## 1. INTRODUCTION

### 1.1 Terms of Reference and Main Task

At the ICES Statutory Meeting in 1990 the Council adopted the following resolution (C. Res. 1990/2:5:6):
"The Study Group on the North American Salmon Fisheries (Chairman: Dr. P. J. Rago, USA) will meet in Leetown, West Virginia, USA from 25 February - 1 March 1991 to prepare the relevant data for presentation to the Working Group on North Atlantic Salmon at its meeting in March 1991."

The agenda for the meeting is in Appendix 1 and a list of working papers reviewed at the meeting is in Appendix 2.

| D. Reddin | Canada |

## 2. THE FISHERIES AND STATUS OF STOCKS

### 2.1. United States of America

2.1.1 Desribe events of the 1990 fisheries with respect to gear, effort, and composition and origin of catch.

The sport catch (number of fish killed) of Atlantic salmon in Maine in 1990 was as follows:

| River | Number of Atlantic Salmon |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1SW | 2SW | 3SW | P.S | Total 1990 | $\begin{array}{r} \text { Tota1 } \\ 1989 \end{array}$ |
| St. Croix | 2 | (gri | only) |  | 2 | 7 |
| Dennys | 1 | 31 | 0 | 1 | 33 | 12 |
| E. Machias | 1 | 46 | 0 | 1 | 48 | 31 |
| Machias | 0 | 2 | 0 | 0 | 2 | 16 |
| Pleasant | 0 | (gri | only) |  | 0 | 0 |
| Narraguagus | 1 | 49 | 0 | 1 | 51 | 39 |
| Union | 0 | 0 | 0 | 0 | 0 | 4 |
| Penobscot | 45 | 348 | 12 | 11 | 416 | 368 |
| Ducktrap | 0 | 3 | 0 | 0 | 3 | 0 |
| Sheepscot | 1 | 8 | 0 | 0 | 9 | 5 |
| Kennebec | 1 | 45 | 0 | 0 | 46 | 2 |
| Saco | 0 | 16 | 0 | 0 | 16 | 3 |
| Other (Marine) | 0 | 1 | 0 | 0 | 1 | 0 |
| Total | 52 | 549 | 12 | 14 | 627 | 487 |

Recreational catches of Atlantic salmon were about $30 \%$ higher in 1990 than in 1989. The increased catch was attributed to increased effort as evidenced by higher sales of licenses (Table 1), excellent angling conditions and, in some instances, larger runs of salmon. The number of salmon caught and released in Maine rivers exceeded the number caught and killed. The only new management measure instituted in 1990 was the reopening of the Pleasant River to grilse-only angling.

### 2.1.2 Status of USA Stocks

The status of Atlantic salmon in USA rivers was assessed by utilizing Maine and documented adult returns and estimated spawning escapements for New England rivers, angling catches and juvenile salmon releases.

Long-Term Angling Catches
Angling catches in Maine rivers in recent years were as follows:

| Years(s) | Rivers with Wild Salmon Runs |  |  |  |  |  | Penob. River | A11 Others | Grand <br> Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Na | Ma | EM | De | Sh | Total |  |  |  |
| 1990 | 51 | 2 | 48 | 33 | 9 | 143 | 416 | 68 | 627 |
| 1989 | 39 | 16 | 31 | 12 | 5 | 103 | 368 | 16 | 487 |
| 1988 | 35 | 8 | 14 | 9 | 1 | 67 | 179 | 13 | 259 |
| 1987 | 7 | 4 | 14 | 1 | 15 | 71 | 184 | 27 | 282 |
| 1967-1986 Av. | 77 | 48 | 25 | 49 | 17 | 216 | 229 | 41 | 48 |

$\mathrm{Na}=$ Narraguagus, $\mathrm{Ma}=$ Machias, $\mathrm{EM}=$ East Machias, De = Dennys,
Sh = Sheepscot
Catches in 1990 in Maine rivers with salmon runs that are primarily of wild origin increased but were $44 \%$ below the long-term average. Angling conditions in the Penobscot River were excellent with favorable flows and temperature prevailing throughout the fishing season. Numbers of fish killed increased in proportion to the run size (8\%) but the estimated number of fish caught and released increased by 35\% (500 in 1989 to 675 in 1990).

## Spawning Escapement, Broodstock Collection, and Egg Take

Egg sources for the New England Atlantic salmon program came from sea-run salmon, captive salmon broodstock, and reconditioned kelts. Broodstock collections in Maine included 543 MSW salmon from Penobscot River and 20 from the Union River. On the Merrimack River 226 salmon were captured for the broodstock program. For the Connecticut River 36 salmon for broodstock were taken from the Leesville trap, 37 from the Rainbow trap, and 170 from the Holyoke trap.

Salmon entering a counting/trapping facility, yet allowed to proceed upstream, included 18 on the Connecticut, 16 on the Merrimack, 2 on the Pawcatuck, and 869 on the Penobscot rivers.

Total observed counts, including hatchery broodstock, of Atlantic salmon at fishway traps were:

| River (Target:MSW Females) | Year Size | Total Run <br> (both sexes) | No. MSW <br> Females |
| :--- | :---: | :---: | :---: |
| Penobscot River (Target: 3,000) | 1985 | 3,356 | 1,400 |
|  | 1986 | 4,529 | 1,750 |
|  | 1987 | 2,510 | 858 |
|  | 1988 | 2,855 | 1,002 |
| Merrimack River (Target: 1,537) | 1989 | 3,087 | 972 |
|  | 1990 | 3,341 | 1,219 |
|  | 1985 |  |  |
|  | 1986 | 214 | 105 |
|  | 1987 | 103 | 53 |
|  | 1988 | 65 | 62 |
|  | 1989 | 84 | 33 |
| Connecticut River (Target: 4,076) | 1990 | 248 | 41 |
|  |  |  | 385 |
|  | 1986 | 310 | 134 |
|  | 1987 | 318 | 153 |
|  | 1988 | 353 | 170 |
|  | 1989 | 95 | 193 |
|  | 1990 | 109 | 59 |
|  |  | 263 | 57 |
|  |  |  | 147 |

In 1990 approximately 5.4 million juvenile Atlantic salmon were released into 15 rivers of New England. This total is nearly equal to the number of juveniles released during the previous year (roughly 5.5 million juvenile salmon). The Connecticut, Merrimack and Penobscot rivers received the greatest share of the total; $38 \%, 21 \%$, and $19 \%$, respectively. The stocking of salmon fry constituted over $50 \%$ of the releases.

Increasing numbers of hatchery reared Atlantic salmon fry, parr and smolts have been released in Maine rivers in recent years. Numbers released have more than tripled in the last 10 years (Table 2).

## Total Documented Adult Returns

Documented Atlantic salmon returns to rivers in the United States totalled 4,442 in 1990 (Table 3). This figure is $23 \%$ greater than that recorded for 1989. Significant increases in run sizes occurred in the Connecticut, Merrimack, Androscoggin, and Saco rivers. The increases for these four rivers amounted to 539 salmon. Moderate increases were observed in most other rivers except for three, the Union, Machias, and St. Croix rivers, where decreases were observed.

It is important to realize that Table 3 represents minimum documented salmon returns, defined as fish counts at traps associated with fish passage facilities and rod catches (fish killed) downstream from the traps.

In contrast, estimates of run size in rivers without trapping facilities are computed by dividing reported angling harvest by the product of the reporting rate of $80 \%$ and long-term exploitation rate of $20 \%$. In years of low abundance, small variations in reporting rate or low reported catches
can yield erroneously low estimates of run size. In some instances, redd counts have indicated many more salmon than the catch-based estimates. The Study Group examined a regression between population estimates derived from redd counts and angler catches. For rivers in which the redd counts were complete, the regression had a significant positive intercept ( $\mathrm{P}<0.05$ ). This indicates that population abundance estimates from angling catches may be imprecise when total catches are low. The relationship between numbers of spawners and redd counts remains to be validated. Until that can be done, the Study Group concluded that changes to the population estimation methodology for the harvest model ( $\operatorname{Sec} 2.2 .4 .1$ ) were not warranted.

## Summary of Status of Stocks-US Rivers

While the total number of juvenile salmon stocked in 1990 remained the same as in 1989, there was an increase in the numbers of fry and smolts and a decrease in parr. The numbers of smolts marked with coded wire tags $(200,000)$ and Carlin tags $(50,000)$ released into Maine rivers did not change from 1989 releases. In recent years, greater emphasis has been placed on fry releases in all US programs.

Recorded returns of adults were higher in 1990 than in 1989 in most US rivers. The Study Group also noted that the number of wild-origin salmon in the Penobscot River has been increasing in recent years for both one and two sea-winter salmon (Table 4). The percent of wild salmon in Penobscot River trap counts has increased from less that $1 \%$ in 1981 to over $8 \%$ for 2SW in 1990 (Fig 1). Increases for 1 SW salmon have been even greater ( $17 \%$ wild in 1990).

### 2.1.3 Exploitation Rate in USA Fisheries

The angling exploitation rate on combined age classes in the Penobscot River for 1990 (13.0\%) was the same as for 1989 (12.6\%). Estimates are based upon the fish passage efficiency (.85) and reporting rates (.80) used in Section 2.2.4.1 (Anon 1990a).

### 2.2 Canada

### 2.2.1 Describe events of the 1990 fisheries with respect to gear and effort.

Two new management measures were introduced in the Newfoundland and Labrador commercial fisheries in 1990:

1) Quotas by Salmon Fishing Area (SFA) (Fig. 2) were introduced in the Newfoundland commercial salmon fishery. The quotas in 1990 are shown in Table 5. Salmon Fishing Area 1 had an allowance of 80 t . An allowance is an estimate of expected catch and not a limitation on allowable harvest. Monitoring of the quotas was conducted by Fisheries Officers who were in contact with buyers and fishermen on a weekly or daily basis.
2) Caution Notices were moved seaward on many major salmon rivers in Newfoundland. Commercial fishing, for any species, is prohibited inside (towards the river) these Caution Notices. Caution Notices were moved outward to increase spawning escapement in specific rivers and to reduce commercial harvest on salmon stocks when salmon are "staging" in or near the estuaries during periods of low river discharge. Fishing
effort was displaced to berths further out in the bays. It is not possible to quantify the effects on the harvests outside the Caution Notices.

Along the Quebec North Shore, the opening of the commercial fishing season, previously 1 June, was delayed by 10 days in Q7 and Q8 and by 1 month in Q9 (Fig. 2). Total quota in numbers was reduced by $12 \%$ to 29,605 salmon. Commercial fishing was prohibited within a 500 m zone from the mouth of the rivers.

A more detailed description of other aspects of the commercial fisheries was provided in Anon (1985) and updated annually by the Working Group (Anon, 1986a,b, 1987, 1988a, 1989a,b, 1990a,b).

The total salmon landings for Canada in 1990 were 870 t (Table 6); this is the lowest recorded landing in the 1960-90 data set. The landings of small salmon ( 405 t) in 1990 were $26 \%$ below the 1989 landings ( 549 t) and $41 \%$ below the previous 5-year mean ( 686 t ). The landings ( 465 t ) of large salmon in 1990 were 21\% below the landings of large salmon in 1989 and $34 \%$ below the previous 5 -year mean ( 699 t ). Of the total Canadian landings by weight, $17 \%$ were in Quebec, $74 \%$ in Newfoundland and Labrador, and $9 \%$ in the Maritimes. The recreational fisheries harvested $22 \%$, commercial fisheries $74 \%$, and Native fisheries harvested $4 \%$ of the total landings by weight. The decline in total commercial landings from 1,596 t in 1987 to 652 t in 1990 was spread over all Salmon Fishing Areas of Newfoundland and Labrador and the Quebec North Shore (Table 5). Landings in Newfoundland and Labrador of $586 t$ were the lowest of a 20 -year data set (1971-90) (Table 7). In Newfoundland and Labrador in 1990 3,194 fishermen were licensed to fish 12,758 units of gear ( 1 unit $=50$ fathoms of gill net or salmon trap), (Table 8). There are $37 \%$ fewer fishermen and $35 \%$ less gear units licensed to fish salmon than in 1983. Total recreational effort in 1990 of 325,00 rod-days was about the same as in 1989.

A description of the commercial, recreational and Native fisheries in 1990 in Atlantic Canada, are provided by SFA (Fig. 2) in Tables 9, 10, and 11, respectively. The most significant change in the fisheries from the description reported for 1989 (Anon, 1990a) was the imposition of quotas in the commercial fisheries for SFAs $2-14$ which resulted in early closure of the commercial fisheries in SFAs $4,5,6,8,10,11,13$, and 14 . Fifty percent of the licensed salmon fishermen are in SFAs 2, 3, 4, 14. About $45 \%$ of the angling effort was in SFAs 16 to 23 . The landings in the commercial (in numbers and weight), and angling fisheries (in numbers) in 1990 by SFA and comparisons to the mean landings $1984-89$ are provided in Tables 12,13 , and 14 , respectively. Historical commercial and recreational landings are presented in Fig. 3. Additional analyses of the 1990 quota are contained in Section 3 and Appendix 3.

The commercial landings of small and large salmon, by weight, declined from the mean landings 1984-89 throughout Newfoundland and Labrador SFA 1 to 14 (Table 13). The early closure in SFAs 4, 5, 6, 8, 10, 11, 13, and 14 contributed to the decrease in landings. However, low abundance of salmon also appears to be a contributing factor, particularly in SFAs 1,2 , and 3. The landings of small salmon in Q7 and Q9, the Quebec north shore, increased by 66\% and $7 \%$ respectively over the mean landings 1985-89; but, declined by $36 \%$ in Q8 (Table 9). The declines in large salmon catch in Q7 (32\%), Q8 (9\%) and Q9 (8\%) may be related to the delay in opening of the fishing season, reductions in quotas and displacement of some fishing gear.

The recreational landings of large salmon in Labrador (SFA 1, 2 and part of SFA 14) were below the 1984-89 mean (Table 14). In Quebec the recreational landings of large salmon declined below the mean landings 1985-89 in Q2, Q7, Q9, Q10 and Q11: whereas increases were noted in Q1, Q3, Q5, Q6 and Q8 (Table 14). The landings of small salmon were below the 1984-89 mean landings in SFAs 1 and 2 (Labrador), SFAs 4-8 (east coast of Newfoundland) and SFAs 10-12 (south coast of Newfoundland). Increases in landings of small salmon in the recreational fisheries were observed in all other SFAs in Canada except for SFAs 15, 16, 22, 23, Q9, Q10 and Q11 (Table 14).

### 2.2.2 Composition and Origin of Catch

Salmon of Canadian and USA stock origin were captured in Canada during 1990. Recaptures of tagged 1SW salmon of USA and Canadian origin occurred in the Newfoundland and Labrador fisheries.

Salmon in twelve commercial salmon fishing ports in Newfoundland and Labrador were scanned for CWTs in 1990. All sampling ports were located within the southern portion of SFA 2 and SFAs 3 and 4. A total of 19,953 salmon (about $16 \%$ of the total landings in the SFAs sampled) were examined from the landings of commercial vessels. Of this sample, 112 salmon were found to be adipose clipped, of which 44 contained coded wire tags (Table 15). Approximately $8 \%$ of the salmon examined were from catches in the Labrador location (SFA 2) with the balance coming from Newfoundland (SFA $3,4)$. The highest percentage of tagged salmon were observed in Harbour Deep, but this can be misleading since the port was not sampled through the entire season.

The CWTs recovered in Canada were of United States and Canadian origin (Table 16). Of the 44 tags recovered, 40 were from USA-origin hatchery releases in the Penobscot, Connecticut and Merrimack rivers. All recoveries were from 1989 releases except one US tag from a 1988 Penobscot release. The Canadian origin tags were from 1989 releases in the Saint John River and a 1987 release in the Margaree River. It would be inappropriate to infer differential exploitation on the USA and Canadian tagged salmon because of the differences in relative numbers of tags at large, and the location and time of sampling.

Carlin tags reported (to date) in 1990 from Penobscot River smolts total 8 which is a $85 \%$ decrease from the 1989 return. Some of this decrease may be due to a $50 \%$ decline in Carlin-tagged smolts from 100,000 in 1988 to 50,000 in 1989. Most tags were recovered in southern Labrador (SFA 2), and northern Insular Newfoundland (SFAs 3, 4).

|  | Salmon Fishing Areas |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 | $7-14$ | Total |
| Penobscot Carlin Tags | 0 | 2 | 2 | 2 | 0 | 0 | 2 | 8 |

Estimates of harvest of USA-origin salmon harvested in the 1990 fishery will not be available until after 1991 returns to homewaters.

### 2.2.3 Status of Canadian Stocks

Biological assessments are available for seven Atlantic salmon stocks. Annual estimates of run size and spawning escapements relative to a target spawning requirement are provided for the Restigouche, (SFA 15; Fig. 2) Miramichi (SFA 16) and Saint John (SFA 23) in New Brunswick, Margaree (SFA 18) and LaHave (SFA 21) in Nova Scotia and Conne River (SFA 11) in Newfoundland (Table 17) as in previous years (Anon. 1990a). An assessment of the Rivière de la Trinite (Q7) in Quebec for 1990 and comparable historical data are presented for the first time (Table 17). The estimated range of returns to the Restigouche in 1990 reflects computations based on sport catch and an upper and lower limit of sport exploitation; the estimated range of returns to the Margaree reflects calculations using the upper and lower limits of the estimated sport. The absence of predictions on all rivers in recent years reflects major changes in the ratio of 1SW:MSW returns from the same smolt class which has reduced the precision of parametric predictors of MSW returns to the extent that they became unreliable.

Estimates of egg depositions in 1990 may have approximated (Restigouche), approximated (Conne and Rivière de la Trinité) or exceeded (Miramichi, Margaree and LaHave) target egg requirements in six rivers. In the Miramichi River, $38 \%$ of MSW spawners were repeat spawning salmon (age at first spawning still being assessed), the highest proportion or number on record. Egg deposition was $32 \%$ below target on the Saint John River. Targets were approximated or exceeded for the first time in nine years on the Restigouche, the seventh time in the last nine years on the Miramichi, the eighth time in nine years on the Rivière de la Trinite, the sixth time in the last eight years on the Margaree and for the eighth and fifth consecutive years on the LaHave and Conne rivers, respectively (Table 17). Egg depositions were below target for the fifth consecutive year on the Saint John. With the exception of the Conne River, most rivers obtained a major component of eggs from MSW salmon.

Additional assessments (based on counts obtained at fishways, counting fences and by divers) made in 1990 suggest that target egg depositions were about $65 \%$ below requirements on Gander River (SFA 4) and about $35 \%$ below requirements on Middle River, Cape Breton (SFA 19) and Western Arm Brook (SFA 14). Four rivers (Big Salmon, Alma, Point Wolfe and Petitcodiac) of inner Bay of Fundy (SFA 23), had returns that were down relative to historical returns. The Liscomb River (SFA 20) was 35\% below target egg deposition. Reasons for shortfalls in target egg deposition vary by river system and include effects of low water levels on juvenile survival in 1987, natural cycles, low pH and increased marine mortality.

Counts of 1 SW and large salmon obtained at fishways and counting fences since 1974 are provided in Tables $18,19,20$, and 21 . Counts of 1 SW fish at 10 of 12 fishways on systems in insular Newfoundland were down from the 1984-1989 mean. In 8 of 12 cases, the few large salmon counted in Newfoundland were below the 1984-1989 mean. In the Maritime provinces, counts of 1 SW salmon were similar to or above the mean at all 3 fishways (in SFA 20, 21, 23); counts of MSW salmon declined at all fishways. Counts of 1SW fish in Quebec increased over the 1984-1989 mean at all fishways; counts of MSW salmon were similar to or increased over the mean at 2 out of 4 fishways.

Stock status in Canada, 1990, may be summarized as follows for grouped management areas.

Labrador, East and South Coast Nfld. (SFAs 1-11):
The total abundance of small and large salmon in SFAs 1 to 9 was well below average. Spawning escapements in rivers of SFAs 1 to 9 were also generally low, except in rivers in SFA 3. In each of the SFAs, there were some rivers with average or above average spawning escapement. In SFA 10, escapements of salmon into most rivers were low in spite of the early closure of the commercial fishery in the SFA. In SFA 11, the escapements to most rivers appeared to be well above average.

There are several factors that may have contributed to the overall low abundance of salmon in SFAs 1-10. In northern areas, there appeared to be low egg depositions in 1983-84. In SFAs 4-10, the exceptionally low water levels and high water temperatures in 1987 may have resulted in high mortalities of juvenile salmon. Also the smolt-to-grilse survival in 1989 and 1990 was $34 \%$ below the survival rates observed in 1987 and 1988 for two rivers (one in SFA 9 and the other in SFA 10).

West Coast Nfld. Gulf NB, NS (SFAs 12-18):
Recreational catch of 1 SW fish and returns to counting facility at Torrent River indicated that abundance was similar to or up relative to the previous 5 years. Returns in 1990 relative to previous 5 years were variable in SFAs $15-18$ although in SFAs 16 and 18, there were large increases in returns of MSW salmon in the fall.

Atlantic Nova Scotia, Bay of Fundy N.S. and N.B. (SFAs 19-23):
Counting facility and river spawner counts indicate, with one exception, that returns of wild 1 SW and wild MSW salmon were lower than either those of 1989 or the 1984-1989 mean.

## Gaspé PQ (Q1-Q4):

Counting facility, river spawner counts and catch statistics show that 1990 1SW returns were above 1989 and the 1984-89 mean; MSW returns were lower than 1989 but slightly above the 1984-1989 mean.

North Shore PQ (Q5-Q9):
Counting facility, and catch statistics show that 1990 1SW returns were above the 1989 and 1984-89 mean; MSW returns were similar to 1989 returns but above the 1984-89 mean.

Anticosti and Ungava $P Q$ (Q10-Q11):
Catch statistics and spawner counts for SFA Q10 and catch statistics for SFA Q11 reveal that both 1SW and MSW returns were lower than 1989 and the 1984-89 mean.

### 2.2.4 Harvest Estimates of USA-Origin Salmon in Canada

### 2.2.4.1 Carlin-Based Estimates

Neither the structure of the harvest model nor its parameter values were changed from the previous assessment in Anon. (1990b). Updated values and the new data for the 1990 run size used to calculate the RATIO parameter are presented in Table 22. There were several minor changes for recent years and modifications of the historical rod catch data for the Machias River. Changes in the Machias rod catch do not reflect any new data, but instead reflect the reallocation of fish to age groups by an improved methodology. Estimates for tags and total run size of 2 SW salmon to Maine rivers, using a fishway efficiency of 85\%, are presented in Table 23. For 1990, the estimates of tags and run size were 172 tags and 4,355 fish, respectively; the RATIO parameter was 0.0394.

The Study Group updated the time series of tag returns and harvest estimates of Maine-origin 1SW salmon in Newfoundland and Labrador. Tag returns for Maine-origin 1SW salmon can be found in Table 24. Estimated harvest of 1 SW salmon in Newfoundland and Labrador are summarized by year for $85 \%$ fish passage efficiency in Table 25. The total harvest of 1717 Maine-origin salmon in the 1989 fishery was distributed primarily in SFAs 1-5. Harvests in SFA 1 were the highest on record for that SFA and were centered around the Nain area. Nearly $90 \%$ of the harvests in SFA 1 occurred after standard week 29; in the other SFAs most of the catches occurred prior to standard week 30 (Table 26). The harvest total of 1717 for the fishery was an increase from the relatively low harvests that occurred during the years 1986 to 1988. Updated values for 1SW:2SW ratios and ratios of harvest to run size of 2 SW salmon are presented in Table 27.

Detailed summaries of the tag returns and harvests for 1 SW salmon in mainland Canada and 2SW salmon in Newfoundland-Labrador and mainland Canada (Anon. 1990a, Tables 39-52) are not presented in this assessment since there were no new tag returns for these areas and age groups.

### 2.2.4.2 CWT-Based Estimates for Locations Sampled

The Study Group considered harvest estimates of Maine-origin stocks in Newfoundland and Labrador, derived from CWT and Carlin-tagged salmon for areas sampled. Estimates based on Carlin tags for the 1989 fishery were calculated identically to the methods used in other reports of Carlinderived harvest estimates (Anon. 1987b, Anon. 1990b). CWT harvest estimates were computed identically to the methods used in Anon (1990b). To compute the tag raising factor for the 1989 recovery the following input data were used:

| Run Estimate | 4355 | 2SW salmon |
| :--- | :--- | :--- |
| Total CWT | 454 |  |
| CWT at the trap | 334 |  |
| Angled CWT | 61 |  |
| Untagged Trap | 2298 |  |
| Untagged Angled | 336 |  |

From these data, the CWT to run ratio was 0.10424 and the raising factor for tags was 9.593. Estimated number of tags for a sample strata in the fishery was first raised for non-catch fishing mortality (Anon 1989a) and raised to total harvest for the strata.

Comparative harvest estimates based on CWT and Carlin tag recoveries for the communities and Statistical Sections sampled are presented in Table 28. As observed in Anon. (1989b) and Anon. (1990b), the ratio between the two estimates varied among locations, but unlike previous experiments, the sectional and community sums tended to suggest parity between the two estimation procedures. Whereas the experiments in 1987 and 1988 suggest reporting rate for Carlin tags may be overestimated in the commercial fisheries, the results for 1989 do not support that conclusion.

### 2.2.4.3 Proportional Harvest Model for Locations Sampled

The proportional harvest method is based on the fact that US and Canadian hatcheries both produce river age 1 salmon and almost no wild river age 1 salmon are produced in North America. The harvests of US salmon in Newfoundland can then be estimated based on the assumption that harvests will be proportional to production in Canadian and US hatcheries. The number of river age 1 salmon in commercial catches can be estimated from scale reading.

The numbers of US and Canadian 1 SW salmon caught were estimated for three communities in Newfoundland from 1980-89: Nain and Square Islands, Labrador, and Twillingate, Newfoundland. All of an individual boat's catch, or catches of several boats, were examined up to approximately 100 salmon per day. A scale sample was taken to obtain an age estimate.

The number of salmon caught per week at each community sampled came from the catch statistics. For samples obtained at Nain, Labrador the total estimated numbers of salmon caught are for the communities of Nain, Black Island, and Cutthroat. Samples obtained at Square Island and Fox Harbour represent catches in the communities of Fox Harbor in 1981 and 1990 and Square Island from 1982 to 1989. Samples obtained at Twillingate represent catches in the communities of Twillingate and Crow Head.

The proportional harvest model used to estimate harvests of Maine-origin 1SW salmon is similar to that developed for Greenland in Anon. (1990b). The only difference is that the proportion of river age 1 salmon in the catches is estimated for those weeks in which samples were available.

## River Age Distribution within a Statistical Area

One of the limitations to the applicability of the proportional harvest model is the difference in river age composition of the catch in Newfoundland. To assess this difference the Study Group examined earlier data from SFA 4.

In 1981 and 1982, salmon caught in commercial fisheries were sampled in SFA 4 (Section 7) at Twillingate, on an island at what could be defined as a 'headland' in Notre Dame Bay, and in the inner part of the bay at Embree and Campbellton. In 1981 and 1982 there were $16 \%$ and $23 \%$ river age 2 1SW salmon caught at Twillingate, while in the inner bay there were $1 \%$ and $5 \%$, respectively. In general, the inner bay catches showed higher percentages of smolt age 3 and 4 salmon (Table 29).

The difference in river age distributions between the two areas was even more pronounced for the MSW salmon component. River age 2 salmon caught at Twillingate represented $42 \%$ and $32 \%$ of the sample in 1981 and 1982, respectively, while at the inner bay locations they were $0 \%$ and $2 \%$. This may imply a greater mixing of stocks in the outer bay area. Similarly, the
inner bay area catches again showed higher percentages of river age 3 and 4 salmon in comparison with Twillingate (Table 29). The river age distributions at inner and outer bay sites, compared by Kolgomorov-Smirnov test, were significantly different from each other as shown below.

| Year | Age | Dmax | P |
| :---: | :---: | :---: | ---: |
|  |  |  |  |
| 81 | 1SW | 0.11 | 0.05 |
| 82 | 1SW | 0.18 | $<0.05$ |
|  |  |  |  |
| 81 | MSW | 0.43 | $<0.05$ |
| 82 | MSW | 0.29 | $<0.05$ |

This illustrates how the contribution of each smolt age can differ even within a single bay and suggests wide variations may occur in interception rates between locations.

## Comparison of Harvest Estimates

It is instructive to compare the proportional harvest estimates with those based on Carlin tag recoveries (Anon. 1990a, Table 37). The total Carlin harvest estimate for the three SFAs should not be lower than the catch in a single community within each SFA. Yet on many occasions the community catch is higher than the catch recorded in Anon. (1990a) for the entire SFA. In total, there are 48 out of 154 instances or $31.6 \%$ when there are harvests from the proportional harvest model with no corresponding harvest listed from the Carlin tag model. There are 52 out of 154 instances or $33.8 \%$ where the proportional harvest model shows a harvest greater than the Carlin tag model. The following table shows the differences (proportional harvest - Carlin harvest) between model results for those instances where proportional harvests were greater than or equal to Carlin tag harvests:

| Difference | 0 | $1-5$ | $6-10$ | $11-15$ | $16-19$ |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  |  |  |  |  |  |
| Frequency | 22 | 9 | 11 | 7 | 3 |
| Percent | 42 | 17 | 21 | 14 | 6 |

## Assumptions and Data Requirements:

1. The weekly distribution of US and Canadian hatchery origin salmon at a given site was assumed to be directly proportional to the production of US and Canadian river age 1 salmon. Previous analyses presented in Anon. (1990a) show that the numbers and proportions of US and Canadian origin salmon of river age 1 and sea age 1 vary independently of each other spatially and temporally. Carlin tag harvests, if available from Canadian and US river age 1 stocks could be used to give a representative sampling of the weekly distribution of Canadian and US salmon in the Newfoundland fishery. Information should be given by week and SFA. Instead of basing harvests on a proportionality factor from production estimates of smolts, the factor could be derived from the Carlin harvests. This will require estimates of Carlin harvests of Canadian and USA salmon based on the entire production of river age 1 salmon.
2. If the proportional harvest model is to be used to estimate harvests in the entire Newfoundland-Labrador fishery, samples sufficient to characterize the spatial and temporal variation of stocks in the
exploited populations of each SFA are required. The following number of sites might be required to apply this method:

| SFA | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 14 | All |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| SFAs |  |  |  |  |  |  |  |  |  |  |  |  |  |
| No. Sites | 2 | 3 | 4 | 4 | 4 | 1 | 1 | 1 | 1 | 2 | 2 | 1 | 26 |

The Study Group concluded that applicability of the proportional harvest model to Canada was limited by the complexity of the fishery and inadequate sampling effort.

### 2.2.4.4 Discrepancies between commercial catch statistics and scientific sampling.

The Study Group was asked to investigate discrepancies between recorded landings in the catch statistics and the numbers of salmon reported by crews sampling for coded-wire tags in Newfoundland-Labrador. The basis of the Newfoundland-Labrador catch record system (Anon. 1985) is the purchase slip issued to commercial salmon fishermen when their catches are sold to salmon buyers. The purchase slip records catches in kilograms, information on size category ( small or large), the community and the date of sale. Purchase slips are sent to the Department of Fisheries and Oceans for compiling and entry into the catch record system. To ensure completeness of the records, fisheries officers are responsible for filing on a monthly basis records of those sales made locally by fishermen that are not recorded on the purchase slips from buyers. Local sales are recorded in kilograms and are not separated by size.

The landings in these catch records are then converted to size categories and numbers of salmon by a statistical system that relies on information on a community basis. Landings on purchase slips which are recorded daily are summed for standard weeks. Local sales are allocated into standard weeks and size categories based on the purchase slips. When information is unavailable from purchase slips, broader geographic categories are used.

Possible sources of errors are summarized below:

1. Errors in Catch Records:

- Incorrect information on local sales or plant records.
- Loss of purchase slips from buyers.
- Fishermen fish from one community but land salmon in another.
- Incorrect recording of dates or communities on buyers' purchase slips.

2. Errors in Catch Statistics:

- Inaccurate estimation of numbers in small and large categories.
- Allocation of monthly local sales into weeks.

The net effect of these possible sources of bias is to reduce the reliability of weekly estimates of small and large salmon. The overall magnitude of the problem is unknown but it is thought to be low for total.

### 2.2.5 Exploitation Rates in Canadian Fisheries

No new information on exploitation rates in commercial fisheries was available to the Study Group. Exploitation rates in the recreational fisheries of three SFAs not previously reported in Anon (1990a) are shown in Table 30. These rates were estimated from mark recapture studies and
include adjustments for reporting rate and tag availability with the exception of Restigouche River which were estimated from angled fish divided by angled fish plus spawners (obtained by visual counts from canoes after closure of river to angling). Exploitation rates on 1SW salmon for Restigouche River have been higher than for the other rivers. Exploitation rates on early run ISW and MSW salmon were higher than on late run salmon. Exploitation rates on MSW salmon from Margaree have consistently been lower than on 1SW salmon (Table 30). Variation in the estimated rates suggest that exploitation rates should be calculated annually or that a range of rates be used when returns to a river are calculated from recreational catch.

### 2.3 France (Islands of St. Pierre and Miquelon)

No new information on the current fisheries of St. Pierre and Miquelon was provided to the Study Group. The Study Group, however, reviewed a report on the 1976 commercial fishery which revealed catches of 831 salmon weighing 2.5 mt . These catches were not markedly different from those reported in Anon (1990) for the period 1987 to 1989.

### 2.4 Aquaculture Production and Influence upon Native Stocks

### 2.4.1 United States

There are about 20 private aquaculture companies in Maine. Harvest has increased from 365 t in 1987 to 2,075 t in 1990 (Table 31). Information on existing aquaculture facilities in other states is unavailable. Most smolts stocked in net pens in Maine are of Penobscot River or Saint John River (N.B.) origin; however, some European stocks (Iceland, Scotland, Norway, Finland) have also been used to a limited extent. While all of the salmon farming sites in Maine are located east of the Penobscot River, most (75\%) are located within Cobscook Bay in close proximity to the Maine - New Brunswick boundary.

The total number of salmon that escape from net pens in Maine is unknown, but the following escapes during 1983, 1988, and 1990 have been documented:

| Date | Number of Fish | Size (kg) | Origin | Location |
| :--- | :---: | :---: | :--- | :--- |
|  |  |  |  |  |
| Dec. 1983 | 25,000 | 0.5 | Penobscot | Cobscook Bay |
| Feb. 1988 | 4,700 | 3.7 | Penobscot | Cobscook Bay |
| Nov. 1990 | $15,000-20,000$ | $0.1-0.6$ | Saint John | Taunton Bay |

Evidence of Atlantic salmon originating from the aquaculture industry in Maine rivers is very limited, since most rivers in the vicinity of net pens do not have counting facilities. About $20 \%$ of the 1990 angling catch (17 of 83) in the East Machias River was comprised of salmon of aquaculture origin. Additionally, a few fish were also captured at the St. Croix River fish trapping facility and one at the Penobscot River trapping facility in 1990.

### 2.4.2 Canada

The production of commercially-cultured Atlantic salmon in Canada (Atlantic seaboard only) for the period 1980-1990 is shown in Table 32. Most of the production in Canada occurs in New Brunswick, where the estimated harvest increased from 10 t in 1980 to 7,810 t in 1990. In southern New Brunswick, aquaculture production is based primarily upon the Saint John River stock which is close to the culture area.

The number of salmon that escape from net pens annually is unknown, although there are occasionally losses of fish due to predators or storm damage. A recent example (1990) was the loss of about 19,000 large salmon from one cage site in southern New Brunswick. The Study Group noted that the aquaculture facility in Quebec is land-based; therefore the probability of escape from this facility is very low.

Documentation of aquaculture escapees in Canadian rivers during 1990 was restricted to the Saint John River at the Mactaquac trap facility. A provisional estimate is that $6 \%$ (221) of the total MSW returns were of farmed origin. The incidence of farmed salmon in the Saint John River will continue to be evaluated annually.

### 2.4.3 Summary

Total annual aquaculture production in the Atlantic Coast of North America now exceeds landings of wild salmon by nearly ten fold. The Study Group recommends that the USA and Canada maintain an inventory of aquaculture production and escapees and continue monitoring the presence of escapees in rivers and fisheries.

## 3. EVALUATE THE EFFECTS OF 1990 QUOTA ON COMMERCIAL SALMON FISHERY OF NEWFOUNDLAND AND LABRADOR ON STOCKS OCCURRING IN THE COMMISSION AREA.

In 1990, Canada introduced quota management for the Newfoundland and Labrador commercial salmon fisheries. The quotas, in tonnes, were set by Salmon Fishing Area (SFA) (Table 33, Fig. 2). The fishing season in 1990 began on June 5 and closed in each SFA when the quota was reached, or October 15 as in previous years. The quota was controlled by weekly and daily monitoring of landings by Fisheries Officers. Quotas were attained in 8 of the 12 SFAs ( $4,5,6,8,10,11,13$ and 14 ) resulting in closing dates in these fisheries ranging from June 21 to July 25 (Table 33). The fisheries in SFAs $1-11$ and 14 harvest salmon of Canadian and U.S.A. origin (Anon, 1990a, b).

To evaluate the effects of the closures, the Study Group used two approaches, both of which relied on the weekly distribution of landings by SFA for 1984 to 1989. In the first approach, the closure date that occurred in each SFA in 1990 was applied to the temporal distribution of catches each SFA and year (1984-1989) to compute the percent reduction in harvest for that year. The minimum, maximum and mean percents were then applied to the 1990 catches to predict the range of catches forgone in 1990. This approach was called the "Fixed Closure Date Predictions". In the second approach, the 1990 quota was applied to the temporal distribution of catches in each SFA for the years 1984 to 1989. The Study Group computed the date on which the quota used in 1990 would have been fulfilled, the landings that would not have been caught, and the estimated reduction in the interceptions of Maine-origin salmon. This approach was called the "Fixed Quota Predictions".

### 3.1 Fixed Closure Date Predictions

The effects of the quotas on Canadian stocks were evaluated by examining the seasonal distribution of catches, 1984-89, in SFAs 4, 5, 6, 8, 10, 11, 13 , and 14. The minimum and maximum percent of the total catch of a given year caught during a time period similar to that which was closed in 1990 , varied among SFAs. For small salmon (mostly 1SW), the range varied from 3\%-15\% for SFA 8 to $35 \%-89 \%$ for SFA 11 (Table 34); similarly, the harvests of large salmon during the same period varied from $2 \%-14 \%$ for SFA 8 to $19 \%$ $72 \%$ of the total landings of large salmon for SFA 11 (Table 34). It would appear that, in the SFAs where the quotas limited the catch, the quotas had a greater effect on proportionally reducing the catch of 1 SW salmon than large salmon. This was to be expected since large salmon tend to migrate along the coast earlier than 1 SW salmon. It is estimated that the numbers of 1 SW salmon not caught in SFAs $4,5,6,8,10,11,13$, and 14 due to early closure was between 20,000 and 120,000 (Table 35). The number of large salmon not caught in these SFAs was between 4,000 and 22,000 (Table 35). Some salmon affected by the closure may be caught in commercial fisheries which remained open or in recreational fisheries. No estimates were made of additional spawning escapement because of the unknown composition of the population affected by the closures and possible subsequent exploitation.

The effects of the introduction of quotas on the harvest of 1SW Maine origin salmon were evaluated by examining the estimates of the weekly distribution of the harvests 1984-89 in SFAs 4, 5, and 6 (Anon. 1990a). The total average harvest of 1SW Maine-origin salmon, 1984-89, was 159 fish, with a range of 0 to 327 fish (Table 36). It is apparent that the number of 1 SW Maine-origin salmon in SFAs $4-6$ is small and there is a high
variability between years in the percent and numbers of salmon in these SFAs. Also, the variability in the percent that could be affected by the closures is high. Thus it is difficult to estimate the effects of the quota on 1SW Maine-origin salmon. The effects could range between $0 \%$ and $71 \%$ reduction in the harvest, equivalent to 0 to 185 fish.

### 3.2 Fixed Quota Predictions

The Study Group examined the effects that the quotas, introduced in 1990 , would have had on landings if the quotas had been in effect in 1984-89. There was no quota limitation in SFA 1 and SFA 12 was closed since 1984. The landings after October 15 in 1984 and 1985 were deducted from each SFA since the fisheries were closed on this date in subsequent years. The date that the fishery would have been closed in each SFA, each year (1984-89) was determined from cumulative catch curves. Results of these analyses are presented in Appendix 3. The predicted reduction in catch and harvest of 1SW salmon of Maine origin is the landings in each SFA, each year after the predicted closure date up to October 15. The Maine-origin harvest of unknown week of capture was prorated over the weekly harvests.

The predicted closure dates are highly variable among years in some SFAs, particularly SFAs 2, 3, and 4. In years of low abundance, the closure dates would be later and have less effect on reducing the total catch and the mortality of 1SW Maine-origin salmon. Some salmon released from one SFA due to closure of fisheries may be caught in fisheries that are still open. This may lower the predicted reduction in harvests.

The predicted reduction in total catch 1984-1989 ranged from 98 t (13\%) to 746 t (53\%) with a mean predicted reduction of 321 t (30\%) (Table 37). The total predicted reduction in harvests of 1 SW salmon of Maine-origin ranged from 130 to 364 fish with a mean reduction of 228 fish (Table 37). The range in the predicted percent reduction was 16 to $75 \%$. The predicted percent reduction of 1 SW salmon of Maine-origin was greater than the percent reduction of total landings in SFAs 2, 3, and 4 (Table 38).

The average number of fishing days for each SFA varied between 26 and 60 (Table 37). The high standard deviation supports high variability between SFAs.

The Study Group noted that Maine-origin fish were harvested in 45 of the 72 cells in the year and SFA matrix ( 6 years and 12 SFA's). Of those 45 cells, reductions in harvest would have occurred in 24 totalling 1,369 fish ( 57 on average over the 24 cells) or $80.4 \%$ of total catch from the SFAs by year. Reduction in harvest over the 1984-1989 period would have averaged 228 fish, ranging between 130 and 364.

The mean predicted reduction in catch and mean reduction in 1 SW salmon of Maine-origin by SFA, 1984-89, are provided in Table 38. The highest predicted reduction in landings occurred in SFAs 2 (70 t) and 3 (48 t). Although the highest percent reduction would occur in SFAs 8 (52\%) and 5 (51\%). The highest predicted reduction in harvest of 1SW salmon of Maineorigin would occur in SFA 3 ( 64 fish); whereas the highest percent reduction would occur in SFA 5 ( $46 \%$ ). It was noted that there was low variability of effort within SFAs over years.

## 4. ADVANCES IN MODELING APPROACHES TO DESCRIBE FISHERY INTERACTIONS AND EFFECTS OF MANAGEMENT MEASURES.

### 4.1 Index Rivers

The term "Index Rivers" is synonymous with "indicator stocks" which was previously defined as an individual stock or a group of stocks which can represent the stocks in a larger geographic area (Anon 1988b). The term "River" is synonymous with "stock" for Atlantic salmon if it is accepted that individual rivers, regardless of size, contain distinct populations or stocks for which the fidelity of returns to the natal river is greater than the straying rate between rivers. Index rivers are those for which sufficient biological information, such as biological characteristics, spawning escapement, productive habitat, etc. has been accumulated over time. The representativeness of these monitored rivers to wider geographical areas depends upon the length of the time series, the productivity of the river relative to others in the geographic area and corroborating information on other rivers within the area. In selecting rivers to be used as an indicator or an index, consideration should be given to the above points. With limited resources, emphasis should be placed on monitoring of annual variation within rivers rather than between rivers.

### 4.2 Regional Run Reconstruction Models

The Study Group reviewed a preliminary run reconstruction model for North American fisheries. The model employs a simple mass balance approach to deduce the total number of 1SW and MSW spawners in North America and the estimated fraction of non-maturing salmon in the major commercial fishery of Canada. A diagram of the model structure is given in Fig. 4. Further aspects of the results of the regional run reconstruction will be examined by the Working Group.

The model examines the general behavior of multiple stocks by estimating the numbers of fish that survive the commercial and recreational fisheries of Greenland and Canada. The model deductions apply to broad geographical areas but offer no insights for specific stocks or fisheries. An alternative approach, using collections of index stocks to reconstruct the total population was discussed by the Study Group. While this approach offers a more mechanistic understanding of the stocks, the paucity of long time series of data and a poor understanding of appropriate regional weighting factors for individual stocks impedes progress in modeling.

The Study Group noted that the model provided some insights into the population dynamics of Atlantic salmon in North America but needed improvements in order to have management utility. Recommendations included:
o Examine the model behavior for presumed smolt classes.

- Examine the behavior of the model over several smolt years. If similar patterns occur over several years the model's general applicability would be strengthened.
- Conduct sensitivity analyses of the exploitation rates used for West Greenland (0.6) and Canada (0.5). Exploitation rates have a major impact on the derived numbers of spawners, maturation rates and in-river exploitation rates.
- Use estimated fraction of non-maturing salmon in the commercial catch rather than deduced values.
- Examine the sensitivity of the model to errors in the designation of sea age in the small and large market categories of the Canadian commercial fishery.
o Obtain estimates of the general range of smolt production for North America.

Questions arising from the analysis include:

- Does a large pool of unexploited salmon exist?
- Can an estimate of the non-maturing fraction of salmon be derived for commercial fisheries?
- What is a plausible range of total smolt production in North America given known estimates of productivity for salmon rivers?
- What is a plausible range of total adult returns to North America given known recreational harvests?
o Are exploitation rates for small salmon greater than those for large salmon in spawning rivers?

General ecological information on the biological productivity of geographical regions and data from existing surveys may answer some of these questions but increased numbers of specific fishery monitoring surveys will be required to answer others.

### 4.3 Estimation of Maturation Rates in Newfoundland-Labrador Fishery.

The Study Group reviewed three techniques to determine the state of maturity of 1 SW salmon caught in the Newfoundland commercial fishery. This fishery exploits 1SW salmon that would have matured and spawned in the year in which they were caught and immature salmon that would not have matured until at least one year after the year the fishery. The proportion of mature 1 SW salmon caught in the commercial fishery in Newfoundland and Labrador is an important parameter in models designed to assess the harvests of non-Newfoundland origin salmon. Also, models recently developed to assess the Greenland fishery require estimates of the proportion of salmon from the same smolt class at Greenland that remain in the Newfoundland area. Little is known however, on maturity rates aside from tagging studies which confirm the presence of immature 1 SW salmon of US and mainland Canadian origin in the Newfoundland fishery.

The data on salmon of unknown maturity came from commercial catches sampled at Twillingate, Newfoundland and Square Islands, Labrador, 1985-88.
Samples of immature salmon were obtained from gill net catches in the Labrador Sea in the fall of 1987-89. Maturing salmon were sampled in the Conne River estuary during a tagging study and from catches of recreational fishermen in Conne River, 1986-88 and 1990. Salmon were measured for whole weight to the nearest 0.01 kg , wet gonad weight to the nearest 0.1 g and fork length to the nearest cm. Gonadosomatic index (GSI) was calculated:

$$
\text { GSI }=\text { gonad weight }(\mathrm{g}) / \text { whole weight }(\mathrm{kg}) \text {. }
$$

The text table below summarizes the available data:

|  | Years |  |  |  |  |  |  |  |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Location | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 | Total |  |
| Conne estuary | - | 344 | 60 | - | - | - | 404 |  |
| Conne River | - | 82 | 120 | 95 | - | 96 | 393 |  |
| Labrador Sea | - | - | 82 | 102 | 102 | - | 286 |  |
| Twillingate | 171 | 457 | 719 | 575 | - | - | 1922 |  |
| Square Is. | 237 | 292 | 314 | 327 | - | - | 1170 |  |
| Total | 408 | 1175 | 1295 | 1099 | 102 | 96 | 4175 |  |

The three techniques examined for estimating the state of maturity are:

1. Fork length distributions:

Fork length distributions were used to examine the possibility that differential growth rates of maturing and immature 1SW salmon could result in bimodality in the fork length distributions similar to those occurring in precocious male parr (Thorpe et al. 1977). Plots of fork length distributions of male and female salmon by week did not indicate bimodality. The usefulness of this technique was further limited by the absence of known maturing and immature salmon from the same time period and location from which the samples were obtained.
2. Gonadal development:

The gonadal development technique uses the distribution of gonadal development stages within GSI groups. The specimens examined histologically to determine stage of gonadal development were sampled in June, 1975 at Bonavista, Newfoundland. The numbers of maturing and immature fish were estimated from the GSI frequencies of 1 SW salmon sampled at Twillingate and Square Is. The reliability of this technique was tested with samples of known maturity from the Labrador Sea, Conne estuary, and Conne River (Table 1). The high level of misclassified salmon (Table 39) was considered unacceptable.
3. Discriminant analysis of GSIs:

This technique uses GSIs from immature salmon caught in the Labrador Sea and from maturing salmon caught in the Conne estuary as a database for discriminant analysis. Quadratic discriminant analysis was used separately for male and female salmon to determine the maturity of salmon sampled in the commercial fishery at Twillingate and Square Is.

Samples of known maturity were also used to test the accuracy of the discriminant analysis by a resubstitution technique. The results for male salmon show a misclassification rate of $4.7 \%$ and error rates of $\pm 0.7 \%$ (Table 40a). The results for female salmon show a misclassification rate of $7.7 \%$ and error rates of $\pm 1.1 \%$ (Table 40 b ). Because samples from Conne River estuary and Labrador Sea were used to develop the discriminant analysis it's accuracy on samples of known maturity from other stocks is unknown. Validation of this technique with other stocks is necessary. Further complications may arise if GSIs increase during the fishery,
particularly for the maturing component.
The results of classifying samples of unknown maturity from Square Islands and Twillingate, 1985-88 are presented in Table 41. For samples collected at Square Is. the mean percentages of immature salmon were $2.0 \%$ for males and $15.8 \%$ for females. For samples collected at Twillingate, mean percentages of immature salmon were $13.1 \%$ for males and $13.6 \%$ for females.

The above maturity rates are not applicable to the entire fishery because samples have not been weighted to the catch and may not be representative (see Section 2.2.4.3). In order to demonstrate the effect of catchweighted versus unweighted maturity rates, the weekly proportions at Twillingate in 1987 were weighted to the weekly catches. The catchweighted fractions immature were $15.5 \%$ for males and $28.6 \%$ for females. In contrast, the unweighted proportions immature were $21.0 \%$ for males and $27.4 \%$ for females. Clearly, to be applicable to the entire fishery the maturity rates should be catch weighted.

Differences in the sea-age and river-age distributions among stocks might allow prediction of stock composition. Most Newfoundland-Labrador salmon mature at 1SW in age while mainland (Maritime Provinces, Quebec and USA) salmon mature at sea ages ranging from one to three. In contrast most Newfoundland salmon smoltify at 3 and 4 years of age while rivers ages of mainland salmon are mostly 2 and 3 years. If it is hypothesized that there should be more mainland origin salmon in the immature group and that Newfoundland-origin salmon should be in the mature group then the river age distributions of maturing and immature should be different from each other. The river age distribution of immature salmon was compared to that of maturing salmon at Twillingate and Square Island for males and females using the Kolgomorov-Smirnov D-statistic. The following table summarizes the results:

| Location | Sex | Dmax | P |
| :--- | :--- | :---: | :---: |
|  |  |  |  |
| Square Is. | male | 0.339 | $<0.05$ |
| Square Is. | female | 0.312 | $<0.05$ |
| Twillingate | male | 0.168 | $<0.05$ |
| Twillingate | female | 0.382 | $<0.05$ |

Results indicate that all of the river age distributions of immature salmon are significantly different from the maturing salmon (Fig. 5 and 6). This test of GSI discriminant technique supports its utility, but the high proportion of river age 1 and 2 fish classified as maturing (Fig. 6) was disturbing because most of these fish are thought to be destined for rivers south of Newfoundland.

## Assumptions and Data Requirements:

1. The discriminant technique, by substituting GSIs of samples from the Labrador Sea for samples of known immature fish at 13-14 months of age, assumes that relative somatic growth and gonadal growth rates are similar from 13 months to 16 months age. The Study Group concluded that this was the most important assumption of this method. If during the summer period somatic growth rates exceed rates gonadal growth then GSIs from the Labrador Sea in October will be lower than those in JuneJuly and their use in the discriminant technique will underestimate the number of immature salmon in the samples from Twillingate and Square Is. It is recommended that samples be obtained to test the hypothesis of equivalent rates between gonadal and somatic growth.
2. The discriminant technique requires samples of salmon from the sea with known maturity status. Maturity status might be determined either histologically or biochemically by measuring levels of gonadotrophins. For some gonadotrophins it will also be necessary to have samples of known maturity. It is recommended that samples of known maturity be obtained to determine histologically or biochemically the state of maturity.
3. The discriminant technique assumes that no between-stock differences in GSIs exist and that Conne estuary and Labrador Sea samples are representative of maturing and immature salmon, respectively. Chadwick et al. (1986) however, demonstrated differences in gonadal characteristics among stocks. It is recommended that this assumption should be tested with Miramichi data.
4. Either analysis assumes that there are no timing differences in GSI and maturity over the weeks and years that the samples were taken. It can be expected that maturity state and GSIs would vary annually with stock mixture, water temperature, and food availability. A significant improvement would be to have samples of known maturity over the entire fishery. It is recommended that future analyses include samples collected over time.
5. Also, it has been observed in sea cages that some salmon that initially appear to be maturing do not mature. The effect of this would be to reduce the overall rates of maturing salmon presented herein.

## 5. RESEARCH NEEDS AND DATA DEFICIENCIES

### 5.1 Progress on Research Needs

The Study Group reviewed the list of research requirements for future meetings from Anon. (1990a, Section 9.2) and Anon (1990b, Section 12.3). The requirements and progress made to date are summarized below:

## Research Requirement

1) Present data on the production of farmed salmon, the number of salmon that have escaped from specific localities, the size and age of the fish, and the time of escape. Present estimates of the proportion of farmed salmon in fisheries and spawning populations in their home waters.
2) Develop run reconstruction models of their stocks for discussion at Study Groups and input to a North Atlantic model at the Working Group. Data useful to the modelling should be brought to the Working Group in the format specified in Appendix 5.
3) Report on progress toward the development of methods to distinguish maturing and nonmaturing components of fisheries.
4) Provide historical records of the recreational harvest (killed) Atlantic salmon in Maine rivers and commercial harvest by year for SFAs 1-14.
5) Review methodology to estimate run-size in Maine rivers without counting traps.

## Progress

Working papers submitted for USA and Canada. See Section 2.4 .

Working paper presented and initial regional model examined. See Section 4.2. No additional data presented related to Appendix 5 of Anon. (1990b)

Working paper submitted. See Section 4.3.

Information was available to Study Group but not summarized in this report.

Methodology was reviewed to use redd counts to estimate run size in rivers without counting traps. Population estimates were compared using redd counts and angling exploitation estimates. Insufficient data were available to make adjustments for all years. See Section 2.1.2.

## Research Requirement

6) Provide estimates of the proportion of Carlin tags that could go undetected where individual salmon are not handled at monitoring facilities.
7) Prepare a computer disk containing catches by week for the Canadian fisheries.
8) Investigate discrepancies between recorded landings in the catch statistics and the numbers of salmon reported by crews sampling for CWTs in communities of Newfoundland-Labrador.
9) Examine historical forecast models for MSW salmon and age at maturity as they relate to observed decreases in the numbers of MSW salmon and increases in the numbers of 1 SW fish returning to some Canadian and USA rivers, particularly during recent years in which management measures have been introduced to increase home river returns of MSW fish.
10) Investigate the use of the proportional harvest method on salmon of 1-year smolts in communities of NewfoundlandLabrador.
11) Estimate $p$ values (proportion of a stock that was in a particular fishery) for Maine and Saint John River stocks that would minimize the differences between exploitation rates generated in the run-reconstruction and hence advance the understanding of migratory patterns of salmon in West Greenland and Canada.

## Progress

No progress.

Computer disk for 1990
catches provided.

Some information provided.
See Section 2.2.4.4.

No new information provided.

Working paper presented; see section 2.2.4.3.

No new information presented.

### 5.2 Requirements for Future Meetings.

1. Investigate stock recruitment relationship for naturally spawning fish in the Penobscot and Saint John Rivers.
2. Examine forecast models for MSW salmon in an attempt to explain observed recent decreases in the numbers of MSW salmon and increases in the numbers of 1 SW salmon returning to some Canadian and USA rivers.
3. Evaluate relationships between redd counts and spawning populations and its applicability for North American rivers.
4. Estimate abundance of returning salmon which remain below Veazie dam on the Penobscot River and continue evaluation of passage efficiency.
5. Consideration should be given to stratifying sampling for CWT's in the commercial fisheries in Newfoundland-Labrador into size categories.
6. Catches by week for the commercial fisheries in SFA's 13 and 14 are to be provided for missing years (1984-88).
7. Provide updated estimates of exploitation rates, where available, on an annual basis.
8. Maintain an inventory of production by area, and escapes from aquaculture sites, as well as estimates of escapees found in rivers and fisheries.
9. With respect to the estimation of maturation rates in salmon in the Newfoundland-Labrador salmon fishery (Section 4.3), the following recommendations were noted:
a. Samples be obtained to test the hypothesis of equivalent rates between gonadal and somatic growth.
b. Samples of known maturity be obtained to determine histologically or biochemically the state of maturity.
c. Test the hypothesis of no stock differences in GSIs between The Conne River estuary and the Labrador Sea by contrasting these GSIs with samples obtained from the Miramichi River.
d. Further studies should investigate temporal trend in maturity over the entire fishery.

### 5.3 Future Meeting

It is recommended that the Study Group meet in 1992 in St. John's, Newfoundland at an appropriate time before the meeting of the Working Group on North Atlantic salmon.

| 1990 | 405 | 222,944 | 465 | 101,910 | 870 | 324,854 |

*Numbers for 1982-84 are estimated (assuming 2.0 kg for average 1 SW salmon;
4.5 kg for large salmon).

The 1990 total catch of salmon ( 870 tonnes) is:

- $37.3 \%$ below the previous 5 year mean ( $1,385.2$ )
- $47.0 \%$ below the previous 10 year mean $(1,637.7$ )
- 51.3\% below the previous 15 year mean ( $1,783.0$ )
- $54.1 \%$ below the previous 20 year mean $(1,889.6)$

The 1990 total catch of large salmon only ( 465 tonnes) is:

- $33.6 \%$ below the previous 5 year mean (698.6)
- $51.2 \%$ below the previous 10 year mean (951.3)
- 58.1\% below the previous 15 year mean ( $1,108.0$ )
- $61.5 \%$ below the previous 20 year mean $(1,205.3)$

The 1990 total catch of grilse only (405 tonnes) is:

- $41.1 \%$ below the previous 5 year mean (686.4)
- 41.1\% below the previous 10 year mean (686.3)
- $40.1 \%$ below the previous 15 year mean (674.9)
- 41.0\% below the previous 20 year mean (684.3)

${ }^{1}$ Defines whether or not Carlin tag recoveries with unknown dates are included in the estimate. "Actual" means that tags with unknown dates are not considered; "Imputed" means that tags with unknown dates are included in the estimate
${ }^{2}$ Defines the geographical region applicable to CWT estimate. S=Section, C=Community only. Section estimates are based entirely on recoveries from single community individually, hence the different section estimates in Section 4.

AGENDA
ICES STUDY GROUP ON NORTH AMERICAN SALMON FISHERIES
1000 - February 25 to 1000-March 1, 1991
National Fisheries Research Center--Leetown
Leetown, West Virginia, USA

1. Adoption of agenda
2. Distribution of documents
3. Organization of meeting
4. Terms of reference
a. Describe events of the 1990 fisheries with respect to gear, effort, composition and origin of the catch.
b. Continue the development of run-reconstruction models of national stocks for input to a North Atlantic salmon model to describe fisheries interactions and stock dynamics;
c. Estimate exploitation rates and status of stocks in homewater and interception fisheries for stocks occurring in the North American Commission area.
d. Evaluate the effects of the newly-introduced quota in the commercial salmon fishery of Newfoundland and Labrador on stocks occurring in the North American Commission area.
e. Specify data deficiencies and research needs.
f. With respect to Atlantic salmon in the NASCO area, provide a definition of the term "Index Rivers" and provide a commentary on how they could be used to assess the status of salmon stocks.
5. Recommendations from Study Group and Working Group meetings in 1990
a. Working Group Report (C.M. 1990/Assess: 11)
b. Study Group Report (C.M. 1990/M:3)
6. Other Business
7. Anonymous. Annual report of the US Atlantic salmon assessment committee. Report No. 3-1990 Activities.
8. Baum, E. T. History and status of the Atlantic salmon farming industry in Maine, USA.
9. Porter, T. R. and D. G. Reddin. Effects of the quotas introduced in 1990 in the commercial salmon fisheries of Newfoundland and Labrador on stocks occurring in the North American Commission Area.
10. Porter. T. R., T. L. Marshall, F. Caron, G. Chaput, M. R. O'Connell, and D. Meerburg. Description of the Atlantic salmon fisheries and status of stocks in Canada in 1990.
11. Rago, P. J. Run reconstruction model for North American fisheries: a speculative hypothesis.
12. Reddin, D. G. and P. R. Downton. Estimation of 1 SW salmon of US origin in Newfoundland fishery - the proportional harvest technique.
13. Reddin, D. G. and P. R. Downton. Maturity of 1 SW salmon in Newfoundland commercial fishery.
14. Carey, T. G. Aquaculture production of Atlantic salmon in Canada.
15. Friedland, K. D., P. J. Rago, and E. T. Baum. Harvest estimates of US origin salmon from coded wire tag and Carlin tag return data in Canada, 1989.
16. Friedland, K. D., P. J. Rago, and E. T. Baum. Carlin tag returns and harvest estimates of US origin salmon in Canada, 1967-1990.
17. Friedland, K. D. and D. G. Reddin. Recoveries of coded wire micro tags in Newfoundland and Labrador during the 1990 fishing season.

## APPENDIX 3

Estimates of reduction in Canadian commercial catches and Maine-Origin Harvests and Predicted Closure Dates for Salmon Fishing Areas (SFA) 2 to 14 for 1984 to 1989.

Table A3.1. Effect of 1990 quota on Nfld-Labrador commercial fisheries, 1984-89 for SFA 2. Opening date was June 5. Quota was 200 t. One (1) Gear unit=50 fathoms.
