Report of Activities

## PELAGIC FISH COMMITTEE

by
A. Maucorps

1983

## BELGIUM

(R. DE CLERCK)

No market sampling of pelagic fish has been carried out in 1983. Research vessel surveys with bottom trawl on the juvenile herring and sprat were continued as given in the table below.

The research was limited to length measurements.

Research vessel catches

## OBJECTIVES

International Young Fish Survey
Recruit Trawling Survey
Larval Survey Acoustic and Trawling Survey
Acoustic and Trawling Survey ${ }^{2}$
Larval Survey ${ }^{1}$
Larval Survey, 1
Larval Survey
Larval Survey
Recruit Trawling Survey
Acoustic Trawling Survey

Notes: 1. In accordance with previous ICES resolutions. 2. In accordance with C. Res. 1980/2:24.

Additional Research Activities

1) Continued evaluation of coded microwire tags in accordance with C. Res. 1980/2:25.
2) Continuation of herring parasitological work with a view to using parasitological data for studying models of migration.

## Tagging

No releases of spurdog were made in 1983. Returns from experiments carried out in 1977-1982 continued with the bulk of returns coming from VIa, the main release area.

## USA

(R. C. Hennemuth)

## SPECIES AND SPECIES GROUPINGS

## ATLANTIC HERRING

The National Marine Fisheries Service's Northeast Fisheries Center (NEFC) prepared an assessment update for Atlantic herring stocks in the Gulf of Maine and for the Cape Hatteras-Nova Scotia region. An evaluation of abundance indices based on research vessel surveys (NEFC and Massachusetts Division of Marine Fisheries), estuarine sampling, and larval herring surveys (Maine Department of Marine Resources) was made and incorporated into the assessment.

A winter survey was completed by NEFC vessels R/V ALBATROSS IV and R/V DELAWARE II during February to study relative year-class strength and distribution patterns.

One-year-old herring were tagged, and an attempt was made to tag spawning herring. Maine Department of Marine Resources and NEFC scientists also continued cooperative studies to evaluate incidence of herring parasites and their use as natural tags. The University of Massachusetts, in cooperation with NEFC, is undertaking stock-identification studies using biochemical methods and morphometric studies.

## ATLANTIC MACKEREL

The NEFC provided an assessment of the status of the Northwest Atlantic mackerel stock (North Carolina to Newfoundland) for use in amending the fishery management plan for 1984-85.

The NEFC, the Polish Sea Fisheries Institute (Gdynia), and the GRYF Deep Sea Fishing Company (Szczecin) cooperated in conducting a research fishery for mackerel during February-May 1983 between Georges Bank and Cape Hatteras, North Carolina. Two Polish factory stern trawlers and the R/V WIECZNO were used in this program.

The NEFC prepared a report on Atlantic mackerel mutation (micronuclear) frequencies in fish sampled in 1982 from Long Island Sound and from several areas in offshore waters. Pathobiological samples collected in 1982 and 1983 from the Polish vessels and from several inshore areas have been analyzed to determine the rate of incidence of hemoparasites and possible vectors. Some mackerel were held in the laboratory for several months to determine the effects of stress on infected fish.

## BUTTERFISH

The NEFC prepared an assessment of the status of butterfish for use in amending the fishery management plan for 1984-85.

## SPINY DOGFISH

Work is in progress at the NEFC to prepare a first analytical assessment of the status of spiny dogfish off the northeastern coast of the USA.

ALEWIVES, BLUEBACK HERRING, AND SHADS
The Atlancic States Marine Fisheries Commission completed a profile of biological, fisheries, and management infomation pertaining to East Coast stocks of these species.

The Maine Department of Natural Resources initiated a new study of alewife reproduction in several Maine lakes.

The Virginia Institute of Marine Science completed a feasibility study for expansion of spawning habitat for anadromous fishes (including alewife, river herring, shads, and striped bass) by constructing fish passage facilities on low-head dams.

The Connecticut Department of Environmental Protection completed studies on feeding dynamics and mortality of larvai American shad in the Connecticut River. They are also examining the relationship between catch per unit effort and stock abundance, and between spawning escapement and subsequent year-class strength.

## BLUEFISH

The NEFC prepared an assessment of bluefish stocks, conducted experiments on feeding behavior of bluefish, and began a voluntary bluefish data collection system with the cooperation of angling clubs in the New York metropolitan area.

The State University of New York at Stony Brook continued examination of the offshore distribution of bluefish, based on NEFC survey data.

## STRIPED BASS

The National Marine Fisheries Service and the US Fish and Wildlife Service continued monitoring the age, sex, and stock composition of the commercial fisheries by gear and location, assessment of annual production of juveniles in
the major spawning rivers, and sampling spawning populations to obtain age, sex, and fecundity data. Experimental studies determine the effects of contaminants and contaminant mixtures on early life-stage survival, effects of sewage-treatment practices on nutrient availability to striped bass larvae, feeding ecology of striped bass Tarvae, and predation on striped bass larvae by other fish species.

## BLUEFIN TUNA

The Southeast Fisheries Center (SEFC) updated its assessment of the stactus of Atlantic bluefin stocks by developing adjusted catch-per-unit-ofeffort (CPUE) indices of stock abundance for recruits and adults based on coastal rod and reel fisheries and high-seas longline fisheries data. A sample survey was carried out to estimate the magnitude of juvenile fish caught by the rod and reel sport fishery and as a bycatch of the purse seine skipjack fishery, and to establish CPUE for rod and reel fisheries. An ichthyoplankton survey was carried out in the Gulf of Mexico spawning grounds, thus continuing the time-series of those data.

BLUE MARLIN, WHITE MARLIN, SAILFISH, AND SWORDFISH
Stock assessment emphasis by SEFC was placed on sailfish assessment in the Western Atlantic Ocean. The appropriateness of various growth models was investigated, mortality rates were estimated, and a yield-per-recruit analysis was conducted.

In cooperation with the State of New Jersey, the SEFC carried out a census survey to estimate the number of Atlantic blue marlin and white marlin caught by US recreational fishermen during 1983. The survey was conducted along the US eastern seaboard, in the Gulf of Mexico, and in Puerto Rico and the Virgin Islands.

## KING MACKEREL

Mark-recapture data were analyzed to examine the movement of individuals between the Gulf of Mexico and the Atlantic Ocean. Total and fishing mortality rates were also estimated by area and year from those tagging data. Temporal changes in size-frequency samples were investigated as an index of changes in exploitation levels. Yield-per-recruit simulations were used to discern possible methods of maximizing yield, and the current status of exploitation levels compared to the maxima. Catch and effort data were used to estimate maximum sustainable yield.

## SHARKS

The NEFC has implemented a data processing system to analyze tag-return and length/weight records from over 100,000 Atlantic sharks, tunas, and swordfish, and to summarize longline catch records for sharks and swordfish taken by research and commercial vessels over the last 20 years. Ongoing research emphasizes the population structure, migratory behavior, age and growth, food habits, and reproductive habits of several species of large sharks.

## AGE DETERMINATION

Dorsal spines and otoliths (sagittae) from blue marlin and white marlin were collected from catches in the Western Atlantic Ocean, Caribbean Sea, and Gulf of Mexico, to see if these structures could be used as a source of age-and-growth information (see 1983 Int. Comm. Conserv. Atl. Tunas Working Doc. SCRS/83/65). Methodologies were developed for sectioning dorsal spines, polishing otoliths, and taking measurements of these two skeletal structures.

Five different approaches were employed to determine the accuracy of age estimates: (1) scanning electron microscope techniques to examine otoliths from juvenile marlin to count daily growth bands; (2) collecting skeletal structures from tag-return marlin where age can be closely approximated from tagging records; (3) determining the month(s) of band formation from collections taken throughout the year; (4) determining the degree of agreement between counts of bands in two different skeletal structures from the same fish; and (5) applying radiochemical techniques for dating skeletal structures.

## ECOSYSTEM STUDIES

The NEFC refined and augmented the energy budget for Georges Bank to include production estimates for pre-recruit fishes and production-biomassconsumption estimates for top predators in the ecosystem (large pelagic sharks and fishes, marine mammals and birds).

The NEFC conducted stomach sampling of major fish predators on the New England shelf, including a special series with focus on incidence of fish larvae in mackerel guts.

USSR
(A.S. SELIVERSTOV)

In 1983 researches on the biology of Atlanto-Scandian herring and blue whiting in the Vorwegian Sea, of blue whiting to the north of Ireland, mackerel in the Bay of Biscay, of capelin and polar cod in the Barents Sea were continued.

The state of stocks, distribution peculiarities,size and age compositions of fish were investigated during the cruises of the RVs "Perseus--III", "Alaid", "menzelinsk", "Kapitan Demidov", "IVkolai Kononov" and scouting vessels.

In March-inay the acoustic survey was performed by the KV "Perseus-III" to assess blue whiting at the spawning grounds. In August the same research vessel participated in the international survey aimed at assessing the blue whiting stocks in the Norwegian Sea under the programme of ICES Pelagic Fish Committee. As in previous years the oceanographic survey of the Norwegian and south Greenland Seas was performed jointly with the Icelandic experts.

The 0-group commercial fishes were surveyed in the Barents Sea and adjacent waters together with the Norwegian scientists in August-September. The acoustic capelin survey was undertaken in September.

The results of the researches have become the base for the ICES Working Groups to recommend the total allowable catches of pelagic fishes for future time.
