps

## BELGIU:

(R. De Clerck)

No market sampling of pelagic fish has been carried out in 1982 Research vessel surveys with bottom trawl on the two juvenile species were continued as given in the table below. The research is limited to length measurements.

Research vessel surveys.

| Area | Season | Objectives |
| :--- | :--- | :--- |
| IVc | April and | Recording densities of |
| Belgian coast | September | immature herring and sprat |

DENMARK
(Per Sparre)
The following sampling of length and age distributions has been carried out in 1982.

## FINLAND

(R. Parmanne \& V. Sjöblom)

No work was carried out on pelagic fish other than that reported to the Baltic Fish Committee.

## FRANCE

```
(G. Biais, A. Maucorps)
```

En 1982, le laboratoire de Boulogne sur Mer a participé avec deux campagnes au programme international d'évaluation de l'abondance de larves et de juvéniles de hareng en Mer du Nord. Il a été continué l'échantillonnage des débarquements (voir tableaux ci-joints). De plus, il a été effectué un suivi de la flottille industrielle en sud Mer du Nord et Manche est dans le but d'etudier l'effort de peche.

## SPECIES AND SPECIES GROUPINGS

## ALEWIVES AND BLUEBACK HERRING

The National Marine Fisheries Service's (NMFS) Northeast Fisheries Center (NEFC) updated information on catch and abundance of alewives and blueback herring in support of a regional fishery management plan being developed by the Atlantic States Marine Fisheries Commission (ASMFC).

The Maine Department of Marine Resources (MDMR) completed a 3-year study of the alewife population of Damariscotta Lake. The study centered on relationships between escapement and subsequent timing, abundance, and size of emigrating fry.

The Virginia Institute of Marine Science continued its studies of the alewife and blueback herring fishery in Virginia's three major river systems: York, James, and Rappahannock.

## AMERICAN AND HICKORY SHADS

The NEFC updated information on catch and abundance of American and hickory shads in support of a regional fishery management plan being developed by the ASMFC.

The Maryland Department of Natural Resources continued its survey of the production of juvenile American and hickory shad in upper Chesapeake Bay.

The Connecticut Department of Environmental Protection continued its study of the fishery and juvenile population of American shad in the Connecticut River.

The MDMR examined the feasibility of transplanting American shad to several rivers in that state.

## ATLANTIC HERRING

The NEFC prepared an assessment update for Atlantic herring stocks in the Gulf of Maine for input to a new fishery management plan being developed jointly by state and federal agencies.

The NEFC is preparing an analysis of environmental influences on herring recruitment in the Gulf of Maine.

A combined bottom trawl-hydroacoustic survey was conducted from Maine to Maryland during February by the NEFC's R/V Delaware II to study the winter distribution of herring by age classes.

The MDMR conducted herring tagging research, and continued a larval monitoring program in coastal Maine waters. Additionally, the MDMR initiated a larval aging program. The MDMR also conducted studies on herring fecundity and herring parasites, respectively, cooperatively with the University of Maine and the NEFC.

## ATLANTIC MACKEREL

The NEFC provided an assessment of the status of the Northwest Atlantic mackerel stock (North Carolina to Newfoundland) for use in amending the fishery management plan for 1983-84.

The NEFC, in cooperation with the Polish Sea Fisheries Institute in Gdynia, conducted a mackerel survey/fishery in the area between Georges Bank and Cape Hatteras, North Carolina, during January-April 1982 using two Polish commercial trawlers, the F/V Admiral Arciszewski and the F/V Kanaryjka. The objectives of this survey/fishery were to: locate and fish on overwintering concentrations of mackerel; collect age, length, and other biological data on mackerel; collect catch-per-unit-of-effort (CPUE) data; monitor bycatch of other species; and collect hydroacoustical data on mackerel schools.

As part of the biological program on mackerel, intensive sampling aboard the Admiral Arciszewski included blood smears and kidney and spleen tissue imprints for cytogenetic and hematozoan studies, gonadal and somatic tissues for contaminants analysis, ectoparasites for identification of potential disease vectors, and observations of external and internal lesions. Samples collected aboard the Polish vessel, as well as other later in the year both from inshore USA waters and off Canada, were analyzed.

Experimental laboratory studies were begun by the NEFC. Adult mackerel were captured and held in aquaria for spawning. Growth studies will be conducted on laboratory-spawned larvae.

Plans were developed for conducting a joint USA-Poland mackerel research survey and fishery during January-April 1983 in the Georges Bank-Cape Hatteras area.

An age-validation study on mackerel was conducted by the NEFC. Mackerel samples were collected from research and commercial catches in USA waters and provided to Canada for a meristic/morphometric analysis on mackerel. The NEFC prepared a report on the use of commercial CPUE data in assessing the mackerel stock.

BLUEFIN TUNA
Stock assessment reports on Atlantic bluefin tuna (as well as blue marlin, white marlin, and sailfish) were prepared by the NMFS Southeast Fisheries Center (SEFC) for the 1982 ICCAT meeting and related international discussions.

An ichthyoplankton survey was conducted by the SEFC, and the data gathered were used to estimate the spawning population of bluefin tuna in the Gulf of Mexico.

BLUEFISH
The NEFC updated information pertaining to survey abundance indices for young-of-the-year and catch statistics.

The State University of New York at Stonybrook began a study of seasonality in the offshore distribution of bluefish, based on surveys conducted by the NEFC.

BLUE MARLIN, WHITE MARLIN, SAILFISH, AND SWORDFISH
Stock assessment reports on swordfish and other billfish species were prepared for a stock assessment workshop held at the SEFC in August 1982. The workshop report will be published in 1983.

Japanese longline catch-and-effort statistics for swordfish were used by the SEFC to estimate annual effective fishing intensity by the Japanese fleet in the Atlantic Ocean. Because of difficulties in estimating total catch, no total stock assessment was attempted. The CPUE was considered an index of local availability.

As part of the NEFC's (in cooperation with the Woods Hole Oceanographic Institution) research on large pelagic fishes a number of experiments were conducted in which transmitters were attached to billfish, sharks, or tunas, allowing them to be followed in course and depth as they swam free in the open ocean.

BUTTERFISH
The NEFC prepared an assessment of the status of butterfish for use in amending the fishery management plan for 1983-84.

## KING MACKEREL

Research in this program is designed to support the Gulf of Mexico and South Atlantic Fishery Management Plan for Coastal Pelagics, which was implemented in 1983. Studies in 1982 concentrated on quantitative information for use in stock assessment. The possible effect of environmental variables on recreational catches was also explored. The state of current knowledge on king mackerel stocks in the southeastern USA was one topic of discussion at a stock assessment workshop held at the SEFC in August 1982.

## LARGE SHARKS

In 1982, a total of 4,553 sharks and teleosts were tagged under the NMFS Cooperative Shark Tagging Program. These represented 36 species of sharks and seven species of teleosts. Of the total number of fish tagged, rod-and-reel fishermen accounted for 44\%; USA longline fishermen, 11\%; USA fishery observers on foreign vessels, $17 \%$; USA R/V Geronimo, $15 \%$; Polish R/V Wieczno, $10 \%$; and the remaining $3 \%$ were released by NMFS biologists.

A total of 139 tags from 18 species were returned in 1982. These came from blue (66), mako (15), sandbar (10), tiger (9), lemon (8), dusky (6), other sharks (20), and teleosts (5). The categories of fishermen who returned tags in 1982 were: USA sportsmen, $41 \%$; USA longliners, $24 \%$; other USA fishermen, $5 \%$; foreign longliners, $21 \%$; and other foreign fishermen, $9 \%$. In the latter categories, tags were returned by fishermen from 15 countries including Japan (11), Mexico (5), Korea (5), Cuba (5), Spain (3), Taiwan (2), Canary Islands (2), Canada (1), West Indies, Bermuda, and Bahama Islands (5), and others (3).

Age and growth of the sandbar shark were estimated by the NEFC from rings in the vertebrae, tagging data, and size-frequency distributions.

The NEFC estimated the USA recreational catch of sharks in the Atlantic. Several past national surveys were examined and it was decided that the most recent survey, directed specifically at sport fishing for billfish and sharks, provided the "best available data" on the number of sharks caught (dogfish were excluded).

ROUND SCAD
A 3-yr sampling project by the SEFC for round scad was completed in 1982. The samples will be used for biological and ecological research. Electrophoretic studies on round scad were initiated in 1982. Investigations on food habits will begin in 1983.

## SPINY DOGFISH

The Virginia Institute of Marine Science completed a study on the life history of the spiny dogfish off the northeastern USA.

## STRIPEU BASS

Monitoring of striped bass stocks off the northeastern USA continued with funds provided through the Emergency Striped Bass Study. Monitoring included characterization of the fisheries and young-of-the-year abundance surveys. Examination of feeding ecology, starvation indices, contamination, and predation in larval populations continued in Chesapeake Bay and Albemarle Sound.

The NEFC conducted a study that related juvenile production to subsequent catch in coastal fisheries and begn automating tagging records of the American Littoral Society.

## AGE DETERMINATION

#### Abstract

An international workshop on "Age Determination of Oceanic Pelagic Fishes--Tunas, Billfishes, and Sharks" was held at the SEFC in February 1978. There were 63 scientists in attendance from 10 states in the continental USA and Hawaij, three provinces in Canada, France, Senegal, Spain, Mexico, Ivory Coast, and New South Wales (Australia). The meeting started with two general overview papers, one on statistical characteristics of aging data for population analysis and another that reviewed age and growth assessment.

The section on tunas addressed age determination of various life stages of six species of scombrids. Examples of aging techiques included: otolith microstructure of young-of-the-year; vertebrae, otolith, and fin-spine analyses of adults and juveniles; stochastic age-frequency estimation using the von Bertalanffy growth equation; and tetracycline and tag-recapture validation of age estimates.

There were three separate papers on: aging swordfish using otoliths and anal spines; age estimation of sailfish from dorsal spines; and a review of anatomical characteristics of otoliths from seven species of billfishes and their potential use as aging structures. A general paper reviewed aging techniques used on California elasmobranchs, while other papers covered silver-nitrate staining of vertebrae, x-radiography, tagging, and lengthfrequency analysis to estimate age as a means to validate age estimates of sharks using vertebrae from several species.

Subjects covered by round-table discussions included age validation, back-calculation of length from growth bands on skeletal hardparts, ring-

counting techniques, and the use of silver nitrate in combination with tetracycline to age sharks. The majority of participants agreed that the lack of validation of age estimates or means to accomplish the same is one of the most serious problems in assessing the age and growth of fishes, particularly oceanic pelagics. The proceedings of the workshop will be published as a NOAA Technical Report in late 1983.

## ECOSYSTEM MODELING

The NEFC continued to investigate the apparent deficit in zooplankton and pelagic fish production per unit of primary production on Georges Bank relative to other ecosystems like the North Sea. Using a logistic model, the effect of water-residence time on primary and zooplankton production and larval fish loss rates was compared to a system without advective loss. The results indicate that the differences in secondary production may be largely accounted for by the advective loss of organisms, since their generation time approaches the residence time of water on the Bank. The NEFC also examined the relation between survival of larvae and 0 -group fish and entrainment of shelf water by warm-core rings, ekman transport, and position of the shelf/slope front. On the time and spatial scale of the available data for seven years, there was no correlation between these physical processes and survival during the first year of life and subsequent year-class strength.

Work continued by the NEFC on a mutlispecies model with increased emphasis on the role of pelagic predators such as spiny dogfish and squid on the survival of fish during the first year of life. Stomach analysis of spiny dogfish has shown significant increases in the occurrence of juvenile Atlantic mackerel in recent years, probably a result of their increased abundance.

## POLLUTANT IMPACTS

The NEFC developed a description of the fish and fisheries that could be impacted by the disposal of chemical wastes from the highly industrialized New York-New Jersey area. The disposal currently occurs at Deepwater Dumpsite 106--106 nautical miles ( nm ) from Ambrose Lightship and 90 nm east of Cape Henlopen, Delaware. Some of the species at risk are spiny dogfish, blueback herring, alewives, Atlantic mackerel, butterfish, yellowfin tuna, big-eye tuna, albacore, white marlin, blue marlin, and swordfish.

## U.S.S.R.

## (A. Seliverstov \& V. Shleinik)

In 1982 the pelagic fish specialists of the PINRO laboratory continued their investigations of the biology of the Barent Sea capelin and polar cod, the Norwegian Sea blue whiting, Atlantic mackerel and herring.

Pelagic fish stock conditions, their migrations, conditions favouring the formation of commercial fish concentrations were studied on the basis of the results of observations on the distribution and behaviour of fish, analyses of stocks,age/length compostion, acoustic survey data obtained during the cuises of the R/Vs"Persey-III", "Alaid", "I. Spiridonov", Menzelonsk", and "Nagorsk".

Observations on migrations of the Barent Sea capelin to the shores for spawning were carried out by the R/Vs "Persey-III" and "Nagorsk" in February - March.

An ichthyoplankton survey of polar cod was carried out by the R/V"Menzelinsk" to study its spawning efficiency in April - July.

Studies of the Norwegian Sea larval herring and the Barent Sea capelin were carried out by the R/V "Alaid" in April - June.

In August - September the O-group survey of the Barent Sea and Spitsbergen area on commercial fish was undertaken jointly with Norwegian scientists. In September - October capelin and polar cod stock assessments were made.

During the whole year a collection of biological data on blue whiting with acoustic surveys were carried out simultaneously in the Norwegian Sea. In August, the Soviet R/V "Persey-III" took part in the international survey of blue whiting on feeding grounds.

A collection of biological data on Atlantic mackerel of the Norwegian Sea was carried out by research vessels simultaneously with that of blue whiting inverstigations in the summer period.
Similar studies will also be continued in 1983.

In 1982, for the study of the biology of commercial fish the following material was collected by AtlantNIRO specialists.

SAMPLING
Species: Mackerel

SPECIES: Blue whiting

In 1982, the RV "Korifena" participated in the International Young Fish Survey of the North Sea.

RESEARCH VESSEL SURVEYS

| Area | Date | Objectives |
| :---: | :---: | :---: |
| IV | 31 Jan. -10 Feb. | Young fish abundance survey |
